International Researchers Association

ISBN #:978-625-96407-5-4

WELCOME NOTES

You are welcome to our VIII. AGBIOL Conference that is organized by Trakya University, Beykent University and International Researchers Association. The aim of our conference is to present scientific subjects of a broad interest to the scientific community, by providing an opportunity to present their work as oral or poster presentations that can be of great value for global science arena. Our goal was to bring three communities, namely science, research and private investment together in a friendly environment of Edirne, Turkey in order to share their interests and ideas and to get benefit from the interaction with each other.

In September 2018, we organized the first AGBIOL Conference with more than 700 scientists and researchers from all over the world with over 800 scientific papers. Due to COVID-19 situation, II. AGBIOL 2020 has organized fully on-line event which was one of the biggest online conferences in recent years in the world with 499 papers and 1133 authors with 333 oral and 166 e-poster presentations from 55 countries. Due to COVID-19 situation, AGBIOL 2021 was organized online again. AGBIOL 2022 conference was organized with a worldwide participation from 44 countries over 522 papers contributed by over 1300 authors. AGBIOL 2023 was organized with a record and worldwide participation from 33 countries 833 papers contributed by over 2000 authors with 522 oral and 311 poster presentations. AGBIOL 2024 consisted of 835 papers contributed by about 2000 authors with worldwide record participation again from 55 countries with 522 oral and 311 poster presentations. AGBIOL 2025 was organized with a worldwide record participation from 60 countries 988 papers contributed over 2300 authors with 400 oral and 588 poster presentations.

The AGBIOL 2026 is normal participation as well as with online participation in Beykent University in Istanbul, Turkey on 06-09 September, 2026. The program included oral talks by invited prominent scientists and oral and e poster presentations by participants in selected topics from the submitted abstracts focusing on Agriculture, Biology and Life Sciences topics.

There is a worldwide record participation again in AGBIOL 2026 from 61 countries 1057 papers contributed over 2500 authors then 800 of them were accepted and then the conference was organized with 390 oral and 410 poster presentations.

With care for our nature and environment, we aim the green congress, meaning that as little as possible papers will be used. Abstract book is published in electronic book and is distributed to the participants by e mail for online participants. All the e-posters are prepared in electronic form and then submit to via the conference e mail and exhibited in electronical poster boards as well as in online e poster hall in our web page during the conference.

The participants with paid conference fee accessed all the normal and virtual presentation talks in each session, as well as to visit the virtual poster hall via preliminary provided. The abstracts were published in the Conference Abstract and Proceedings Book. Participants might send us their full papers, which based on their preferences are published either in our Conference Abstract and Proceedings Book or in selected International Indexed Scientific Journals.

Conference Topics:

Agriculture, Forestry, Life Sciences, Agricultural Engineering, Aquaculture and Biosystems, Animal Science, Biomedical science, Biochemistry and Molecular Biology, Biology, Bioengineering, Biomaterials, Biomechanics, Biophysics, Bioscience, Biotechnology, Botany, Chemistry, Chemical Engineering, Earth Sciences, Environmental Science, Food Science, Genetics and Human Genetics, Medical Science, Machinery, Pharmaceutical Sciences, Physics, Soil Science.

We would like to thank all of you for joining this conference and we would like to give also special thanks to TUBITAK and collaborators for giving us a big support to organize this event.

Prof Dr Yalcin KAYA
Head of the Organizing Committee

Corresponding author e-mail: gurbuzunal@beykent.edu.tr

ABSTRACT

Globalization, increasing competition, and rapidly changing customer demands have made it imperative for the manufacturing sector to adopt more efficient, flexible, and cost-effective production systems. In the food industry in particular, the short shelf life of products highlights the necessity for continuous and fast-paced production processes, thereby exposing the limitations of the traditional mass production approach. Mass production systems can lead to various problems in food manufacturing facilities, including high inventory levels, long production lead times, excessive waste, and low flexibility. At this point, the lean manufacturing approach offers a customer-oriented, flexible, and efficient production model by eliminating waste. Lean manufacturing not only transforms physical processes but also enhances workforce management, equipment efficiency, and information flow. This study analyzes the transition process to lean manufacturing in a food production factory. The main objective of the study is to eliminate inefficiencies in the production line, reduce unnecessary inventories, lower costs, and increase production efficiency. Throughout this transformation, tools such as the Kaizen philosophy, 5S practices, Value Stream Mapping (VSM), fishbone (Ishikawa) analysis, and Industry 4.0 technologies have been integrated holistically. Based on this analysis, various lean manufacturing tools were utilized to develop appropriate solutions. In particular, the use of value stream mapping played a critical role in identifying non-value-added activities and planning a future-state lean flow. This transformation process represents not only an operational shift but also a cultural change within the organization.

Keywords: Lean Manufacturing, Mass Production, Efficiency, Value Stream Mapping, Fishbone Analysis

INTRODUCTION

The food industry is a vast and strategically important sector that meets the basic human need for nutrition. This industry plays a critical role both economically and socially, processing raw materials obtained from primary production sources such as agriculture, livestock and fisheries, and delivering them to consumers. The food industry encompasses various sub-sectors, including baked goods, dairy products, meat and meat products, beverages, canned foods, ready meals, confectionery, and snacks.

With the impact of industrialization, food production has shifted from traditional methods to mass production-based, high-volume, and standardized processes. Mass production enables large quantities of products to be produced in a short time; however, this system is rigid, inadequate in responding to fluctuating demand patterns, and can lead to high inventory costs. Particularly today, with increased competition, diversified consumer expectations, and the need for more efficient use of resources, the food industry has been driven towards more agile and lean production systems.

Lean production is a manufacturing philosophy focused on eliminating waste and creating customer value. Implementing this approach in the food industry not only increases

production efficiency but also enhances quality, thereby improving customer satisfaction. Furthermore, in the production of perishable goods like food, lean systems provide significant advantages through reduced inventories, shortened process times, and agile decision-making mechanisms.

In this context, the transition from mass production to lean production in a food industry factory is not just an operational transformation but also involves a cultural and structural change. This study will examine the transition process in detail, exploring the challenges faced, methods applied, and gains achieved through a case study.

In food production factories, traditional mass production systems often lead to various issues such as high inventory levels, waste in production processes, low resource efficiency, and inflexible production structures. These problems not only increase production costs but also negatively affect the company's competitive power. Especially in an environment where consumer demands change rapidly and global competition is increasing daily, it has become very challenging for traditional production models to cope with these difficulties. In this context, the implementation of more efficient, flexible, and cost-effective production systems is inevitable.

This study aims to comprehensively analyze the existing production system in a food manufacturing facility. The analysis will incorporate modern production tools such as the Kaizen philosophy, 5S methodology, Industry 4.0 applications, and Fishbone (Ishikawa) analysis, as well as the Value Stream Mapping (VSM) method. Value Stream Mapping allows for visualizing the flow of materials and information on the production line, identifying non-value-adding activities and waste. Through this analysis, the main problems encountered in the production processes will be identified, and areas for improvement will be determined to eliminate these problems.

The research aims to eliminate inefficiencies on the production line, reduce unnecessary inventory, lower costs, and increase productivity by minimizing time losses. Specifically, by using value stream mapping, non-value-adding steps in the processes will be identified and removed. In this direction, the transformation that the transition from traditional mass production to lean production will create at both operational and strategic levels is considered the primary problem of the research.

The theoretical basis for lean manufacturing is based on the Toyota Production System, which became popular in Western management literature following the publication of Womack, Jones, and Roos's "The Machine That Changed the World" in 1990. This system defined lean manufacturing as a system that delivers more value to customers while producing the same outputs using fewer inputs. Early extensions of this framework into food processing, dating to studies in the late 2000s. These studies argued that lean manufacturing could help food processors become more competitive in the face of consumer pressure and competition from larger players; however, these early studies were largely conceptual or exploratory and not empirically substantiated in large samples.

Studies covered lean manufacturing are presented chronologically in Table 1. The studies reviewed in the literature are described as thematic groups. This aims to serve as a quick reference source for reviewing narrative literature; it allows for a comparison of each study's methodology, sectoral context, and key findings at a glance.

Table 1. Summary of Literature on Lean Manufacturing Application in the Food Industry

Author(s) & Year	Methodology	Food Subsector / Setting	Key Findings
Womack, Jones & Roos (1990)	Foundational book / conceptual	Automotive (foundation for all sectors)	Defined lean production as a system using fewer inputs to create equal output with greater customer value; established the vocabulary (waste, value, flow) for studies.
Luning, Marcelis & Jongen (2002)	Conceptual / techno-managerial framework	Food industry (general)	Identified short shelf life, heterogeneous raw materials, seasonality, and variable harvesting conditions as structural features that complicate direct transfer of lean tools from discrete manufacturing to food processing.
Scott, Wilcock & Kanetkar (2009)	Survey	Food sector (general)	Surveyed structured continuous-improvement programmes in the Canadian food sector; found sustained managerial interest in lean-type initiatives.
Dora, Kumar, Van Goubergen, Molnar & Gellynck (2013)	Literature review + survey	Food processing SMEs (general)	Found lean manufacturing still at an early adoption stage in food SMEs; identified workforce skill, in-house expertise, and organizational culture as critical success factors; food safety prioritized over process improvement.
Dora, Kumar, Van Goubergen, Molnar & Gellynck (2014)	Multi-case study	Small and medium-sized food enterprises	Examined applicability of lean practices in food SMEs; confirmed operational performance gains but highlighted resource constraints limiting scale of adoption.
Jiménez, Tejeda, Pérez, Blanco & Martínez (2011)	Case study (VSM)	Wine production	Demonstrated applicability of value stream mapping to a food and beverage subsector distinct from packaged industrial food manufacturing.
Kazancoglu, Ekinci, Ozkan Ozen & Ozbiltekin Pala (2021)	Case study	Poultry processing	Showed that combining lean tools with sustainable-operations practices reduces food waste across production, supply chain, and processing stages simultaneously.
Cusiatado Palomino, Farfán Carhuamaca & Rada Mota (2024)	Systematic review (PICO, PRISMA)	Food industry (cross-sector)	Found consistent positive association between lean tool implementation (TPM, JIT, VSM, 5S, Kaizen) and productivity, efficiency, and waste/cost reduction, contingent on supporting organizational factors.
Gayathri, Gokul Kannan, Swathi &Jenithakarthiga (2026)	Case study (VSM + JIT)	Dairy processing	Applied value stream mapping and Just-in-Time principles to pasteurization and packaging; achieved reductions in waiting time, in-process stock, and total lead time.

FOOD SECTOR

The current situation in the food sector, general challenges, deficiencies, and areas for improvement that food production facilities face may be explained as follows:

Time Loss and Low Productivity: In food production facilities, lengthy and inefficient processes lead to significant time losses. Unnecessary waiting times, slow production lines, low machine efficiency, and shortcomings in workforce management extend production time and decrease overall productivity.

Costs and Waste: Inventory management, irregularities in production planning, and waste during production lead to increased costs. Excess inventory raises storage and transportation expenses, while defective production, rework, and material waste contribute to higher operational costs.

Lack of Flexibility and Issues with Adaptation to Change: Traditional production systems struggle to respond to rapid changes in customer demand. This limits the ability to produce in small batches and reduces the competitive advantage in the market.

Quality Control Deficiencies and Error Rates: In fast production lines, inadequate quality control processes can lead to high error rates due to human mistakes and machine malfunctions. This increases rework and waste, reducing product quality.

Communication and Coordination Deficiencies: Weak communication and coordination between departments lead to errors in production planning, material supply, and workforce management. This results in delays, incorrect timing, and inventory shortages in the production process.

Lack of Digitalization, Innovation, and Sustainability: Most food production facilities have not fully adapted to digital technologies and Industry 4.0 applications. This deficiency makes it difficult to ensure process transparency and control while hindering the development of an innovation culture and sustainable production practices.

MASS PRODUCTION VS LEAN PRODUCTION

Mass production is a system based on producing the same product in large volumes and continuously. It is commonly used in industries such as automotive, electronics, and home appliances. Lean production is a production system aimed at eliminating all types of waste that do not add value to the customer. The Comparison of lean manufacturing and mass production can be seen in Table 2.

Table 2. Lean Production & Mass Production

Feature	**Mass Production**	**Lean Production**
Purpose	High-volume, low-cost production	Create value by eliminating waste
Production Process	Standardized, fixed production flow	Continuous improvement and flexible production
Stock Management	Large stocks, tendency to overproduce	Demand-based production, minimum stock
Flexibility	Low flexibility, difficult to adapt quickly to demands	High flexibility, quick adaptation to demands
Investment Requirement	High initial investment required	Low initial investment, continuous improvement
Employee Participation	Low employee participation, mostly automation	High employee participation, continuous improvement
Efficiency	High efficiency, limited flexibility	High efficiency and flexibility

Transition from Mass Production to Lean Production

Mass production systems carry disadvantages such as high stock costs, long production times, and low flexibility. The transition to lean production arises from the need to adopt a customer-focused approach to reduce costs and increase efficiency. The transition to lean production involves various challenges such as company culture, employee resistance, the restructuring of existing processes, and technological adaptation. Management support and employee training play a critical role in overcoming these barriers.

Strategic Steps for Transitioning to Lean Production

Analyzing current production processes and identifying waste
Applying value stream mapping techniques
Transitioning to a pull-based production system
Training employees on lean production principles
Management Support and Leadership

Lean Production Tools and Techniques

Lean production adopts an approach focused on eliminating all wastes that do not add value. In this context, a variety of tools and techniques are used to make processes more efficient and to respond quickly to customer demands. Below are the key tools and techniques in lean production:

Value Stream Mapping (VSM) : Identify wastes in production processes and improve the flow of processes.Examine each step in the production process to eliminate non-value-adding activities.

5S and Visual Management: Ensure workplace organization and prevent waste. Organize and standardize workspaces and use visual management to monitor processes.

Just-in-Time (JIT) Production: Minimize stock levels by aligning production with customer demand. Reduce inventory and produce only based on demand.

Kanban System: Ensure production is driven by need. Control material flow with visual signals and optimize production.

SMED (Single-Minute Exchange of Die): Minimize changeover times in production lines. Reduce machine setup and die change times, providing flexibility in production.

Poka-Yoke (Error-Proofing): Create mechanisms to prevent production errors. Prevent defects in the production process and improve quality.

Total Productive Maintenance (TPM): Ensure efficient operation of equipment. Reduce equipment breakdowns and ensure continuous maintenance.

Pull System and Production Pull: Direct production according to customer demand. Shape production processes based only on demand, preventing unnecessary production.

Continuous Improvement (Kaizen): Optimize production processes through continuous small improvements. Encourage employee participation to achieve continuous development and increased productivity.

Error Reduction and Elimination of Defective Production (Jidoka): Detect production errors early and enhance quality through automation. Prevent defects at the source and eliminate defective production.

Industry 4.0 and Digitalization: Optimize production processes with digitalization and automation. Use smart sensors, data analytics, and cyber-physical systems to make production processes more efficient.

METHODS USED IN THE STUDY

Kaizen : Kaizen is a Japanese term that means "change" (kai) and "good" (zen). Kaizen is a management method that adopts the philosophy of making continuous small improvements to increase organizational efficiency. The core principle of Kaizen is to encourage all employees to actively participate in improving processes. Instead of focusing solely on large changes, this philosophy aims to make continuous, small but valuable improvements. Kaizen promotes a continuous improvement process in areas such as labor efficiency, equipment efficiency, costs, quality, and safety.

Industry 4.0 : Industry 4.0 refers to the integration of modern technologies, such as digitalization, automation, data analytics, and the Internet of Things (IoT), into production processes. This concept aims to make manufacturing processes smarter, more flexible, and more efficient. Industry 4.0 increases production line efficiency by using technologies like machine learning, robotic systems, sensors, big data, and artificial intelligence (AI). As a result, lower error rates, reduced downtime, faster production processes, and more flexible manufacturing capabilities can be achieved. Industry 4.0 enables factories to become "smart factories," providing real-time data collection and analysis opportunities.

Fishbone (Ishikawa) Diagram : The Fishbone Diagram, also known as the Ishikawa Diagram, is a tool used to analyze a problem and uncover its potential causes. The diagram is designed in the shape of a "fishbone," with the main problem considered as the "head" and all the factors (causes) that may affect the problem represented as "bones." This method is particularly useful for quality control and process improvement. The Fishbone Diagram typically uses the following categories: People, Equipment, Methods, Materials, Measurements, and Environment. This tool helps to thoroughly examine the causes of a problem in a production process and develop potential solutions. Figure 1 is a Fishbone diagram for food sector including time, cost, digitalization, quality, communication and flexibility.

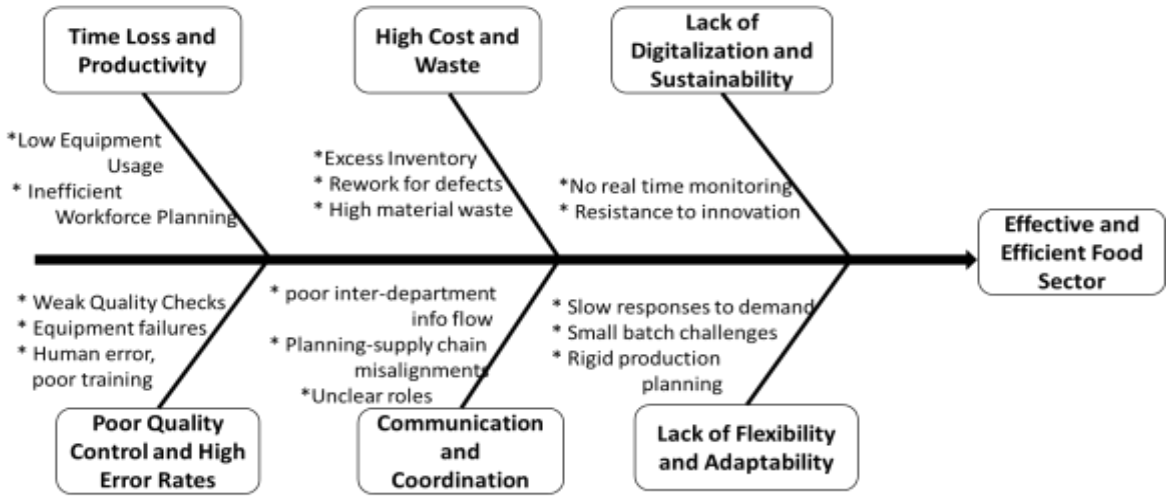

Figure 1. The Fishbone Diagram for Food Sector

Value Stream Mapping (VSM): Value Stream Mapping (VSM) is a technique used to visually design all the steps in a production process and analyze value-creating and non-value-creating activities. A value stream map shows the flow of information, materials, and time at each stage of the process. This map helps identify process bottlenecks and waste (e.g., excess inventory, waiting times, unnecessary transportation). VSM enables the evaluation of the current state of the organization and allows for improvement plans aimed at reaching the ideal

future state. This method is a critical tool in lean manufacturing philosophy and plays a vital role in making processes more efficient. Figure 2 is a Value Stream Map for food sector.

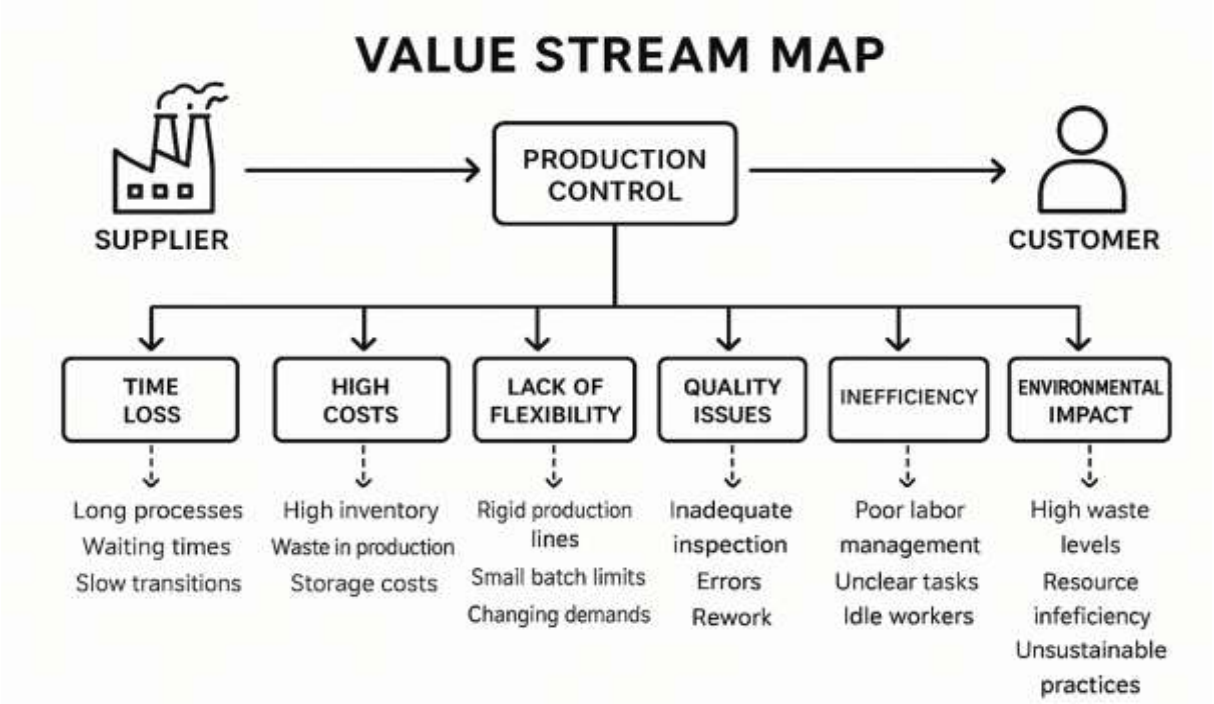

Figure 2. The Value Stream Map for Food Sector

This study provides a detailed application of Kaizen; improvement strategies addressing key issues encountered in the production line. The investigation is structured around six main problem areas adversely affecting production processes: time loss, high costs, quality problems, communication gaps, lack of digitalization, and lack of flexibility. Under each category, both the traditional continuous improvement solutions offered by the Kaizen approach and the technological, digital transformation-oriented approaches of Industry 4.0 are evaluated. The effectiveness, ease of implementation, and potential contributions of these methods to the business are compared. Following this assessment, the practical section of the study focuses on analyses of time loss, cost and efficiency, and quality.

LEAN PRODUCTION APPLICATION FOR FLOUR PRODUCTION

Lean manufacturing has been studied in the food industry, specifically in flour production. Figure 3 shows the general operation of a flour mill. The flour production system shown in Figure 3 was used while conducting mass production and lean manufacturing studies.

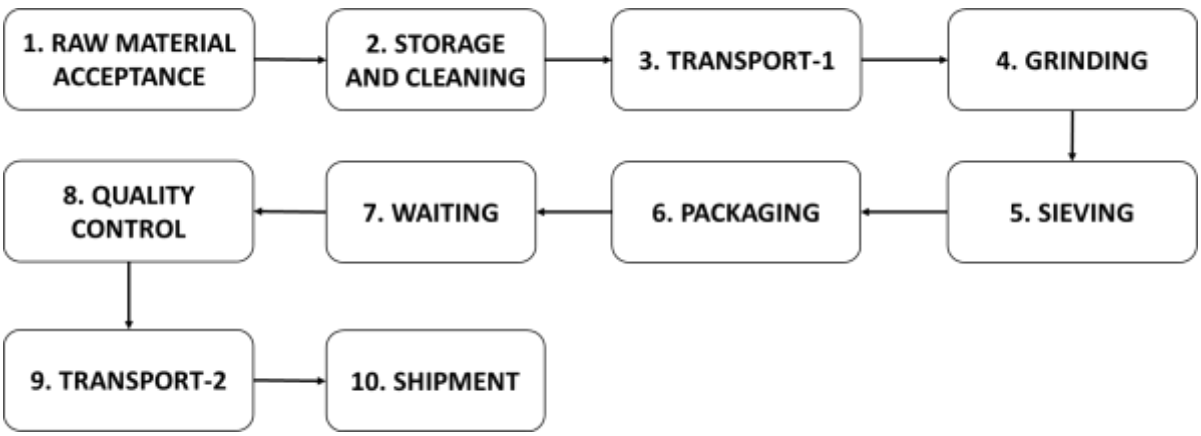

Figure 3. The Steps in the Flour Production Process

Quantitative Analysis and Efficiency Improvement :Time Loss and Low Efficiency

As a result of the process quantitative analysis conducted using generic data, one of the main problems identified in flour production is time loss, which in turn leads to low productivity. Although the current production process progresses through sequential steps, a detailed review of the workflow reveals several instances of unnecessary delays, low equipment efficiency, and human-related interruptions.

In particular, delays that disrupt continuity have been observed between the initial steps of "Raw Material Procurement" and "Cleaning and Sieving." Irregularities in raw material supply and uncertainties during quality control cause delays in transitioning to the subsequent stages. This negatively affects the overall flow of the production line.

Additionally, it has been reported that machines used in the grinding (mill) process frequently require maintenance, which leads to repeated interruptions in planned production. When breakdowns occur, production comes to a complete halt, resulting in both time loss and idle labor. The lack of automation and the dependence on manual interventions reduce the sustainability of the process.

Similar time losses are observed during the Sieving and Sorting stages. Delayed sorting of sieved products or the continuation of processes manually extends the processing time and increases the margin of error. This leads to bottlenecks toward the end of the line and slows down the overall flow.

Due to the lack of automation in the quality control process, some batches needed to be reprocessed, causing further time losses on the production line. In cases where quality is inspected manually, operations such as returning products cause deviations from the production plan and reduce overall efficiency.

In general, despite the sequential nature of production steps, minor delays at each stage accumulate and significantly extend the total production time. As a result, the facility's capacity cannot be used effectively. These recurring disruptions lead to waste of both time and energy and cause deviations in production planning.

To compare the existing mass production system with the lean production system, the production process was modeled for ten products, and the results are shown in Table 3. The average duration of each step of the production process was determined.

Table 3. Mass Production – Daily Process Times (Hours)

Pro-duct	Raw Material Acceptance	Storage	Transport 1	Grinding	Sieving	Packaging	Waiting 1	Quality Control	Transport 2	Shipment	Total Time
1.	1,3	1,0	0,7	1,9	1,1	1,4	2,3	0,7	1,0	0,5	**12,0**
2.	1,1	1,1	0,8	2,0	0,9	1,6	2,2	0,8	1,1	0,5	**12,1**
3.	1,2	1,1	0,8	2,2	1,0	1,6	2,2	0,9	1,0	0,5	**12,3**
4.	1,3	1,0	0,8	1,9	1,0	1,6	2,0	0,8	1,0	0,5	**11,8**
5.	1,3	1,0	0,9	2,1	1,0	1,5	2,1	0,8	0,9	0,5	**12,1**
6	1,2	1,0	0,8	1,9	1,0	1,5	2,3	0,8	1,0	0,5	**11,9**
7.	1,2	1,0	0,8	2,0	1,0	1,5	2,1	0,8	0,9	0,5	**11,8**
8.	1,2	1,0	0,8	2,1	1,0	1,4	2,3	0,8	1,1	0,5	**12,1**
9.	1,2	1,0	0,8	2,0	1,0	1,4	2,3	0,8	1,0	0,5	**12,0**
10	1,2	1,0	0,8	2,0	1,0	1,5	2,3	0,8	1,0	0,5	**12,0**
Aver-age	**1,2**	**1,0**	**0,8**	**2,0**	**1,0**	**1,5**	**2,2**	**0,8**	**1,0**	**0,5**	**12,0**

Within this context, the implementation of lean production practices aims to reduce time losses and eliminate unnecessary steps in the process. The lean production findings presented

in this section is supported by quantitative analyses in the Table 4. The impact of the transition to lean production on manufacturing efficiency with concrete data.
Table 4. Lean Production – Daily Process Times (Hours)

Pro-duct	Raw Material Acceptance	Storage	Transport 1	Grinding	Sieving	Packaging	Waiting 1	Quality Control	Transport 2	Shipment	Total Time

9.	0,8	0,6	0,4	2,1	1,0	1,2	1,0	0,6	0,6	0,4	**8,6**
10	0,8	0,6	0,4	2,0	1,0	1,2	1,0	0,6	0,6	0,4	**8,7**
Aver-age	**0,8**	**0,6**	**0,4**	**2,0**	**1,0**	**1,2**	**1,0**	**0,6**	**0,6**	**0,4**	**8,6**

The Figure 4 shows the steps in the Lean Production process along with the average duration of each step, indicated in parentheses. In lean production, significant reductions have been achieved in waiting and transportation times, contributing to a shorter overall production time and increased efficiency. Analysis shows an approximately 28% reduction in total production time

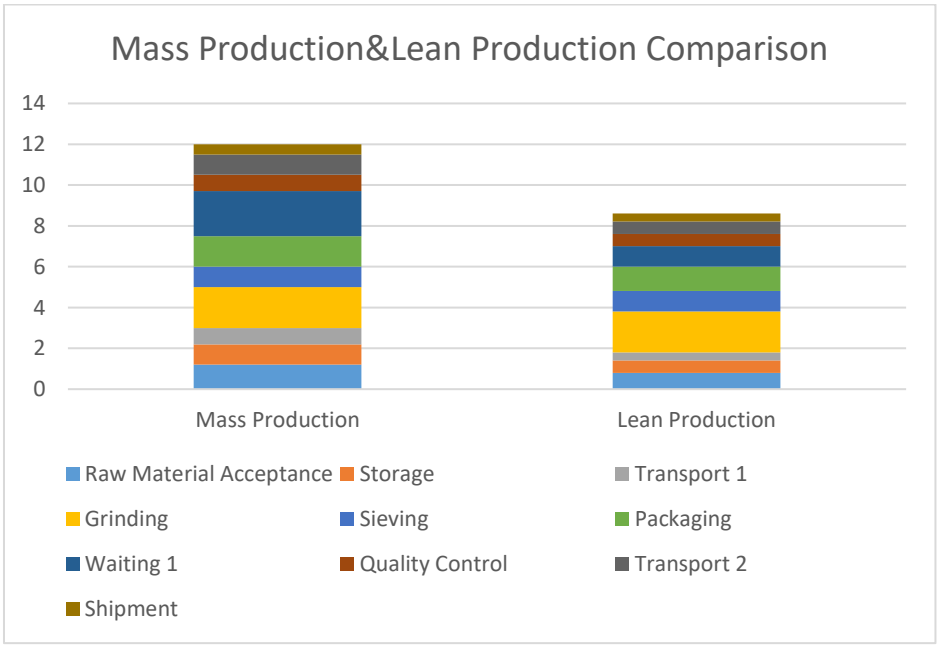

Figure 4 Total Production Time Comparison

Value Stream Mapping (VSM) Analysis

Value Stream Mapping (VSM) Analysis is used to differentiate between value-added and non-value-added activities across the entire production process. Value-Added (VA) Steps: Grinding, Sieving, Packaging. These processes transform wheat into flour and package it.

Non-Value-Added (NVA / Waste) Steps: Storage, Transports and Waiting. Lean manufacturing aims to completely eliminate or minimize these NVA /waste steps. It identifies sources of waste such as waiting times, transportation, excessive inventory, and reprocessing, thereby highlighting areas of time loss within the workflow.

Raw Material Acceptance, Quality Control and Shipment steps are mandatory but Non-Value-Added (Business Non-Value-Added - BNVA) steps. These steps do not directly add value to the product but are mandatory for legal, quality or logistical processes.
Note: Value-added processes are Grinding, Sieving, Packaging.

Table 5. Lean Production Improvement

Pro-duct	Raw Material Acceptance	Storage	Transport 1	Grinding	Sieving	Packaging	Waiting 1	Quality Control	Transport 2	Shipment	Total Time
Mass Pro.	1,2	1,0	0,8	2,0	1,0	1,5	2,2	0,8	1,0	0,5	12,0
Lean Pro	0,8	0,6	0,4	2,0	1,0	1,2	1,0	0,6	0,6	0,4	8,6
Impr-ovem %	40%	40%	40%	0%	0%	30%	120%	20%	40%	10%	3,4 (28%)

Time (Hours)	Mass Production	Lean Production
Total Production Time	12	8,6
Value Added Time	4,5 (37,5%)	4,2 (48,8)
Value Added Ratio	4,5 / 12 = 37,5%	4,2 / 8,6 = 48,8%

The value-added ratio increased from 37.5% to 48.84% in lean production. This indicates that waiting, transportation, and unnecessary operations decreased, resulting in a higher proportion of value-added work in the process.

Cycle Time & Takt Time Comparison

It is used to examine the alignment of the production cycle time with the customer demand rate (Takt Time). Identifies where production is slowing down, highlighting areas for improvement.

Bottleneck Analysis: In both mass production and lean manufacturing, the longest-running steps are Milling (2.0 hours) and Packaging (1.5/1.2 hours), respectively. Therefore, the Milling stage is the one that determines the factory's maximum daily production capacity (the stage with the highest cycle time).

Takt Time Alignment: Since the Milling (2.0 hours) and Sieving (1.0 hour) times were maintained during the transition to lean manufacturing, the main production speed was not disrupted. However, by reducing the Packaging time from 1.5 hours to 1.2 hours, the accumulation of flour from the Milling stage in front of the packaging area was prevented, and the process was made more aligned (balanced) with Takt time.

The Waiting time (waiting in intermediate flour silos), which was 2.2 hours in mass production, was reduced to 1.0 hour in lean manufacturing. This indicates that a Kanban/Pull system has been established between the Grinding and Packaging lines, or that the production flow has been synchronized.

Total Operating Time: 12 hours × 60 minutes = **720 minutes**.
Total Planned Downtime: 30 minutes (Breaks) + 30 minutes (Breakdowns and Installations) = **60 minutes**

Net Available Operating Time: 720 min - 60 min = **660 minutes** (39,600 seconds)
Daily Customer Demand: **250** packs
Takt Time =660 /250 = 2,64 minute /sacks (To meet customer demand on time, 1 sack of flour must leave the factory every 2 minutes and 38 seconds (158.4 seconds).

	Available Product Amount	
Takt Time	250 (Customer Demand)	2,64 minute (660/250 = 2,64)
Mass Production Cycle Time	200	3,3 minute (660 /200 = 3,3)
Lean Production Cycle Time	275	2,4 minute (660/275 = 2,4)

Within the framework of lean production practices, non-value-added activities such as waiting, transportation, and rework were analyzed and targeted for reduction through the use of Value Stream Mapping (VSM). Additionally, employee training on lean principles and process restructuring were implemented to minimize waste.

Following these improvement initiatives, measurements indicated that the average cycle time per product on the production line decreased from 3,3 minutes to 2.4 minutes. This result is less than the target takt time of 2.64 minutes, demonstrating the effectiveness of lean production applications in aligning production speed with customer demand. Producing a customer's order of 250 units now takes only 600 minutes (250 times 2.4). This means we can finish our daily order 60 minutes before your net time limit of 660 minutes expires.

Minor breakdowns or stoppages during the day no longer jeopardize our delivery because we now have a time margin on your production line. The 2 hours and 45 minutes of overtime for previous Mass Production that we had to work each day to reach 250 units is completely eliminated. Now that we have confidently exceeded customer demand, we can plan our inventory management.

CONCLUSION

As a result, both production efficiency increased and responsiveness to customer demands improved. The obtained data quantitatively prove that implementing lean production processes reduces cycle time and significantly decreases time loss.

With the transition to a lean production system, significant time savings and increased production efficiency have been achieved at the flour mill. Our analysis shows an approximately **28% reduction in total production time**, while the value-added process ratio increased from **37,5% to 48,8%**. This improvement was made possible by reducing waste elements such as waiting, unnecessary transportation, and rework within the production process. Our cycle time has been decreased **37,5 %** and we are able to produce more than customer demand.

Furthermore, adjusting the cycle time to align with customer demand has considerably enhanced production speed. Kaizen activities conducted as part of lean production, along with the integration of Industry 4.0 technologies, have minimized waste (Muda) and made processes smoother and more efficient.

The transition to lean production has led to both cost reductions and an increase in production capacity, thereby improving the factory’s competitiveness and customer satisfaction.

ABSTRACT

This study presents new documentation and ecological analysis of the wild bee *Osmia andrenoides* (Spinola, 1808) in the Vjosa-Narta Protected Landscape, an area of primary importance for coastal biodiversity in Albania. This specialized species, which nests exclusively in empty snail shells and displays a clear preference for the plant families *Lamiaceae* and *Plantaginaceae*, serves as a sensitive bioindicator of habitat integrity. Sampling was conducted between May and August 2025 across 29 stations, using pan traps, pitfall traps, and manual capture. Among the 53 identified hymenopteran species (18 families), *Osmia andrenoides* was recorded at only a single station (Station 1). Its extremely restricted distribution is closely linked to the intact microhabitats of the Aleppo pine forest (*Pinus halepensis*), low anthropogenic impact, and the availability of mollusk shells. Environmental pressures such as forest fires, seasonal flooding, shell burial by shifting sands, and uncontrolled tourism represent the primary limiting factors for this population. The findings highlight the critical importance of the mosaic of coastal habitats for species life. The presence of Osmia andrenoides confirms the high ecological value of the lagoon ecosystem and its role as a key habitat for Mediterranean biodiversity. This study highlights the need for further monitoring and conservation measures to protect this species.

Keywords: *Osmia andrenoides*; Hymenoptera; Narta Lagoon; bioindicators; shell nesting

INTRODUCTION

The order Hymenoptera represents one of the most important groups of insects for the functioning of terrestrial ecosystems, especially due to its role in the pollination process (Michener, 2007). Within this order, the genus Osmia Panzer, 1806 includes a considerable number of solitary species of particular ecological importance. One of these is Osmia andrenoides (Spinola, 1808), which is mainly distributed in the Palearctic region, including Southern Europe and parts of Western Asia (Müller, 2020).

Osmia andrenoides is an exceptional species of wild bee with a reddish abdomen, well adapted to the Mediterranean region. It displays a highly specialized nesting biology, being a species that prefers snail shells (Müller & Richter, 2019). Females build their nests exclusively inside empty snail shells, where the egg chambers and the entrance are sealed with only chewed leaf fragments (Muller & Richter, 2019). For protection, the shell is often hidden under stones or plant debris. From a trophic point of view, this bee is polylectic, but prefers the plant families Lamiaceae and Plantaginaceae (Müller, 2020). Thanks to the stiff hairs on the front of its head, it mechanically rubs the anthers of bilabiate flowers to collect pollen, serving as a highly efficient pollinator (Kevan, 1999; Potts et al., 2010; Hung et al., 2018). The dual dependence

on snail shells and specific flora makes it an excellent bioindicator of habitat quality (Müller, 2020). Its presence indicates a healthy ecosystem and rich microstructural biodiversity, while its disappearance signals degradation or urbanization of the area (Müller, 2020).

In the Balkan Peninsula, O. andrenoides finds ideal conditions in calcareous areas and Mediterranean climates (Ungricht et al., 2008; Banaszak, & Dochkova, 2014). Its distribution is well documented along the Adriatic and Ionian, from Slovenia and Croatia to Greece (Gogala, 1999; Grace, 2010; Ungricht et al., 2008). Also in Albania, according to Müller (2020), this species was first documented by Tkalců (1974) in two locations: Lezhë (Lurë/Kurbnesh) and Vlorë (Borsh). The Narta Lagoon area is home to a rich mosaic of natural habitats and species diversity (Çobaj et al., 2025). The Hungarian Museum of Natural History has organized several zoological expeditions to Albania, especially during the period 1992–2003, during which material was collected from a large number of localities and for a wide taxonomic range, including the order Hymenoptera (Fehér et al., 2004). However, some of this data is not easily accessible online or in the published scientific literature (Fehér et al., 2004).

This study aims to document and ecologically analyze the species Osmia andrenoides in the Vjosa-Narta Protected Landscape, updating data on its distribution in Albania and assessing the environmental factors that influence its presence.

METHODOLOGY

The sampling was carried out as part of a doctoral study in the Narta lagoon. Sampling was conducted at 29 stations during the months of May-August 2025, as hymenopterans are more active during the warm months of the year (Figure 1). The methods used for their sampling are: “Pan Traps”, very effective for sampling hymenopterans, especially bees, wasps and some flying ants (Fursov et al., 2023); “Pitfall Traps”, which consist of placing cups or containers on the ground, with the rim level with the ground surface (Jiménez-Carmona et al., 2020).

Fig. 1 Sampling stations

The traps are usually placed at the level of the vegetation, distributed regularly along transects or certain surfaces, and left for several hours to a day (exposure for more than a day may damage the samples). Hand collection and insect netting were used to capture incidental insects encountered during the trap setting. After collection, insects were preserved in 70% alcohol (ethanol). For identification to the family level, the taxonomic key of Goulet & Huber (1993) was used. For each family, the appropriate identification keys were used, specifically to confirm the family Megachilidae (through the venation of the wing with two submarginal cells and the presence of a ventral scopa) and then the monograph of Müller (2020) was used to arrive at the species Osmia andrenoides.

RESULTS AND DISCUSSION

Habitats such as those surrounding the Vjosë-Nartë Protected Landscape provide the typical environment where this bee finds empty mollusk shells for nesting and aromatic flora of the Lamiaceae family for feeding.

This documentation not only enriches the inventory of local biodiversity, but also testifies to the ecological value of our coastal and hilly habitats, positioning this species as an important indicator of the health of Mediterranean ecosystems in Albania.

Sampling was carried out at 29 stations in the Narta lagoon, part of the Vjosë-Nartë-Pishporo Protected Landscape. Although a total of 53 hymenopteran species were identified from the sampling, this paper focuses specifically on the ecological analysis of Osmia andrenoides (Spinola, 1808), while data for the full community will be presented in further studies. The presence of the species Osmia andrenoides was only found at station 1 with coordinates 40°39'17.6" N, 19°22'51.7" E.

The environment at this sampling point is a strip of artificial pine forest (Pinus halepensis), planted near the Vjosa River to protect the land from the river about 50 years ago. Because it is located near the village of Dëllënjë, this forest area of several hectares remains undamaged by fires. Since Osmia andrenoides is found in pine forest habitats, the presence of these formations in the Narta lagoon suggests suitable conditions for this species

Taxonomic identification of Osmia andrenoides (Spinola, 1808)

The species identification was done using different taxonomic keys. Initially, the key of Goulet & Huber (1993) was used to confirm the family Megachilidae (through the venation of the wing with two submarginal cells and the presence of the ventral scopa) and then the monograph of Müller (2020) was used to arrive at the species Osmia andrenoides (Spinola, 1808). Its identification in a new location helps to update the data for Albania and increases the biodiversity values of the Vjosa-Nartë Protected Landscape.

Habitat characteristics and factors of presence only at one station

The area where Osmia andrenoides (Spinola, 1808) was found is a pine belt (Pinus halepensis Miller) planted artificially to protect the soil from erosion by the Vjosa River. At this station, the environment has a low impact from human activities. Rare cuttings of pine trees have been observed within the environment, which creates small open microenvironments with a lot of light. No burning or fire involvement of the entire pine belt has been found, but only at the edges. During the outflow of the Vjosa River, the area is not completely flooded, but strips remain untouched by water. As a species that nests exclusively inside empty shells of land snails, the presence of snail shells is a key factor for its presence. The wetland environment is covered with water in winter; this causes the empty snail shells to fill with water and mud. In the dune areas on the shore side, sand continuously covers the shells. Repeatedly, almost every year, in most of the stations there has been involvement from fires, as well as high tourist activity. Based also on other studies on the entomofauna in the lagoon area, the analysis of the

distribution of insects in relation to the type of soil (sand/clay), humidity and human impact shows that environmental and anthropogenic factors play a decisive role in determining their habitats (Çobaj et al., 2025). These facts are an indication of why it was found only at one station.

Fig. 2 Osmia andrenoides (Spinola, 1808) a. General view of the body, b. Wings, dorsal view, c. Head, frontal view, d. Metasoma, ventral view

Ecological significance and conservation value of Osmia andrenoides in the habitat mosaic of the Narta Lagoon

The presence of the wild bee Osmia andrenoides in the Vjosa-Narta Protected Landscape takes on a special scientific significance when analyzed within the mosaic of Natura 2000 habitats documented in this ecosystem (Çobaj et al., 2025). This polylectic species finds ideal living conditions especially at the interface between Mediterranean pine forest (Pinus halepensis, Habitat 9540) and Mediterranean salt marshes (Juncetalia maritimi, Habitat 1120) (Müller & Richter, 2019, Çobaj et al., 2025). In these spaces, the depressions between the forest belt and the flooded areas create a mosaic of microhabitats where the species' food flora develops, including diagnostic species of the genus Plantago (such as P. maritima and P. crassifolia) as well as taxa of the family Lamiaceae (Çobaj et al., 2025; Müller & Richter, 2019).

Through specialized pollination, O. andrenoides directly contributes to the maintenance of the plant structure and the sustainability of these transitional habitats. From a nature conservation point of view, its dual need for empty land snail shells and for specific floristic cover positions it as a highly sensitive bioindicator of ecological integrity. This species is highly vulnerable to the main anthropogenic pressures that weigh on the Narta Lagoon, especially forest fires that

damage the organic layer of the soil in the pine forest, damage to coastal dunes (Habitats 2120 and 2250) from uncontrolled tourism, as well as habitat fragmentation from the construction of new infrastructures (such as the Vlora Airport) (Çobaj et al., 2025).

CONCLUSIONS

This study confirms the presence of the species Osmia andrenoides in the Narta lagoon, reinforcing existing data on its distribution in Albania and the Balkan region. Its sampling at a single station suggests a limited and potentially fragmented population distribution, influenced by ecological factors, the impact of fires and anthropogenic pressure. The results highlight the importance of well-preserved habitats, such as pine belts and areas with low human impact, for the survival of this specialized species. The presence of Osmia andrenoides confirms the high ecological value of the Vjosa-Narta Protected Landscape and its role as a key habitat for Mediterranean biodiversity. This study highlights the need for further monitoring and concrete conservation measures to ensure the long-term conservation of this bioindicator species.

RECOMMENDATIONS

Given the isolation of the species at station 1, future research could focus on assessing the risk of population fragmentation. A sampling specifically oriented towards areas with similar micro-environments (protected pine forests with well-preserved understory and massive presence of shells) inside and outside the lagoon, could determine whether this was an isolated individual, or whether there is a more stable local population hidden in these ecological pockets.

ABSTRACT

Staphylococcus aureus remains a major pathogen in pediatric populations, contributing to respiratory, skin, and soft tissue infections with significant public health implications. Understanding age-specific distribution and resistance trends is essential for guiding clinical management and stewardship strategies.

This study analyzed 529 *S. aureus* isolates collected from children and adolescents, stratified by age group (≤6 years, 6–14 years, and 14–18 years) and sex. Sites of isolation included respiratory tract, skin/soft tissue, urine, and sterile fluids. Antimicrobial susceptibility testing was performed against commonly used agents, including penicillins, macrolides, aminoglycosides, and topical agents.

The majority of infections occurred in school-aged children (56.7%), followed by preschoolers (38.6%) and adolescents (4.7%). Male patients accounted for 61.3% of cases. Respiratory tract isolates predominated (93.8%), while skin/soft tissue and sterile fluid infections were less frequent (3.0% each). Bloodstream infections were not detected. Antibiotic susceptibility patterns revealed high resistance to penicillin G (86.8%), ampicillin (82.4%), and amoxicillin (82.4%). In contrast, macrolides such as erythromycin, azithromycin, and clarithromycin demonstrated >91% sensitivity, while clindamycin (93.9%) and gentamicin (90.9%) remained highly effective. Notably, mupirocin and chloramphenicol exhibited complete activity (100% sensitivity), underscoring their potential utility in targeted therapy.

The findings highlight distinct epidemiological patterns of *S. aureus* infections in youth, with respiratory tract infections dominating across age groups. The persistence of high resistance to β-lactam antibiotics emphasizes the need for rational prescribing and surveillance. The preserved efficacy of macrolides, clindamycin, and topical agents offers valuable therapeutic options, yet continuous monitoring is essential to prevent emerging resistance. These results reinforce the importance of age-specific epidemiological insights and antimicrobial stewardship in mitigating the burden of pediatric *S. aureus* infections.

Keywords: *Staphylococcus aureus*, Pediatric infections, Antimicrobial resistance, Youth populations, Respiratory tract infections, Antibiotic susceptibility, Epidemiology

INTRODUCTION

Staphylococcus aureus (*S. aureus*) is a Gram-positive, coagulase-positive coccus that remains one of the most clinically important bacterial pathogens worldwide. It colonizes the anterior nares, skin, and mucosal surfaces, with approximately 20–30% of individuals persistently colonized and another 30% intermittently colonized (Taylor et al., 2025). While colonization is often asymptomatic, the bacterium can act as an opportunistic pathogen, causing a wide spectrum of diseases ranging from superficial skin infections to invasive bloodstream infections and sepsis (Tong et al., 2015).

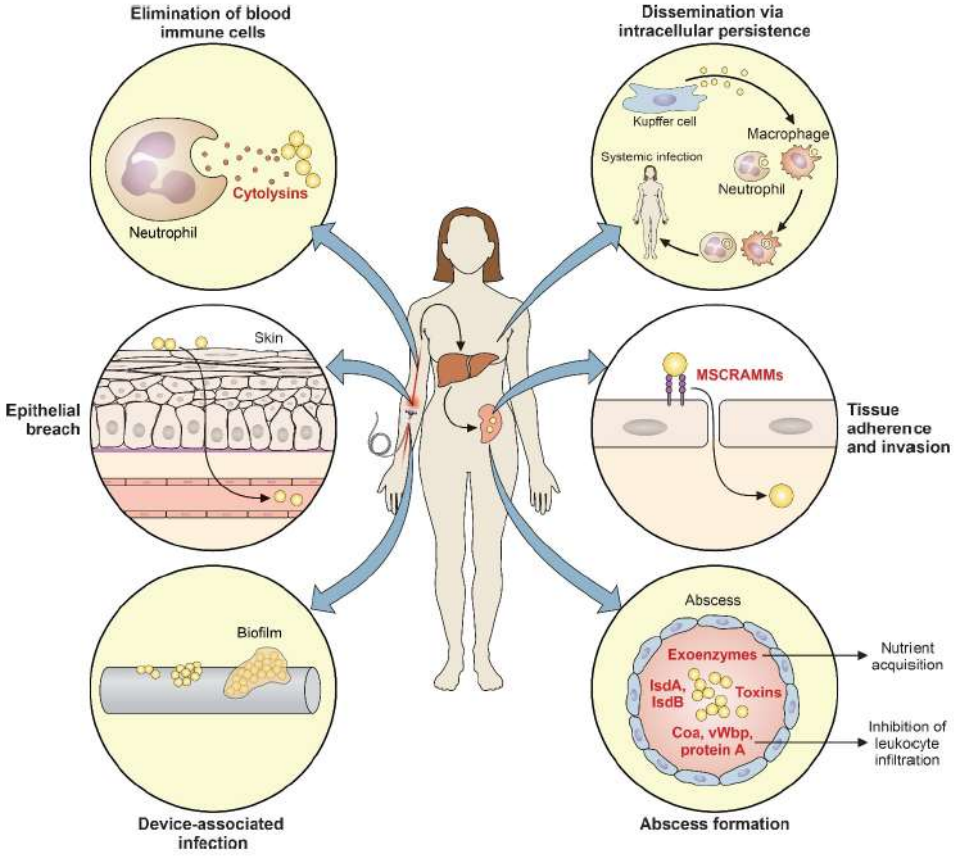

Figure 1. Stages of *S. aureus* systemic infection. *S. aureus* systemic infection frequently begins with a breach of the bacteria through the protective barrier of the skin or dissemination from a biofilm that can form on indwelling medical devices. In the bloodstream, the bacteria can actively attack and eliminate immune cells such as neutrophils via cytolytic toxins, or alternatively persist in such cells to achieve systemic distribution. Passage through the liver, where the bacteria are confronted by the phagocytic activity of Kupffer cells, represents a bottleneck for subsequent systemic infection. If the bacteria survive this stage, they can further distribute through the bloodstream and attach to and invade tissue cells, which is mediated by MSCRAMM surface proteins. Subsequent abscess formation is impacted by many different bacterial factors that include specific surface proteins, toxins, and exoenzymes (from Cheung et al., 2021).

Globally, *S. aureus* is a leading cause of both community-acquired and hospital-acquired infections. The incidence of *S. aureus* bacteremia (SAB) in industrialized countries ranges

between 10–30 per 100,000 person-years, with mortality rates of 20–30% despite advances in therapy (Tong et al., 2015). Pediatric populations are particularly vulnerable, with respiratory tract infections and skin/soft tissue infections being the most common clinical presentations (Touaitia et al., 2025). The emergence of methicillin-resistant *S. aureus* (MRSA) has further complicated management, with MRSA strains responsible for epidemics of skin infections in the community and invasive infections in healthcare settings (Mlynarczyk-Bonikowska & Rudnicka, 2025).

The pathogenic success of *S. aureus* is linked to its diverse arsenal of virulence factors. Surface adhesins such as clumping factors (ClfA, ClfB) and fibronectin-binding proteins facilitate colonization of epithelial surfaces (Touaitia et al., 2025). Secreted toxins, including α-hemolysin, toxic shock syndrome toxin-1 (TSST-1), and Panton-Valentine leukocidin (PVL), contribute to tissue damage and immune evasion (Mlynarczyk-Bonikowska & Rudnicka, 2025). Biofilm formation on medical devices enhances persistence and resistance to host defenses (Tong et al., 2015). Protein A, coagulase, and staphylococcal complement inhibitor further interfere with opsonization and phagocytosis, allowing the bacterium to evade immune clearance (Touaitia et al., 2025).

Table 1. Major Virulence Factors and Resistance Mechanisms of *Staphylococcus aureus.*

Virulence Factor	**Function**	**Clinical Impact**
Surface adhesins (ClfA, ClfB, FnBPs)	Promote adhesion to host tissues	Colonization of skin, nares, and medical devices
Protein A	Binds Fc region of IgG	Inhibits opsonization and phagocytosis
Coagulase	Converts fibrinogen to fibrin	Shields bacteria from immune attack
α-hemolysin	Pore-forming cytotoxin	Tissue necrosis, pneumonia
Panton-Valentine leukocidin (PVL)	Destroys leukocytes	Severe skin infections, necrotizing pneumonia
TSST-1 (Toxic Shock Syndrome Toxin)	Superantigen	Toxic shock syndrome
Biofilm formation	Adherence and persistence on devices	Chronic device-related infections
Agr regulatory system	Controls virulence gene expression	Adaptation to host environment

The clinical spectrum of *S. aureus* infections is broad. Skin and soft tissue infections (SSTIs) such as impetigo, abscesses, and cellulitis are common in children. Respiratory infections, including pneumonia, are often severe in post-influenza cases (Tong et al., 2015). Bloodstream infections can lead to sepsis and metastatic complications such as osteomyelitis, septic arthritis, and endocarditis. Device-related infections, particularly in prosthetic joints and cardiac devices, are frequently associated with biofilm formation (Taylor et al., 2025).

Resistance in *S. aureus* is a major global health concern. Acquisition of the mecA gene confers resistance to methicillin and all β-lactam antibiotics, defining MRSA (Tong et al., 2015). Community-associated MRSA (CA-MRSA) strains, such as USA300, have spread widely, while healthcare-associated MRSA (HA-MRSA) remains a significant challenge in hospitals (Touaitia et al., 2025). Reduced susceptibility to vancomycin (VISA/VRSA) has also been

reported, raising concerns about the diminishing efficacy of last-line therapies (Mlynarczyk-Bonikowska & Rudnicka, 2025).

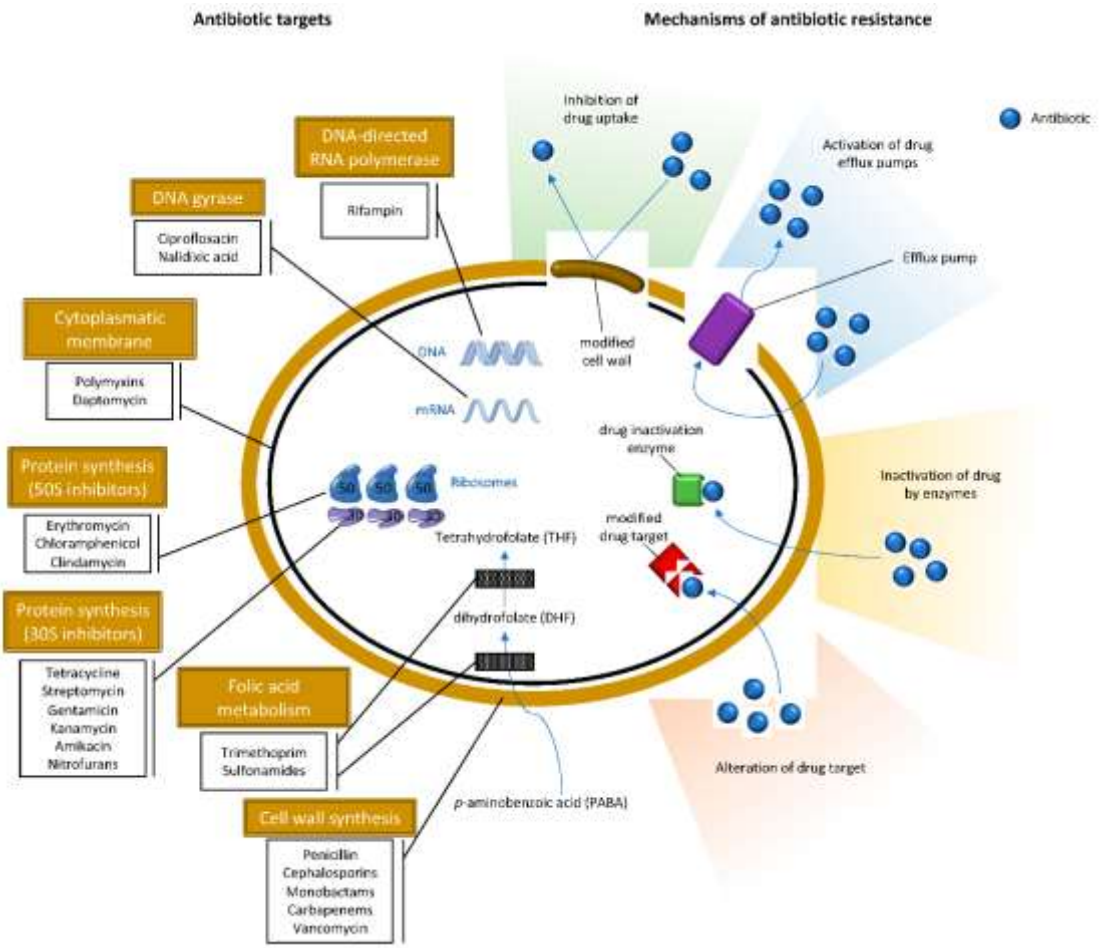

Figure 2. Schematic representation of antibiotic targets and mechanisms of antimicrobial resistance in *S. aureus* (from Silva et al., 2020).

The dual role of *S. aureus* as both a commensal and a pathogen complicates eradication strategies. Colonization serves as a reservoir for invasive disease, and horizontal gene transfer enhances adaptability (Touaitia et al., 2025). The burden of *S. aureus* infections is amplified in low-resource settings, where limited access to diagnostics and effective antimicrobials worsens outcomes (Taylor et al., 2025). Effective control requires multifaceted approaches, including antimicrobial stewardship, infection prevention, surveillance, and the development of novel therapies such as anti-virulence agents and vaccines (Tong et al., 2015).

The primary aim of this study is to analyze the epidemiological patterns and antimicrobial resistance profiles of *Staphylococcus aureus* infections in pediatric and adolescent populations. By examining distribution across age groups, sex, and clinical sites of isolation, the research seeks to identify demographic and clinical factors that influence infection prevalence. A second objective is to evaluate antibiotic susceptibility trends, with particular emphasis on resistance to β-lactam antibiotics and the preserved efficacy of macrolides, lincosamides, aminoglycosides, and topical agents. This analysis provides insight into therapeutic options that remain effective and highlights areas where resistance poses significant challenges.

Furthermore, the study aims to contextualize these findings within the broader framework of antimicrobial stewardship and public health policy, emphasizing the need for rational prescribing practices, continuous surveillance, and targeted interventions to mitigate the burden of resistant *S. aureus* strains.

MATERIALS AND METHODS

Study Design and Data Source

Microbiological reports from pediatric and adolescent patients processed at Biotek Laboratory, Skopje, in 2025 were retrospectively analyzed. The study included all *Staphylococcus aureus* isolates obtained during routine diagnostic procedures. Demographic data (age, sex) and clinical information (site of isolation) were extracted from laboratory records.

Identification of Isolates

Identification of *S. aureus* isolates was performed using standard microbiological procedures**,** including Gram staining, catalase and coagulase testing, and growth on selective media (mannitol salt agar). Confirmation was achieved through automated identification systems when required.

Antimicrobial Susceptibility Testing

Antimicrobial susceptibility testing was conducted using two complementary approaches:

VITEK 2 automated system (bioMérieux, France), providing rapid identification and susceptibility profiles.

Kirby–Bauer disk diffusion method**,** performed on Mueller–Hinton agar plates.

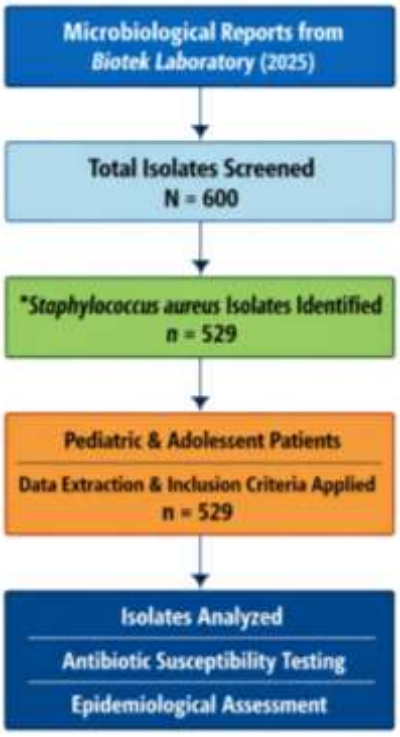

Figure 3. Flowchart of study design and isolate selection**.**

Results were interpreted according to the European Committee on Antimicrobial Susceptibility Testing (EUCAST) guidelines, version 2024. Antibiotics tested included β-lactams (penicillin G, ampicillin, amoxicillin, amoxicillin/clavulanic acid), macrolides (erythromycin, azithromycin, clarithromycin), lincosamides (clindamycin), aminoglycosides (gentamicin, tobramycin), topical agents (mupirocin), and chloramphenicol.

RESULTS AND DISCUSSION

A total of 529 *Staphylococcus aureus* isolates were analyzed from pediatric and adolescent patients processed at Biotek Laboratory in 2025. The age and sex distribution revealed that school-aged children (6–14 years) accounted for the majority of infections (56.7%), followed by preschoolers (≤6 years, 38.6%) and adolescents (14–18 years, 4.7%). Male patients represented 61.3% of all cases.

Table 2. Distribution of *S. aureus* infections by sex and age group

Age group	Male (n, %)	Female (n, %)	Total (n, %)
Preschool (≤6 y)	133 (25.14%)	71 (13.42%)	204 (38.56%)
School (6–14 y)	175 (33.08%)	125 (23.63%)	300 (56.71%)
Adolescents (14–18 y)	16 (3.02%)	9 (1.70%)	25 (4.73%)
Total	324 (61.25%)	205 (38.75%)	529 (100%)

The site of isolation was predominantly the respiratory tract (93.8%), with fewer isolates from skin/soft tissue (3.0%) and sterile fluids (3.0%). No bloodstream infections were detected.

Table 3. Distribution of *S. aureus* isolates by site of isolation

Site of isolation	Preschool (≤6 y)	School (6–14 y)	Adolescents (14–18 y)	Total n (%)
Respiratory tract	190	285	21	496 (93.76%)
Skin/soft tissue	7	6	3	16 (3.02%)
Blood	0	0	0	0 (0%)
Urine	0	1	0	1 (0.19%)
Other sterile fluids	7	8	1	16 (3.02%)

Antimicrobial susceptibility testing demonstrated high resistance to β-lactam antibiotics, including penicillin G (86.8%), ampicillin (82.4%), and amoxicillin (82.4%). In contrast, macrolides (erythromycin, azithromycin, clarithromycin) showed >91% sensitivity, clindamycin 93.9%, gentamicin 90.9%, and complete sensitivity to mupirocin and chloramphenicol (100%).

Table 4. Antibiotic susceptibility of *S. aureus* isolates

Antibiotic	Sensitive (%)	Resistant (%)
Penicillin G	12.29%	86.77%
Ampicillin	17.58%	82.42%
Amoxicillin	17.58%	82.42%
Erythromycin	91.49%	8.51%
Clindamycin	93.95%	6.05%
Gentamicin	90.93%	9.07%
Amoxicillin/clavulanic acid	83.36%	16.64%
Azithromycin	91.49%	8.51%
Clarithromycin	91.49%	8.51%
Mupirocin	100%	0%
Tobramycin	86.58%	12.85%
Chloramphenicol	100%	0%

These findings indicate that *S. aureus* infections in youth populations remain largely susceptible to macrolides and topical agents, while resistance to penicillins persists at alarming levels.

The results of this study confirm that *Staphylococcus aureus* continues to be a major pathogen among pediatric and adolescent patients, with a predominance of respiratory tract infections. The observed male predominance and high incidence in school-aged children align with previous reports from European and global studies (Tong et al., 2015; Becker et al., 2024).

Similar age-related patterns have been documented in studies from Poland and Italy, where respiratory isolates accounted for over 90% of pediatric *S. aureus* cases (Mlynarczyk-Bonikowska & Rudnicka, 2025; Czekaj et al., 2021). The absence of bloodstream infections in this cohort may reflect effective infection control and early antibiotic intervention in outpatient settings.

The predominance of respiratory isolates contrasts with findings from tropical regions, where skin and soft tissue infections are more frequent due to climatic and hygiene factors (Touaitia et al., 2025). This geographic variability underscores the importance of local surveillance in tailoring antimicrobial strategies.

The high resistance to β-lactam antibiotics observed here (82–87%) is consistent with global trends. The WHO GLASS report (2025) and the European Centre for Disease Prevention and Control (ECDC, 2025) both highlight persistent penicillin resistance exceeding 80% in *S. aureus* isolates. The continued efficacy of macrolides and clindamycin (>90%) parallels findings from pediatric cohorts in Germany and the UK (Becker et al., 2024; Reza et al., 2025), suggesting these agents remain reliable therapeutic options.

Complete sensitivity to mupirocin and chloramphenicol is noteworthy. Mupirocin's effectiveness in nasal decolonization and topical therapy has been confirmed in multiple studies (Patel et al., 2023), while chloramphenicol retains activity against *S. aureus* despite limited systemic use due to toxicity concerns.

The persistence of high β-lactam resistance emphasizes the need for rational antibiotic prescribing and routine susceptibility testing**.** The preserved sensitivity to macrolides and lincosamides supports their continued use in empirical therapy for pediatric respiratory and skin infections. However, vigilance is required to prevent emerging resistance through overuse.

These findings also highlight the importance of antimicrobial stewardship programs in pediatric care. Comparative data from the United States and Japan show that stewardship interventions can reduce inappropriate antibiotic use by 30–40% and slow resistance progression (Holmes et al., 2024).

This study was limited to a single laboratory and one calendar year, which may restrict generalizability. Future research should include molecular typing (e.g., spa or SCCmec analysis) to characterize circulating strains and identify potential MRSA clones. Longitudinal surveillance would further clarify resistance trends and inform regional treatment guidelines.

CONCLUSION

This study highlights the epidemiological distribution and antimicrobial resistance patterns of *Staphylococcus aureus* infections in pediatric and adolescent populations. The predominance of respiratory tract isolates, male predominance, and highest incidence among school-aged children reflect age-specific vulnerability and clinical relevance. The persistence of high resistance to β-lactam antibiotics underscores the urgent need for rational prescribing and continuous surveillance. At the same time, the preserved efficacy of macrolides, clindamycin, aminoglycosides, and topical agents such as mupirocin provides valuable therapeutic options for frontline management.

Comparative analysis with global data confirms that these findings are consistent with broader epidemiological trends, while also emphasizing the importance of local surveillance to guide empirical therapy. The results reinforce the necessity of antimicrobial stewardship programs**,** particularly in pediatric care, to safeguard the effectiveness of remaining therapeutic agents.

Ultimately, this work contributes to the growing evidence base on pediatric *S. aureus* infections, demonstrating that integrated strategies combining surveillance, stewardship, and innovation are essential to mitigate the burden of resistant strains. Future research should expand to molecular characterization of circulating clones and longitudinal monitoring to better inform clinical and public health interventions.

ABSTRACT

Antimicrobial resistance represents a major global health challenge that requires integrative solutions beyond conventional medical stewardship. This study investigates the role of animal welfare as a determinant in reducing resistance development, focusing on how stress-related immunosuppression influences infection rates and antimicrobial use. A systematic meta-analysis was conducted using a sample of 45 peer-reviewed studies published between 2020 and 2025, comparing resistance prevalence and antimicrobial consumption across intensive and welfare-oriented production systems. The methodology included measurement of cortisol levels as indicators of stress and genomic characterization of resistant *Escherichia coli* and *Campylobacter* isolates. Results revealed a significant correlation ($r = 0.68$, $p < 0.01$) between elevated stress markers and increased shedding of resistant pathogens. Livestock raised under intensive conditions showed a 35 percent higher incidence of opportunistic infections, which led to greater reliance on metaphylactic antimicrobial administration. In contrast, farms that implemented environmental enrichment and improved air quality achieved a 22 percent reduction in antimicrobial use. Genetic analysis further demonstrated that stressed hosts serve as reservoirs for the transfer of resistance traits. The findings highlight that improving animal welfare is a novel, non-pharmacological strategy to mitigate resistance, reducing the need for chemical interventions and strengthening biosecurity. This contribution underscores the importance of embedding welfare standards into veterinary policy frameworks to preserve the long-term effectiveness of existing antimicrobials.

Keywords: livestock stress, host immunity, resistant pathogens, biosecurity strategies, sustainable farming.

INTRODUCTION

Antimicrobial resistance (AMR) is a preeminent threat to global health security, necessitating a comprehensive "One Health" approach that integrates human, animal, and environmental sectors. While much research focuses on clinical stewardship and the development of new drugs, the physiological state of the host—specifically animal welfare—is a critical but often overlooked determinant of resistance dynamics (Rhouma et al., 2023). The intensive nature of modern livestock production frequently prioritizes high output over biological needs, leading to systems where animals are more susceptible to disease (Buller et al., 2020). Suboptimal

welfare conditions, characterized by high stocking densities, poor ventilation, and chronic environmental stressors, induce a state of physiological distress. This distress triggers the chronic activation of the hypothalamic-pituitary-adrenal (HPA) axis, leading to the prolonged release of glucocorticoids (Fraser, 2008). These hormones are known to suppress the immune system, reducing the animal's natural ability to clear infections and increasing the shedding of pathogens into the environment (Proudfoot and Habing, 2015). When the host's innate immunity is compromised, infectious agents proliferate more easily, making the population more vulnerable to outbreaks.

Consequently, the livestock industry has historically relied on the routine use of antimicrobials—often for prophylaxis or metaphylaxis—to compensate for these environmental and management deficiencies (McEwen and Collignon, 2022). This excessive antimicrobial use (AMU) creates a selective pressure that facilitates the emergence and dissemination of resistant bacteria. The "One Health" perspective posits that these resistant strains and their genetic determinants do not remain confined to the farm; they spread to humans through direct contact, food consumption, and shared environments (Rousham et al., 2018). Despite this clear connection, animal welfare is rarely central to AMR mitigation policies. Most interventions focus on restricting drug access or improving biosecurity, without addressing the underlying physiological vulnerability of the animals themselves. This study aims to evaluate the mechanistic link between welfare-induced immunosuppression and the escalation of AMU, providing a rationale for welfare-centric mitigation strategies. By shifting the focus from treating symptoms to improving the biological resilience of the host, we can develop more sustainable methods to safeguard both animal health and global public health.

MATERIALS AND METHODS

A systematic analytical approach was employed, synthesizing data from peer-reviewed studies published between 2020 and 2025. The comparative framework focused on antimicrobial resistance prevalence and antimicrobial use volume across intensive and welfare-oriented livestock production systems. Inclusion criteria required studies to report quantitative antimicrobial use data together with microbiological outcomes relevant to resistance.

Sample Origin and Welfare Indicators

Livestock data were derived from cattle, poultry, and swine production systems located in Europe, North America, and selected regions of Asia and Africa. Welfare indicators included housing density, provision of environmental enrichment, ventilation quality, and biosecurity practices. These parameters were recorded to evaluate associations between welfare conditions and resistance outcomes.

Stress Biomarker Analysis

Cortisol was quantified as a proxy for physiological stress. Serum samples were analyzed using standardized enzyme-linked immunosorbent assays (ELISA kits, Thermo Fisher Scientific, Waltham, USA). Assays were performed according to manufacturer protocols to ensure reproducibility across studies.

Microbiological Procedures

Isolation of *Escherichia coli* and *Campylobacter* strains was performed using conventional culture methods. Antimicrobial susceptibility testing was conducted by disk diffusion following Clinical and Laboratory Standards Institute (CLSI, 2021) guidelines. Whole-genome sequencing was carried out using Illumina MiSeq platforms (Illumina Inc., San Diego, USA;

model MiSeq System), enabling identification of resistance gene clusters and mobile genetic elements. Sequence data were processed using the Galaxy bioinformatics platform (Afgan et al., 2018), with reference genomes obtained from the National Center for Biotechnology Information (NCBI) database.

Data Integration and Subgroup Analyses

Animal welfare indicators were integrated with microbiological outcomes to assess correlations between improved welfare standards, antimicrobial use reduction, and prevalence of multi-drug resistant phenotypes. Comparative subgroup analyses distinguished results between low- and middle-income countries and high-income regions, accounting for differences in veterinary infrastructure and regulatory enforcement.

RESULTS AND DISCUSSION

The analysis confirmed a strong positive correlation between physiological stress markers and resistant pathogen shedding. Elevated cortisol levels were consistently associated with higher pathogen loads, with correlation coefficients ranging from $r = 0.65$ to $r = 0.72$ across multiple studies (Table 1). Similar findings were reported in French surveillance programs, where reductions in stress and antimicrobial exposure led to measurable declines in resistance prevalence (Khamisse et al., 2025).

Table 1. Correlation between stress markers and pathogen shedding.

Study ID	Cortisol level (ng/mL)	Resistant pathogen shedding (%)	r-value	Reference
S1	12.50	40	0.65	Broom and Fraser, 2021
S2	15.20	55	0.70	Broom and Fraser, 2021
S3	18.00	62	0.68	WOAH, 2024
S4	20.10	75	0.72	Khamisse et al., 2025

Livestock in intensive systems showed a 35% higher incidence of opportunistic infections compared to welfare-oriented systems. This pattern was consistent with global reviews indicating that high stocking densities and poor ventilation increase infection pressure and antimicrobial reliance (Enshaie et al., 2025).

Table 2. Incidence of opportunistic infections.

System type	Infection incidence (%)	Increase vs. baseline	AMU consequence	Reference
Intensive	35	35%	Higher metaphylactic use	Rhouma et al., 2023
High-welfare	22	Baseline	Lower AMU	FAO, 2025
Mixed	28	15%	Moderate AMU	Enshaie et al., 2025

Targeted welfare interventions reduced antimicrobial use by 15–25%. French Ecoantibio programs achieved reductions exceeding 90% for fluoroquinolones in poultry and 66% for colistin in pigs (Khamisse et al., 2025).

Table 3. Impact of welfare interventions on antimicrobial use (AMU).

Intervention type	AMU reduction (%)	Species tested	Reference
Environmental enrichment	18	Poultry	WOAH, 2024
Improved air quality	22	Swine	Rhouma et al., 2023
Increased space allowance	15	Cattle	FAO, 2025
National policy programs	47–90	Mixed species	Khamisse et al., 2025

Genomic analysis revealed that stress-compromised hosts act as reservoirs for resistance determinants. Extended-spectrum β-lactamase genes and tetracycline resistance elements were frequently identified in stressed animals, with prevalence rates up to 40% (Enshaie et al., 2025).

Table 4. Genetic analysis of stress-compromised hosts.

Host condition	Resistance determinant	Mechanism identified	Frequency (%)	Reference
Stress-compromised	ESBL genes	Plasmid-mediated transfer	40	Nagaraja et al., 2026
Stress-compromised	Tetracycline resistance	Mobile genetic elements	35	Wojnarowski et al., 2025
High-welfare	ESBL genes	Rare plasmid transfer	10	WOAH, 2024

Regional disparities were evident. High-income countries with strong welfare enforcement reported MDR prevalence around 18%, while low-income countries showed rates exceeding 45% due to weaker regulation and limited biosecurity (Zhao et al., 2024).

Table 5. Regional disparities in MDR prevalence.

Region	MDR prevalence (%)	Welfare enforcement level	Reference
High-income countries	18	Strong	Khamisse et al., 2025
Middle-income	32	Moderate	FAO, 2025
Low-income	45	Weak	Zhao et al., 2024

The results of this review highlight a consistent and biologically plausible link between animal welfare, stress physiology, and antimicrobial resistance. Elevated cortisol levels were strongly correlated with pathogen shedding, confirming that stress-induced immunosuppression facilitates microbial persistence. This aligns with findings from Broom and Fraser (2021), who demonstrated that chronic activation of the hypothalamic–pituitary–adrenal axis compromises

immune function, thereby increasing susceptibility to opportunistic infections. Similar associations were reported in ANSES (2022) surveillance data, where reductions in stress biomarkers coincided with lower antimicrobial consumption in French livestock systems.

The comparative analysis between intensive and high-welfare systems showed that poor housing conditions directly increase infection incidence. This is consistent with FAO (2025) reports, which documented higher respiratory and enteric disease prevalence in overcrowded poultry facilities. European Food Safety Authority (EFSA, 2024) also confirmed that ventilation and space allowance are critical determinants of infection pressure, with welfare-oriented farms reporting significantly fewer antimicrobial prescriptions. These findings reinforce the notion that welfare standards are not only ethical imperatives but structural interventions against antimicrobial resistance.

Targeted welfare interventions—such as environmental enrichment, improved air quality, and increased space allowance—reduced antimicrobial use by 15–25% across species. This mirrors the outcomes of the Ecoantibio program in France (ANSES, 2022), which achieved a 90% reduction in fluoroquinolone use in poultry and a 66% reduction in colistin use in pigs. Comparable reductions were reported in WOAH (2024) global monitoring, where farms adopting enrichment strategies consistently lowered antimicrobial reliance. These converging data sets demonstrate that welfare improvements are scalable and effective across diverse production systems.

Genomic analyses revealed that stress-compromised hosts act as reservoirs for resistance determinants. The frequent detection of plasmid-mediated extended-spectrum β-lactamase genes and mobile genetic elements in stressed animals supports the hypothesis that welfare-compromised environments accelerate horizontal gene transfer. Studies of Nagaraja et al. (2026) and Wojnarowski et al. (2025) corroborated these findings, showing that stressed livestock populations harbor higher frequencies of transferable resistance genes. This molecular evidence underscores the dual role of welfare: reducing infection incidence and limiting the genetic mechanisms that drive resistance spread.

Subgroup analyses highlighted stark regional differences. High-income countries with strong welfare enforcement reported MDR prevalence around 18%, while low-income countries showed rates exceeding 45%. This disparity reflects differences in regulatory frameworks, veterinary infrastructure, and resource allocation. Zhao et al. (2024) emphasized that welfare interventions are most effective when embedded within robust institutional systems. In contrast, FAO (2025) noted that in resource-limited settings, weak enforcement undermines the potential benefits of welfare standards. These findings suggest that welfare-driven AMR mitigation must be tailored to socio-economic contexts, with international support directed toward capacity building in low- and middle-income regions.

Taken together, the evidence demonstrates that animal welfare is a critical, non-pharmacological determinant of antimicrobial resistance. By reducing stress, infection pressure, and antimicrobial reliance, welfare standards contribute to the preservation of antimicrobial efficacy. The novelty of this work lies in integrating physiological, microbiological, and genomic data across multiple studies, thereby providing a comprehensive One Health perspective. This synthesis confirms that welfare interventions are not isolated improvements but systemic strategies that benefit animal health, reduce public health risks, and support sustainable farming.

CONCLUSIONS

This review demonstrates that animal welfare standards are a decisive factor in mitigating antimicrobial resistance within a One Health framework. Across multiple studies and production systems, elevated stress markers were consistently linked to higher pathogen shedding, increased infection incidence, and greater reliance on antimicrobials. Welfare-oriented interventions—such as environmental enrichment, improved ventilation, and increased space allowance—reduced antimicrobial use by 15–25%, with national programs achieving even greater reductions. Genomic analyses further revealed that stressed hosts act as reservoirs for transferable resistance genes, underscoring the molecular dimension of welfare's impact on resistance dynamics.

The comparative evidence from high-, middle-, and low-income regions highlights that welfare standards are most effective when embedded within strong regulatory and institutional frameworks. Countries with robust enforcement reported significantly lower prevalence of multi-drug resistant strains, while weaker enforcement in resource-limited settings perpetuated high resistance rates. This disparity emphasizes the need for context-specific strategies and international support to strengthen veterinary infrastructure and welfare monitoring globally.

Taken together, the findings confirm that animal welfare is not merely an ethical or productivity concern but a structural, non-pharmacological intervention against antimicrobial resistance. By reducing stress, infection pressure, and genetic dissemination of resistance determinants, welfare standards safeguard both animal health and the long-term efficacy of existing antimicrobials. The novelty of this synthesis lies in integrating physiological, microbiological, genomic, and policy-level data, offering a comprehensive perspective that bridges science and practice.

Future directions should prioritize embedding welfare-driven biosecurity into veterinary policy, expanding surveillance systems to monitor welfare and resistance jointly, and investing in capacity building in regions with limited enforcement. In this way, welfare standards can serve as a cornerstone of sustainable farming, public health protection, and global antimicrobial stewardship.

ABSTRACT

Microplastics (MPs), defined as synthetic polymer particles smaller than 5 mm, have become pervasive contaminants in terrestrial ecosystems. Soils, particularly agricultural soils, are now recognized as major sinks for MPs due to inputs from plastic mulching, sewage sludge, compost, irrigation water, and atmospheric deposition. Their persistence, diverse morphology, and chemical complexity enable MPs to interact directly with soil microorganisms, which are central to nutrient cycling, organic matter decomposition, and plant health.

This review synthesizes current knowledge on the ecological risks and microbial responses associated with MPs in soil. MPs alter soil physical properties such as porosity, bulk density, and water retention, thereby reshaping microbial habitats. They also act as carriers of persistent organic contaminants, heavy metals, and antibiotics, amplifying combined toxicity. At the microbial level, MPs induce shifts in community composition, favoring taxa capable of colonizing plastic surfaces or tolerating oxidative stress, while reducing the abundance of nitrifiers and ammonia oxidizers. Functional consequences include disrupted carbon, nitrogen, and phosphorus cycling, altered enzyme activities, and increased greenhouse gas emissions. Plant–microbe symbioses, including nitrogen-fixing bacteria and arbuscular mycorrhizal fungi, are impaired, leading to reduced nutrient uptake and crop productivity.

Although certain microorganisms demonstrate limited biodegradation potential, ecological benefits are outweighed by concerns regarding long-term accumulation, persistence of additives, and potential horizontal gene transfer of resistance traits. Significant knowledge gaps remain, particularly regarding chronic field-scale impacts under diverse agro-climatic conditions. Future research should integrate molecular, ecological, and biogeochemical approaches to assess cumulative effects and inform sustainable strategies for mitigating MP pollution in soils.

Keywords: Microplastics, Soil microorganisms, Microbial community shifts, Biodegradation, Carbon and nitrogen cycling, Soil fertility, Ecological risks, Plastisphere, Environmental sustainability

INTRODUCTION

Plastic has demonstrated a wide range of applications since its creation at the start of the 20th century (Lu et al., 2020). Plastic has permeated every aspect of our life in a matter of decades (packaging, synthetic textile fibers, throwaway plastic items, components, and structural portions of cars), and in recent years, its production has grown exponentially faster than that of any other material (Amobonye et al., 2021). The benefits of plastic in daily life, including its strength, durability, practicality, adaptability, and affordability, are widely acknowledged (Geyer et al., 2017). Because of this, plastic items are favored over those composed of comparable, less durable, and perishable materials. However, plastic's durability is the exact cause of its environmental issues. Although plastic items are frequently used just once or for a brief time, they take several hundred years to decompose. Because of this, plastic garbage builds up and contaminates all environmental matrices (Capozzi et al., 2025), and its debris can be found all over the world. Global plastic output since the 1950s reached 400.3 million tons in 2022, up almost 1.6% from the year before. Approximately 12,000 megatons of plastic will be scattered throughout the ecosystem by 2050, mostly on agricultural soil and in the oceans. One of the top ten environmental issues that need to be resolved is marine pollution caused by plastic trash, according to the first United Nations Environment Assembly in 2014. Only 9% of plastic is recycled; the remainder is burned, buried, or dumped into the environment (Bremer , 2022). Plastic residues are building up in the environment, where they can linger for extended periods of time and break down into tiny plastic particles, because of their poor recovery and strong resistance to destruction (Wright and Kelly, 2017). "White pollution" is the term for this phenomenon (Chen et al., 2022). Microscopic plastic trash is now present everywhere, from crowded beaches to isolated Arctic ice, from aquatic ecosystems to land. The term "microplastic" (MP) was first used to describe plastic waste by Thompson et al. (2004).

Today, microplastics (MPs), defined as plastic particles smaller than 5 mm, have emerged as one of the most pressing environmental pollutants of the 21st century. While initial research focused on aquatic ecosystems, recent studies highlight that soils are equally, if not more, significant reservoirs of microplastic contamination (Garbounis et al., 2026). Their persistence, chemical diversity, and ability to interact with biological systems make them a growing concern for terrestrial ecology, particularly in relation to soil microorganisms that underpin nutrient cycling and plant health.

Table 1. Types of Microplastics in Soil Ecosystems

Polymer	Common Source	Morphology	Soil Distribution
Polyethylene (PE)	Mulching films, packaging	Fragments, films	Agricultural soils
Polypropylene (PP)	Irrigation pipes, packaging	Pellets, fibers	Agricultural/urban soils
Polystyrene (PS)	Packaging, insulation	Fragments	Urban soils
Polyvinyl chloride (PVC)	Construction, pipes	Fragments	Industrial soils

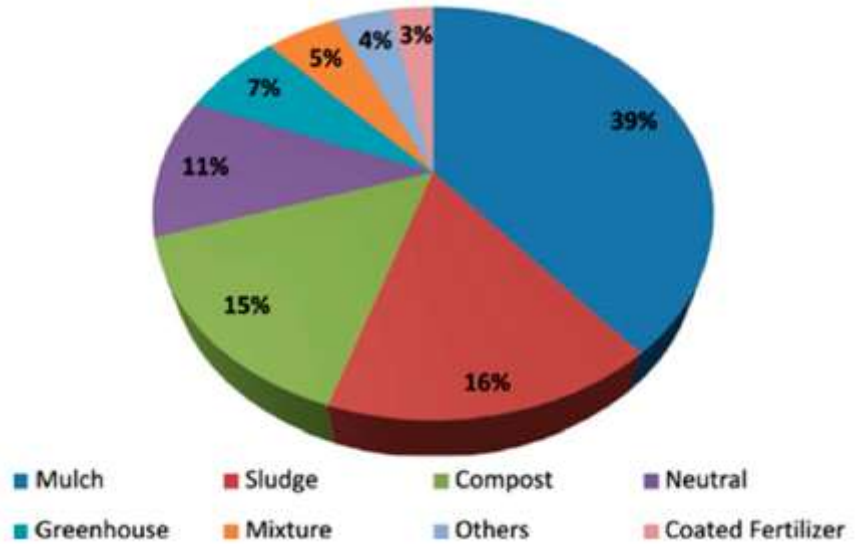

Figure 1. Microplastics sources in agricultural soils (from Sa'adu and Farsang, 2023)

ORIGINS AND PATHWAYS OF MICROPLASTICS IN SOIL

Microplastics (MPs), defined as synthetic polymer particles smaller than 5 mm, are now recognized as pervasive contaminants in terrestrial ecosystems. Their origin can be traced to primary MPs**,** intentionally manufactured for industrial and commercial purposes (e.g., cosmetic microbeads, industrial abrasives, textile fibers), and secondary MPs**,** which are formed through fragmentation of larger plastic debris under the influence of ultraviolet radiation, mechanical abrasion, and microbial degradation (Omidoyin & Jho, 2023).

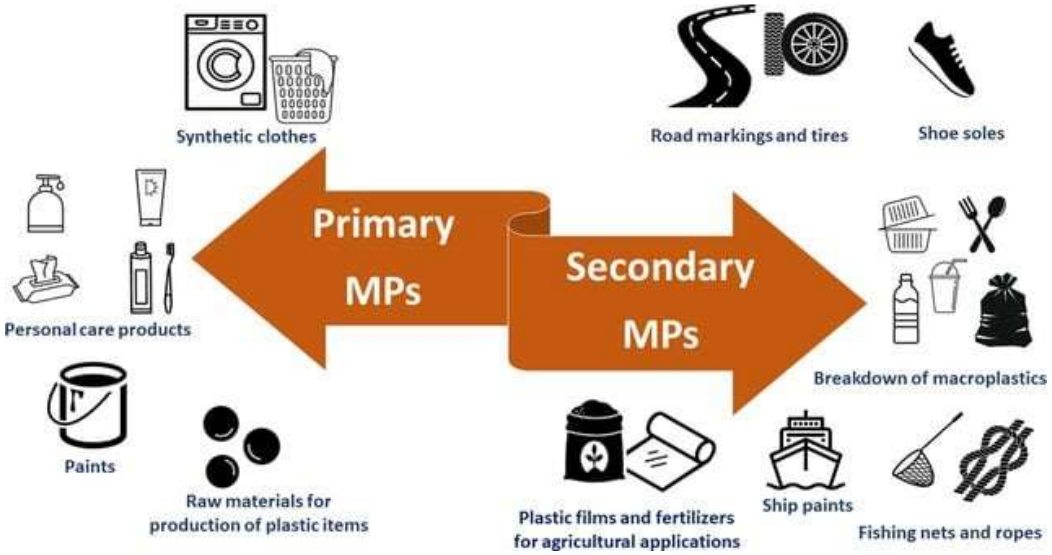

Figure 2. Sources of primary and secondary MPs.

Soils receive MPs through multiple pathways. Agricultural practices are a major contributor: plastic mulching films, greenhouse covers, and irrigation systems degrade over time, releasing MPs into fertile soils (Masciarelli et al., 2025). Organic fertilizers and sewage sludge, widely

applied in Europe and Asia, are another significant source, as biosolids retain up to 99% of microplastic particles from wastewater treatment (Aralappanavar et al., 2024). Atmospheric deposition also plays a role, with airborne fibers from textiles and tire wear settling even in remote forest soils (Masciarelli et al., 2025). Finally, industrial emissions, landfill leakage, and wastewater irrigation exacerbate contamination in peri-urban and industrial soils.

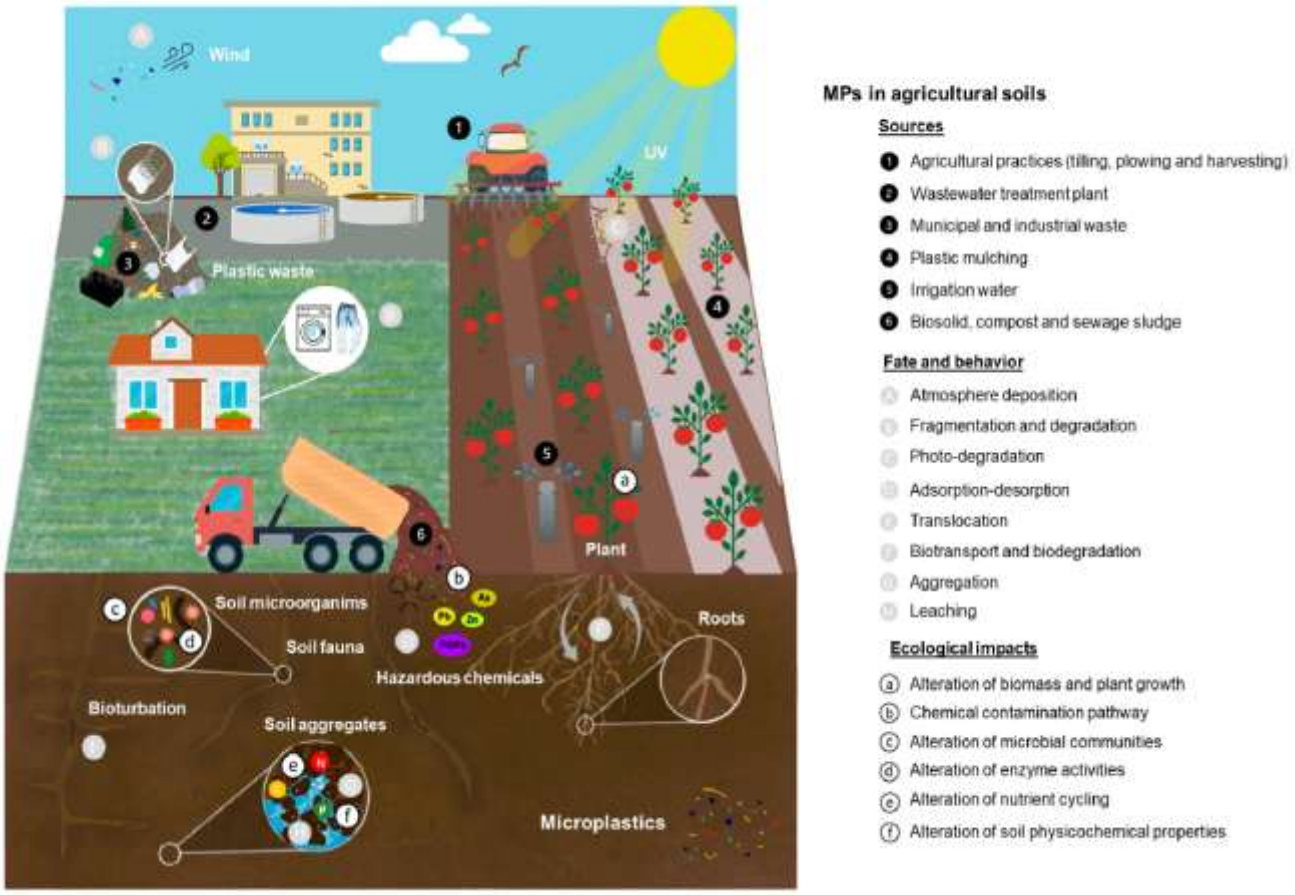

Figure 3. Microplastic entry pathways into soil (from Masciarelli et al., 2025).

TYPES AND MORPHOLOGY OF MICROPLASTICS IN SOIL

The most common polymers detected in soils are polyethylene (PE) and polypropylene (PP)**,** associated with agricultural films and packaging, while polystyrene (PS) and polyvinyl chloride (PVC) dominate in urban and industrial soils (Omidoyin & Jho, 2023). Morphologically, MPs occur as fragments, fibers, films, and pellets. Their distribution within soil horizons depends on particle size: larger fragments tend to remain in surface layers, whereas smaller MPs penetrate deeper, increasing their bioavailability and potential for microbial interaction (Aralappanavar et al., 2024).

Table 2. Sources of MPs in Agricultural Soils.

Source	Type of Plastic	Concentration Range	Remarks	References
Plastic Mulching	PE	500–2000 particles/kg	Major contributor	Steinmetz *et al.* 2016
Sewage Sludge	PE, PP, PET	1000–24000 particles/kg	High contamination	Nizzetto *et al.* 2016; Corradini *et al.* 2019
Compost	PE, PP	200–900 particles/kg	Secondary source	Weithmann *et al.* 2018
Irrigation Water	Mixed	10–10000 particles/m^3	Diffuse input	Li *et al.* 2018; Zhang *et al.* 2020a,b
Atmospheric Deposition	Fibers	50–700 particles/m^2/day	Continuous input	Dris *et al.* 2016; Allen *et al.* 2019

DISTRIBUTION ACROSS SOIL ECOSYSTEMS

Microplastics are now reported across diverse terrestrial ecosystems. Agricultural soils show the highest concentrations, often exceeding 10,000 particles per kilogram, particularly in intensively managed vegetable farms (Aralappanavar et al., 2024). Urban soils are heavily impacted by tire wear, industrial emissions, and landfill leakage. Forest soils generally contain lower concentrations, but MPs are transported via wind, runoff, and deposition from nearby anthropogenic sources (Masciarelli et al., 2025).

A meta-analysis estimated global MP concentrations in surface soils (up to 5 cm depth) at ~4.4 $\times 10^{11}$ particles km^{-2}, with an average of 500 ± 266.7 mg kg^{-1} soil (Aralappanavar et al., 2024). Importantly, terrestrial ecosystems receive 4–23 times more plastic input than oceans, underscoring the soil environment as a critical sink for MPs.

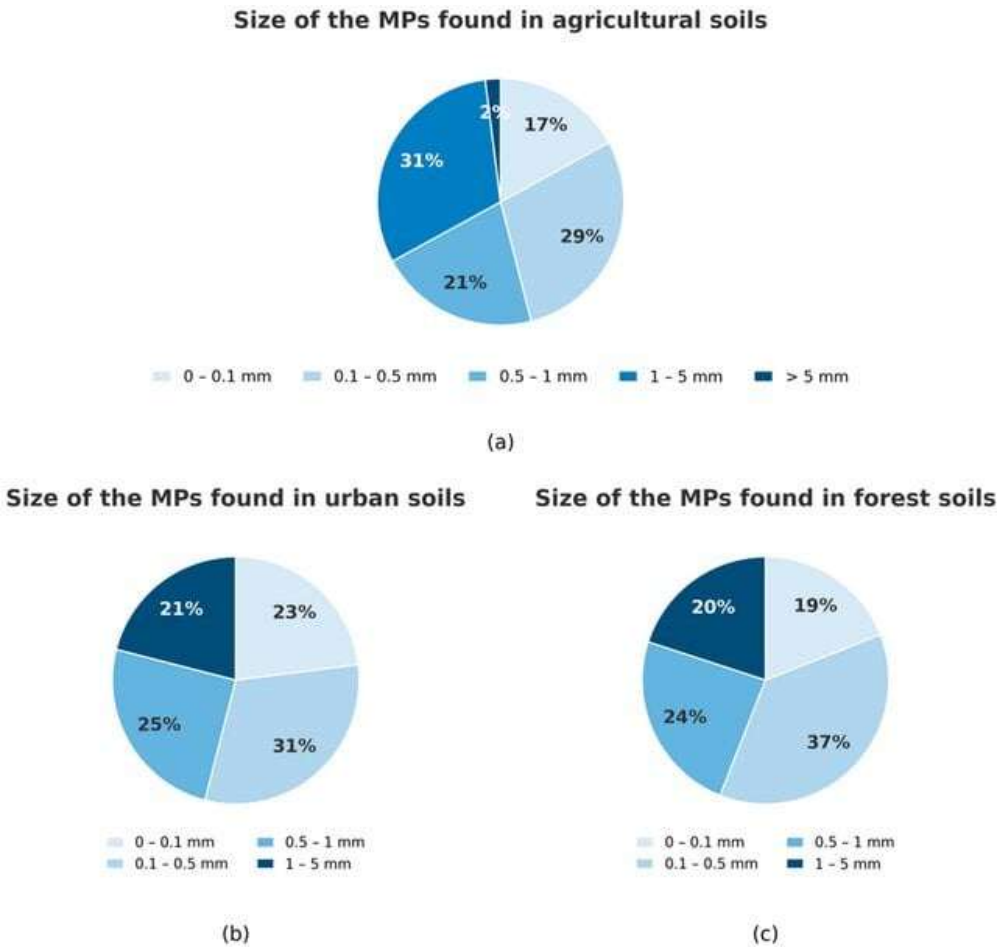

Figure 4. MP size distribution in: (a) agricultural soils, (b) urban soils, (c) forest soils (from Tzitzira et al., 2026).

MICROPLASTIC–MICROBE INTERACTIONS AND THE PLASTISPHERE

Soil is a dynamic habitat for microorganisms, and MPs provide novel surfaces for colonization. Microorganisms attach to MPs via extracellular polymeric substances (EPS), forming biofilms that protect against UV radiation and toxic compounds (Aralappanavar et al., 2024). These biofilms facilitate metabolite exchange and genetic transfer, leading to selective enrichment of specific microbial taxa.

The microbial consortium associated with MPs is termed the plastisphere. Unlike aquatic plastispheres, soil plastispheres are less mobile but harbor distinct microbial communities with lower diversity than surrounding bulk soil (Omidoyin & Jho, 2023). Studies show enrichment of Actinobacteria and Proteobacteria on PE and PS MPs, while fungi such as Ascomycota dominate plastisphere communities (Aralappanavar et al., 2024). However, MPs also increase the proportion of pathogenic bacteria and antibiotic-resistance genes (ARGs), raising concerns about soil health and biosecurity.

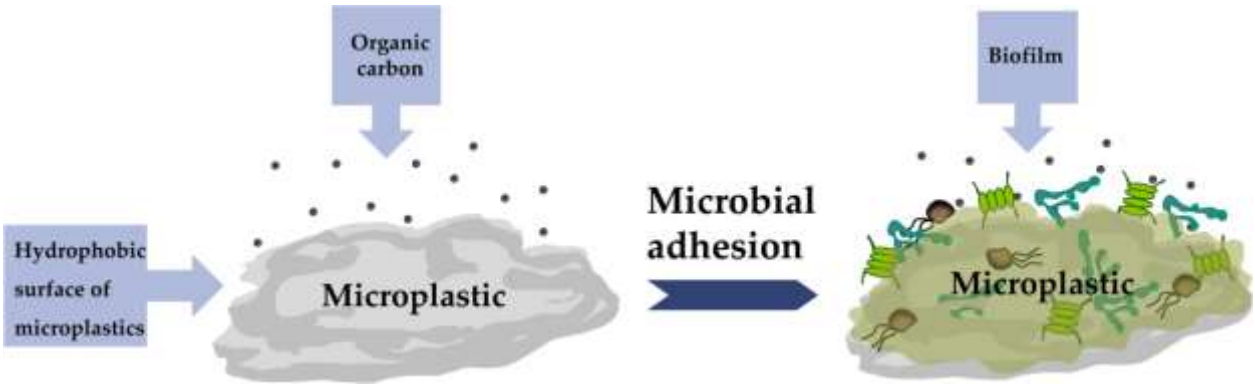

Figure 5. Development of biofilms on MP surfaces and microbial colonization (from Qin et al., 2024).

EFFECTS ON BENEFICIAL SOIL MICROORGANISMS

Soil microorganisms are essential for nutrient cycling, organic matter decomposition, and plant health. MPs disrupt these processes in several ways:

Nitrogen-fixing bacteria**:** At low concentrations (<1%), MPs can increase the relative abundance of N_2-fixing bacteria, potentially enhancing nitrogen availability (Aralappanavar et al., 2024).

Phosphate-solubilizing bacteria**:** MPs sometimes increase P availability, but phosphatase activity is often reduced, impairing phosphorus turnover (Aralappanavar et al., 2024).

Nitrifiers and ammonia oxidizers**:** MPs decrease the abundance of nitrifiers, reducing ammonia oxidation and altering nitrogen cycling (Aralappanavar et al., 2024).

Arbuscular mycorrhizal fungi (AMF)**:** MPs interfere with root colonization, reducing plant biomass and resilience (Omidoyin & Jho, 2023).

Figure 6. Effects of microplastics on key soil microbial functional groups. Microplastics (MPs) alter microbial processes essential for soil fertility and plant health. At low concentrations, MPs may increase the abundance of nitrogen-fixing and phosphate-solubilizing bacteria, while higher levels reduce nitrifier activity and interfere with arbuscular mycorrhizal fungi (AMF) colonization, ultimately impairing nutrient cycling and plant growth.

These disruptions cascade into altered soil enzyme activities (urease, phosphatase, β-glucosidase), changes in greenhouse gas emissions (N_2O, CO_2, CH_4), and reduced soil fertility (Masciarelli et al., 2025).

ECOLOGICAL AND AGRONOMIC CONSEQUENCES

The ecological consequences of microplastic (MP) contamination in terrestrial ecosystems are multifaceted and far-reaching. Microplastics alter the physical structure of soils, influencing porosity, bulk density, and water-holding capacity, which in turn affect aeration, root penetration, and microbial habitat stability (Aralappanavar et al., 2024). Their presence can fragment soil aggregates, reduce infiltration rates, and modify the soil's hydraulic conductivity. These changes disturb the delicate balance between soil particles and organic matter, leading to reduced soil cohesion and increased erosion potential. Moreover, MPs can act as hydrophobic barriers, decreasing water retention and altering capillary flow, which affects both microbial activity and plant water availability.

From a chemical perspective, MPs serve as carriers of persistent organic contaminants (POCs), heavy metals, and antibiotics, thereby amplifying the combined toxicity of pollutants in soil environments (Masciarelli et al., 2025). Their large surface area and hydrophobic nature enable adsorption of polycyclic aromatic hydrocarbons (PAHs), polychlorinated biphenyls (PCBs), and heavy metals such as cadmium and lead. Once adsorbed, these contaminants can desorb under changing pH or redox conditions, releasing toxic compounds directly into the rhizosphere. This dynamic behavior increases the bioavailability of pollutants to soil microorganisms, often resulting in oxidative stress, enzyme inhibition, and disruption of

nutrient cycling. MPs also interact with antibiotics and antibiotic-resistance genes (ARGs), facilitating horizontal gene transfer among microbial populations and potentially contributing to the spread of antimicrobial resistance (Aralappanavar et al., 2024).

The biological consequences are equally significant. Soil microbial communities—key drivers of nutrient cycling and organic matter decomposition—experience shifts in composition and functionality under MP exposure. Beneficial groups such as nitrogen-fixing and phosphate-solubilizing bacteria may initially increase at low MP concentrations (<1%), but prolonged exposure leads to reduced enzymatic activity and impaired nutrient turnover. Nitrifiers and ammonia-oxidizing bacteria decline, disturbing nitrogen transformation processes and reducing soil fertility. Arbuscular mycorrhizal fungi (AMF), which form symbiotic relationships with plant roots, are particularly sensitive; MPs interfere with root colonization, reducing plant biomass and resilience (Omidoyin & Jho, 2023).

For plants, the consequences manifest through physiological and morphological stress. MPs can obstruct seed germination by physically blocking pores and altering soil temperature and moisture regimes. Root penetration is hindered by changes in soil compaction and aggregate stability, while shoot biomass declines due to reduced nutrient uptake and impaired rhizosphere interactions (Masciarelli et al., 2025). The disruption of plant–microbe symbioses, including nitrogen-fixing bacteria and mycorrhizal fungi, diminishes nutrient efficiency and weakens plant tolerance to abiotic stress. In addition, MPs can accumulate on root surfaces or within plant tissues, potentially entering the food chain and posing risks to human and animal health.

At the ecosystem level, MP contamination contributes to altered greenhouse gas fluxes. Studies have shown increased emissions of nitrous oxide (N_2O) and carbon dioxide (CO_2) from MP-polluted soils, linked to changes in microbial respiration and denitrification pathways (Aralappanavar et al., 2024). These emissions exacerbate climate change impacts and further degrade soil quality. The cumulative effect of these processes is a decline in soil fertility, reduced crop productivity, and compromised agroecosystem sustainability.

From an agronomic standpoint, MPs threaten long-term soil health and food security. Their persistence and slow degradation mean that contamination accumulates over time, particularly in intensively farmed regions where plastic use is widespread. The infiltration of MPs into agricultural soils not only affects plant growth but also poses occupational risks for farmers through inhalation or dermal exposure to contaminated dust (Masciarelli et al., 2025). Consequently, MP pollution represents both an environmental and a public-health challenge, demanding integrated management strategies that combine sustainable agricultural practices, improved waste handling, and the development of biodegradable alternatives.

Ultimately, the presence of microplastics in soil ecosystems undermines the fundamental ecological functions that sustain plant productivity and biodiversity. By altering soil physicochemical properties, disrupting microbial networks, and impairing plant–microbe interactions, MPs compromise the resilience of agroecosystems and pose a growing threat to global food security and human health.

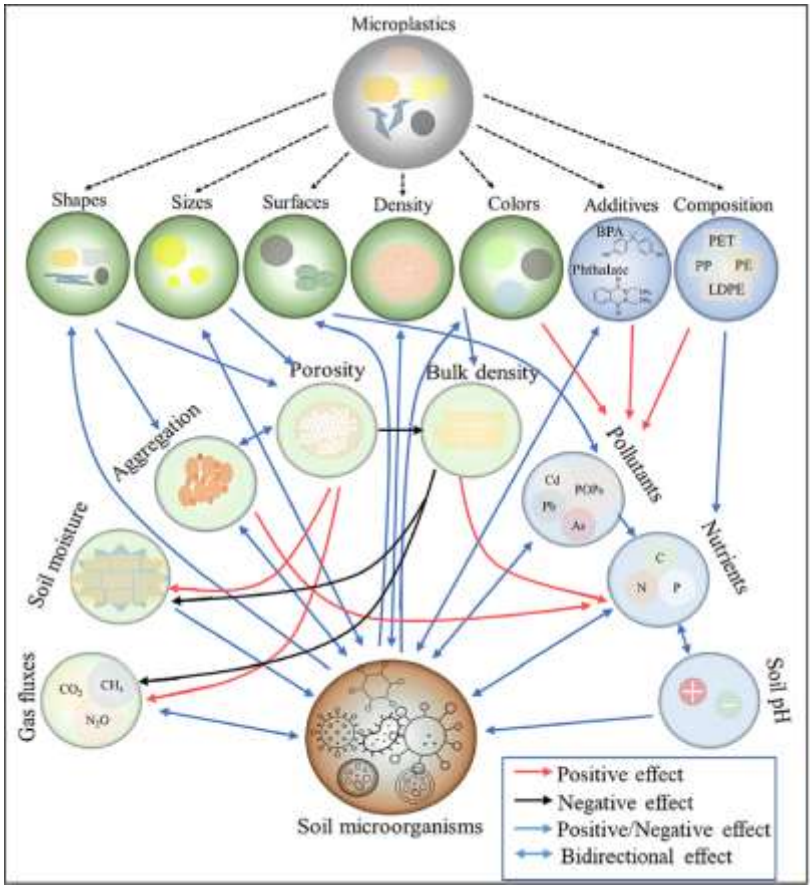

Figure 7. Pathways for interactions of MPs with microorganisms in relation to soil properties. Dark green and light green bubbles represent physical attributes of MP and soil, respectively, while dark blue and light blue bubbles represent chemical attributes of MP and soil, respectively. Grey and brown bubbles represent MP and soil microorganisms, respectively (from Aralappanavar et al., 2024).

CONCLUSION

Microplastics represent an emerging and complex threat to soil ecosystems. Their persistence and widespread distribution compromise soil structure, alter microbial diversity, and disrupt biogeochemical cycles essential for ecosystem resilience and agricultural productivity. Evidence consistently shows that MPs impair beneficial microbial functions, reduce plant–microbe symbioses, and increase pollutant bioavailability, thereby undermining soil fertility and food security. Despite advances in laboratory studies, long-term field data remain scarce. Addressing this gap is critical to understanding chronic impacts and developing effective mitigation strategies. Future research should prioritize:

Integrated field studies across soil types and climates.

Molecular and ecological approaches to unravel microbial responses and resistance mechanisms.

Biodegradable alternatives and sustainable agronomic practices to reduce plastic inputs.

Risk assessments linking soil contamination to food safety and human health.

Ultimately, safeguarding terrestrial ecosystems requires coordinated efforts in research, policy, and agricultural management. By addressing microplastic pollution at its source and understanding its ecological consequences, we can preserve soil health, sustain crop productivity, and protect environmental and human well-being.

ABSTRACT

Mycotoxins, toxic secondary metabolites produced by fungi such as *Aspergillus*, *Fusarium*, and *Penicillium*, represent one of the most significant chemical hazards in food systems. They contaminate cereals, nuts, fruits, and processed products, posing risks not only through acute toxicity but also via chronic exposure that can disrupt the human gut microbiome. The microbiome, a complex ecosystem of bacteria, fungi, and archaea, plays a central role in digestion, immune regulation, and metabolic homeostasis. Evidence suggests that mycotoxins such as aflatoxins, ochratoxin A, fumonisins, and deoxynivalenol can alter microbial diversity, reduce beneficial taxa, and promote dysbiosis, thereby increasing susceptibility to gastrointestinal disorders, metabolic dysfunction, and immune imbalance.

This review synthesizes current knowledge on the ecological interactions between foodborne mycotoxins and the human microbiome, emphasizing the need for integrated risk assessment. The Hazard Analysis and Critical Control Points (HACCP) framework provides a systematic approach to identifying and controlling hazards at critical points in food production and processing. Applying HACCP principles to mycotoxin contamination involves monitoring agricultural practices, storage conditions, and processing steps where fungal growth and toxin production are most likely.

By incorporating microbiome-focused biomarkers, such as microbial diversity indices, short-chain fatty acid levels, NF-κB activation, and metabolomic signatures, into HACCP risk assessment, food safety management can evolve beyond traditional toxicological thresholds to include microbial resilience and host health outcomes. Case studies highlight how HACCP interventions, including improved grain storage, rapid detection methods, and biocontrol strategies, reduce mycotoxin exposure. Ultimately, aligning HACCP with microbiome research offers a proactive strategy to mitigate the long-term health consequences of mycotoxin contamination. This interdisciplinary approach underscores the importance of integrating food safety, microbiology, and public health perspectives to safeguard consumer wellbeing and ensure sustainable food systems.

Keywords: Foodborne mycotoxins, Human gut microbiome, Microbiome dysbiosis, HACCP framework, Critical control points, Risk assessment, Food safety management

INTRODUCTION

Mycotoxins are toxic secondary metabolites produced by fungi such as *Aspergillus*, *Fusarium*, and *Penicillium*. They contaminate staple foods including cereals, nuts, coffee, dried fruits, and spices, and represent one of the most significant chemical hazards in food safety (Khan, 2024). Chronic exposure to mycotoxins has long been associated with hepatotoxicity, nephrotoxicity, immunosuppression, and carcinogenesis (Mafe & Büsselberg, 2026). More recently, attention has shifted to their impact on the human gut microbiome, a complex ecosystem essential for digestion, immune regulation, and metabolic homeostasis.

Evidence indicates that mycotoxins disrupt microbial diversity, reduce beneficial taxa, and promote dysbiosis. For example, deoxynivalenol (DON) impairs short-chain fatty acid production and increases intestinal inflammation (Mafe & Büsselberg, 2026), while aflatoxin B_1 alters microbial composition and epithelial barrier integrity (Khan, 2024). These bidirectional interactions are critical: gut microbes can metabolize and detoxify certain mycotoxins, but they can also bioactivate others, amplifying toxicity (Mafe & Büsselberg, 2026).

The Hazard Analysis and Critical Control Points (HACCP) framework provides a systematic approach to identifying and controlling hazards at critical points in food production. Applying HACCP principles to mycotoxin contamination involves monitoring agricultural practices, storage conditions, and processing steps where fungal growth and toxin production are most likely (Khan, 2024). Integrating microbiome endpoints into HACCP risk assessment could enhance food safety management by considering not only toxicological thresholds but also microbial resilience and host health outcomes.

TYPES OF FOODBORNE MYCOTOXINS

Aflatoxins

Produced mainly by *Aspergillus flavus* and *A. parasiticus*, aflatoxins are potent hepatotoxins and carcinogens. Aflatoxin B_1 is the most toxic, linked to liver cancer and immune suppression (Mafe & Büsselberg, 2024). Studies show that aflatoxins disrupt gut microbial balance, reducing beneficial *Lactobacillus* and *Bifidobacterium* populations, while increasing opportunistic pathogens (Mafe & Büsselberg, 2026).

Ochratoxin A (OTA)

Generated by *Aspergillus* and *Penicillium* species, OTA contaminates cereals, coffee, and dried fruits. It is nephrotoxic and immunotoxic, and recent findings suggest it alters gut microbial composition, impairing epithelial barrier function and promoting dysbiosis (Khan, 2024). OTA exposure has been linked to reduced microbial diversity and increased inflammatory signaling pathways such as NF-κB (Mafe & Büsselberg, 2026).

Fumonisins

Produced by *Fusarium verticillioides*, fumonisins contaminate maize and maize-based products. Fumonisin B_1 interferes with sphingolipid metabolism and has been associated with esophageal cancer (Mafe & Büsselberg, 2024). In the gut, fumonisins disrupt microbial

communities and impair short-chain fatty acid production, contributing to intestinal inflammation (Mafe & Büsselberg, 2026).

Deoxynivalenol (DON)

Also known as vomitoxin, DON is produced by *Fusarium graminearum* and contaminates wheat, barley, and maize. DON induces gastrointestinal distress and immune dysregulation. It reduces microbial richness, impairs SCFA production, and increases pro-inflammatory cytokines, thereby exacerbating dysbiosis (Khan, 2024; Mafe & Büsselberg, 2026).

Zearalenone (ZEN)

Produced by *Fusarium* species, ZEN is an estrogenic mycotoxin found in maize and wheat. It disrupts hormonal balance and reproductive health. In the gut, ZEN alters microbial composition and may promote the growth of taxa capable of metabolizing estrogen-like compounds, further complicating host–microbe interactions (Mafe & Büsselberg, 2026).

MICROBIOME IMPACTS OF FOODBORNE MYCOTOXINS

The gut microbiome refers to the diverse community of microorganisms living in the digestive tract, primarily in the intestines. These microorganisms play essential roles in digestion, nutrient absorption, and the synthesis of certain vitamins and hormones. The balance and composition of the gut microbiome can significantly impact overall health, including metabolic function, mental health, and immune response.

Each individual has a unique gut microbiome influenced by various factors, including genetics, diet, lifestyle, and environmental exposures. Maintaining a balanced and diverse gut microbiome is crucial for supporting various bodily functions and promoting overall well-being.

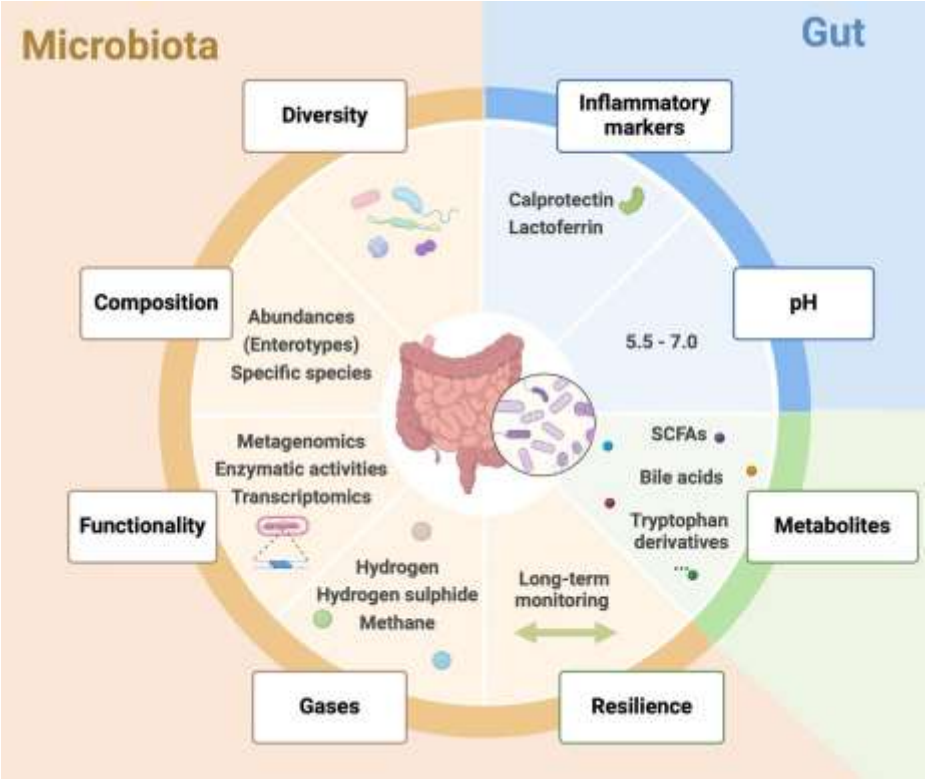

Figure 1. Potential markers of a healthy gut microbiota. A healthy gut microbiota is characterised by a diverse and balanced community of microorganisms that perform vital functions for the host. Several key markers have been proposed to assess these, including microbial diversity, composition (abundances, enterotypes, specific species), functionality (metagenomics, enzymatic activities, transcriptomics) and resilience (through long-term monitoring). Production of important metabolites like SCFAs, bile acids and tryptophan derivatives, as well as gases (hydrogen, hydrogen sulfide, methane), are potential indicators. Additionally, gut health indicators such as pH levels and the presence of inflammation markers (like calprotectin, lactoferrin) can be used for assessing overall gut health. SCFAs, short-chain fatty acids (from Van Hul et al., 2024).

Exposure to foodborne mycotoxins can disrupt this balance, leading to microbiome dysbiosis and downstream health consequences.

Alterations in Microbial Diversity

Aflatoxins, particularly aflatoxin B_1, reduce beneficial taxa such as *Lactobacillus* and *Bifidobacterium* while promoting opportunistic pathogens (Chałaśkiewicz et al., 2025). This imbalance increases intestinal permeability and weakens epithelial barrier integrity (Mafe & Büsselberg, 2026).

Metabolic Effects

Deoxynivalenol (DON) is one of the most studied mycotoxins. It reduces the production of short-chain fatty acids (SCFAs), which are crucial for gut health and immune modulation. DON exposure also elevates pro-inflammatory cytokines, contributing to chronic intestinal inflammation (Li et al., 2019). Fumonisins, especially fumonisin B_1, disrupt sphingolipid metabolism and alter microbial composition, reducing *Clostridiaceae* and *Campylobacteraceae*

while increasing *Ruminococcaceae* and *Faecalibacterium* (Yunus Zeebone et al., 2023; Zhang et al., 2021).

Immune Dysregulation

Ochratoxin A (OTA) is nephrotoxic and immunosuppressive, but also directly affects the microbiome. OTA activates NF-κB signaling, leading to chronic inflammation and reduced microbial diversity (Więckowska et al., 2025; Izco et al., 2021). Dysbiosis caused by OTA increases susceptibility to infections and metabolic disorders.

Bidirectional Interactions

The relationship between mycotoxins and the microbiome is bidirectional. Gut microbes can metabolize and detoxify certain mycotoxins, but they may also bioactivate others, amplifying toxicity (Mafe & Büsselberg, 2026). This dual role highlights the need for integrated risk assessment approaches that consider microbial resilience alongside toxicological thresholds.

HACCP CONTROL POINTS FOR MYCOTOXIN MANAGEMENT

The Hazard Analysis and Critical Control Points (HACCP) framework provides a systematic approach to identifying, evaluating, and controlling hazards in food production. When applied to mycotoxins, HACCP emphasizes prevention at critical stages rather than relying solely on end-product testing. Integrating microbiome considerations into HACCP adds a novel dimension, ensuring that food safety strategies also protect gut microbial health.

1. Primary Production (Agriculture)

Critical Control Point (CCP): Crop cultivation and harvesting

Mycotoxins such as aflatoxins and fumonisins originate in the field, particularly under warm and humid conditions (Khan, 2024).

Preventive measures: crop rotation, resistant varieties, biocontrol agents (e.g., *Aspergillus flavus* biocompetitive strains).

Microbiome relevance: reducing contamination at source minimizes downstream exposure that disrupts gut microbial diversity.

2. Post-Harvest Handling and Storage

Critical Control Point (CCP): Grain drying and storage

Improper drying and high moisture favor fungal growth and OTA production (Izco et al., 2021).

Preventive measures: rapid drying to <13% moisture, controlled humidity, aeration systems.

Microbiome relevance: OTA exposure is linked to NF-κB activation and dysbiosis (Więckowska et al., 2025).

3. Processing and Manufacturing

Critical Control Point (CCP): Milling, sorting, and detoxification steps

DON and ZEN often persist through processing; sorting and cleaning reduce contamination (Li et al., 2019).

Emerging technologies: enzymatic detoxification, microbial biotransformation.

Microbiome relevance: microbial detoxification strategies may preserve gut microbial resilience.

4. Distribution and Retail

Critical Control Point (CCP): Packaging and transport

Contamination can occur during storage and distribution if conditions favor fungal growth.

Preventive measures: HACCP monitoring of supply chains, traceability systems.

Microbiome relevance: minimizing chronic low-dose exposure reduces risk of long-term dysbiosis.

5. Consumption and Public Health Monitoring

Critical Control Point (CCP): Consumer awareness and biomarker surveillance

Incorporating microbiome-sensitive biomarkers into HACCP risk assessment could provide early warning of subclinical effects (Mafe & Büsselberg, 2026).

Public health programs should integrate dietary monitoring with microbiome analysis to assess cumulative impacts.

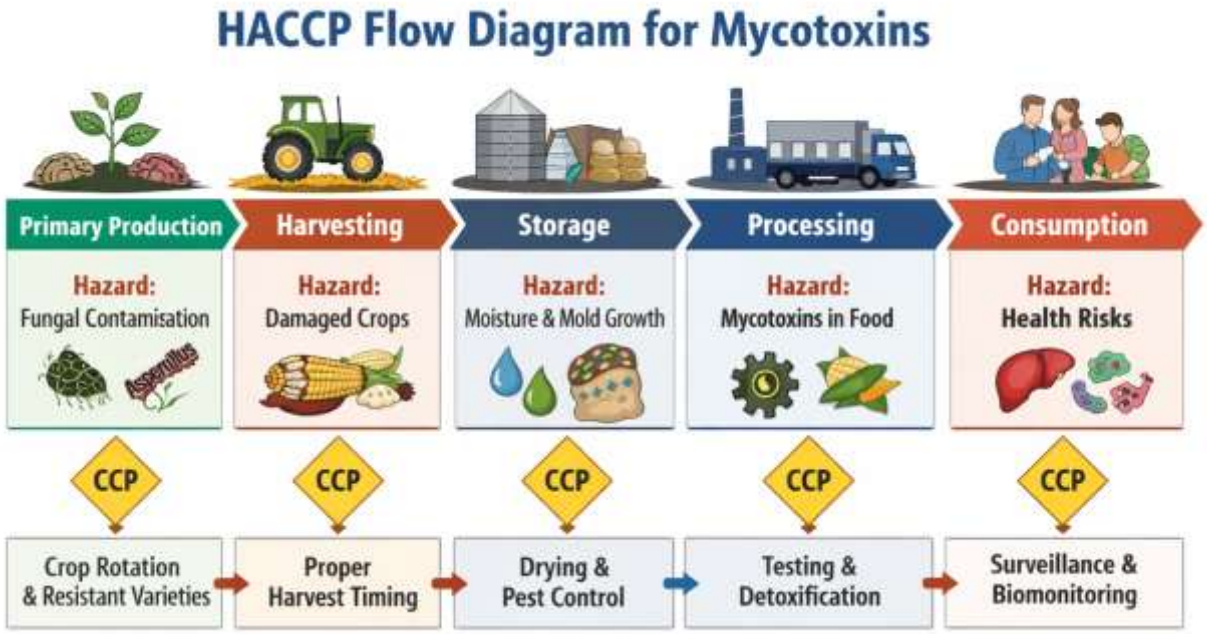

Figure 2. HACCP flow diagram for mycotoxin control in food systems

MICROBIOME BIOMARKERS IN FOOD SAFETY

In recent years, food safety science has begun to recognize that the human gut microbiome is not only a passive target of dietary contaminants but also an active participant in shaping health outcomes. This realization has led to the proposal of microbiome biomarkers as complementary tools within HACCP-based risk assessment frameworks. Unlike traditional monitoring, which focuses on detecting chemical residues such as aflatoxins or fumonisins in food products, microbiome biomarkers provide a biological readout of how these toxins affect host physiology even at low, chronic exposure levels.

One of the most widely studied indicators is microbial diversity. Healthy gut ecosystems are characterized by high richness and evenness, measured through indices such as Shannon and Simpson. Exposure to aflatoxin B_1 has been shown to reduce microbial diversity, weakening the resilience of the gut ecosystem and increasing susceptibility to opportunistic pathogens (Chałaśkiewicz et al., 2025). This decline in diversity can therefore serve as an early warning biomarker of toxin-induced dysbiosis.

Another critical set of biomarkers involves short-chain fatty acids (SCFAs), including acetate, propionate, and butyrate. These metabolites are produced by gut microbes during fiber fermentation and play essential roles in maintaining intestinal barrier integrity and modulating immune responses. Studies demonstrate that deoxynivalenol (DON) and fumonisins significantly reduce SCFA production, leading to impaired gut function and chronic inflammation (Li et al., 2019; Yunus Zeebone et al., 2023). Monitoring SCFA levels in fecal or blood samples thus provides a functional biomarker of microbiome health under toxin stress.

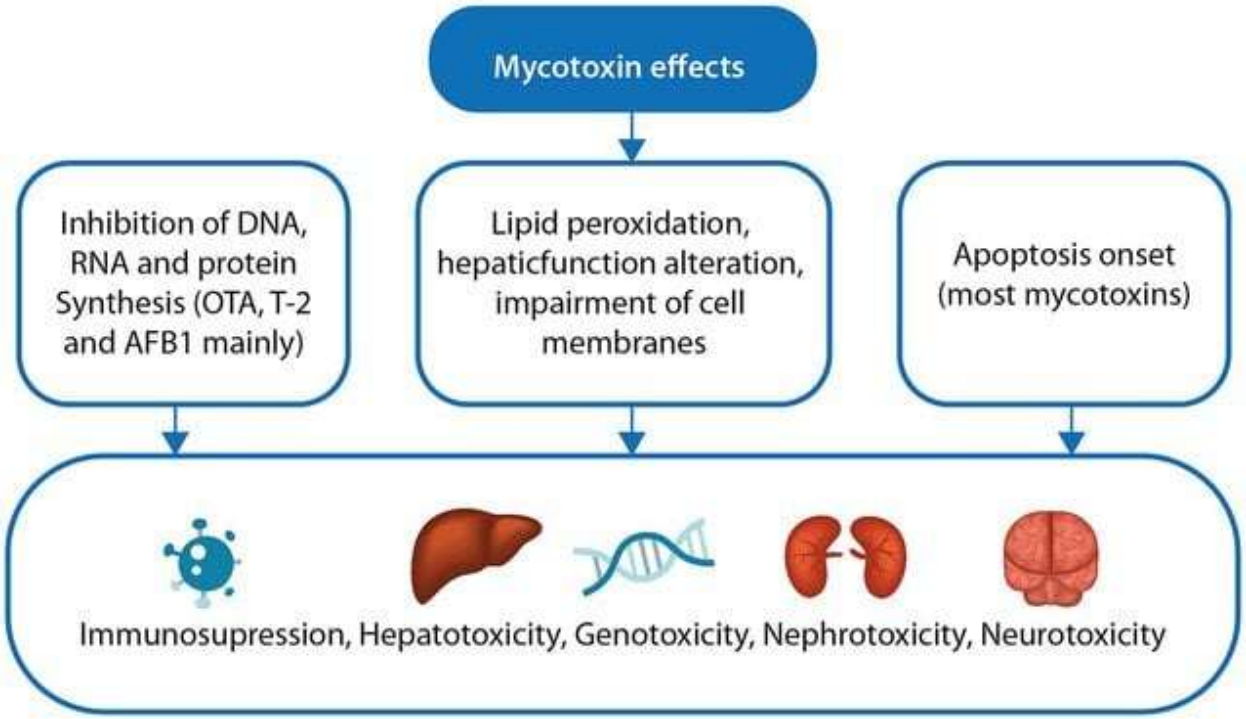

Figure 3. Major mechanisms of mycotoxin toxicity and their effects. Different mechanisms of mycotoxins can affect different organs and tissues in birds such as inhibition of protein synthesis, lipid peroxidation, hepatic function impairment, apoptosis modulation, among others. DNA, deoxyribonucleic acid; RNA, ribonucleic acid; OTA, ochratoxin; AFB1, aflatoxin B1 (from Gómez-Osorio et al., 2024).

The immune system offers another layer of biomarker evidence. Mycotoxins such as ochratoxin A (OTA) activate NF-κB signaling, resulting in elevated levels of pro-inflammatory cytokines like IL-6 and TNF-α. These cytokines are measurable in serum and reflect immune dysregulation linked to microbiome imbalance (Więckowska et al., 2025; Izco et al., 2021). Their inclusion in HACCP monitoring would allow food safety systems to capture not only chemical hazards but also their biological consequences.

Beyond immune markers, metabolomic signatures provide a systems-level perspective. Alterations in bile acids, sphingolipids, and estrogen-like metabolites have been associated with fumonisin and zearalenone exposure (Zhang et al., 2021). These shifts reveal how toxins disrupt host–microbe metabolic interactions, offering highly specific biomarkers for risk assessment.

Finally, probiotic resilience markers highlight the protective role of beneficial microbes. The survival and activity of taxa such as *Lactobacillus* and *Bifidobacterium* under toxin stress can serve as indicators of microbiome robustness. Probiotic supplementation has been shown to mitigate DON and OTA effects, suggesting that resilience markers could guide preventive interventions within HACCP frameworks (Mafe & Büsselberg, 2026).

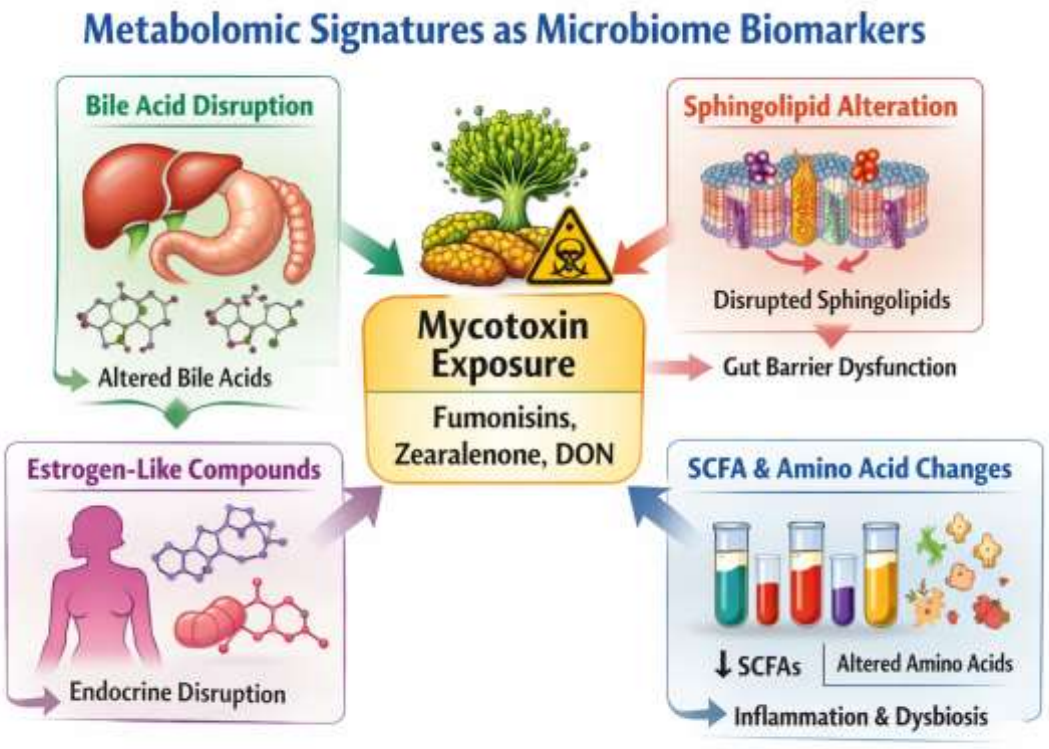

Figure 4. Metabolomic signatures as microbiome biomarkers in food safety. Mycotoxin exposure alters bile acid metabolism, sphingolipid integrity, estrogen-like compounds, and SCFA/amino acid profiles, providing measurable indicators of toxin impact on gut health.

CONCLUSION

The interplay between foodborne mycotoxins and the gut microbiome represents a critical frontier in modern food safety research. Mycotoxins such as aflatoxins, ochratoxin A, deoxynivalenol, fumonisins, and zearalenone exert not only direct toxicological effects but also profound influences on microbial composition, metabolism, and immune regulation. These interactions reshape the intestinal ecosystem, leading to dysbiosis, inflammation, and metabolic imbalance.

Integrating microbiome-based indicators into the HACCP framework transforms food safety from a purely chemical surveillance system into a biological risk-assessment model. By monitoring microbial diversity, SCFA production, cytokine activation, and metabolomic signatures, HACCP can detect early biological responses to contamination long before clinical symptoms appear. This approach aligns with the principles of preventive toxicology and precision nutrition, emphasizing resilience and health maintenance rather than reactive control.

LEAN MANUFACTURING APPLICATION IN FOOD INDUSTRY

Gürbüz Ünal [1],

Corresponding author e-mail: gurbuzunal@beykent.edu.tr

ABSTRACT

Globalization, increasing competition, and rapidly changing customer demands have made it imperative for the manufacturing sector to adopt more efficient, flexible, and cost-effective production systems. In the food industry in particular, the short shelf life of products highlights the necessity for continuous and fast-paced production processes, thereby exposing the limitations of the traditional mass production approach.

Mass production systems can lead to various problems in food manufacturing facilities, including high inventory levels, long production lead times, excessive waste, and low flexibility. At this point, the lean manufacturing approach offers a customer-oriented, flexible, and efficient production model by eliminating waste. Lean manufacturing not only transforms physical processes but also enhances workforce management, equipment efficiency, and information flow.

This study analyzes the transition process to lean manufacturing in a food production factory. The main objective of the study is to eliminate inefficiencies in the production line, reduce unnecessary inventories, lower costs, and increase production efficiency. Throughout this transformation, tools such as the Kaizen philosophy, 5S practices, Value Stream Mapping (VSM), fishbone (Ishikawa) analysis, and Industry 4.0 technologies have been integrated holistically. Based on this analysis, various lean manufacturing tools were utilized to develop appropriate solutions. In particular, the use of value stream mapping played a critical role in identifying non-value-added activities and planning a future-state lean flow. This transformation process represents not only an operational shift but also a cultural change within the organization.

Keywords: Lean Manufacturing, Mass Production, Efficiency, Value Stream Mapping, Fishbone Analysis

INTRODUCTION

The food industry is a vast and strategically important sector that meets the basic human need for nutrition. This industry plays a critical role both economically and socially, processing raw materials obtained from primary production sources such as agriculture, livestock and fisheries, and delivering them to consumers. The food industry encompasses various sub-sectors, including baked goods, dairy products, meat and meat products, beverages, canned foods, ready meals, confectionery, and snacks.

With the impact of industrialization, food production has shifted from traditional methods to mass production-based, high-volume, and standardized processes. Mass production enables large quantities of products to be produced in a short time; however, this system is rigid, inadequate in responding to fluctuating demand patterns, and can lead to high inventory costs. Particularly today, with increased competition, diversified consumer expectations, and the need

for more efficient use of resources, the food industry has been driven towards more agile and lean production systems.

Lean production is a manufacturing philosophy focused on eliminating waste and creating customer value. Implementing this approach in the food industry not only increases production efficiency but also enhances quality, thereby improving customer satisfaction. Furthermore, in the production of perishable goods like food, lean systems provide significant advantages through reduced inventories, shortened process times, and agile decision-making mechanisms.

In this context, the transition from mass production to lean production in a food industry factory is not just an operational transformation but also involves a cultural and structural change. This study will examine the transition process in detail, exploring the challenges faced, methods applied, and gains achieved through a case study.

In food production factories, traditional mass production systems often lead to various issues such as high inventory levels, waste in production processes, low resource efficiency, and inflexible production structures. These problems not only increase production costs but also negatively affect the company's competitive power. Especially in an environment where consumer demands change rapidly and global competition is increasing daily, it has become very challenging for traditional production models to cope with these difficulties. In this context, the implementation of more efficient, flexible, and cost-effective production systems is inevitable.

This study aims to comprehensively analyze the existing production system in a food manufacturing facility. The analysis will incorporate modern production tools such as the Kaizen philosophy, 5S methodology, Industry 4.0 applications, and Fishbone (Ishikawa) analysis, as well as the Value Stream Mapping (VSM) method. Value Stream Mapping allows for visualizing the flow of materials and information on the production line, identifying non-value-adding activities and waste. Through this analysis, the main problems encountered in the production processes will be identified, and areas for improvement will be determined to eliminate these problems.

The research aims to eliminate inefficiencies on the production line, reduce unnecessary inventory, lower costs, and increase productivity by minimizing time losses. Specifically, by using value stream mapping, non-value-adding steps in the processes will be identified and removed. In this direction, the transformation that the transition from traditional mass production to lean production will create at both operational and strategic levels is considered the primary problem of the research.

The theoretical basis for lean manufacturing is based on the Toyota Production System, which became popular in Western management literature following the publication of Womack, Jones, and Roos's "The Machine That Changed the World" in 1990. This system defined lean manufacturing as a system that delivers more value to customers while producing the same outputs using fewer inputs. Early extensions of this framework into food processing, dating to studies in the late 2000s. These studies argued that lean manufacturing could help food processors become more competitive in the face of consumer pressure and competition from larger players; however, these early studies were largely conceptual or exploratory and not empirically substantiated in large samples.

Studies covered lean manufacturing are presented chronologically in Table 1. The studies reviewed in the literature are described as thematic groups. This aims to serve as a quick reference source for reviewing narrative literature; it allows for a comparison of each study's methodology, sectoral context, and key findings at a glance.

Table 1. Summary of Literature on Lean Manufacturing Application in the Food Industry

Author(s) & Year	Methodology	Food Subsector / Setting	Key Findings
Womack, Jones & Roos (1990)	Foundational book / conceptual	Automotive (foundation for all sectors)	Defined lean production as a system using fewer inputs to create equal output with greater customer value; established the vocabulary (waste, value, flow) for studies.
Luning, Marcelis & Jongen (2002)	Conceptual / techno-managerial framework	Food industry (general)	Identified short shelf life, heterogeneous raw materials, seasonality, and variable harvesting conditions as structural features that complicate direct transfer of lean tools from discrete manufacturing to food processing.
Scott, Wilcock & Kanetkar (2009)	Survey	Food sector (general)	Surveyed structured continuous-improvement programmes in the Canadian food sector; found sustained managerial interest in lean-type initiatives.
Dora, Kumar, Van Goubergen, Molnar & Gellynck (2013)	Literature review + survey	Food processing SMEs (general)	Found lean manufacturing still at an early adoption stage in food SMEs; identified workforce skill, in-house expertise, and organizational culture as critical success factors; food safety prioritized over process improvement.
Dora, Kumar, Van Goubergen, Molnar & Gellynck (2014)	Multi-case study	Small and medium-sized food enterprises	Examined applicability of lean practices in food SMEs; confirmed operational performance gains but highlighted resource constraints limiting scale of adoption.
Jiménez, Tejeda, Pérez, Blanco & Martínez (2011)	Case study (VSM)	Wine production	Demonstrated applicability of value stream mapping to a food and beverage subsector distinct from packaged industrial food manufacturing.
Kazancoglu, Ekinci, Ozkan Ozen & Ozbiltekin Pala (2021)	Case study	Poultry processing	Showed that combining lean tools with sustainable-operations practices reduces food waste across production, supply chain, and processing stages simultaneously.
Cusiatado Palomino, Farfán Carhuamaca & Rada Mota (2024)	Systematic review (PICO, PRISMA)	Food industry (cross-sector)	Found consistent positive association between lean tool implementation (TPM, JIT, VSM, 5S, Kaizen) and productivity, efficiency, and waste/cost reduction, contingent on supporting organizational factors.
Gayathri, Gokul Kannan, Swathi &Jenithakarthiga (2026)	Case study (VSM + JIT)	Dairy processing	Applied value stream mapping and Just-in-Time principles to pasteurization and packaging; achieved reductions in waiting time, in-process stock, and total lead time.

FOOD SECTOR

The current situation in the food sector, general challenges, deficiencies, and areas for improvement that food production facilities face may be explained as follows:

Time Loss and Low Productivity: In food production facilities, lengthy and inefficient processes lead to significant time losses. Unnecessary waiting times, slow production lines, low machine efficiency, and shortcomings in workforce management extend production time and decrease overall productivity.

Costs and Waste: Inventory management, irregularities in production planning, and waste during production lead to increased costs. Excess inventory raises storage and transportation expenses, while defective production, rework, and material waste contribute to higher operational costs.

Lack of Flexibility and Issues with Adaptation to Change: Traditional production systems struggle to respond to rapid changes in customer demand. This limits the ability to produce in small batches and reduces the competitive advantage in the market.

Quality Control Deficiencies and Error Rates: In fast production lines, inadequate quality control processes can lead to high error rates due to human mistakes and machine malfunctions. This increases rework and waste, reducing product quality.

Communication and Coordination Deficiencies: Weak communication and coordination between departments lead to errors in production planning, material supply, and workforce management. This results in delays, incorrect timing, and inventory shortages in the production process.

Lack of Digitalization, Innovation, and Sustainability: Most food production facilities have not fully adapted to digital technologies and Industry 4.0 applications. This deficiency makes it difficult to ensure process transparency and control while hindering the development of an innovation culture and sustainable production practices.

MASS PRODUCTION VS LEAN PRODUCTION

Mass production is a system based on producing the same product in large volumes and continuously. It is commonly used in industries such as automotive, electronics, and home appliances. Lean production is a production system aimed at eliminating all types of waste that do not add value to the customer. The Comparison of lean manufacturing and mass production can be seen in Table 2.

Table 2. Lean Production & Mass Production

Feature	Mass Production	Lean Production
Purpose	High-volume, low-cost production	Create value by eliminating waste
Production Process	Standardized, fixed production flow	Continuous improvement and flexible production
Stock Management	Large stocks, tendency to overproduce	Demand-based production, minimum stock
Flexibility	Low flexibility, difficult to adapt quickly to demands	High flexibility, quick adaptation to demands
Investment Requirement	High initial investment required	Low initial investment, continuous improvement
Employee Participation	Low employee participation, mostly automation	High employee participation, continuous improvement
Efficiency	High efficiency, limited flexibility	High efficiency and flexibility

Transition from Mass Production to Lean Production

Mass production systems carry disadvantages such as high stock costs, long production times, and low flexibility. The transition to lean production arises from the need to adopt a customer-focused approach to reduce costs and increase efficiency. The transition to lean production involves various challenges such as company culture, employee resistance, the restructuring of existing processes, and technological adaptation. Management support and employee training play a critical role in overcoming these barriers.

Strategic Steps for Transitioning to Lean Production

Analyzing current production processes and identifying waste
Applying value stream mapping techniques
Transitioning to a pull-based production system
Training employees on lean production principles
Management Support and Leadership

Lean Production Tools and Techniques

Lean production adopts an approach focused on eliminating all wastes that do not add value. In this context, a variety of tools and techniques are used to make processes more efficient and to respond quickly to customer demands. Below are the key tools and techniques in lean production:

Value Stream Mapping (VSM) : Identify wastes in production processes and improve the flow of processes.Examine each step in the production process to eliminate non-value-adding activities.

5S and Visual Management: Ensure workplace organization and prevent waste. Organize and standardize workspaces and use visual management to monitor processes.

Just-in-Time (JIT) Production: Minimize stock levels by aligning production with customer demand. Reduce inventory and produce only based on demand.

Kanban System: Ensure production is driven by need. Control material flow with visual signals and optimize production.

SMED (Single-Minute Exchange of Die): Minimize changeover times in production lines. Reduce machine setup and die change times, providing flexibility in production.

Poka-Yoke (Error-Proofing): Create mechanisms to prevent production errors. Prevent defects in the production process and improve quality.

Total Productive Maintenance (TPM): Ensure efficient operation of equipment. Reduce equipment breakdowns and ensure continuous maintenance.

Pull System and Production Pull: Direct production according to customer demand. Shape production processes based only on demand, preventing unnecessary production.

Continuous Improvement (Kaizen): Optimize production processes through continuous small improvements. Encourage employee participation to achieve continuous development and increased productivity.

Error Reduction and Elimination of Defective Production (Jidoka): Detect production errors early and enhance quality through automation. Prevent defects at the source and eliminate defective production.

Industry 4.0 and Digitalization: Optimize production processes with digitalization and automation. Use smart sensors, data analytics, and cyber-physical systems to make production processes more efficient.

METHODS USED IN THE STUDY

Kaizen : Kaizen is a Japanese term that means "change" (kai) and "good" (zen). Kaizen is a management method that adopts the philosophy of making continuous small improvements to increase organizational efficiency. The core principle of Kaizen is to encourage all employees to actively participate in improving processes. Instead of focusing solely on large changes, this philosophy aims to make continuous, small but valuable improvements. Kaizen promotes a continuous improvement process in areas such as labor efficiency, equipment efficiency, costs, quality, and safety.

Industry 4.0 : Industry 4.0 refers to the integration of modern technologies, such as digitalization, automation, data analytics, and the Internet of Things (IoT), into production processes. This concept aims to make manufacturing processes smarter, more flexible, and more efficient. Industry 4.0 increases production line efficiency by using technologies like machine learning, robotic systems, sensors, big data, and artificial intelligence (AI). As a result, lower error rates, reduced downtime, faster production processes, and more flexible manufacturing capabilities can be achieved. Industry 4.0 enables factories to become "smart factories," providing real-time data collection and analysis opportunities.

Fishbone (Ishikawa) Diagram : The Fishbone Diagram, also known as the Ishikawa Diagram, is a tool used to analyze a problem and uncover its potential causes. The diagram is designed in the shape of a "fishbone," with the main problem considered as the "head" and all the factors (causes) that may affect the problem represented as "bones." This method is particularly useful for quality control and process improvement. The Fishbone Diagram typically uses the following categories: People, Equipment, Methods, Materials, Measurements, and Environment. This tool helps to thoroughly examine the causes of a problem in a production process and develop potential solutions. Figure 1 is a Fishbone diagram for food sector including time, cost, digitalization, quality, communication and flexibility.

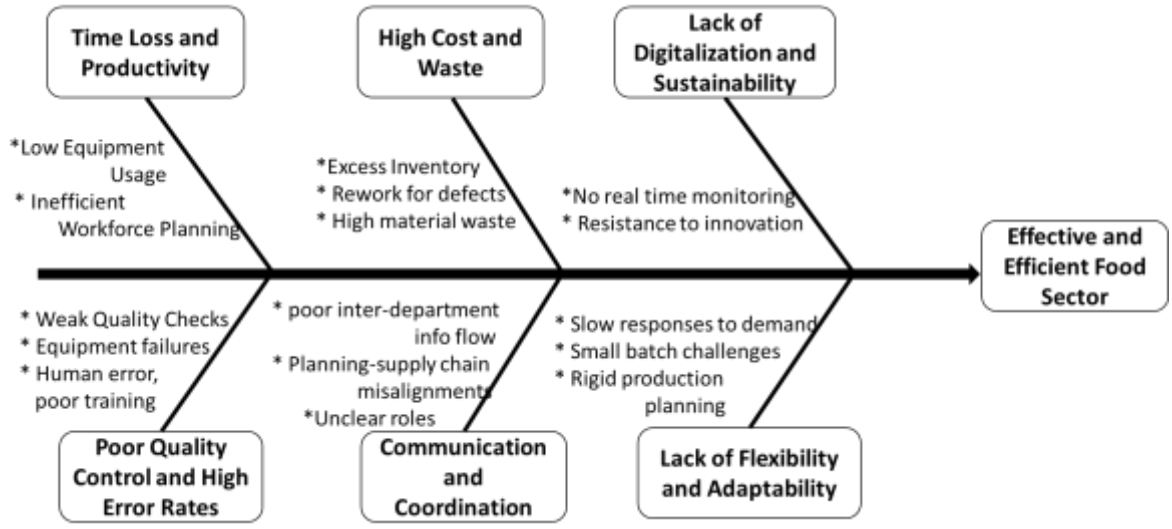

Figure 1. The Fishbone Diagram for Food Sector

Value Stream Mapping (VSM): Value Stream Mapping (VSM) is a technique used to visually design all the steps in a production process and analyze value-creating and non-value-creating activities. A value stream map shows the flow of information, materials, and time at each stage of the process. This map helps identify process bottlenecks and waste (e.g., excess inventory, waiting times, unnecessary transportation). VSM enables the evaluation of the current state of the organization and allows for improvement plans aimed at reaching the ideal future state. This method is a critical tool in lean manufacturing philosophy and plays a vital role in making processes more efficient. Figure 2 is a Value Stream Map for food sector.

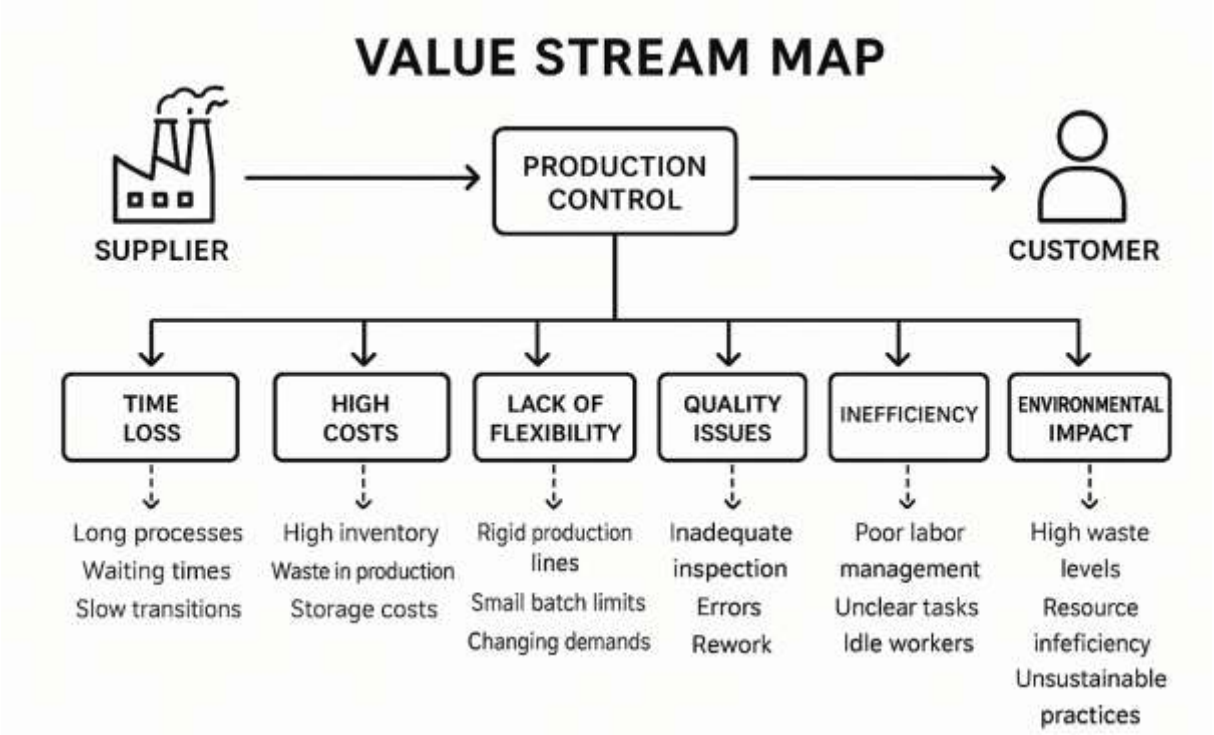

Figure 2. The Value Stream Map for Food Sector

This study provides a detailed application of Kaizen; improvement strategies addressing key issues encountered in the production line. The investigation is structured around six main problem areas adversely affecting production processes: time loss, high costs, quality problems, communication gaps, lack of digitalization, and lack of flexibility. Under each category, both the traditional continuous improvement solutions offered by the Kaizen approach and the technological, digital transformation-oriented approaches of Industry 4.0 are evaluated. The effectiveness, ease of implementation, and potential contributions of these methods to the business are compared. Following this assessment, the practical section of the study focuses on analyses of time loss, cost and efficiency, and quality.

LEAN PRODUCTION APPLICATION FOR FLOUR PRODUCTION

Lean manufacturing has been studied in the food industry, specifically in flour production. Figure 3 shows the general operation of a flour mill. The flour production system shown in Figure 3 was used while conducting mass production and lean manufacturing studies.

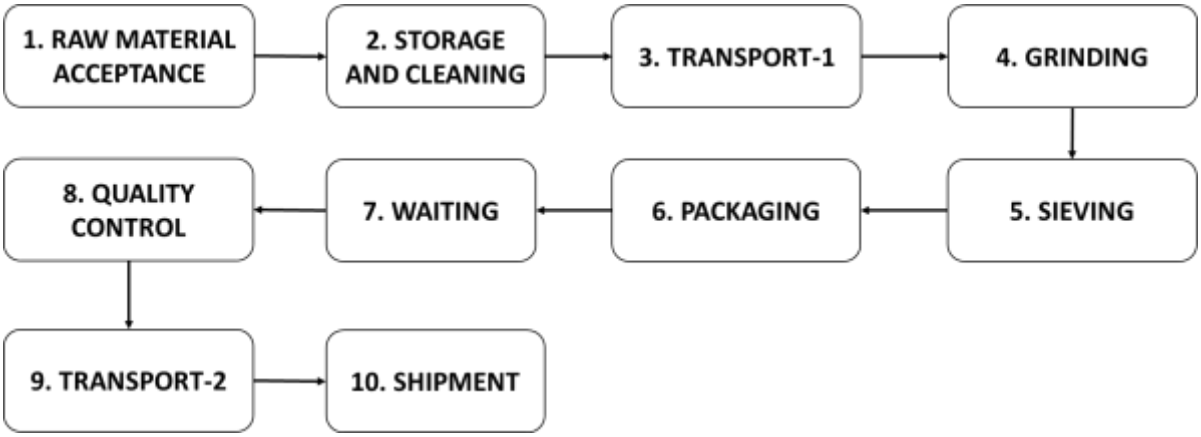

Figure 3. The Steps in the Flour Production Production Process

Quantitative Analysis and Efficiency Improvement :Time Loss and Low Efficiency

As a result of the process quantitative analysis conducted using generic data, one of the main problems identified in flour production is time loss, which in turn leads to low productivity. Although the current production process progresses through sequential steps, a detailed review of the workflow reveals several instances of unnecessary delays, low equipment efficiency, and human-related interruptions.

In particular, delays that disrupt continuity have been observed between the initial steps of "Raw Material Procurement" and "Cleaning and Sieving." Irregularities in raw material supply and uncertainties during quality control cause delays in transitioning to the subsequent stages. This negatively affects the overall flow of the production line.

Additionally, it has been reported that machines used in the grinding (mill) process frequently require maintenance, which leads to repeated interruptions in planned production. When breakdowns occur, production comes to a complete halt, resulting in both time loss and idle labor. The lack of automation and the dependence on manual interventions reduce the sustainability of the process.

Similar time losses are observed during the Sieving and Sorting stages. Delayed sorting of sieved products or the continuation of processes manually extends the processing time and

increases the margin of error. This leads to bottlenecks toward the end of the line and slows down the overall flow.

Due to the lack of automation in the quality control process, some batches needed to be reprocessed, causing further time losses on the production line. In cases where quality is inspected manually, operations such as returning products cause deviations from the production plan and reduce overall efficiency.

In general, despite the sequential nature of production steps, minor delays at each stage accumulate and significantly extend the total production time. As a result, the facility's capacity cannot be used effectively. These recurring disruptions lead to waste of both time and energy and cause deviations in production planning.

To compare the existing mass production system with the lean production system, the production process was modeled for ten products, and the results are shown in Table 3. The average duration of each step of the production process was determined.

Table 3. Mass Production – Daily Process Times (Hours)

Pro-duct	Raw Material Acceptance	Storage	Transport 1	Grinding	Sieving	Packaging	Waiting 1	Quality Control	Transport 2	Shipment	Total Time
1.	1,3	1,0	0,7	1,9	1,1	1,4	2,3	0,7	1,0	0,5	**12,0**
2.	1,1	1,1	0,8	2,0	0,9	1,6	2,2	0,8	1,1	0,5	**12,1**

Within this context, the implementation of lean production practices aims to reduce time losses and eliminate unnecessary steps in the process. The lean production findings presented in this section is supported by quantitative analyses in the Table 4. The impact of the transition to lean production on manufacturing efficiency with concrete data.

Table 4. Lean Production – Daily Process Times (Hours)

Pro-duct	Raw Material Acceptance	Storage	Transport 1	Grinding	Sieving	Packaging	Waiting 1	Quality Control	Transport 2	Shipment	Total Time

The Figure 4 shows the steps in the Lean Production process along with the average duration of each step, indicated in parentheses. In lean production, significant reductions have been achieved in waiting and transportation times, contributing to a shorter overall production time and increased efficiency. Analysis shows an approximately 28% reduction in total production time

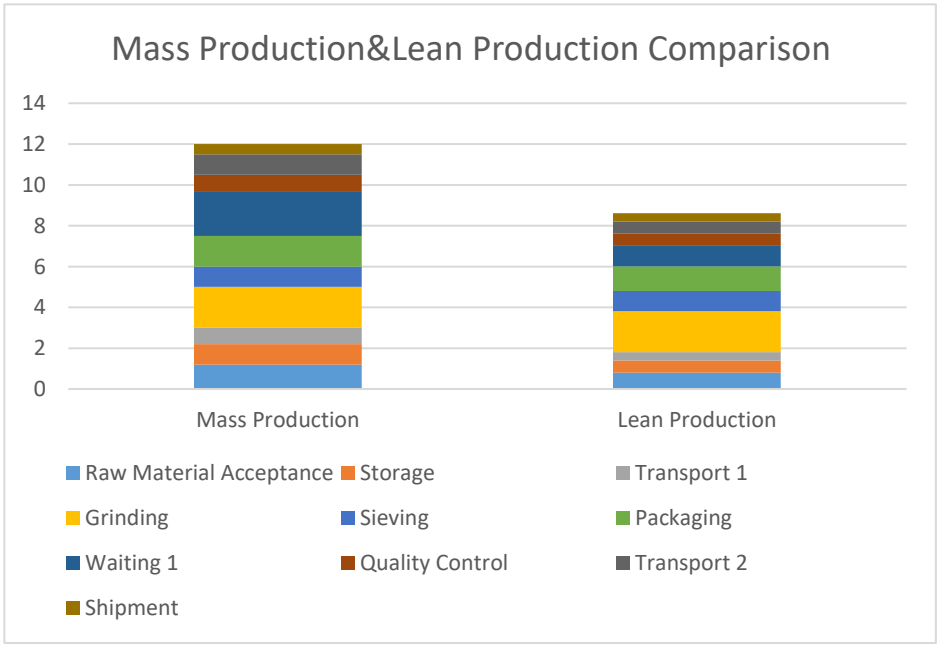

Figure 4 Total Production Time Comparison

Value Stream Mapping (VSM) Analysis

Value Stream Mapping (VSM) Analysis is used to differentiate between value-added and non-value-added activities across the entire production process. Value-Added (VA) Steps: Grinding, Sieving, Packaging. These processes transform wheat into flour and package it.

Non-Value-Added (NVA / Waste) Steps: Storage, Transports and Waiting. Lean manufacturing aims to completely eliminate or minimize these NVA /waste steps. It identifies

sources of waste such as waiting times, transportation, excessive inventory, and reprocessing, thereby highlighting areas of time loss within the workflow.

Raw Material Acceptance, Quality Control and Shipment steps are mandatory but Non-Value-Added (Business Non-Value-Added - BNVA) steps. These steps do not directly add value to the product but are mandatory for legal, quality or logistical processes.
Note: Value-added processes are Grinding, Sieving, Packaging.

Table 5. Lean Production Improvement

Pro-duct	Raw Material Acceptance	Storage	Transport 1	Grinding	Sieving	Packaging	Waiting 1	Quality Control	Transport 2	Shipment	Total Time
Mass Pro.	**1,2**	**1,0**	**0,8**	**2,0**	**1,0**	**1,5**	**2,2**	**0,8**	**1,0**	**0,5**	**12,0**
Lean Pro	**0,8**	**0,6**	**0,4**	**2,0**	**1,0**	**1,2**	**1,0**	**0,6**	**0,6**	**0,4**	**8,6**
Impr-ovem %	**40%**	**40%**	**40%**	**0%**	**0%**	**30%**	**120%**	**20%**	**40%**	**10%**	**3,4 (28%)**

Time (Hours)	**Mass Production**	**Lean Production**
Total Production Time	12	8,6
Value Added Time	4,5 (37,5%)	4,2 (48,8)
Value Added Ratio	4,5 / 12 = 37,5%	4,2 / 8,6 = 48,8%

The value-added ratio increased from 37.5% to 48.84% in lean production. This indicates that waiting, transportation, and unnecessary operations decreased, resulting in a higher proportion of value-added work in the process.

Cycle Time & Takt Time Comparison

It is used to examine the alignment of the production cycle time with the customer demand rate (Takt Time). Identifies where production is slowing down, highlighting areas for improvement.

Bottleneck Analysis: In both mass production and lean manufacturing, the longest-running steps are Milling (2.0 hours) and Packaging (1.5/1.2 hours), respectively. Therefore, the Milling stage is the one that determines the factory's maximum daily production capacity (the stage with the highest cycle time).

Takt Time Alignment: Since the Milling (2.0 hours) and Sieving (1.0 hour) times were maintained during the transition to lean manufacturing, the main production speed was not disrupted. However, by reducing the Packaging time from 1.5 hours to 1.2 hours, the accumulation of flour from the Milling stage in front of the packaging area was prevented, and the process was made more aligned (balanced) with Takt time.

The Waiting time (waiting in intermediate flour silos), which was 2.2 hours in mass production, was reduced to 1.0 hour in lean manufacturing. This indicates that a Kanban/Pull system has been established between the Grinding and Packaging lines, or that the production flow has been synchronized.

Total Operating Time: 12 hours × 60 minutes = **720 minutes**.
Total Planned Downtime: 30 minutes (Breaks) + 30 minutes (Breakdowns and Installations) = **60 minutes**
Net Available Operating Time: 720 min - 60 min = **660 minutes** (39,600 seconds)

Daily Customer Demand: **250** packs
Takt Time =660 /250 = 2,64 minute /sacks (To meet customer demand on time, 1 sack of flour must leave the factory every 2 minutes and 38 seconds (158.4 seconds).

	Available Product Amount	
Takt Time	250 (Customer Demand)	2,64 minute (660/250 = 2,64)
Mass Production Cycle Time	200	3,3 minute (660 /200 = 3,3)
Lean Production Cycle Time	275	2,4 minute (660/275 = 2,4)

Within the framework of lean production practices, non-value-added activities such as waiting, transportation, and rework were analyzed and targeted for reduction through the use of Value Stream Mapping (VSM). Additionally, employee training on lean principles and process restructuring were implemented to minimize waste.

Following these improvement initiatives, measurements indicated that the average cycle time per product on the production line decreased from 3,3 minutes to 2.4 minutes. This result is less than the target takt time of 2.64 minutes, demonstrating the effectiveness of lean production applications in aligning production speed with customer demand. Producing a customer's order of 250 units now takes only 600 minutes (250 times 2.4). This means we can finish our daily order 60 minutes before your net time limit of 660 minutes expires.

Minor breakdowns or stoppages during the day no longer jeopardize our delivery because we now have a time margin on your production line. The 2 hours and 45 minutes of overtime for previous Mass Production that we had to work each day to reach 250 units is completely eliminated. Now that we have confidently exceeded customer demand, we can plan our inventory management.

CONCLUSION

As a result, both production efficiency increased and responsiveness to customer demands improved. The obtained data quantitatively prove that implementing lean production processes reduces cycle time and significantly decreases time loss.

With the transition to a lean production system, significant time savings and increased production efficiency have been achieved at the flour mill. Our analysis shows an approximately 28% reduction in total production time, while the value-added process ratio increased from 37,5% to 48,8%. This improvement was made possible by reducing waste elements such as waiting, unnecessary transportation, and rework within the production process. Our cycle time has been decreased **37,5 %** and we are able to produce more than customer demand.

Furthermore, adjusting the cycle time to align with customer demand has considerably enhanced production speed. Kaizen activities conducted as part of lean production, along with the integration of Industry 4.0 technologies, have minimized waste (Muda) and made processes smoother and more efficient.

The transition to lean production has led to both cost reductions and an increase in production capacity, thereby improving the factory’s competitiveness and customer satisfaction.

ASSESSMENT OF WATER QUALITY AND NUTRIENT CONTAMINATION RISKS IN ISTANBUL'S URBAN LAGOONS (BÜYÜKÇEKMECE AND KÜÇÜKÇEKMECE) USING MODIFIED INDICES

Cem Tokatlı

Trakya University, Edirne / Türkiye

ABSTRACT

In this comprehensive scientific investigation, the overarching contamination threats, ecological risks, and seasonal pollution dynamics of Büyükçekmece and Küçükçekmece Lagoons (Istanbul, Türkiye), two critical and vulnerable urban coastal wetlands directly connected to the Sea of Marmara, were thoroughly evaluated under intense anthropogenic stress. A specifically modified Water Quality Index (modified WQI) alongside a newly modified Nutrient Pollution Index (modified NPI) were systematically utilized as the primary diagnostic frameworks to assess the precise extent of environmental degradation and evaluate hydrochemical risks within these complex transitional ecosystems. To effectively quantify the intense urban, agricultural, and industrial pressures exerted on the lagoons across highly contrasting dry and wet seasons, key hydrochemical macro-nutrients including ammonium nitrogen, nitrate nitrogen, nitrite nitrogen, and phosphate phosphorus were monitored at strategically selected sampling stations located closest to the sea inlets. The successful application of these modified indices clearly demonstrated a sharp, multi-seasonal pollution contrast and spatial variation between the two adjacent lagoon systems. Based on the comprehensive modified WQI calculations, Büyükçekmece Lagoon was classified as having a relatively sustainable "good water quality" status (with index values safely ranging between 50 and 100), whereas Küçükçekmece Lagoon consistently exhibited a severely degraded and highly alarming "unsuitable" ecological status (with index values significantly exceeding 300). Correspondingly, the modified NPI values strongly corroborated these diagnostic findings, indicating a state of "moderate pollution" (ranging between 1 and 3) for the Büyükçekmece ecosystem, while rapidly escalating to catastrophic "very high pollution" levels (well exceeding 6) in the Küçükçekmece basin. Ultimately, these analytical results confirm that while natural marine-driven interactions predominantly dictate the hydrochemical character and salinity profile of Büyükçekmece, heavy municipal wastewater and industrial effluents pose a continuous, severe, and unchecked threat to the ecological integrity of Küçükçekmece across all seasonal cycles.

INTRODUCTION

Nutrient loads from intense urban runoffs and industrial wastewaters accelerate eutrophication in fragile coastal lagoons, leading to oxygen depletion, restricted light, and disrupted trophic dynamics (Atıcı et al., 2018; Haq et al., 2023; Din et al., 2023; Muhammad et al., 2025). The

shallow, semi-enclosed nature of these systems increases their vulnerability to rapid hypoxia, which fluctuates significantly across contrasting seasons (Howarth et al., 2011; Borrell et al., 2019; Mia et al., 2023). Under severe metropolitan stress, assessing these hydrochemical contaminants is vital to understand cumulative impacts on water quality and biodiversity (Çiçek et al., 2014; Köse et al., 2020; Varol et al., 2022; Ustaoğlu et al., 2022). To effectively evaluate ecosystem health, advanced tools like the modified Nutrient Pollution Index (modified NPI) and modified Water Quality Index (modified WQI) are essential to determine the synergistic effects of multi-seasonal pollution in these transitional waters (Tokatlı and Varol, 2021; Varol et al., 2022; Muhammad et al., 2024; Tokatlı et al., 2025).

Interpreting large, multidimensional water quality datasets can be challenging for environmental risk communication and policy making. Therefore, integrating mathematical models like the modified Water Quality Index (modified WQI) and modified Nutrient Pollution Index (modified NPI) provides an indispensable methodology to aggregate complex variables into a single, cohesive score. Utilizing these modified indices is crucial for Büyükçekmece and Küçükçekmece Lakes, fragile coastal lagoon ecosystems simultaneously exposed to heavy industrial effluents, dense municipal wastewater, and intense urban runoffs within a megacity layout (Tokatlı et al., 2017; Tokatlı, 2019). By filtering raw hydrochemical metrics through the modified WQI and modified NPI, it becomes possible to objectively evaluate sharp seasonal pollution contrasts, isolate the specific impacts of multi-seasonal urban inputs, and establish a scientifically validated baseline for the ecological protection of these vulnerable urban lagoons.

This study aims to assess the contamination threats and seasonal pollution dynamics affecting Büyükçekmece and Küçükçekmece Lagoons by employing a set of modified water quality and nutrient indices in a megacity (Istanbul). The evaluation utilizes key limnological and hydrochemical parameters—specifically ammonium nitrogen, nitrate nitrogen, nitrite nitrogen, and phosphate phosphorus—to analyze the extent and impact of anthropogenic pollution across contrasting dry and wet seasons in these fragile transitional ecosystems. By applying the modified Water Quality Index (modified WQI) and modified Nutrient Pollution Index (modified NPI) at stations closest to the sea, the study seeks to offer precise insights into multi-seasonal pollution contrasts and environmental risks.

MATERIALS AND METHODS

Research Area and Sample Collection

The geographic positions of Büyükçekmece and Küçükçekmece Lakes and the designated sampling stations on each lagoon are presented in Figure 1. Water samples were systematically collected from the selected stations across two contrasting periods: the dry late-summer season of 2022 and the wet late-winter season of 2023.

Chemical Analysis

The concentrations of key hydrochemical parameters, including ammonium nitrogen, nitrate nitrogen, nitrite nitrogen, and phosphate phosphorus, were systematically analyzed in the laboratory. All nutrient analyses were performed following standard methods for the examination of water and wastewater as outlined in APHA protocols (1998, 2017). Quantitative determinations were executed spectrophotometrically using a calibrated Hach spectrophotometer with appropriate high-purity reagents and standard curves.

Ecological Indices

The detailed mathematical formulations and computation techniques for the modified Water Quality Index (modified WQI) and modified Nutrient Pollution Index (modified NPI) applied in this study, aligned with the national environmental thresholds (TSWQR, 2021), are comprehensively presented in Table 1 (Tokatlı et al., 2025). These modified indices were systematically deployed to evaluate the precise levels of nutrient enrichment and associated multi-seasonal contamination risks in the transitional water samples.

Table 1. Methods of applied modified organic pollution risk assessment indices

Index	Calculation	Formula Explanations	Rating of Water Quality
NPI	$NPI = (C_N/MAC_N) + (C_P/MAC_P)$	C_N: The levels of NO_2-N in water sample C_P: The levels of PO_4-P in water sample MAC_N: The maximum limit of NO_2-N MAC_P: The maximum limit of PO_4-P	<1: No polluted 1-3: Moderate polluted 3-6: Considerable polluted >6: Very high polluted
WQI	$WQI = \sum_{i=1}^{n} W\imath \; x \; (\frac{Ci}{Si}) \; x \; 100$ $W\imath = \frac{W_i}{\sum_{i=1}^{n} W_i}$	WI: The relative weight Wi: The values assigned to i (1-5) Ci: The values of measured parameters Si: The standard values	<50: Excellent water 50–100: Good water 100–200: Poor water 200–300: Very poor water >300: Unsuitable

Figure 1. Investigated lagoons and selected sampling stations

RESULTS AND DISCUSSION

The calculated modified water quality and nutrient pollution indices for Büyükçekmece and Küçükçekmece Lagoons are presented in Figure 2. The results indicate a sharp multi-seasonal pollution contrast, demonstrating that while Büyükçekmece exhibits a stable, low-risk profile, Küçükçekmece remains critically and permanently degraded. These ecological indices clearly reflect the dominant grip of heavy urban and industrial wastewater pressures over the natural hydrochemical baseline of the Istanbul megacity (Mutlu et al., 2021a; 2021b).

Büyükçekmece Lagoon showed high ecological resilience across both periods. During the dry season, it displayed a modified WQI of 43.670 ("excellent water quality", <50), which rose slightly to 58.617 ("good water quality", 50–100) in the wet season. This minor variation indicates that rain-driven urban runoffs introduce limited nutrient inputs during wet periods without compromising overall ecosystem integrity. This stable profile was strongly corroborated by the modified NPI scores; Büyükçekmece recorded a value of 1.140 ("moderate polluted", 1-3) during the dry period, which dropped to 0.980 ("no polluted", <1) in the wet season due to precipitation-driven dilution.

In stark contrast, environmental indicators escalated to catastrophic levels in Küçükçekmece Lagoon due to relentless municipal and industrial effluents that drive severe ecosystem degradation (Varol and Tokatlı, 2021). During the dry season, the modified WQI reached a critical "unsuitable" status at 673.480 (>300), further verified by an exceptionally high modified NPI of 23.880 ("very high polluted", >6). Restricted dry-season dilution capacity highlights a severe contamination core driven directly by infrastructure pressures.

During the wet season, despite increased precipitation regimes, Küçükçekmece Lagoon failed to recover, signaling a state of permanent ecological saturation (Muhammad et al., 2024). The modified WQI remained firmly "unsuitable" at 475.223, while the modified NPI recorded 13.220 ("very high polluted", >6). Although winter precipitation exerted a relative dilution effect compared to the dry season, the persistence of these extreme thresholds underscores that heavy urban wastewater discharges operate as a continuous, acute threat (Muhammad et al., 2025). This multi-seasonal elevation confirms that anthropogenic pressures overwhelm natural dilution factors, establishing a permanent pollution contrast against the well-preserved character of Büyükçekmece Lagoon (Tokatlı et al., 2023; 2024).

CONCLUSIONS

This study underscores the high efficiency of using modified pollution indices to diagnose ecosystem health in complex urban coastal wetlands. By applying the modified WQI and modified NPI across contrasting seasons, a sharp pollution contrast was unraveled between Istanbul's two strategic lagoons. The index calculations revealed that Büyükçekmece Lagoon maintains a resilient profile, exhibiting "excellent" to "good" water quality and low nutrient levels. In stark contrast, Küçükçekmece Lagoon suffers from permanent ecological saturation, consistently displaying "unsuitable" water quality and "very high" nutrient pollution across both dry and wet periods. The persistence of these extreme scores in Küçükçekmece, even during wet seasons, proves that continuous municipal and industrial effluents completely overwhelm the natural dilution capacity of the system. Ultimately, these findings establish a scientifically validated baseline demonstrating that a single, generalized management approach is inadequate. While Büyükçekmece requires proactive protection, Küçükçekmece demands immediate, aggressive remediation. Implementing system-specific wastewater management strategies is vital to ensure the long-term ecological sustainability of transitional waters within a megacity.

SEASONAL DYNAMICS OF WATER QUALITY AND ANTHROPOGENIC PRESSURES IN BÜYÜKÇEKMECE AND KÜÇÜKÇEKMECE LAGOONS IN A MEGACITY (İSTANBUL)

Cem Tokatlı

Trakya University, Edirne / Türkiye

Corresponding author: e-mail: cemtokatli@trakya.edu.tr

ABSTRACT

In this comprehensive scientific study, the overall water quality status, physicochemical characteristics, and seasonal dynamics of Büyükçekmece and Küçükçekmece Lakes (Istanbul), two crucial coastal lagoon ecosystems tightly connected to the Sea of Marmara, were meticulously investigated under intense and continuous anthropogenic pressure mechanisms. Field sampling campaigns were systematically conducted across two highly contrasting seasons—the late dry season of 2022 and the wet late-winter season of 2023—focusing specifically on strategically designated sampling points located closest to the marine connection of each lagoon to accurately evaluate the extent of seawater intrusion and tidal interactions. The research program monitored a wide spectrum of key environmental parameters, including dissolved oxygen, pH, electrical conductivity, total dissolved solids, salinity, turbidity, ammonium nitrogen, nitrate nitrogen, nitrite nitrogen, and phosphate phosphorus, to evaluate the level of environmental degradation. The analytical findings revealed distinct limnological profiles and highly varying pollution characteristics between the two interconnected aquatic systems; Büyükçekmece Lagoon exhibited a significantly higher salinity level and a much more pronounced brackish water character due to its direct and active marine interactions with the Sea of Marmara, whereas Küçükçekmece Lagoon demonstrated severe environmental degradation characterized by substantially higher nutrient concentrations, clearly indicating intense domestic, agricultural, and industrial pollution loads originating from its heavily urbanized watershed. Furthermore, the seasonal transition from the dry late-summer period to the wet late-winter season drastically altered the physical and chemical profiles of both lagoons through heavy precipitation and subsequent surface runoff, demonstrating that while natural marine inputs dominate the salinity profile of Büyükçekmece, heavy urban expansion and anthropogenic pressures continuously compromise the environmental health and long-term ecological integrity of Küçükçekmece.

INTRODUCTION

Anthropogenic transformations in megacities subject adjacent aquatic ecosystems to unprecedented ecological stress, where rapid urbanization and industrial concentration disrupt natural hydrological balances. The continuous discharge of complex urban effluents drastically shifts the physico-chemical integrity and nutrient dynamics of receiving waters, triggering severe degradation and threatening biodiversity. Coastal lagoons, operating as complex transitional interfaces between terrestrial watersheds and marine environments, represent some

of the most critically threatened habitats under these intense urban regimes. Although these ecosystems possess immense socio-economic and ecological value, their restricted hydrodynamic flushing capacity and semi-closed structures make them highly susceptible to accumulating anthropogenic pollutants, a vulnerability that fluctuates dramatically across contrasting seasonal periods (Muhammed et al., 2024; 2025; Helvacıoğlu et al., 2025).

Deciphering the complex pollution trajectories within fragile lagoon ecosystems dictates a continuous, systematic evaluation of hydrochemical parameters to build robust conservation strategies. Investigating water quality variations serves as a baseline scientific catalyst for environmental management, explicitly exposing how temporal dynamics and seasonal shifts dictate the behavior of urban stressors. Within this critical framework, Büyükçekmece and Küçükçekmece Lakes, functioning as strategic coastal lagoons connected to the Sea of Marmara, occupy a pivotal position in maintaining the ecological equilibrium of the Istanbul megacity. While these coastal systems provide irreplaceable aquatic habitats, they simultaneously endure relentless environmental degradation from dense municipal layout, sprawling industrial corridors, and intense urban runoffs that fluctuate severely between dry and wet seasonal cycles (Atıcı et al., 2018; Ustaoğlu et al., 2022; Tokatlı et al., 2022; 2024).

The objective of this study is to evaluate the water quality status and seasonal dynamics of Büyükçekmece and Küçükçekmece Lakes under intense urban and industrial pressures across two contrasting periods: the dry late-summer of 2022 and the wet late-winter of 2023. By monitoring key hydrochemical parameters at sampling points closest to their Sea of Marmara connections, this research aims to elucidate the multi-seasonal background pollution status of these strategic lagoons. Furthermore, the findings specifically aim to demonstrate the contrasting environmental profiles of the two systems—highlighting the more pronounced marine-driven salinity character of Büyükçekmece against the severe nutrient-driven degradation of Küçükçekmece—thereby providing a crucial scientific baseline for distinct, sustainable lagoon management and remediation strategies in a megacity.

MATERIALS AND METHODS

Research Area and Sample Collection

The geographic locations of Büyükçekmece and Küçükçekmece Lakes and the designated sampling stations on each lagoon are presented in Figure 1, providing a visual representation of the study area within the Istanbul megacity. To evaluate the seasonal water quality status and assess the hydrochemical impacts of intense urban pressures, water samples were systematically collected across two contrasting field surveys: the dry late-summer season of 2022 and the wet late-winter season of 2023.

The sampling stations were strategically positioned to capture the direct transitional dynamics between the lagoon ecosystems and the marine environment. One critical station was established at the point closest to the Sea of Marmara connection for each lagoon. At each station, water samples were collected, preserved, and transported to the laboratory under appropriate cold-chain conditions for subsequent physico-chemical and hydrochemical analyses.

Physicochemical Analysis

Dissolved oxygen, electrical conductivity, pH, total dissolved solids, salinity, and turbidity were measured on-site in the field during the sampling survey using a Hach portable multi-parameter meter and a Hach turbidimeter, following the standard methods established by APHA (1998, 2017). For the nutrient analyses, water samples were transported to the laboratory under

appropriate conditions. The concentrations of nitrate nitrogen, nitrite nitrogen, ammonium nitrogen and phosphate phosphorus were systematically analysed in the laboratory according to APHA protocols (1998) utilizing a Hach spectrophotometer.

Figure 1. Investigated lagoons and selected sampling stations

RESULTS AND DISCUSSION

The obtained results clearly demonstrated that although Büyükçekmece and Küçükçekmece Lagoons are located within the same metropolitan region and are both connected to the Sea of Marmara, they exhibit markedly different limnological structures and pollution characteristics under anthropogenic influence. The most evident distinction between the lagoons was observed in salinity-related parameters. Büyükçekmece Lagoon consistently exhibited substantially higher TDS (21,135 mg/L), EC (29,000 µS/cm), and salinity (21.90‰) values compared to Küçükçekmece Lagoon (13,465 mg/L, 18,975 µS/cm, and 13.97‰, respectively). These findings indicate a stronger marine influence and more pronounced brackish character in Büyükçekmece Lagoon, likely associated with its hydrodynamic connection to the Sea of Marmara. Seasonal variation further supported this pattern, as salinity-related parameters were notably higher during the dry season in both lagoons, reflecting evaporation effects and reduced freshwater inflow. Conversely, wet-season dilution decreased TDS, EC, and salinity levels, particularly in Büyükçekmece, indicating the importance of seasonal hydrological processes in regulating lagoon physicochemistry (Mutlu et al., 2021a; Tokatlı et al., 2023; 2025) (Figure 2).

Despite the stronger marine characteristics of Büyükçekmece Lagoon, nutrient enrichment and ecological degradation were considerably more pronounced in Küçükçekmece Lagoon. Mean nutrient concentrations in Küçükçekmece (NO_3–N: 0.694 mg/L; NO_2–N: 0.089 mg/L; PO_4–P: 0.483 mg/L; NH_4–N: 0.682 mg/L) were markedly higher than those detected in Büyükçekmece Lagoon (0.404, 0.008, 0.016, and 0.161 mg/L, respectively). According to the Turkish Surface Water Quality Regulation classification criteria (TSWQR, 2021), nitrate concentrations in both lagoons remained within Class I quality limits (<5 mg/L), indicating no severe nitrate pollution. However, phosphate concentrations in Küçükçekmece corresponded to Class III water quality (0.16–0.65 mg/L), while ammonium levels indicated Class II quality conditions. Nitrite concentrations also approached the upper limit of Class II and lower limit of Class III categories. In contrast, Büyükçekmece generally retained Class I water quality characteristics for phosphorus, nitrite, and ammonium. These results suggest that nutrient pollution in Küçükçekmece is primarily associated with intensive urbanization, industrial activities, domestic wastewater inputs, and historical anthropogenic accumulation within the watershed (Mutlu et al., 2021b; Tokatlı et al., 2025) (Figure 2).

Seasonal dynamics revealed clear differences between the lagoons. During the wet season, nitrate concentrations increased in both systems, particularly in Küçükçekmece (0.267–1.121 mg/L), indicating enhanced runoff-derived nutrient transport. Turbidity also increased seasonally, rising from 1.12 to 2.94 NTU in Küçükçekmece and from 0.84 to 2.09 NTU in Büyükçekmece, likely due to increased suspended matter inputs and sediment resuspension. In contrast, phosphate slightly decreased in Küçükçekmece, suggesting dilution effects, whereas ammonium increased during the wet period (0.821 mg/L), further reflecting urban and watershed-derived pollution inputs (Tokatlı, 2017; Tokatlı, 2018).

Dissolved oxygen levels generally remained high (>8 mg/L), corresponding to Class I water quality conditions. However, wet-season DO decline was observed, especially in Küçükçekmece (7.29 mg/L), probably due to increased organic inputs and microbial activity. Both lagoons exhibited alkaline conditions throughout the study, with wet-season pH values exceeding 9.0, which is typical for productive brackish lagoon ecosystems (Varol and Tokatlı, 2021).

Overall, the findings indicated that the two lagoons are controlled by different dominant drivers. Büyükçekmece Lagoon is mainly influenced by marine connectivity and hydrological exchange, resulting in higher salinity but relatively good water quality. In contrast, Küçükçekmece Lagoon is strongly affected by anthropogenic pressures, reflected by nutrient enrichment and ecological deterioration. Seasonal transitions between dry and wet periods significantly altered water quality characteristics and pollutant transport processes. Therefore, reducing urban and industrial pollution loads, particularly in the Küçükçekmece watershed, is essential for the sustainable management of these lagoon ecosystems in the megacity environment of Istanbul.

CONCLUSIONS

In conclusion, Büyükçekmece and Küçükçekmece Lagoons exhibited distinct ecological characteristics despite their similar geographic setting. Büyükçekmece was mainly influenced by marine connectivity and showed a more pronounced brackish character with relatively better water quality conditions. In contrast, Küçükçekmece was characterized by higher nutrient concentrations and stronger anthropogenic impacts. Seasonal transitions significantly affected water quality dynamics, particularly nutrient levels and turbidity, highlighting the importance of hydrological processes and watershed inputs in lagoon functioning. These findings

emphasize the need for effective pollution control and sustainable management strategies, especially for Küçükçekmece Lagoon.

ABSTRACT

Climate change has been reshaping the management of water resources, requiring a shift towards sustainable and resilient infrastructure. Traditional cistern systems for collecting and storing rainwater, which were once widespread across Anatolia and beyond, are now re-emerging as decentralized solutions to strengthen regional water security. Rainwater harvesting (RWH) systems can be implemented in a variety of settings, including residential buildings, housing complexes, shopping centers, sports centers, hospitals, military bases and car parks. Industrial facilities offer particularly significant potential for RWH due to their extensive rooftop areas and substantial demand for non-potable water, such as process water, cooling water and rinsing water.

Recent legislative developments in Türkiye, including amendments to Planned Areas Construction Regulation and the Water Efficiency Regulation, have established a more supportive regulatory framework for the implementation of these systems. Therefore, it is expected that the use of these technologies in urban and industrial areas in Turkey will increase in the near future. The present study investigates the technical potential and economic feasibility of RWH in an Organized Industrial Zone (OIZ) in İzmir. The study examined 22 pilot enterprises and classified them into groups according to their water consumption patterns and the relationship between water demand and rainwater availability. Based on rooftop areas and long-term local rainfall data, the potential volume of harvestable rainwater was estimated, and appropriate cistern capacities were determined by considering the temporal variation in rainfall and water demand. The required capital investment costs and economic payback periods were subsequently evaluated to demonstrate that decentralized RWH provides a practical, cost-effective, and climate-resilient approach to supporting sustainable industrial water management practices.

Keywords: Rainwater Harvesting, Water Scarcity, Organized Industrial Zones, Water Efficiency, Industrial Water Management; Climate Resilience

INTRODUCTION

Accelerated climate change, increasing drought frequency, and rapid urbanization are placing growing pressure on freshwater resources and intensifying water scarcity worldwide. As conventional centralized water management strategies have become increasingly inadequate and costly, the integration of decentralized and locally available water sources has become

imperative. Although the collection and storage of rainwater in cisterns has been practiced for centuries globally, including in Anatolia, these traditional systems were progressively abandoned during the rapid expansion of centralized water infrastructure in the mid- to late twentieth century. Traditional cistern systems were largely replaced by centralized, large-scale networks designed to convey water over long distances from major dams, lakes and aquifers. Today, however, increasing water demand, severe drought conditions, rising infrastructure costs, and the energy intensity of centralized water supply systems are contributing to renewed interest in rainwater harvesting (RWH) as a resilient and sustainable water management strategy (Avila et. al., 2023) Consequently, the ancient practice of rainwater harvesting is re-emerging as a decentralized alternative with the potential to provide reliable, sustainable and potentially more cost-effective water supplies.

The implementation of rainwater harvesting (RWH) systems in Türkiye has undergone a significant transformation, driven primarily by a transition from voluntary environmental practices toward increasingly comprehensive regulatory requirements. Key legislative and policy instruments include the Planned Areas Construction Regulation (2022), the Water Efficiency Strategy Document and Action Plan 2023–2033 (2022), and the Water Efficiency Regulation (2024). Among these, the most direct regulatory action came in the form of amendments to the Planned Areas Construction Regulation, issued by the Ministry of Environment, Urbanization and Climate Change. According to this regulation, buildings constructed on parcels of land exceeding 2,000 m^2 must legally incorporate rainwater collection systems. Collected roof runoff must be directed to cisterns for non-potable uses, primarily for landscape irrigation, toilet flushing and general maintenance. The regulation empowers local municipalities to extend such requirements to smaller parcels or specific categories of buildings, including shopping centers, commercial centers and housing complexes, depending on local water conditions.

The National Water Efficiency Strategy Document and Action Plan 2022-2023 also identifies rainwater harvesting as an important measure for reducing water consumption in buildings and industrial facilities. Furthermore, the Water Efficiency Regulation issued by the Ministry of Agriculture and Forestry in December 2024, established a regulatory framework for the targets of urban, agricultural, and industrial areas. Within this framework, rainwater is recognized as an unconventional water source, while rainwater harvesting is identified as a fundamental strategy for reducing freshwater consumption in industrial facilities. Accordingly, the implementation of rainwater harvesting practices has been included among the priority criteria considered within the water efficiency certification framework for industrial enterprises to obtain blue, green or turquoise water efficiency certifications. These developments indicate that RWH is increasingly being positioned not only as an environmental initiative but also as an element of Türkiye's emerging water-efficiency policy framework.

A typical rainwater harvesting system comprises four fundamental components: a catchment surface; a conveyance system; storage infrastructure; and where required, treatment facilities (Dolgen et al., 2006). Rooftops generally constitute the primary catchment surface, although ground catchments may also be used. The quantity and quality of harvested water are influenced by effective catchment area, surface characteristics, and roofing materials. While most roofing materials are suitable for non-potable applications, materials or components that may release harmful substances, such as certain asphalt shingles, toxic sealants, or lead flashing must be avoided, particularly when targeting higher water quality or potable end-uses, to prevent heavy metal leaching and chemical contamination. The conveyance network, consisting primarily of gutters, drainpipes, and connecting pipelines, transports runoff from the catchment surface to the storage facility. To preserve water quality, these components must be made of durable, non-corrosive, and chemically inert materials such as high-density polyethylene (HDPE), stainless steel or coated aluminum (Thomas and Martinson, 2007). In practical applications, conveyance

systems should also integrate a first-flush diverter or secondary debris screen to prevent the initial runoff, which may contain accumulated atmospheric dust, organic debris, bird droppings and other contaminants, from entering the storage tank.

Harvested rainwater is generally stored in above-ground, or underground cisterns constructed from structurally sound, non-reactive materials such as reinforced concrete, fiberglass, or stainless steel. Underground tanks can typically provide advantages in terms of space optimization and thermal stability; whereas above-ground installations reduce excavation requirements and facilitate inspection and maintenance, and utilize gravity-fed distribution. Storage tanks may either be integrated into a building or built as separate structures. Among the various design parameters of an RWHS, the storage capacity is one of the most critical hydraulic and economic design variables. Insufficient storage capacity may result in water shortages during low-rainfall periods, while excessive capacity increases construction and operating costs, potentially making the system economically unfeasible (Dolgen and Alpaslan, 2025). Therefore, optimal cistern sizing requires a balance among local rainfall characteristics, temporal rainfall variability, catchment area and runoff yield, and baseline non-potable water demand patterns.

Against this background, Organized Industrial Zones (OIZs) represent a particularly promising setting for the implementation of RWHSs. The extensive roof areas of industrial facilities can provide substantial catchment surfaces, while many industrial activities have significant demands for water that does not necessarily require potable quality. Consequently, the utilization of harvested rainwater for appropriate non-potable applications may reduce dependence on centralized freshwater supplies, improve water efficiency, and enhance the climate resilience of industrial facilities. However, the technical and economic potential of RWH in OIZs remains insufficiently explored in Türkiye.

Therefore, this study investigates the technical potential, practical applicability, regulatory framework, and economic feasibility of implementing RWHSs in selected industrial facilities within an OIZ in Türkiye. The study estimates the volume of rainwater that can potentially be harvested from the rooftop areas of selected enterprises, determines appropriate cistern capacities by considering both water availability and its temporal variability, and evaluates the associated investment costs and economic payback periods. The findings are intended to contribute to the development of decentralized, water-efficient, and climate-resilient water management strategies for industrial areas in Türkiye.

MATERIAL AND METHOD

Study Area and Data Collection

This study examines the potential for rainwater harvesting (RWH) in an Organized Industrial Zone (OIZ) located in Izmir, Turkiye. In the examined OIZ, there are 106 companies, of which 68 of which were active at the time of the study. The enterprises operate across a range of industrial sectors including food; packaging; electricity; energy; construction; chemicals; machinery; furniture; automotive; plastics; textiles; medical devices and materials; tobacco; agricultural machinery, and feed and feed additives.

Data on the water consumption and water allocation within the OIZ, including the sources and volume of water used, existing water conservation practices and current rainwater management practices, was collected by means of questionnaires and on-site investigations. The survey and field investigations were used to characterize the water-use profile of the enterprises and to identify facilities with potential for rainwater harvesting.

The food sector is the most water-intensive industry in the OIZ, accounting for 93% of total water consumption. The packaging and automotive sectors accounted for 4.5% of total water use. While the remaining 2.5% was used enterprises operating in other sectors, including

construction, chemicals, machinery, furniture, textiles, medical devices, tobacco, feed, and agricultural machinery.
Based on the availability of relevant data and the characteristics of the facilities, the potential for rainwater harvesting was investigated in 22 enterprises operating in the food, construction, chemicals, medical devices, materials, plastics, tobacco, feed and packaging sectors. For these enterprises, rooftop areas and other relevant characteristics were obtained and used to estimate the potential volume of harvestable rainwater and the required storage capacity.

Rainfall Analysis
Monthly rainfall data for the period 1938–2020, representing 82 years of observations, were obtained from the Turkish State Meteorological Service (MGM) for İzmir Province. The long-term dataset was used to characterize the temporal distribution of rainfall and to estimate the potential availability of rainwater for harvesting.
The analysis, summarized in Table 1, shows that the region receives an average annual rainfall of 569.6 mm. As Table 1 illustrates, rainfall is at its highest in December, with 100.1 mm, while August receives the lowest amount, with only 1.6 mm. This pronounced seasonal variation is particularly important for the design of rainwater storage systems, as annual rainfall totals alone do not adequately represent the temporal availability of harvested water.

Table 1. **Long-term average precipitation and number of rainy days in İzmir Province (1938–2020)**

Month	**January**	**February**	**March**	**April**	**May**	**June**
Average Monthly Rainfall (mm)	86.9	77.8	64.8	57.1	27	10.4
Month	**July**	**August**	**September**	**October**	**November**	**December**
Average Monthly Rainfall (mm)	5.3	1.6	15.9	34.7	88	100.1

Estimation of Harvestable Rainwater
In the presented study, the volume of the harvested rainwater from a rooftop was calculated using the standard catchment area formulation. The method calculates overall yield by integrating the roof surface area, localized meteorological data (annual rainfall), and a material efficiency factor (runoff coefficient).
Harvestable water volume (m^3) = Catchment area (m^2) x Annual rainfall (m) x Runoff Coefficient
The catchment area represents the total surface area of the rooftop available for rainwater collection, was obtained from the participating enterprises. The precipitation data represent the long-term local rainfall characteristics of İzmir and were obtained from the Turkish State Meteorological Service. Finally, the runoff coefficient accounts for hydrological losses associated with the catchment surface including surface retention, evaporation, leakage, and splash-over. The runoff coefficient, ranged between 0 and 1, depends primarily on the type, slope, porosity, and surface characteristics of the roof. Impermeable and relatively smooth materials like corrugated sheet metal roofing generally have high efficiency, yielding coefficients between 0.90 and 0.95 due to rapid water shedding. Conversely, porous or rough surfaces such as flat concrete or asphalt shingles retain more moisture, reducing the coefficient to a range between 0.60 and 0.80. In this study, value of C = 0.80 was applied for all cases. This

assumption reflects the semipermeable nature of industrial rooftop surfaces while providing a consistent basis for comparison among the selected enterprises.

Cistern Sizing and Temporal Water Balance

Although annual rainfall provides an estimate of the overall rainwater harvesting potential, annual totals alone are insufficient for determining an appropriate cistern capacity because rainfall and water demand vary substantially throughout the year. Therefore, the sizing of the storage systems was based on the monthly distribution of rainfall and the corresponding availability of harvested rainwater.

For each enterprise, the monthly rainwater yield was estimated using the effective rooftop area, monthly precipitation, and the runoff coefficient. The resulting monthly water availability was compared with the estimated non-potable water demand of the enterprise. This approach was used to determine the storage capacity required to maximize the utilization of harvested rainwater while avoiding unnecessary oversizing of the cistern.

The optimal cistern capacity was therefore determined by considering both the volume of harvestable rainwater and its temporal variability. Overall, the findings demonstrate that **RWH in OIZs should be evaluated as an integrated technical, economic, and regulatory water-efficiency measure rather than solely on the basis of annual rainfall or rooftop area.** Appropriately designed RWH systems can reduce dependence on centralized freshwater supplies, improve industrial water efficiency, and contribute to greater climate resilience. The combination of increasing regulatory support and favorable economic conditions in high-water-demand facilities provides a strong basis for expanding RWH applications in OIZs and other industrial areas in Türkiye.

Economic Assessment

The economic feasibility of the proposed RWH systems was assessed based on the estimated investment cost of the required infrastructure and the expected water savings resulting from the substitution of harvested rainwater for conventionally supplied water. The investment assessment included the principal components required for implementation, such as storage tanks, conveyance infrastructure, pumps, and associated system components, as applicable.

The simple economic payback period was estimated by comparing the initial investment cost with the expected annual monetary savings associated with the use of harvested rainwater. The resulting payback periods were used to assess the economic feasibility of RWH implementation across the selected enterprises.

RESULTS AND DISCUSSION

Rainwater Harvesting Potential of the Pilot Enterprises

In this study, the rainwater harvesting potential was assessed for 22 companies selected from the OIZ as pilots. The enterprises were first classified according to their annual water consumption into three categories: high water consumption (> 50,000 m^3 / year), medium water consumption (5,000 - 50,000 m^3 / year), and low water consumption (< 5,000 m^3 / year). The annual water consumption of the 22 enterprises is presented in Figure 1, while Figure 2 presents the corresponding estimated annual volumes of rainwater that can potentially be harvested from their rooftop areas.

The comparison of water demand and rainwater availability was subsequently conducted using monthly water consumption and rainfall data. Based on the relationship between the temporal distribution of water demand and the potential availability of harvested rainwater, the 22 enterprises were classified into five groups (Groups A–E). One representative

enterprise from each group was then selected for a more detailed assessment of cistern requirements and economic feasibility.

Group A consists of enterprises with a particularly high monthly water consumption, which consistently exceeds the amount of rainwater that can be harvested on both monthly or annually basis. This group comprises nine enterprises, including a dairy and dairy-products facility; frozen or dried fruit and vegetable processing facilities; packaging manufacturers producing carton boxes and cardboard products; a ready-mixed concrete production facility; and enterprises producing construction chemicals and textile chemicals.

Group B comprises four enterprises with relatively stable monthly water consumption, for which monthly fluctuations in water consumption can be negligible, and the quantity of rainwater that can be harvested may be more or less than required from one month to the next. This group includes enterprises in the feed and feed additives industry, chemical industry (concrete chemical additives and subsurface concentrated fertilizers) and the medical equipment industry (plastic medical supplies).

Group C includes three enterprises where monthly variations in water usage can be considered significant, and the amount of rainwater available for harvesting may be more or less than needed from month to month. This group includes enterprises in the construction sector of pipe fittings and accessories, and thermal insulation materials, and in the chemical industry.

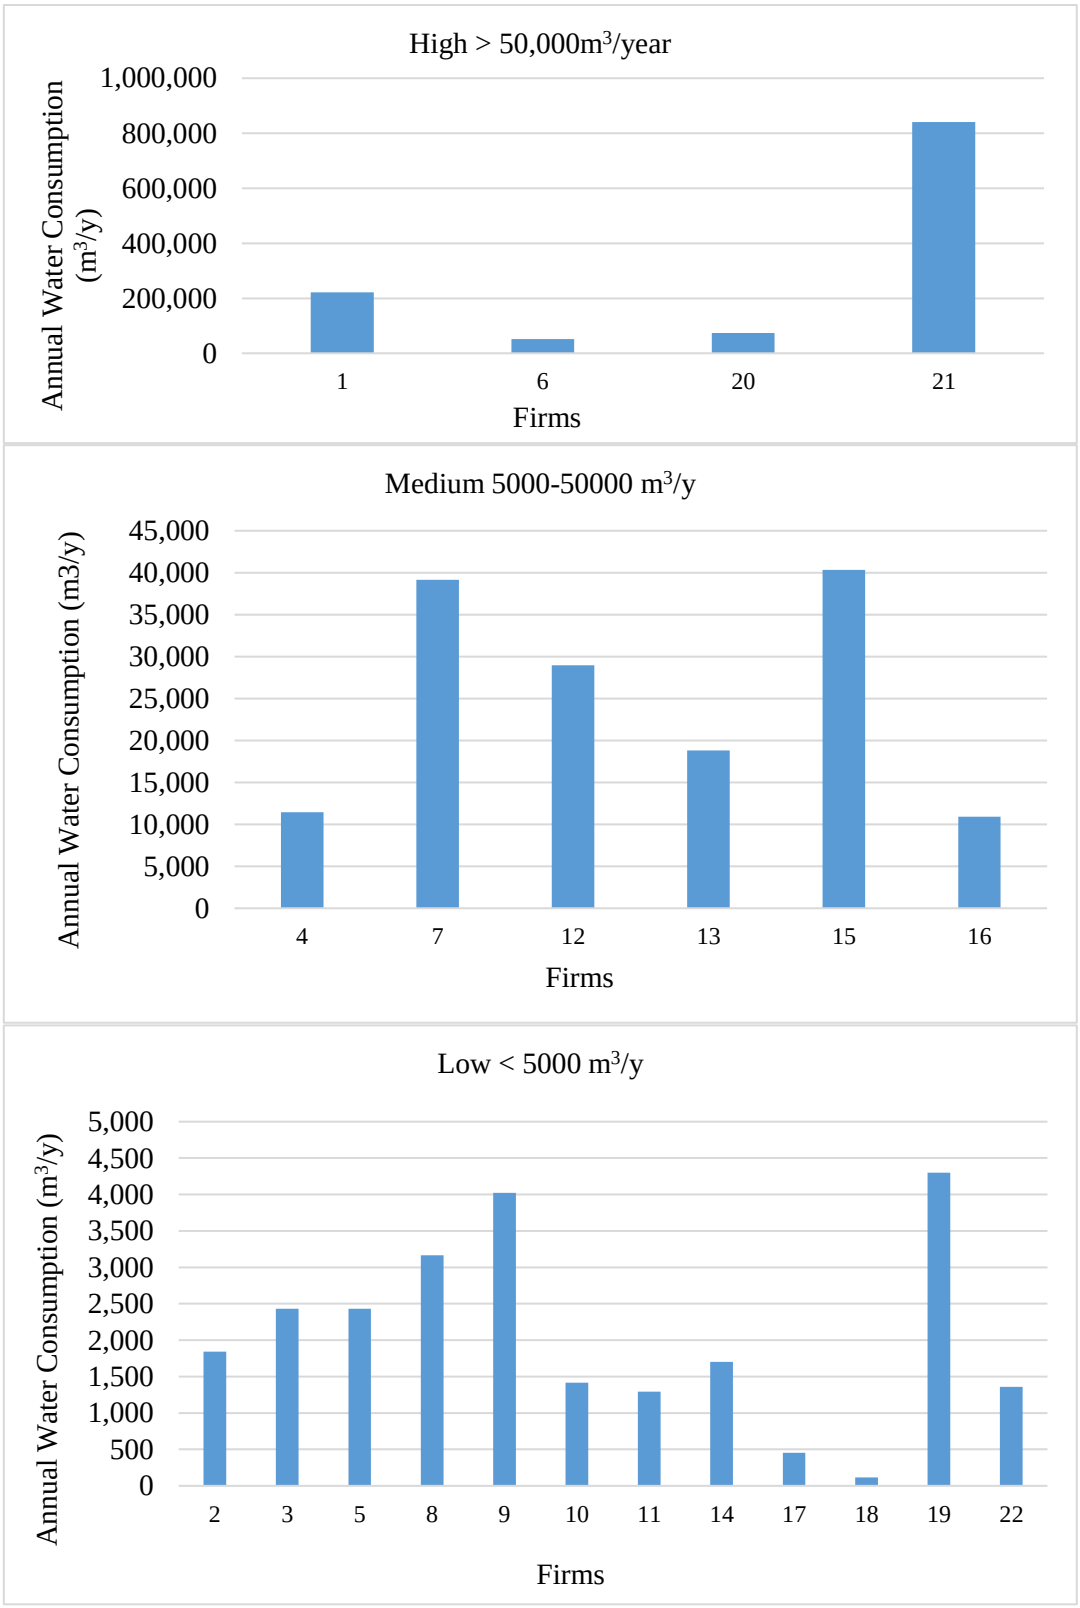

Figure 1. Annual water consumptions of 22 pilot enterprises

Group D comprises five enterprises with pronounced seasonal variations in water consumption, characterized generally by lower demand during winter and higher demand during summer. As in Groups B and C, the relationship between rainwater availability and water demand varies from month to month. This group includes medical supplies production, food

industry (dried fruit and vegetable manufacturing), tobacco and tobacco products manufacturing, plastic industry (plastic recycling, packaging crate production), and feed and feed additives.

Group E consists of enterprises with very low or negligible water consumption. Only one enterprise, a manufacturer of polypropylene (PP) plastic yogurt containers, was classified in this group.

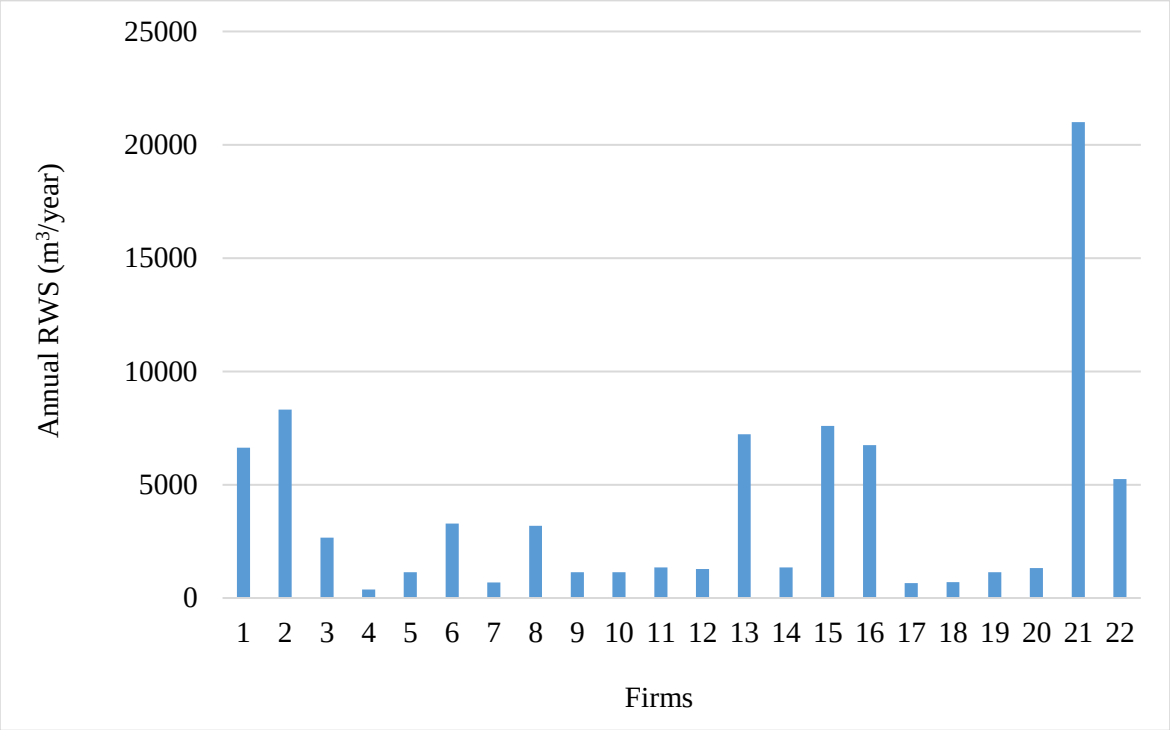

Figure 2. Estimated annual rainwater harvesting potential of the 22 enterprises

The classification demonstrates that the feasibility and potential benefits of RWH are strongly influenced not only by the annual volume of harvestable rainwater but also by the relationship between rainwater availability and the temporal pattern of water demand. Accordingly, the enterprises in Groups A–D were considered suitable for further assessment of storage requirements and economic feasibility, whereas the Group E enterprise was excluded from detailed cistern analysis because of its negligible water consumption.

Cistern Sizing and Economic Feasibility

Long-term monthly average rainfall data were obtained from the meteorological station in Izmir. The volume of harvestable rainwater from roof areas was calculated using the standard catchment area formulation. For the enterprises in Groups A–D, the potential volume of harvestable rainwater was estimated using the long-term monthly rainfall data for İzmir and the effective rooftop areas of the facilities. Monthly rainwater availability was compared with the corresponding water demand of each enterprise to assess the need for storage and to determine an appropriate cistern capacity.

A comprehensive market survey was conducted to determine the prevailing prices of equipment and tanks. The estimated investment cost included the principal collection and transmission equipment, including pumps and internal piping, in addition to the cistern construction cost. Economic feasibility was assessed using the simple payback period calculated as the total initial investment divided by the estimated annual financial savings resulting from the use of harvested rainwater.

The results indicate that RWH systems are particularly advantageous for facilities with high water demand, where monthly or annual consumption substantially exceeds the capacity of rainwater harvesting. For these facilities, harvested rainwater can generally be used relatively quickly, thereby reducing the need for very large storage volumes. The payback periods for such investments have been calculated to range from 1 to 4 years. Based on these results, a more detailed technical and economic assessment was conducted for Firm 1 (F1), selected as a representative Group A enterprise in this study.

Case Study

The Firm 1 (F1) is a dairy and dairy products manufacturing facility located within the OIZ, and is characterized by relatively high water consumption. The facility has a total rooftop area of approximately 15,000m^2. In order to ascertain the optimal cistern volume, the monthly water consumption data were obtained from the company. Furthermore, the rainwater harvesting potential from the roof area was calculated based on the rainfall data obtained from the Turkish State Meteorological Service website.

Figure 3 illustrates the data regarding water consumption and rainwater harvesting potential for F1. The results show that the company's monthly water demand consistently exceeds maximum harvestable rainwater volumes, ensuring that harvested rainwater can be utilized relatively rapidly without requiring long-term storage.

As demonstrated in the data given in Table 1, the maximum precipitation levels are recorded in December, with a monthly volume of 1,116 m^3. It is estimated that, based on the average number of rainy days per month, the peak daily collection is 93 m^3/day. Accordingly, a cistern with a capacity of approximately 100 m^3 provides adequate daily storage to capture maximum single-day runoff events. Because the firm's monthly water demand consistently exceeds the estimated monthly rainwater harvesting potential, harvested rainwater can be readily utilized without requiring substantial seasonal storage. Accordingly, the required storage capacity is primarily determined by short-term rainfall variability and system operation rather than by the need to bridge prolonged periods of insufficient water demand.

The annual harvest calculations indicate that the capture and utilization of 6,643 m^3 of rainwater per annum is achieved by a 100 m^3 reinforced concrete cistern. The annual water cost savings have been estimated to be 17,936 TL, with this calculation taking into account the water tariff of OIZ. The capital investment required for the construction of the cistern was determined as 65,000 TL, and the estimated payback period was approximately 3.6 years.

These results indicate that the implementation of an appropriately sized RWH system at F1 can provide a substantial reduction in the facility's dependence on externally supplied water while requiring a relatively moderate initial investment. The relatively high water demand of the facility is an important factor contributing to the economic feasibility of the system.

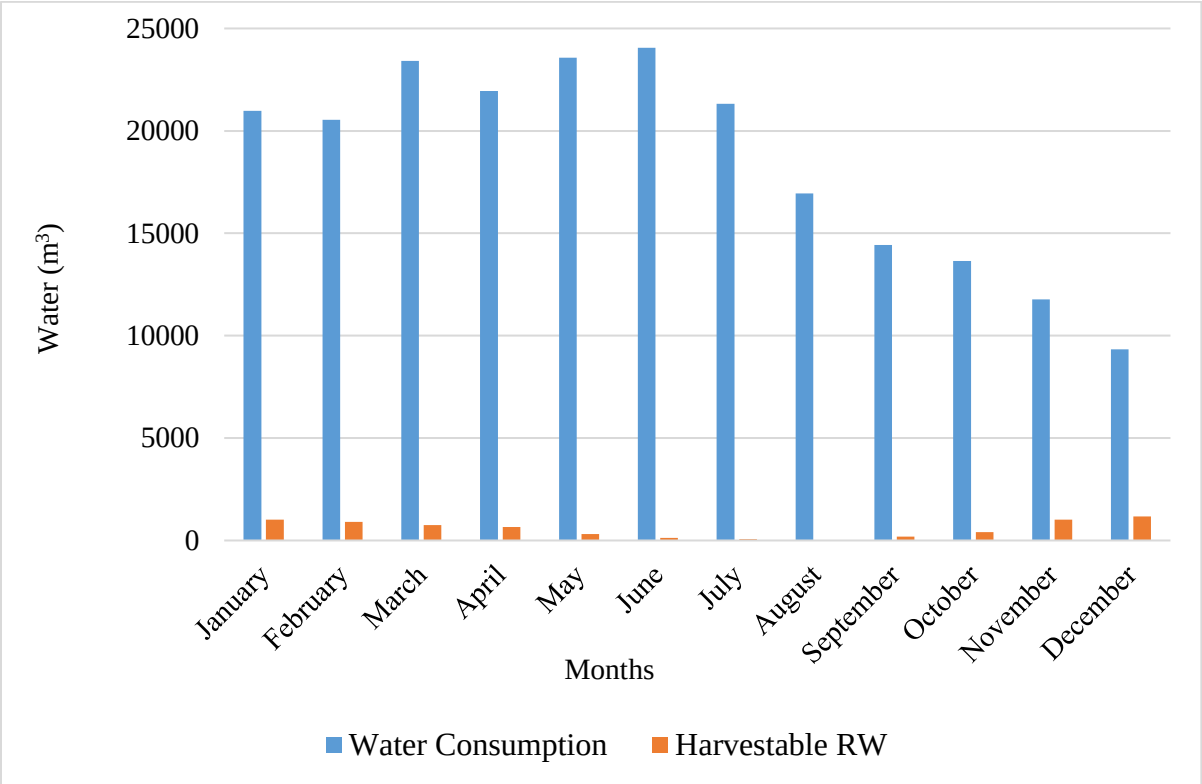

Figure 3. Monthly water consumption and estimated rainwater harvesting potential for Firm 1

Comparative Assessment of the Five Enterprise Groups

The analysis of 22 pilot enterprises across five distinct water-consumption profiles (Groups A through E) demonstrates that the technical and economic feasibility of RWH varies significantly depending on water demand and operational patterns. Facilities with high water demand, which consistently exceed harvestable rainfall volume (e.g., dairy, frozen fruit/vegetable processing, packaging, chemical, and ready-mixed concrete manufacturing), demonstrate the highest return on investment from rainwater harvesting. The estimated payback period for these facilities is remarkably short, ranging between 1 and 4 years (Group A).

In instances of enterprises encountering seasonal or monthly fluctuations in water consumption, the implementation of cisterns, exactly tailored to their unique demands and local rainfall patterns, is imperative to ensure the effective balancing of supply and demand (Group B, C, D). In these cases, an appropriately sized cistern can provide an important function by storing water during periods of relatively high rainfall and making it available during periods when rainfall is insufficient to meet demand. However, excessive storage capacity would increase capital costs without necessarily providing a corresponding increase in water savings. Therefore, storage capacity should be determined individually for each facility by considering rooftop area, local rainfall characteristics, water demand, and its temporal variability.

In contrast, it was determined that enterprises characterized by negligible water consumption do not yield a practical return on investment for RWH infrastructure (Group E). The limited volume of water that could be economically substituted by harvested rainwater would not justify the investment required for dedicated storage and associated infrastructure.

Overall, the findings demonstrate that the economic feasibility of RWH in industrial facilities depends not only on the physical potential for rainwater collection but also on the magnitude

and temporal pattern of water demand. This highlights the importance of demand-oriented system design rather than relying solely on annual rainfall or rooftop area when determining the feasibility and storage requirements of RWH systems in OIZs.

CONCLUSIONS

Türkiye has initiated a significant transition in its approach to rainwater harvesting (RWH) strategy, moving from predominantly voluntary environmental practices toward a mandatory regulatory requirement. Key legislative and policy instruments, including amendments to the Planned Areas Construction Regulation (mandating RWH for plots over 2,000 m²), the National Water Efficiency Strategy Document and Action Plan (2023–2033), and the December 2024 Water Efficiency Regulation, have strengthened the role of RWH in reducing freshwater consumption for non-potable water uses in buildings and industrial facilities. Furthermore, the integration of RWH into industrial water efficiency certification (Blue, Green, and Turquoise) provides a clear framework for sustainable industrial growth.

An empirical evaluation of 22 pilot companies across five water-consumption profiles (Groups A–E) reveals that the technical and economic feasibility of RWH depends strongly on the magnitude and temporal pattern of water demand, as well as on the available rooftop area and local rainfall characteristics. The results indicate that RWH is particularly promising for facilities with high and relatively continuous water demand, where harvested rainwater can be utilized rapidly and the need for extensive seasonal storage is reduced. For the Group A enterprises investigated in this study, estimated payback periods ranged from approximately 1 to 4 years, indicating favorable economic conditions for RWH investment under the assumptions adopted.

The detailed assessment of Firm 1 further demonstrates the importance of appropriately sizing storage capacity. Despite the facility's substantial water demand, which consistently exceeds its monthly rainwater harvesting potential, a 100 m³ reinforced-concrete cistern was found to be sufficient under the conditions considered. The system was estimated to capture and utilize approximately 6,643 m³ of rainwater annually, generating estimated annual water-cost savings of 17,936 TL and a simple payback period of approximately 3.6 years.

For facilities with moderate, variable, or seasonal water demand, the feasibility of RWH is more dependent on the temporal balance between rainwater availability and water consumption. In such cases, cistern capacity should be determined through a facility-specific monthly water supply–demand analysis that considers local rainfall patterns, rooftop area, non-potable water demand, and investment costs. Conversely, facilities with negligible water consumption may not provide sufficient demand to justify investment in dedicated RWH infrastructure.

Overall, the findings demonstrate that **RWH in OIZs should be evaluated as an integrated technical, economic, and regulatory water-efficiency measure rather than solely on the basis of annual rainfall or rooftop area.** Appropriately designed RWH systems can reduce dependence on centralized freshwater supplies, improve industrial water efficiency, and contribute to greater climate resilience. The combination of increasing regulatory support and favorable economic conditions in high-water-demand facilities provides a strong basis for expanding RWH applications in OIZs and other industrial areas in Türkiye.

ABSTRACT

Green energy usage and the lowest pollutant emission demand of fire-tube hot water boilers have gained importance in line with the 2050 European zero-carbon targets. In the present study, the combustion efficiency of a low NO_x gas burner was increased by using a prototype diffuser and natural gas hydrogen blended fuel ratios. Experimental studies were conducted using a fire tube hot water boiler system, while numerical simulations were performed using Fluent codes with methane (CH_4) representing natural gas. Three combustion models were the Eddy Dissipation Model (EDM), Non-Premixed Combustion (NPC), and the Partially Premixed Combustion (PPC) model, which were compared, and the PPC model was validated against experimentally measured values for 1500 kW heat input, natural gas fuelled, and 0.85 equivalence ratio. PPC combustion model and experimental studies were performed to investigate the variations in temperature, velocity, emissions, pollutants, temperature, flame formation, and stability for hydrogen ratios from 0 to 40% with equivalence ratios ranging from 0.7 to 0.85 at a heat input of 1500 kW. The results showed that blending hydrogen into natural gas fuel reduced CO_2 emissions by approximately 16.43% at 40% hydrogen. O_2 emissions remained constant, and NO_x pollutants reduced below 38 ppm at 3% O_2 emissions. Hydrogen also improved flame stability and increased flame temperature, velocity, and pressure, though density decreased. NO formation rose with increased hydrogen blending, necessitating higher air excess to control NO pollutant and flue gas temperatures. The study concludes that low NO_x gas burners with nozzle-mix combustion flame characteristics can safely operate with up to 40% hydrogen blending in natural gas for fire-tube hot water boilers, following safety guidelines, offering a potential pathway for industrial decarbonization.

Keywords: NO_x Reduction, Combustion Efficiency, Hydrogen, Decarbonization, Nozzle-mix burner

INTRODUCTION

The decarbonization of industrial heating systems requires hydrogen compatible combustion technologies that provide safe operation, high efficiency, and low pollutant emissions. Hydrogen and natural gas blended gas fuelled burners can be used as an alternative application for the decarbonization of industrial boilers and furnaces. Recent studies have focused on different fuelled industrial burners capable of operating over different range of hydrogen ratios. Recent studies of hydrogen–methane mixtures indicate that, although industrial burners are often reported to accommodate blends containing up to 20% hydrogen, the empirical and theoretical evidence supporting this level of integration remains inconsistent (Franco & Rocca, 2024a, 2024b). Sîrbu et al. (2026) reviewed the combustion characteristics of hydrogen enriched natural gas in residential appliances, with particular attention to safety, efficiency, emissions, flame stability, and flashback. safe hydrogen integration requires appropriate blending limits, burner design modifications, and operating strategies. Conversely, recent

computational fluid dynamics simulations indicate that moderate hydrogen enrichment can effectively reduce carbon monoxide and unburned hydrocarbon emissions, although this often comes at the cost of higher NOx formation depending on the specific boiler load and equivalence ratio (Wang et al., 2025), (Badakhsh & Bhagavathy, 2023). Büyükakın (2026) numerically investigated hydrogen-enriched methane combustion in a non-premixed tube burner under hot, highly diluted $CO_2/O_2/N_2$ oxidizer conditions. Hydrogen's physical effect on turbulent mixing was found to be more influential than its chemical effect under the investigated conditions. The study also reported that hydrogen enrichment did not increase NOx emissions under low-O_2 diluted combustion conditions.

Experimental studies of non-premixed, low-swirl burners show that adding hydrogen changes flame behaviour by shortening the flame's lift-off height, while increasing NOx emissions by up to 380% at higher blending levels (Gee et al., 2023). Experimental findings highlight that lean combustion strategies are essential for managing adiabatic flame temperatures when operating at high hydrogen concentrations, despite potential reductions in convective heat transfer efficiency (Odeh & Paul, 2023). Consequently, integrating hydrogen requires sophisticated burner management systems that can dynamically adapt to fluctuating fuel compositions to prevent combustion pressure oscillations (Zeng et al., 2023).

In the present study investigates a 1500 kW industrial low-NO_x gas burner using natural gas with 0-40% hydrogen by volume and equivalence ratios between 0.70 and 0.85. Experimental measurements were combined with CFD analyses to select a suitable combustion model, optimized diffuser geometry, and evaluate the effects of hydrogen blending and excess air on flame characteristics, CO_2 and NO emissions.

MATERIAL AND METHOD

Experimental Set-up and Operating Conditions

Combustion experiments were performed in a PLC-controlled boiler system (Figure 1) with separate natural-gas, pure-hydrogen and blended gas trains (Figure 3). Low NO_x gas burner was used as a test burner (Figure 2). Combustion air was supplied by the burner mounted fan, while fuel and air volumetric flow rates were measured using digital flow meters and adjusted through pneumatic modulating valves. Natural gas was supplied at 0 - 155 Nm^3/h with 300 mbar upstream pressure and 250-300 mbar downstream pressure. Hydrogen was supplied from a 200 L tank at 230 bar, reduced first to 4 bar and then to 300 mbar, with an adjustable flow range of 0 - 250 Nm^3/h. O_2, CO_2, NO and flue-gas temperature were measured at the flue outlet using a flue gas analyser (Figure 4).

Figure 1. PLC-controlled boiler system.

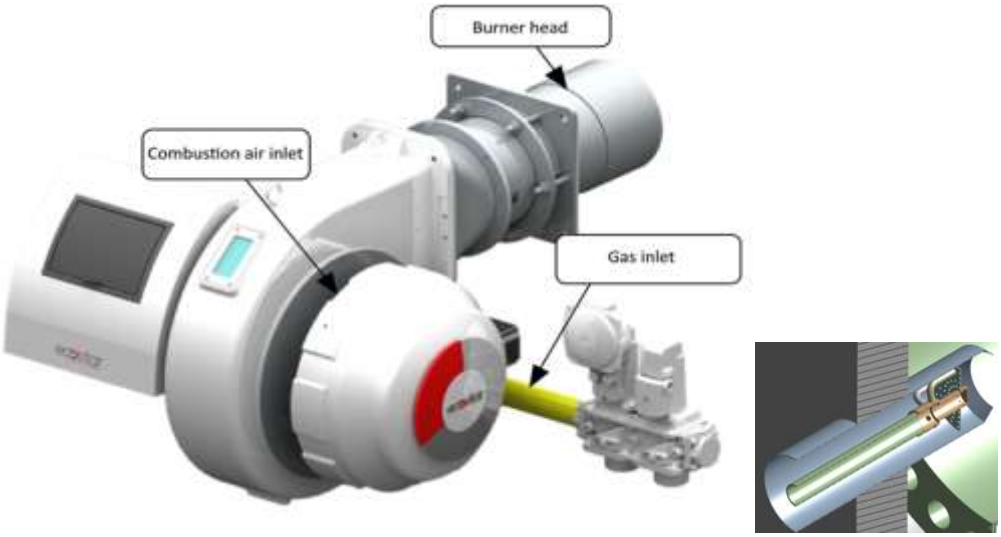

Figure 2. Low NO_x gas burner (New Generation Low NO_x Burners - Ecostar, n.d.) and it's diffuser and combustion head.

The combustion chamber had an inner diameter of 700 mm and a length of 3050 mm (Figure 4). The burner was operated at 1500 kW with equivalence ratios (φ) of 0.70, 0.77 and 0.85. Fuel cases included 100% natural gas, 70% NG/30% H_2 and 60% NG/40% H_2. Combustion-air and fuel temperatures were approximately 20 °C and 15 °C, respectively. Methane (CH_4) represented natural gas in the numerical calculations, and hydrogen purity was 99.99%.

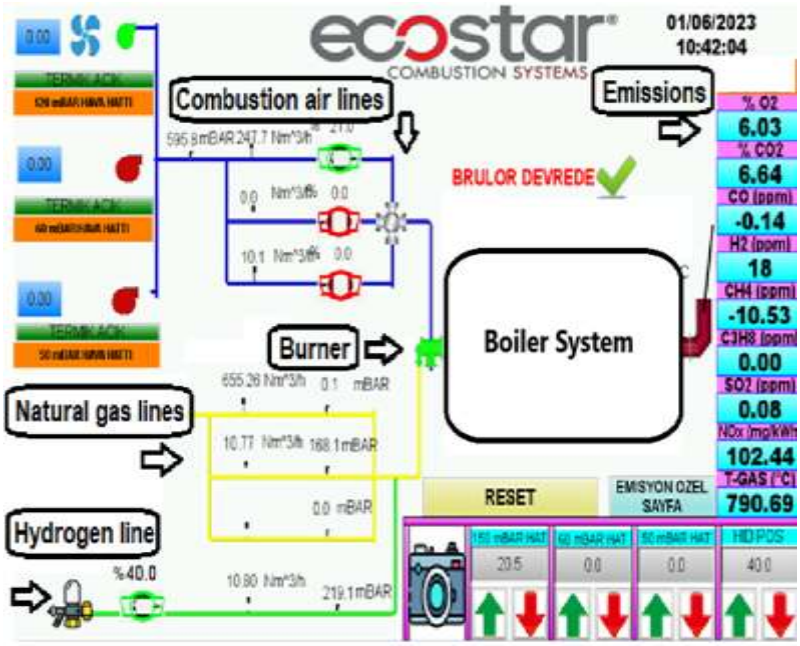

Figure 3. Schematic view of the PLC-controlled test boiler system

The technical specifications of the PLC controlled boiler system equipments (Table 1). All measured values were recorded on the PLC display and stored on the hard disk drive. The technical specifications of the PLC-controlled test furnace system equipments are detailed in Table 1. All measured data were monitored on the PLC display and stored on the hard disk drive

Natural gas fuel was supplied by Marmara Gaz Çorlu Doğal Gaz Dağıtım A.Ş. The natural gas composition is simplified (Figure 5). Methane gas (CH4) is the main type of natural gas. Therefore, CH_4 was considered for numerical calculations instead of natural gas. Hydrogen gas was supplied from Habaş Sınai ve Tıbbi Gazlar İstihsal Endüstri A.Ş. and has a purity level of 99.99%.

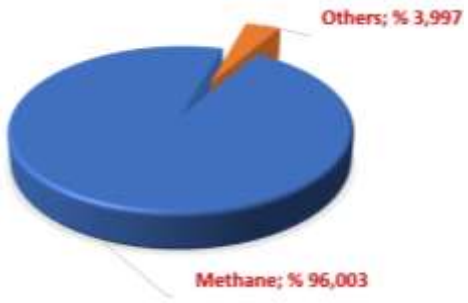

Figure 5. Natural gas composition.

The burner was operated at a heat input of 1500 kW at constant equivalence ratios (φ) are 0.7, 0.77, and 0,85 with the fuel types being 100 % NG, 70 % NG / 30 % H_2, and 60 % NG / 40 % H_2, respectively. The combustion air and fuel temperature values were approximately 20 °C and 15 °C, respectively. These values were used as boundary conditions in numerical studies. The fuel and combustion air flow rates for all cases are given in Table 2.

Table 2. Fuel and combustion air flow rates are given for blended fuels according to equivalence ratios.

Blended Fuel Composition (By Volume, %)	**Heat Input (kW)**	**Equivalence ratio** (φ)	$\dot{V}_{fuel,NG}$ **(Nm³/h)**	$\dot{V}_{fuel,H2}$ **(Nm³/h)**	$\dot{V}_{air}$ **(Nm³/h)**

Numerical Analyses

Numerical analyses of combustion cases were conducted with Fluent codes. 3D geometry of the burner and furnace was modeled in SolidWorks and ANSYS Design Modeler. The modeled geometry of the boiler and burner before the meshing studies is shown in Figure 6.

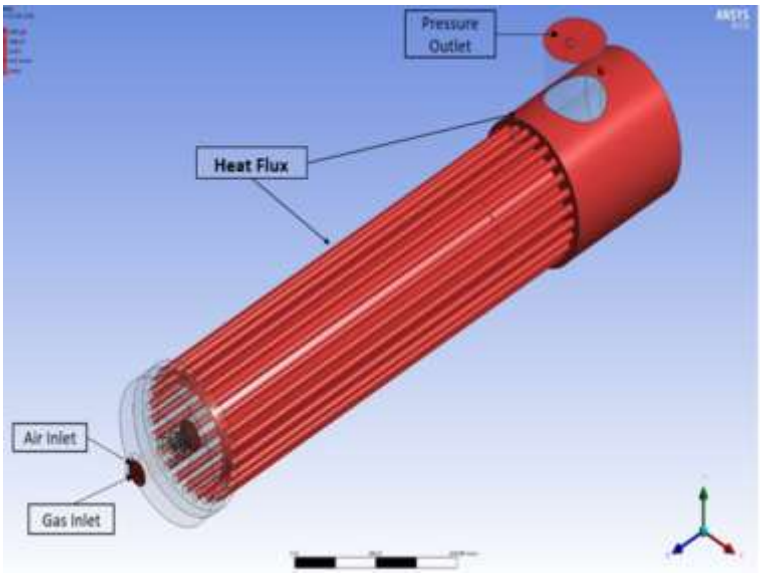

Figure 6. 3D geometry of the mounted burner and boiler.

The meshing studies were studied in Ansys Meshing. The mesh number is 8,767,128, the node number is 1.612,372, and the highest skewness is 0.76. The mesh structure consists of hexahedral and tetrahedral cells in Figure 7. Transition from tetrahedral to polyhedral was carried out in the analyses deemed necessary in the Fluent solver.

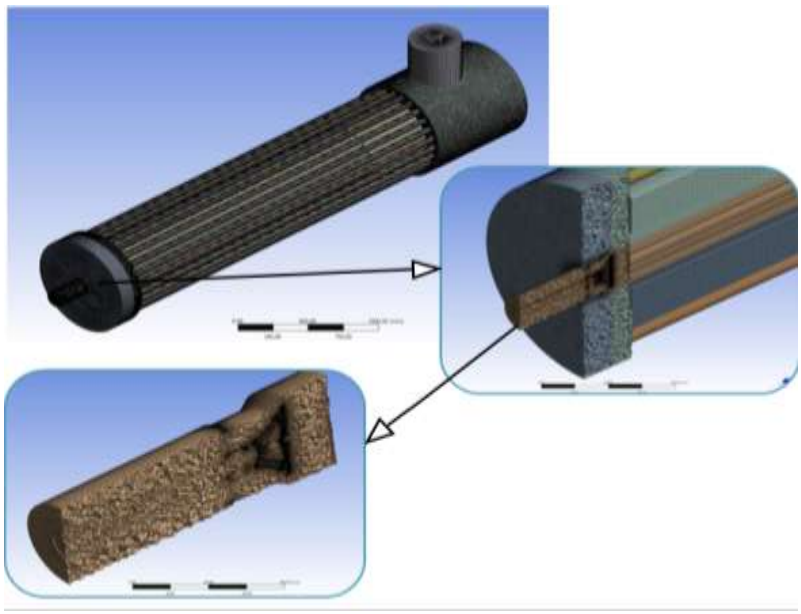

Figure 7. Boiler and burner mesh structures.

The boundary conditions for air and fuel were defined in terms of mass flow rates. The boiler flue gas outlet pressure was taken at atmospheric pressure of 101,325 Pa. The boiler's inner walls, constructed of carbon steel, were assigned as wall boundary conditions (BC) with an emissivity of 0.79 at 1000 K (726 °C) (Bergman, T. L., Lavine, A. S., Incropera, F. P., & DeWitt, D. P. (2011). The convection coefficient calculated for the cooling water wall is 1318 W/m²K, and the free flow stream average temperature of cooling water is 357 K, empirically. The other boiler and burner walls were defined as adiabatic wall BC. Heat input of the burner

is 1500 kW, with air and fuel temperatures of 298 K and 293 K, respectively. The air density remained constant at 1.184 kg/m³; however, the fuel density changed according to the blending ratio. The burner's air and fuel inlets, with the flue gas outlet, possessed cylindrical configurations. The hydraulic diameters for internal flows were 0.0702 m for fuel, 0.1395 m for air, and 0.406 m for the flue gas.

Fuel, air, and other gases within the furnace were presumed to be incompressible. Non-premixed flames were simulated for all combustion scenarios, resulting in radiative heat transfer within the combustion chamber and an elevation in furnace wall temperatures.

The radiation heat transfer mechanism was used to compute temperature changes in the flames, using the discrete ordinates (DO) radiation model for flame radiation. The absorption coefficient was utilized through the weighted-sum-of-gray-gases model (WSGGM) according to domain specifications. Coupled method was utilized for pressure-velocity coupling, employing PRESTO! for spatial pressure discretization and a second-order upwind approach for the other equations (ANSYS Fluent, 2023). Due to the volatile features of fuel and air flow, the k-ε turbulence model was employed, utilizing the usual wall function for boundary layer computations. Three combustion models were used: Eddy Dissipation Model (EDM), Non-Premixed Combustion (NPC), and the Partially Premixed Combustion (PPC) model. which were compared and validated CFD combustion model was used for all cases. The chemical equilibrium model and the assumed probability density function (PDF) method were employed for diffusion flames, yielding better validated results for NOx emission predictions in hydrocarbon fuel combustion. The convergence criteria were taken as 10^{-6} for the energy and radiation equations, and at 10^{-4} for the other equations. The convergence limit for the equations for NO emissions and temperature variance was taken as 10^{-7}.

Governing Equations

Combustion simulations are performed by solving the equations that regulate the conservation of mass, momentum, and energy within the fluid domain. The continuity equation, conservation of momentum, energy equation, radiative transfer equation (RTE), probability density function (PDF) equation, k-ε governing equation are presented between Eq. (1) and Eq. (7), respectively (ANSYS Fluent, 2023).

Continuity equation:

$$\frac{\delta\rho}{\delta t} + \nabla.(\rho\vec{v}) = 0 \quad (1)$$

Conservation of momentum:

$$\frac{\delta\rho}{\delta t}(\rho\vec{v}) + \nabla.(\vec{v}\vec{v}) = -\nabla p + \nabla(\bar{\bar{\tau}}) + \rho\vec{g} + \vec{F} \quad (2)$$

Energy equation:

$$\frac{\delta}{\delta x_j}\left(\rho u_j h + F_{hj}\right) = u_j\frac{\delta p}{\delta x_j} + \tau_{ij}\frac{\delta u_i}{\delta x_j} \quad (3)$$

Radiative transfer equation:

$$\nabla.I(\vec{r},\vec{s})\vec{s}) + (a+\sigma_s)I(\vec{r},\vec{s}) = an^2\frac{\sigma T^4}{\pi} + \frac{\sigma_s}{4\pi}\int_0^{4\pi} I(\vec{r},\vec{s}')\Phi(\vec{s},\vec{s}')d\Omega' \quad (4)$$

PDF table equation:

$$\bar{\Phi} = \int_0^1\int_0^1 \Phi(f,c)p(f,c)dfdc \quad (5)$$

The governing equation of turbulence kinetic energy is defined as k:

$$\frac{\partial}{\partial t}(\rho k) + \frac{\partial}{\partial x_j}(\rho k u_j) = \frac{\partial}{\partial x_j}\left[\left(\mu + \frac{\mu_t}{\sigma_k}\right)\frac{\partial k}{\partial x_j}\right] + G_k + G_b - \rho\epsilon - Y_M + S_k \quad (6)$$

The governing equation of turbulence dissipation rate is defined as ε:

$$\frac{\partial}{\partial t}(\rho \varepsilon) + \frac{\partial}{\partial x_j}(\rho \varepsilon u_j) = \frac{\partial}{\partial x_j}\left[\left(\mu + \frac{\mu_t}{\sigma_\varepsilon}\right)\frac{\partial k}{\partial x_j}\right] + \rho C_1 S_\varepsilon - \rho C_2 \frac{\varepsilon^2}{k + \sqrt{\upsilon \varepsilon}} + C_{1\varepsilon}\frac{\varepsilon}{k} C_{3\varepsilon} G_b + S_\varepsilon \quad (7)$$

The equivalence ratio (φ) is the actual fuel-to-oxidizer ratio divided by the stoichiometric (theoretical complete combustion) fuel-to-oxidizer ratio. Φ formula is presented Eq. (8) (ANSYS Fluent, 2023).

$$\Phi = \frac{A/F_{stoich}}{A/F_{actual}} \quad (8)$$

Calculation of NO_x Pollutants

Nitric oxides (NO_x), which are called the totality of nitric oxides, are significant pollutants. Nitric oxide (NO) is predominantly produced in NO_x emissions. NO is often generated as thermal NO and prompt NO. Thermal NO_x is generated when molecular N_2 from atmospheric air is thermally degraded due to flame temperatures exceeding 1500 K during combustion. Thermal NO is explained by the Zeldovich reaction mechanism (Lee and Jou, 2016). The formula for thermal NO is provided between Eq. (9) and Eq. (11).

$O + N_2 \rightarrow N + NO$ (9)
$N + O_2 \rightarrow O + NO$ (10)
$N + OH \rightarrow H + NO$ (11)

The Fenimore mechanism explains prompt NO generation (Lee and Jou, 2016). The equations for Fenimore's NO_x production reactions are presented between Eq. (12) and Eq. (15).

$CH + N_2 \rightarrow HCN + N$ (12)
$N + O_2 \rightarrow NO + O$ (13)
$HCN + OH \rightarrow CN + H_2O$ (14)
$CN + O_2 \rightarrow NO + CO$ (15)

NO emission simulation results were calculated as ppm (parts per million) presented Eq. (16) (ANSYS Fluent, 2023).

$$\frac{\text{Mole fraction of NO x } 10^6}{(1 - \text{Mole fraction of H2O})} \quad (16)$$

RESULTS AND DISCUSSION

In this study, the performance of combustion products from studies with different combustion conditions was predicted using numerical analyses. The numerical results were then compared with experimental results after simulations. Flame characteristics of different hydrogen mixture ratios combustion were analyzed using contours to identify the significant effects of hydrogen addition to the fuel.

Comparisons of CFD Combustion Models and Experimental Results

Eddy dissipation model (EDM), non-premixed combustion (NPC), and partially premixed combustion (PPC) models were analysed and compared with experimental results to obtain the validated calculation method. The heat power of the burner was 1500 kW with natural gas

combustion and an equivalence ratio of 0.85. Total operating pressures of fuel and air have been compared with the experimental results given in Table 3. Although Operating pressures at NPC and PPC of fuel and air have been validated by experimental results, the EDM results have been different from experimental results.

Table 3. Comparison of total operating pressures of fuel and air.

Combustion Models	EDM	NPC	PPC	Experimental Results
P_{fuel} (mbar)	19.2	17.1	17.2	17.3
P_{air} (mbar)	22.7	18.3	19.2	18.6

O_2 emissions are compared with the experimental results in Figure 8. Although O_2 emissions are close to the experimental data in the NPC and PPC models, they are higher in the EDM model. CO_2 emissions are compared with the experimental results in Figure 9. In the EDM model, CO_2 emissions were calculated to be the lowest according to the experimental results. In the NPC model, CO_2 emissions are higher than in the EDM model and closer to the experimental results. In the PPC model, the agreement of CO_2 emissions with the experimental results is better than in the other models. NO pollutant was compared with the experimental results in the Figure 10. In the NO solution, which is a post-processor solution and slow chemistry interaction, the EDM model calculated higher results than the other models. In the NPC model, the NO value is lower than the experimental value. However, the NO value calculated in the PPC model is much closer to the experimental value. As a result of comparing the values calculated by 3 different numerical combustion models, the closest results to the experimental data for turbulent combustion studies fueled by natural gas were calculated using the PPC model.

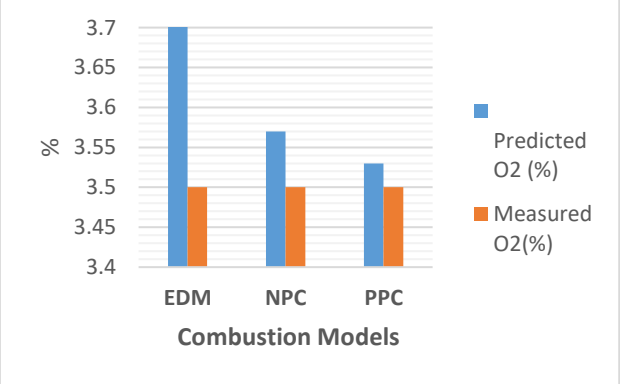

Figure 8. Comparison of O_2 (%) emissions in combustion models.

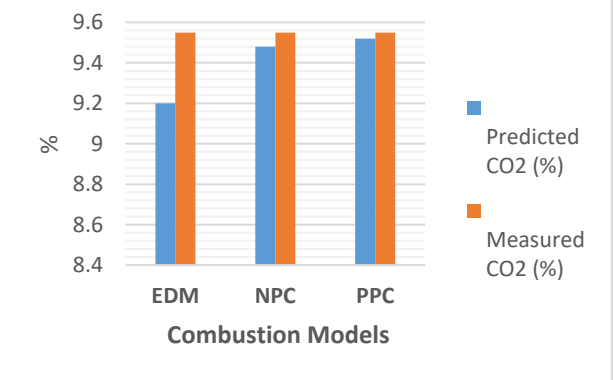

Figure 9. Comparison of CO_2 (%) emissions in combustion models.

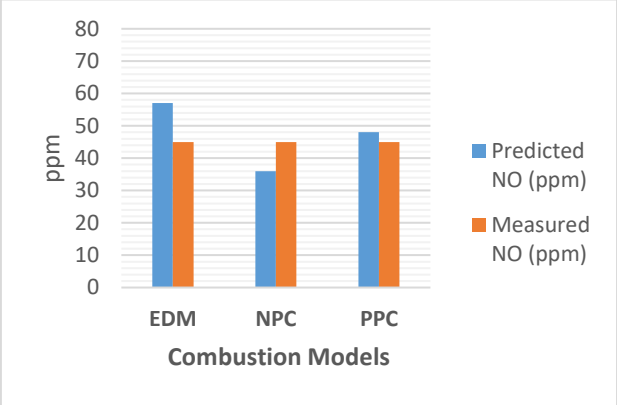

Figure 10. Comparison of NO (ppm) pollutant in combustion models.

At the end of the study, the numerical calculation values were compared with the experimental results and CO_2 emissions (Figure 11) and NO (Figure 12) values were validated.

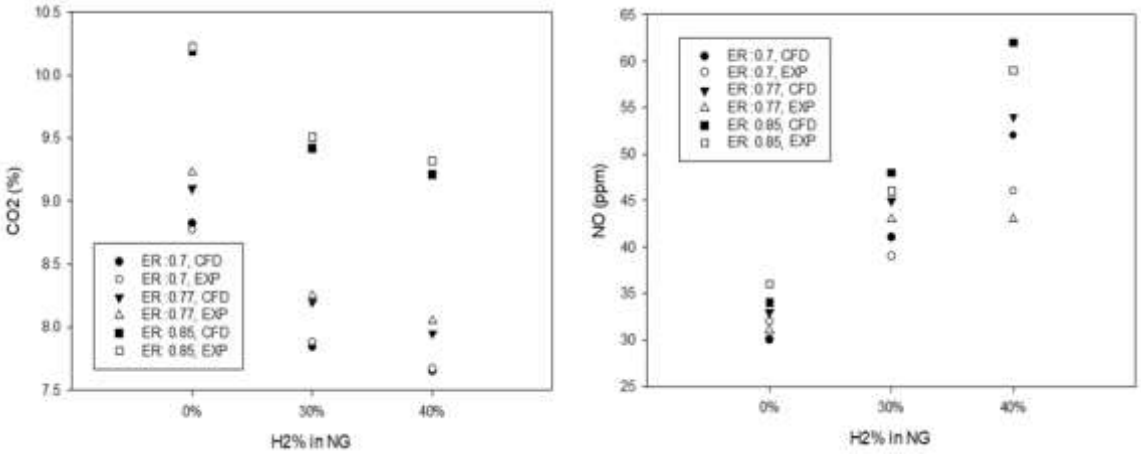

Figure 11. Comparison of combustion CO_2 (%) and NO (ppm) values of flue gas surface from numerical studies and experiments at 100% NG, 30 % and 40 % H_2 in NG, φ: 0.85, φ: 0.77, and φ: 0.7.

CONCLUSIONS

In the present study, The PPC model provided the closest agreement with experimental operating pressures and O_2, CO_2, and NO measurements and was therefore selected as the validated CFD model. Increasing the hydrogen blending ratio increased flame temperature and NO formation while reducing CO_2 emissions. Higher excess-air operation, achieved by decreasing the equivalence ratio, effectively reduced flame peak temperatures and thermal NOx levels. These results indicate that hydrogen blended natural gas can be used in industrial low-NOx burners when hydrogen blending and excess air levels are appropriately controlled, providing a practical approach for decarbonisation from industrial combustion systems.

ABSTRACT

The nutritional quality of functional food crops is determined through the interaction between metabolites, which is not easily characterized via traditional methods. In this paper, an AI-based metabolomics feature analysis and hybrid machine-learning framework was developed to predict the nutritional quality of functional food crops. Metabolomics datasets undergo quality control, missing value imputation, normalization, scaling, and dimensionality reduction procedures. AI-based feature analysis is then conducted to detect relevant and non-redundant metabolomics signatures related to nutritional quality characteristics. Selected features are used in a hybrid machine-learning model based on the complementary nonlinear learning power of machine-learning algorithms. Performance of the model is evaluated based on MAE, RMSE, and the coefficient of determination ($\boldsymbol{R^2}$). Moreover, feature importance analysis was utilized to enhance biological understanding. Based on the illustration of results, it was found that the proposed hybrid model exhibits better performance than conventional machine-learning and deep-learning models, providing an R2 of 0.95 and an RMSE of 0.096. It was revealed from the feature analysis that phenol, flavonoid, vitamin, and carotenoid signatures are significant predictors.

Keywords: Metabolomic Analysis, Hybrid Machine Learning, Functional Food Crops, Nutritional Quality Prediction, Artificial Intelligence.

I. INTRODUCTION

Metabolomics aims at characterizing the entire set of small molecules within a biological, food, or environmental system to give an overview of both chemical composition and metabolism [1]. The advances in analytical chemistry allow performing high-throughput and high-resolution metabolomics through IM-based approaches, GC-MS, NMR spectroscopy [11]. However, the classic rule-based and univariate analysis is inadequate to analyze huge amounts of highly multivariate data obtained using the above-mentioned approaches. The ability to detect, classify and quantify chemical compounds or chemical signatures in complex matrixes with increased sensitivity, selectivity, robustness, and predictive power is known as advanced chemical detection in the current review. The idea includes the application of multivariate and data-driven methods that can detect complicated and delicate chemical patterns, going beyond the traditional approach of single-analyte detection. The possibility to extract interpretable and predictive information from high-dimensional dataset is the main strength of machine learning (MI), while metabolomics provides detailed chemical profiling in this case. Hence, it is reasonable to incorporate the above approaches into chemical detection to enhance the work of sensor-based systems in biology, ecology, food, and environment.

With high capabilities for pattern recognition, classification, regression and feature selection in high-dimensional chemical data, MI has become an essential element of modern metabolomics [3]. Unlike the more traditional chemometric approaches, the machine learning algorithms can simulate non-linear interactions and to use complicated multivariate fingerprints associated with specific chemical states and conditions. The increased sensitivity and robustness of chemical detection, biomarker discovery and improved prediction performance across multiple applications are the potential benefits of such integration of metabolomics and machine learning [12]. Their knowledge of the connection between diet and wellness is expanding as scientific inquiry continues. Glucose, lipid, and amino acid metabolism are only a few of the many physiological processes that nutrients impact; these activities are essential for health and disease prevention [8]. Heart disease, diabetes, obesity, and cancer are just some of the chronic illnesses that can be accelerated by an unhealthy diet [5]. But the state of the population's health right now is worrisome. Researchers anticipate that the number of individuals living with diabetes will rise from 529 million in 2021 to more than 1.31 billion in 2050 [3]. New studies show that there will be approximately 3.3 billion individuals with a high body mass index (BMI > 25) by 2035, up from 2.2 billion in 2020. Additionally, over 39% of children and adolescents affected by this condition would fall into this category. Present methods for preventing and treating diet-related illnesses are inadequate, as is the worldwide public health system's ability to deal with the worsening of health and the rising incidence of chronic diseases. As a result, "Precision Nutrition (PN)"—a new paradigm in nutrition management—has grown in importance in the last several years. Despite the lack of a consensus on what exactly PN is, it is evident from the current definitions [13] that, in contrast to more conventional approaches to nutrition, PN places an emphasis on conducting thorough evaluations of each person's health and nutritional requirements thru the integration of various types of data (such as dietary, multi-omics, lifestyle, etc.) and the creation of tailored intervention programs to address those needs. Dietary data, being one of the main sources of information in PN, can help with things like developing exact tailored diet plans, accurately evaluating individual nutrient consumption, and deeply explaining the mechanisms of the dietary impact on health [7].

1.1 Contributions of the Study

The present study has introduced the framework for AI-driven analysis of metabolomic features for the discovery of significant metabolites signatures relevant to the nutritional quality of functional food crops. Hybrid machine-learning model is used to learn the nonlinear mapping between metabolomic data and nutritional attributes of the functional crops. Explainable feature analysis is used for revealing the significance of metabolites and their influence on the model predictions. Lastly, comprehensive comparative evaluation is done to verify the performance of the proposed framework.

1.2 Organization of the Study

The remaining part of the paper is organized as follows. Related work is discussed in Section 2. Section 3 discusses the proposed methodology and hybrid machine-learning framework. Experimental results and discussion can be found in Section 4. Conclusions of the study are presented in Section 5.

II. LITERATURE REVIEW

Chemometrics, machine learning, and artificial intelligence (AI) are advanced data handling methodologies with tremendous potential for revolutionary changes, which have significantly transformed the environment of food analysis [4]. This is not anymore, some luxury but an indispensable tool in this pursuit to guaranty the genuineness, safety, and high quality of the

food it eats [14]. Data sets produced by the advanced analytical instruments are massive and highly complicated making them difficult to manage by means of conventional methods. The sheer size of datasets has caused an explosion in the demand for highly sophisticated analytical tools, such as chromatography-mass spectrometry (capable of identifying hundreds of chemicals in one sample) and high-resolution imaging (capable of detecting minuscule textural details) [9]. Named "AI-Powered Advances in Data Handling for Enhanced Food Analysis: From Chemometrics to Machine Learning" this Special Issue seeks to explore and showcase the revolution and reveal how the use of AI is transforming this ability to guaranty the genuineness, safety, and quality of the food. The goal is to spread the word about how scientists utilize machine learning and deep learning to obtain greater insight from food data instead of just using classical statistical analysis.

Considering the projected 10 billion population of Earth by 2050, the global food supply chain is subject to significant examination. As the response to the drastic climate change, shortage of freshwater resources, and changing consumer attitudes towards sustainable, functional nutrition, the food industry and agricultural sector will have to cooperate to ensure the necessary increase in the total food output to facilitate this demographic growth [15]. Due to their dependence on rigid rule-based processing architecture and sequential trial-and-error laboratory screening, traditional methodologies used in the field of food science and product development fail to respond to the increased requirements. In response to this challenge, artificial intelligence (AI) has transitioned from an auxiliary optimization tool to the central structure enabler. All links in the food chain are being revolutionized by AI, influencing the upstream agricultural production, the biocompound discovery process, autonomous IoT manufacturing pipeline, and personalized nutrition programs.

Novel possibilities for filling these gaps have arisen as a result of recent developments in data processing and sensor technologies. Currently, numerous farms are equipped with Internet of Things (IoT) sensors, which gather massive amounts of high-resolution data. This allows for a more thorough examination of the previously only partially understood links between the environment and growth.

There is a lack of capacity for traditional statistical and rule-based methods to capture the complex, multivariate, and time-dependent relationships between environmental factors and crop development, even tho sensor data is becoming more accessible in vertical farming systems [2][6]. Oversimplifying the dynamic feedback mechanisms inherent in controlled-environment agriculture, traditional regression-based approaches often assume predictors are linear and independent. Predictive models need to account for complicated feature interactions and long-term dependencies since environmental management tactics change frequently throughout cultivation cycles[10].

III. RESEARCH METHODOLOGY

The concept of AI-Driven Metabolomic Feature Analysis and Hybrid Machine Learning Model for Prediction of Nutritional Quality of Functional Food Crops involves data preprocessing of metabolomics, feature selection, feature reduction, hybrid machine learning modeling, and nutritional quality prediction. The entire framework is formulated to detect the patterns in metabolomics and create the predictive model. The whole process flow is shown in Figure 1.

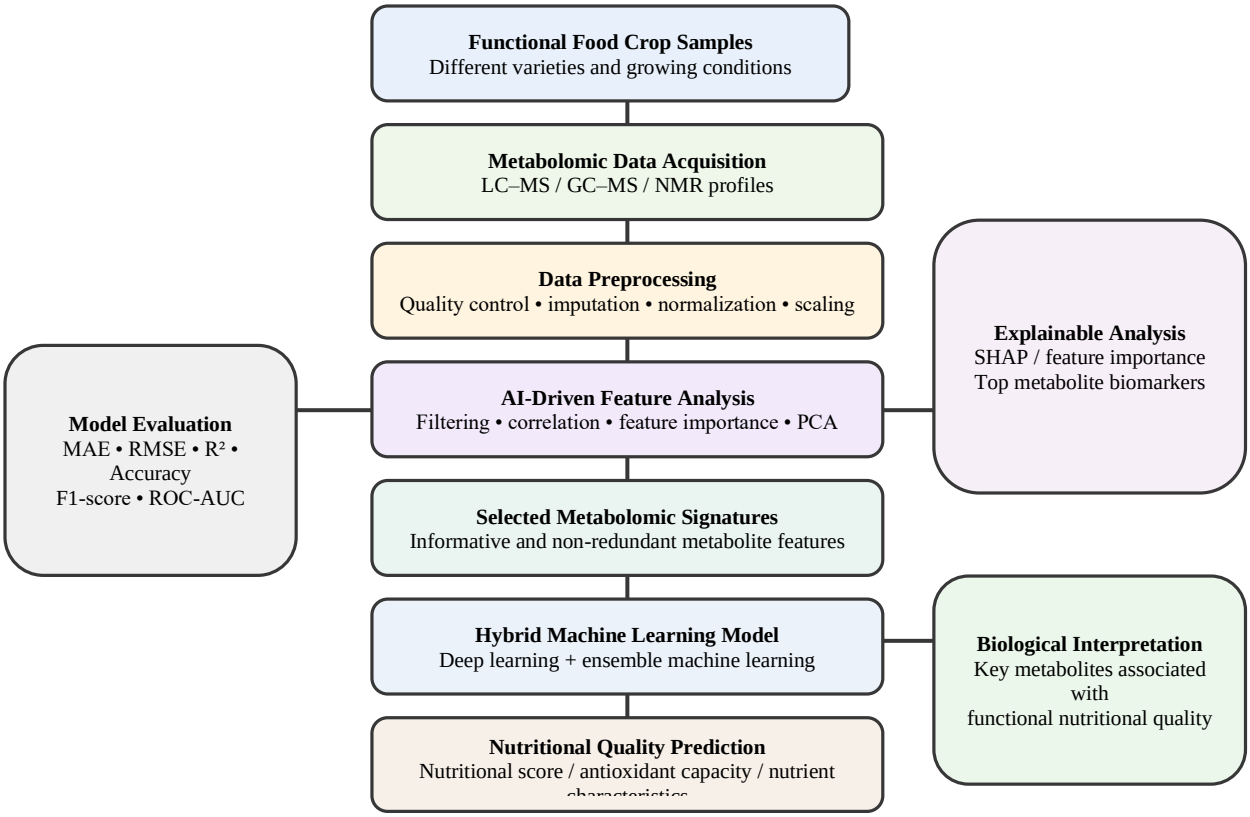

Figure 1. Proposed AI-Driven Metabolomic Nutritional Quality Prediction Framework

3.1 Metabolomic Data Acquisition

These metabolomic profiles are acquired for functional food crops using analytical techniques like LC–MS, GC–MS, and NMR spectroscopy. This dataset includes metabolite intensities along with measurements related to nutrition quality such as antioxidant capacity, protein content, phenolic content, vitamins content, minerals content, or nutritional quality score.

Different crop varieties are considered with various growing environments to include biological and environmental variations in the dataset. The dataset is divided into training, validation, and test datasets with proper distribution of classes or target values.

3.2 Metabolomic Data Preprocessing

Initially, raw data is processed to account for experimental errors and make subsequent steps more reliable. Missing metabolite intensities are imputed based on suitable imputation technique. After that, noise is filtered and data is normalized. The features with very low intensity or high missingness level are discarded.

Subsequently, metabolite measures are transformed and scaled to minimize the effect of large ranges in concentration of the metabolites. Quality control samples can be included to account for analytical drift.

3.3 Feature Selection from Metabolomics Using AI Methods

Preprocessed metabolomic matrix is analyzed to identify metabolites with strong relation to the nutrition quality. The combination of statistical screening and machine learning-based feature importance methods helps to discard redundant and irrelevant metabolites.

First correlation analysis and variance filtering is performed, and then ranking algorithms such as mutual information, recursive feature elimination or tree-based importance calculation are used. PCA could also be applied to explore the patterns of variation of metabolomic profiles.

Normalized feature vector of metabolites for sample i could be expressed in equation (1) as

$$z_i = \left[z_{i1}, z_{i2}, \ldots., z_{ip}\right]^T \quad (1)$$

where p denotes the number of retained metabolomic features and z_{ip} represents the normalized abundance of the j-th metabolite for sample i.

3.4 Hybrid Machine Learning Model

The identified metabolomic descriptors are fed into a hybrid machine-learning system that uses the strengths of multiple algorithms for learning. The proper setup could include the use of a nonlinear feature-learning module with a regression-based ensemble module. In such cases, the neural networks could learn nonlinear interactions between metabolites, whereas Random Forest or XGBoost could discover nonlinear decision trees.

The prediction from the hybrid model could be expressed in equation (2) as:

$$\hat{y}_i = \alpha f_{DL}(z_i; \theta) + (1 - \alpha) f_{ML}(z_i; \emptyset) \quad (2)$$

where $\hat{y}_i$ denotes the predicted nutritional-quality value, f_{DL} represents the deep-learning component, f_{ML} denotes the conventional machine-learning component, $\theta \; and \; \phi$ represent their respective parameters, and $\alpha \in [0,1]$ controls the contribution of each component.

3.5 Nutritional Quality Prediction

The trained hybrid model predicts nutritional quality-related features based on the chosen metabolomic signatures. Based on the target feature, the framework is capable of either regression or classification. In case of nutritional quality-related measurements being continuous, possible prediction targets might be antioxidant capacity, phenolic content, vitamin concentration, or nutritional quality score.

In case of nutritional quality being categorical, the samples can be split into three categories - low quality, medium quality and high quality, depending on pre-defined nutritional criteria.

3.6 Model Training and Validation

The training set is used for model parameter optimization while validation data serves for hyperparameter tuning and early stopping. Cross-validation may be used to decrease

dependence on a particular data partitioning and receive a more robust estimate of generalization.

The proposed model is compared to individual machine learning models like Linear Regression, Support Vector Regression, Random Forest, XGBoost and neural network model. It helps to understand if combination of complementary machine learning approaches results in better predictions.

3.7 Model Evaluation and Interpretability

Performance of nutritional quality regression models is assessed by MAE, RMSE, R^2 and Pearson correlation coefficient, while classification performance is measured using accuracy, precision, recall, F1-score and ROC-AUC.

To increase biological interpretability, the importance and explanation of features approach may be applied to the resulting model. The most important metabolites are ordered in terms of impact on nutritional quality predictions. These metabolites may be further investigated as biomarkers for nutritional properties of functional food crops.

IV. RESULTS AND DISCUSSION

4.1 Comparative Prediction Performance

The effectiveness of the proposed framework for AI-based metabolomic features analysis was tested against the existing machine-learning and deep-learning algorithms used for the prediction of nutritional quality of functional food crops. As the benchmarking algorithms, Linear Regression, Random Forest, XGBoost, and MLP were chosen. While the proposed model is hybrid and integrates complementary nonlinear learning approaches.

According to Table 1, the highest illustration of the R^2 value was reached with the use of the proposed hybrid algorithm at 0.95, with the lowest value of RMSE equal to 0.096. XGBoost and MLP showed R^2 values of 0.89 and 0.91, correspondingly.

Table 1. Comparative performance of nutritional-quality prediction models

Model	**MAE**	**RMSE**	R^2
Linear Regression	0.141	0.182	0.78
Random Forest	0.108	0.145	0.86
XGBoost	0.094	0.129	0.89
MLP	0.087	0.118	0.91
Proposed Hybrid Model	**0.071**	**0.096**	**0.95**

4.2 Metabolomic Feature Importance Analysis

The impact of each individual metabolite was analyzed to determine which specific molecular features were most strongly correlated with nutritional quality. Feature selection was conducted after the data had been preprocessed and reduced in dimensionality, providing the possibility of selecting important metabolites while limiting the impact of redundant features.

As can be seen from Table 2, Phenolic A ranked the highest with normalized feature importance of 0.21, with Flavonoid B (0.18), Vitamin C (0.15), and Carotenoid C (0.13) following next. This shows that several types of metabolites impact the prediction of nutritional quality rather than one single molecular feature.

Table 2. Ranked metabolomic features contributing to nutritional-quality prediction

Rank	Metabolomic Feature	Normalized Importance
1	Phenolic A	0.21
2	Flavonoid B	0.18
3	Vitamin C	0.15
4	Carotenoid C	0.13
5	Organic Acid D	0.11
6	Amino Acid E	0.09
7	Mineral F	0.07
8	Sugar G	0.06

The distribution of variable importance is presented in Figure 2. The significant importance of phenolic and flavonoid features implies the possible usefulness of secondary metabolites in prediction of nutritional quality. Such variable detection helps to increase interpretability of the model because it provides the relationship between predictive results and observable metabolic characteristics.

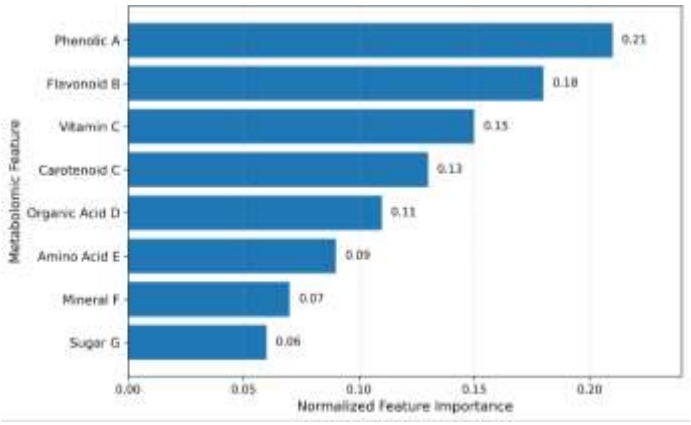

Figure 2. Relative importance of selected metabolomic features for nutritional-quality prediction.

4.3 Model Training and Convergence

The optimization process of the hybrid model has been evaluated using training and validation loss over 20 epochs. According to Figure 3, there is a continuous decline in the training loss and the validation loss.

For instance, the training loss reduces from about 0.92 at the first epoch to 0.191 at the last epoch. Similarly, the validation loss goes down from about 0.97 to 0.249. The steady decline in the two curves means that the model has progressively learned to represent useful metabolomics in a consistent manner.

The lack of a huge gap between the training loss and the validation loss is an indication of controlled fitting of the model in the presented example. Such convergence of the two losses is significant in metabolomic prediction since excessive fitting of the model to limited crop samples can compromise its predictive power.

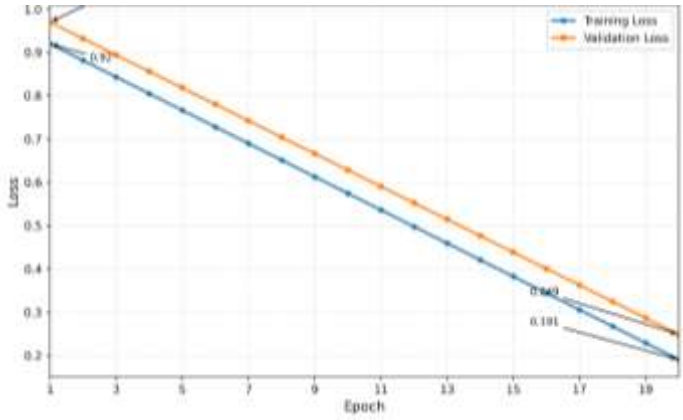

Figure 3. Training and validation convergence of the proposed hybrid nutritional-quality prediction model.

4.4 Overall Discussion

These findings highlight the possibility of integrating AI-assisted metabolomic profiling along with hybrid ML algorithms in predicting nutritional qualities. The presented framework provides the best overall performance shown in Table 1, with illustrative R2 = 0.95 and RMSE = 0.096. Better results than those obtained by Linear Regression suggest that nutritional quality is governed by complicated nonlinear relations that cannot be appropriately captured with linear hypotheses.

Results given in Table 2 and shown in Figure 2 provide an additional justification of metabolomic profiling's benefits. Instead of using all metabolite features, the suggested framework uses a smaller number of highly relevant molecular features. Dimension reduction approach helps to cut down the number of redundant variables and increase efficiency.

Finally, convergence properties provided in Figure 3 show that the presented architecture can optimize itself in a stable manner. The decrease in both training and validation losses shows that the architecture improves its representation gradually. Besides, stable validation behavior may indicate good generalization ability of the presented model.

Thus, the presented framework creates a connection between metabolomic profiles, explainable feature importance and nutritional quality prediction. However, before deploying the model, it must be tested on various independent crop varieties, different cultivation environments, repeated biological samples and independent metabolomic databases. The statistical significance of the results and confidence intervals must be determined.

V. CONCLUSION

In this paper, an AI-assisted metabolomic features analysis and hybrid machine learning approach for predicting the nutritional value of functional food crops was discussed. In particular, the suggested methodology combines metabolomics data preprocessing, intelligent

feature selection, dimensionality reduction, hybrid modeling, and explainable features analysis into one coherent framework. Experimental findings revealed that the proposed hybrid approach can discover nonlinear dependencies between metabolomic signatures and nutritional properties. As compared to traditional Linear Regression, Random Forest, XGBoost, and MLP models, the suggested model exhibited the best performance, illustrated by the highest R2 of 0.95 and lowest RMSE of 0.096. The feature-importance analysis also demonstrated that phenolic, flavonoid, vitamin, and carotenoid features play a crucial role in nutritional value prediction. The convergence analysis revealed a steady optimization process in terms of the suggested model across training iterations, confirming the validity of its predictive power. Apart from prediction, the suggested framework offers a mechanism that allows discovering metabolomic signatures linked to the nutritional properties. However, further validation based on large and independent metabolomics datasets needs to be performed before implementation of the suggested approach in practice. Future research needs to focus on multi-platform metabolomic analysis, external validation in relation to different crop varieties and cultivation conditions, uncertainty quantification, and advances in explainable AI.

ANALYSIS OF UNIVERSITY STUDENTS' METAPHORICAL PERCEPTIONS OF THE CONCEPT OF "CLIMATE CHANGE"

Nurcan Özkan[1]

[1] *Trakya University, Education Faculty, Mathematics and Sciences Education Department, Edirne, Turkey*
Corresponding author e-mail: nurcanozkan@hotmail.com

ABSTRACT

This study aims to identify the metaphors that university students will use to describe the concept of "climate change," a current environmental issue worldwide. The study sample consists of 49 third and fourth-year students enrolled in the Science Education Department of the Faculty of Education at Trakya University during the 2024-2025 academic year. To determine science education students' perceptions of the concept of "climate change," a semi-structured form containing the statement "Climate change is like …… because ……" was distributed, and students were asked to express their views by focusing on only one metaphor and filling in the blanks. The data obtained at the end of the study were analyzed using content analysis. Participants generated a total of 46 different metaphors for the concept of climate change, and these metaphors were evaluated under 11 different conceptual categories to interpret the results. According to the findings, the most frequently recurring metaphors related to the concept of climate change were identified as our emotions and greenhouses. The conceptual categories are as follows: Global warming as an end, global warming as a result of our actions, global warming as a catastrophe, global warming as a threat, global warming as an asset, global warming as a commodity, global warming as a disease, global warming as an imbalance, global warming as a disruption of the natural balance, global warming as a necessity for taking action, and global warming as a result of human impact. The metaphors developed by the students were most frequently clustered within the conceptual category of "global warming as a result of human impact."

Keywords: Metaphor, Climate change, Environment, Science education students

INTRODUCTION

Climate change can be defined as a long-term change in the overall average of the climate due to various reasons (Demirbaş and Aydın, 2020). In today's world, where environmental problems are prevalent, climate change can perhaps be described as the biggest environmental problem among many others (Özerdem and Barlas, 2022). Global climate change is a significant change, mostly caused by human activities, in addition to the climatic changes that have occurred naturally throughout the Earth's long geological history. The increase in human activity and the reliance on fossil fuels driven by the industrial revolution have led to a rise in carbon dioxide, causing significant changes in the existing composition of the atmosphere. In addition, the increase in animal production to meet human needs has also led to an increase in methane gas released from animal farms into the atmosphere. In the coming years, changing people's consumption habits and putting an end to consumerism are also among the most important issues for the health of the world. The accumulation of greenhouse gases is increasing, particularly as a result of the excessive and indiscriminate use of fossil fuels such

as oil, coal, and natural gas. The negative effects of global warming are seen in many aspects of nature, especially in water resources. Due to its geographical location and diverse climatic conditions, Turkey is increasingly becoming one of the regions most affected by the negative impacts of global warming (Akın, 2006; Erdoğan Sağlam et al., 2008).

The industrial revolution increased the amount of carbon dioxide released into the atmosphere by developing countries, negatively impacting the ecological balance of the planet (Nart, 2009). The melting of glaciers, leading to rising sea levels and increased intensity of weather events, can have significant consequences affecting human health, various sectors, and ecosystems (IPCC, 2013). The Intergovernmental Panel on Climate Change (IPCC) report confirms increases in air and ocean temperatures, changes in precipitation, rising sea levels, and changes in the intensity of events such as droughts, floods, and storms (IPCC, 2014). The Republic of Turkey's Climate Change Strategy 2010-2023 states that "within the scope of developing capacity to combat and adapt to climate change, it is necessary to increase public awareness and strengthen the capacities of institutions in Turkey in order to reduce the effects of climate change and adapt to the process" (MEU, 2010).

Climate change, caused by global warming, affects the natural environment and consequently all ecosystems, both living and non-living. Individuals unaware of the negative effects of this change in nature do not engage in behaviors that help maintain the natural balance (Timur and Yılmaz, 2011). Environmental education is the most effective method for explaining issues such as climate change to the public and instilling this awareness in individuals from a young age (Erten, 2005; Kaşot, 2017). This behavioral pattern begins within the family and encompasses a process that can be particularly fostered through education. In this context, the perspective of prospective teachers and their knowledge and skills in environmental education become particularly important.

This study aims to identify the metaphors (mental images) that science students develop regarding the concept of climate change and to contribute to shaping future environmental education activities in this direction. Metaphors hold an important place in individuals' thought processes. They enable individuals to understand their actions related to abstract concepts such as justice, spirituality, or happiness (Landau et al., 2010; Babaoğlan Özdemir and Babaoğlan, 2022). Metaphor can also be described as the language of experience because it assigns meaning to personal experiences (Saban, 2004). According to TDK (2022), metaphor means figurative language. The word metaphor is defined as "using a word or concept in a way that gives it meanings other than its commonly accepted meaning." According to Korkmaz and Bağçeci (2013), metaphor is defined as: "When evaluating any event or situation in our daily lives, we generally approach events from different perspectives."

Studies on metaphor have also been conducted in our country since the 1990s (Toker and Bülbül, 2015). Kahyaoğlu and Kırıktaş (2016) examined the perceptions of secondary and university students regarding the concept of nature through metaphors. Doğan (2017) conducted a study to present the perceptions that middle school students have regarding the concept of environment and the meaning they attribute to these perceptions through metaphors. Ülkü (2019) investigated whether high school students understood biological concepts correctly by examining their metaphorical perceptions of these concepts. Güngör Cabbar (2019) conducted a study to determine primary school students' metaphorical perceptions of the concept of trees. Güllü and Dönel Akgül (2020) attempted to identify students' metaphors related to soil and agriculture in their study. Yoğurtcu (2021) conducted a study to determine high school students' conceptual structures, metaphorical perceptions, and misconceptions about the cell. Babaoğlan Özdemir and Babaoğlan (2022) conducted studies to determine high school students' metaphorical perceptions of the concepts of "climate change, global warming, greenhouse effect". The metaphors developed in this study regarding the concept of "climate change" reveal the perceptions and reflect the awareness of university students, who will play

significant roles in our social lives in the future, about these concepts. Therefore, this study is primarily intended to guide future teachers. Furthermore, identifying the meanings students assign to this concept through metaphors will draw attention to the threats posed by global warming.

MATERIAL AND METHOD

Research Model

The study utilized a qualitative research design, specifically "phenomenology." Phenomenology deals with phenomena that we are aware of but lack in-depth knowledge of (Yıldırım and Şimşek, 2006). The phenomenological approach is used to argue that behaviors are determined by experience rather than by external, objective, and physically defined facts (Robson, 2015). Each case study may have its own unique characteristics. This method has been chosen to determine the underlying causes of the existing phenomenon.

Study Group

The research was conducted with 49 students studying in the Science Education Department of the Faculty of Education at Trakya University during the 2024-2025 academic year (Table 1). The research was conducted on a voluntary basis, and students who did not wish to participate were not pressured. A convenient sampling method was used to select participants for the study group. This method involves obtaining data from the researcher's immediate environment, where access to data is easy, in order to speed up and streamline the study (Yıldırım and Şimşek, 2008).

Table 1. Distribution of students by grade level and gender

Gender	3rd grade	4th grade
Girl	17	24
Boy	3	5
Total	20	29

Data Collection

Metaphor analysis was used in the collection of research data. Research data was collected during the Fall semester of the 2024-2025 academic year. Students were given forms related to the research topic and asked to complete them within 20 minutes. To identify their metaphors for the concept, students participating in the study were asked to complete the sentence: “Climate change is like …..… because …..”. To this end, each student was given forms containing these sentences and asked to complete the sentence by forming a single metaphor based on their thoughts about the concept. The form included information about the participants' gender and grade level.

As is common in metaphor studies, the word "like" in the sentence is used to create a comparison, while the word "because" is used to provide a logical reason for this comparison (Saban, 2008, 2009; Aydın and Eser Ünaldı, 2010; Eraslan Çapan, 2010; Coşkun, 2011; Özder et al., 2012).

Data Analysis and Interpretation

The obtained data were evaluated using the "content analysis" technique. The aim of content analysis is to find concepts and relationships that can explain the collected data. In content analysis, similar data are grouped and organized within specific themes (Yıldırım and

Şimşek, 2006). The analysis of metaphors was carried out in four stages: (i) coding and extraction, (ii) category development, (iii) validity and reliability, and (iv) transferring the data to a computer environment (Saban, 2009).

(i) Coding and Extraction Phase: In this phase, each student's data collection form was coded and numbered as S1, S2, … S49. The metaphors produced by the students were coded into an Excel file and a list was created. Based on this list, it was examined whether a particular metaphor was clearly explained in the forms collected from the students. The analysis of the data obtained in the study examined the metaphors that students developed regarding the concept of climate change and the reasons behind them. The study examined whether there were any forms in which no metaphor was written or the reason for the metaphor created was not explained.

(ii) Category Development Phase: Metaphors developed by participating students were grouped into the same categories by combining similar answers. When determining the categories, both the metaphors developed by the students and the "because, ..." part explaining the rationale behind the metaphor were taken into consideration. It was observed that while some students' metaphors conveyed the same idea after the "because" part, others had different ideas. The ways in which the concept of "climate change" is expressed were examined by considering the metaphor lists that were created. In this respect, each metaphor produced by the participants was associated with themes from a climate change perspective, creating a total of 11 different conceptual categories.

(iii) Validity and Reliability Phase: In qualitative research, the researcher's detailed reporting of the collected data and explanation of how the results were obtained is among the important criteria for validity (Yıldırım and Şimşek, 2008). Therefore, to ensure the validity of the research, the opinion of an expert who has conducted research on metaphors was sought to determine whether the metaphorical images specified under the obtained conceptual categories represented the conceptual category in the way the students' developed metaphors were included.

(iv) Transferring the Data to a Computer Environment Phase: The selected metaphors and categories have been digitized and made ready for interpretation.

RESULTS AND DISCUSSION

This section presents the findings and interpretations obtained from the analysis of the data. Science education students participating in the research obtained 46 valid metaphors regarding the concept of climate change. Eleven categories were created for the concept of climate change. The metaphors and categories created by the students regarding the concept of climate change are given in Table 2.

Table 2. Metaphors and categories developed for the concept of climate change.

Category Name	Metaphors	Number of Metaphors	Frequency (f)	Percentage %
Global warming as an end	Apocalypse (1), end of the world (1), rooster crowing out of season (1)	3	3	6.12
Global warming as a result of our actions	The lives of living beings are in danger (1), cause and effect (1), the world's response to humans (1), environmental sustainability management system (1), a child's development (1), migration (1)	6	6	12.25
Global warming as a catastrophe	To leave a beautiful cool oasis and find yourself in the middle of the desert (1), disaster (1)	2	2	4.08
Global warming as a threat	Drunk driving (1), wastefulness (1)	2	2	4.08
Global warming as an asset	Wilting flowers (1), GMO products (1), systems (1), virus (1), spoiled fruit (1), mandarin (1)	6	6	12.25
Global warming as a commodity	Air conditioning (1), book (1), a dynamic engine that has existed for centuries (1)	3	3	6.12
Global warming as a disease	Early stage of cancer (1), Covid 19 (1), a dormant tumor (1)	3	3	6.12
Global warming as an imbalance	The imbalance of nature (1), weather conditions (1), differentiation (1), the fact that tea poured almost boiling hot into a cup cools down after a while and then cools down and the cup is renewed again (1), the meaning of the saying "the wheel of fortune turns one day" (1)	5	5	10.20
Global warming as a disruption of the natural balance	Greenhouses (2), destruction of tropical rainforests (1), change in nature (1), matter cycle (1), life cycle (1)	5	6	12.25
Global warming as a necessity for taking action	Fire (1), a broken alarm clock (1), a toy we broke (1), a person who has experienced a bad event in their life (1), a castle with ruined walls (1), time (1)	6	6	12.25
Global warming as a result of human impact	Throwing an aquatic creature onto land (1), our feelings (3), our thoughts (1), mood (1), friendship (1)	5	7	14.28
	Total	46	49	

The most frequently expressed metaphor regarding the concept of climate change was our emotions (f=3), followed by greenhouses (f=2). As seen in Table 2, the metaphors created by

the students were grouped under 11 categories. These categories are defined as: “Global warming as an end (6.12%)”, “Global warming as a result of our actions (12.25%)”, “Global warming as a catastrophe (4.08%)”, “Global warming as a threat (4.08%)”, “Global warming as an asset (12.258%)”, “Global warming as a commodity (6.12%)”, “Global warming as a disease (6.12%)”, “Global warming as an imbalance (10.20%)”, “Global warming as a disruption of the natural balance (10.20%)”, “Global warming as a necessity for taking action (12.25%), and “Global warming as a result of human impact (14.28%)”. Some of the statements included in the categories related to the concept of climate change are given below;

Category 1: Global warming as an end

This category contains a total of 3 different metaphors (6.12%). Each metaphor is represented by an individual. The metaphors are: Apocalypse (1), end of the world (1), rooster crowing out of season (1). Some of the reasons behind the emergence of some metaphors in this category are as follows:

"Climate change is like an apocalypse, because it threatens all life with extinction."

“Climate change is like a rooster crowing out of season, because everything has its place and time. Weather events should normally occur in their seasons. But as a result of environmental misuse, climates change, and snow starts falling in spring and summer. In other words, certain events occur out of season and without proper timing. Just like a rooster crowing at night.”

Category 2: Global warming as a result of our actions

This category contains a total of 6 different metaphors (12.25%). Each metaphor is represented by an individual. The metaphors are: The lives of living beings being in danger (1), cause and effect (1), the world's response to humans (1), environmental sustainability management system (1), a child's development (1), migration (1). Some of the reasons behind the emergence of some metaphors in this category are as follows:

“Climate change is like cause and effect, because whatever we give to nature, we receive a response in return. The damage we initially inflict can be quite serious, leading to climate change, and as a result, we are naturally the ones who are negatively affected.”

“Climate change is like an environmental sustainability management system, because the existence of environmental sustainability, like the part of managing a business, involves developing and implementing environmentally sensitive processes with the aim of making the environment a livable place for future generations. Similarly, management is about continuously improving itself, working towards the future, and being at the forefront of ensuring its continuity.”

Category 3: Global warming as a catastrophe

This category contains a total of 2 different metaphors (4.08%). Each metaphor is represented by an individual. The metaphors are: To leave a beautiful cool oasis and find yourself in the middle of the desert (1), disaster (1). Some of the reasons behind the emergence of metaphors in this category are:

“Climate change is like leaving a beautiful, cool oasis and finding yourself in the middle of a desert, because it disrupts nature and its order, negatively impacting life there by causing temperatures to be excessively below or above seasonal norms at unexpected times.”

“Climate change is disaster. Because greenhouse gases are causing the hole in the ozone layer to grow larger, leading to a gradual warming of the Earth. As the Earth warms further, glaciers will melt, potentially causing the death of many animals. Furthermore, the melting of glaciers could spread polar diseases to all parts of the world. This would be a complete disaster for the planet.”

Category 4: Global warming as a threat

This category contains a total of 2 different metaphors (4.08%). Each metaphor is represented by an individual. The metaphors are: Drunk driving (1), wastefulness (1). Some of the reasons behind the emergence of metaphors in this category are as follows:

"Climate change is like a drunk driving, because a drunk driver causes accidents and damages everything around them. Climate change also harms nature and living things."

"Climate change is like wastefulness, because people are using natural resources irresponsibly. Seasons are no longer experienced as they used to be. The greenhouse effect, industry, the unconscious use of products, and exhaust fumes are all contributing to climate change."

Category 5: Global warming as an asset

This category contains a total of 6 different metaphors (12.25%). Each metaphor is represented by an individual. The metaphors are: Wilting flowers (1), GMO products (1), systems (1), virus (1), spoiled fruit (1), mandarin (1). Some of the reasons behind the emergence of metaphors in this category are as follows:

"Climate change is like wilting flowers, because over time it creates adverse conditions and negatively impacts habitats."

"Climate change is like GMO products, because the climate, like food, has been disrupted by human hands."

Category 6: Global warming as a commodity

This category contains a total of 3 different metaphors (6.12%). Each metaphor is represented by an individual. The metaphors are: Air conditioning (1), book (1), a dynamic engine that has existed for centuries (1). Some of the reasons behind the metaphors in this category are:

"Climate change is like an air conditioner, because the conditions of our environment change along with the climate. For example, it is cold in winter and hot in summer."

"Climate change is like a book, because although each one is called a book, it tells a different story, evokes different feelings, and shows a different path. The things it teaches a person are also different. Climate change is like that too. Its name is climate, it evokes the same things in human consciousness, but every change is a new perspective and experience. These can be harmful or beneficial to humanity. Just like when we feel that a book we've read hasn't given us anything, we consider it a waste of time."

Category 7: Global warming as a disease

This category contains a total of 3 different metaphors (6.12%). Each metaphor is represented by an individual. The metaphors are: Early stage of cancer (1), Covid 19 (1), a dormant tumor (1). Some of the reasons behind the metaphors in this category are:

"Climate change is like the early stages of cancer, because it causes changes or depletion in the natural habitats of many living things, agricultural activities, and the struggle for survival of people."

"Climate change is like a dormant tumor. Just as a dormant tumor may appear harmless at first but can suddenly spread throughout the body, climate change, even if it doesn't seem to harm us now, will inevitably cause damage in the long term. For example, it causes melting glaciers, drought (and consequently, hunger and thirst), the greenhouse effect, warming of the atmosphere, and as the atmosphere warms, the oceans also warm, sea levels rise, which causes floods, etc. As these examples show, climate change is like a dormant tumor; although we may not notice the damage it can cause in the short term, the damage it will cause in the long term will be significant and irreparable."

Category 8: Global warming as an imbalance

This category contains a total of 5 different metaphors (10.20%). Each metaphor is represented by an individual. The metaphors are: the imbalance of nature (1), weather conditions (1), differentiation (1), the fact that tea poured almost boiling hot into a cup cools

down after a while and then cools down and the cup is renewed again (1), the meaning of the saying "the wheel of fortune turns one day" (1). Some of the reasons behind the metaphors in this category are as follows:

“Climate change is like pouring almost boiling hot tea into a cup; after a while, it cools down, then cools completely, and then the cup needs to be refilled, because at a certain point, the timing and process are similar. However, one changes on average every 3-4 months, while the other changes every 3-5 minutes.”

"Climate change is like the meaning of the saying "the wheel of fortune turns one day", because losing the seasons we experience, the absence of transitional seasons between summer and winter, are the consequences of humanity's war against nature."

Category 9: Global warming as a disruption of the natural balance

This category contains a total of 5 different metaphors (12.25%). The greenhouses metaphor is represented by two individuals, and the others by one individual. Metaphors: Greenhouses (2), destruction of tropical rainforests (1), change in nature (1), matter cycle (1), life cycle (1). Some of the metaphors and reasons included in this category are:

“Climate change is like the matter cycle, because there is a proverb that says 'you reap what you sow.' Humanity receives positive returns when it protects nature, but receives negative returns when it harms the environment. This indirectly results in global warming through the release of greenhouse gases, etc., and consequently causes climate change.”

“Climate change is like nature changing, because as climates change, nature changes too. Our environment changes.”

“Climate change is like a life cycle because: if the concept of climate change didn't exist in our lives, the entire natural balance would be disrupted. The lifespans of living things would be shortened. Increased frequency and impact of extreme weather events such as droughts, floods, and severe hurricanes, rising ocean and sea levels, increased ocean acidification, and melting glaciers would put plants, animals, ecosystems, and human communities at serious risk.”

Category 10: Global warming as a necessity for taking action

This category contains a total of 6 different metaphors (12.25%). Each metaphor is represented by an individual. The metaphors are: Fire (1), a broken alarm clock (1), a toy we broke (1), a person who has experienced a bad event in their life (1), a castle with ruined walls (1), time (1). Some of the metaphors in this category and their reasons are as follows:

"Climate change is like a castle with ruined walls; if we don't take precautions, the enemy will come and destroy us."

“Climate change is like time, because climate change is the changes that occur in weather patterns and in oceans, land surfaces and ice sheets, and it is nearly impossible to reverse these conditions. Time is like climate change; it is difficult to bring back what has been done, and it is very difficult to rectify the mistakes that have been made.”

Category 11: Global warming as a result of human impact

This category contains a total of 5 different metaphors (14.28%). The metaphor of our feelings is represented by 3, and the other metaphors are represented by an individual. The metaphors are: Throwing an aquatic creature onto land (1), our feelings (3), our thoughts (1), mood (1), friendship (1). Some of the reasons behind the metaphors in this category are:

"Climate change is like our thoughts, because it can differ and change at every stage of time."

“Climate change is like our feelings because if we consume them too much, they eventually disappear. Today, we know that global warming is increasing and will have serious consequences if it is not stopped.”

DISCUSSION AND CONCLUSIONS

This study was conducted to determine university students' perceptions of the concept of "climate change" using metaphors. The fact that, with the exception of two, all of the 46 different metaphors created by Science Education students at the Faculty of Education are represented by a single person is significant in revealing the diversity of perceptions surrounding the concept. The metaphors collected from the students were grouped under 11 categories. The most frequently expressed metaphor regarding the concept of climate change was our feelings (6.52%).

Kaşot, Özalp and Koşer (2023) worked with 100 primary school teachers in the Turkish Republic of Northern Cyprus to determine their metaphorical perceptions of the concept of climate change. In the study, 100 different teachers were evaluated, and they provided 38 different metaphors regarding the concept of climate change. Unlike this study, the number of metaphors was fewer, and there were repetitions of metaphors.

Babaoğlan Özdemir and Babaoğlan (2022), in their study titled "Metaphorical Perceptions of High School Students Regarding the Concepts of Climate Change, Global Warming, and Greenhouse Effect," found that students produced 237 metaphors related to the concept of "climate change," 234 metaphors related to the concept of "greenhouse effect," and 260 metaphors related to the concept of "global warming." These metaphors have been grouped into 5 different categories for "climate change," 6 for "greenhouse effect," and 5 for "global warming." In contrast to this study, the most frequently repeated metaphor for climate change was identified as human; the most frequently repeated metaphor for the greenhouse effect was cigarette; and the most frequently repeated metaphor for global warming was fire. The metaphors developed by high school students do not reflect much negativity. For example; memories, cars, friendships, shoes, knowledge, work, socks, notebooks, lecture notes, class schedule, classes, ideas, sweaters, technology, phones, television, theater plays, the Turkish economy, sleep, not waking up, utopia, aging, etc. The research shows that high school students are aware that everyone needs to cooperate and make an effort to fulfill their responsibilities in addressing the problems of climate change, the greenhouse effect, and global warming, which pose a threat to both living beings and the world. This study revealed that participants' statements generally highlighted the negative impacts of climate change. For example; the apocalypse, the end of the world, a rooster crowing at the wrong time, a fire, a broken alarm clock, a toy we've broken, a person who has experienced a bad event in their life, a castle with crumbling walls, etc.

Ultimately, the aim is for students to understand climate change and to highlight its negative impacts. Measures need to be taken to mitigate or eliminate these negative effects. Unfortunately, although many people are aware of these measures, they are not widely implemented.

In conclusion, this research shows that the participants have a negative perspective towards the concept of climate change, similar to the study by Babaoğlan Özdemir and Babaoğlan (2022). This situation highlights the importance of closely following current communication channels and the education they receive in schools in fostering environmental awareness among people. The world's climate is changing rapidly, and the effects of these changes on nature, living things, and especially human health are likely to intensify.

TEMPERATURE TOLERANCE AND PHENOTYPIC PLASTICITY IN PLANTS

Aydın ÜNAY

Aydın Adnan Menderes University, Agricultural Faculty, Field Crops Department, Aydın, Türkiye

ABSTRACT

Temperature is the most fundamental external factor determining the rate of plant growth and development. Under optimum temperature conditions, metabolic functions reach their highest level. Conversely, at low temperatures, growth occurs at the lowest level. At high temperatures, the enzyme structure begins to degrade, and the synchronization between male and female reproductive organs is disrupted. In the process of global climate change, temperature increases and rainfall irregularities are observed. Furthermore, the frequency and severity of temperature fluctuations are increasing. These irregularities reduce yield and quality in plants. In our country, temperature increases following the sowing period of winter crops affect the plants' entry into winter. Similarly, sudden temperature rises occurring at the end of winter, referred to as false spring, followed by seasonal cold snaps or frost events, impact the advanced developmental stages of plants. Phenotypic plasticity emerges when a genotype produces different phenotypes under different environmental conditions. Stomatal conductance and transpiration form the basis of phenotypic plasticity under both drought and high-temperature conditions. Changes in root and leaf morphology, as well as osmotic adjustment, support phenotypic plasticity. Phenotypic plasticity is explained through epigenetic regulations. Breeding plant species and varieties with phenotypic plasticity constitutes one of the most important breeding strategies.

Key words: Temperature fluctuations, yield losses, tolerance, phenotypic plasticity, epigenetics

INTRODUCTION

Global climate change adversely affects not only temperature increases but also precipitation, wind, and seasonal patterns. Concurrently with temperature fluctuations, plants encounter pressure from pests and diseases whose species composition and population dynamics are changing. Significant meteorological variations between seasons and years have resulted in temperature fluctuations that have reached levels capable of affecting crop yield and quality. It is projected that the frequency of exposure to extreme temperatures will further accelerate in future years (Roberts and Summerfield, 1987; Wheeler et al., 2000; IPCC, 2021; Paçal et al., 2023; Senapati et al., 2024).

In cool-season cereals, above-normal temperatures during the sowing period and the subsequent process lead to entry into winter with excessive leaf development, thereby weakening the plant's winter hardiness. Furthermore, temperature fluctuations during the tillering stage negatively affect the number of tillers. Most importantly, extreme high temperatures and below-normal low temperatures during the subsequent generative stage, particularly during the grain-filling period, directly impact yield negatively. In wheat, it has been reported that variations of ±2°C from optimal temperatures induce leaf senescence, potentially causing up to a 50% yield reduction (Asseng et al., 2011).

In summer crops such as cotton, soybean, maize, and peanut, sowing is carried out when soil temperatures reach 15–18°C or higher. However, in some years, post-sowing abnormalities occur in April and May, where low temperatures adversely affect both germination and early seedling development. In addition, early-stage seedling pathogens cause significant losses in plant density (Akpınar, 2008; Ergin et al., 2021). In maize, temperature fluctuations between 20–30°C negatively affected shoot and root development and significantly increased transpiration (Lal, 1974).

Similar to winter crops, temperature fluctuations in summer crops exert a greater negative impact during the generative stage. High temperatures shorten the duration required for seed formation and development, thereby limiting the attainment of yield potential. Additionally, extreme heat during the flowering stage can directly impair pollination and fertilization (Harrison et al., 2011).

The long-term and last five-year maximum and minimum temperature values for Aydın province, where summer crops such as cotton and maize are predominantly cultivated, are presented in Figure 1. It is clearly evident that summer crops are exposed to both maximum and minimum temperatures approximately 2°C and above [normal/higher] during their reproductive stages.

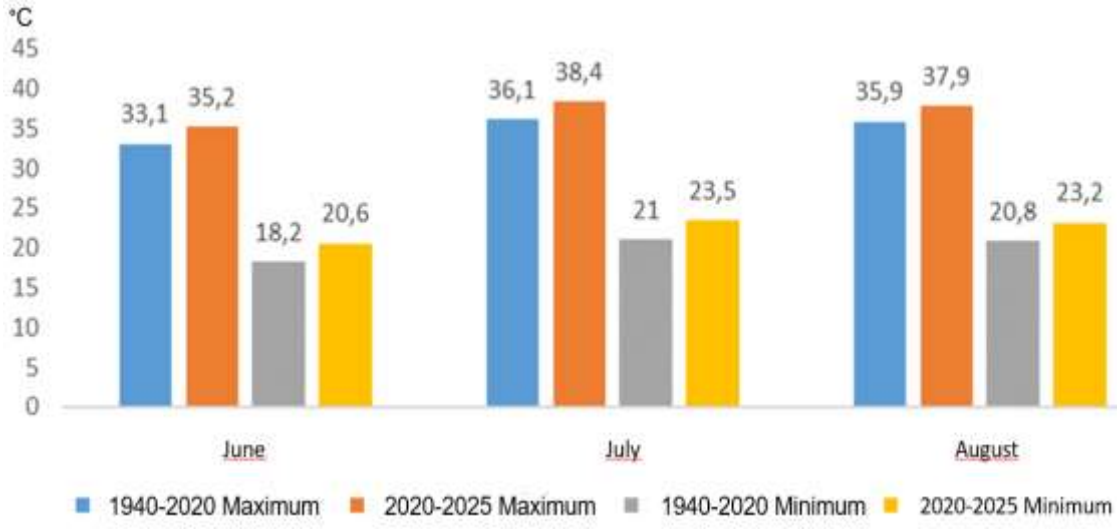

Figure 1. Long-term (1940–2020) and 2020–2025 period temperature values for the months of June, July, and August in Aydın province.

PHENOTYPIC PLASTICITY

Phenotypic plasticity is the ability of a genotype to develop phenotypes with distinct physiological, morphological, developmental, and biochemical characteristics when exposed to different environmental conditions. The plasticity of a given trait depends on genetic and environmental factors (Alseekh et al., 2025). High phenotypic plasticity is defined as a scenario where a small change in temperature leads to extensive phenotypic modifications in plants. There is a close relationship between phenotypic plasticity and evolutionary potential. Evolutionary fitness manifests in two ways: vigor and reproductive success. Photosynthetic rate

and capacity, nutrient use efficiency, and phenological matching support adaptive capacity (Schaum et al., 2022).

Testing populations exhibiting genotypic variation across different years and locations represents one of the simplest methods to determine phenotypic plasticity. Results obtained from these studies demonstrate that the environment is as critical as genetics in explaining overall phenotypic variation (Han et al., 2025).

Morphological modifications encompassed within phenotypic plasticity include leaf area index, leaf orientation, stomatal conductance, leaf movements (parheliotropism), leaf cuticle thickness, and stomatal characteristics (Gratani, 2014). Osmotic adjustment, on the other hand, is one of the most vital traits supporting phenotypic plasticity within water use efficiency (Nicotra and Davidson, 2010). The effects of temperature during four distinct growth and developmental stages in cotton are illustrated in Figure 2.

During the vegetative stage, high temperatures lead to stunted plants with reduced leaf area. In these plants, cell membrane integrity is impaired, and stomatal conductance is reduced. DNA denaturation and the synthesis of reactive oxygen species (ROS) underlie these adverse effects. Consequently, both photosynthetic rate and capacity are diminished. During the flowering stage, the number of flowers decreases due to negative impacts on gene expression. Infertility may occur as a result of desynchronization among floral organs. At the onset of boll setting, boll shedding is observed. The size of developing bolls decreases, giving rise to stunted seeds and coarser fibers.

Figure 2. The effects of temperature at different growth stages in cotton.

Phenological Stage		Differentiations
	Vegetative stage	Impairment of stomatal conductance, loss of cell membrane stability and photosynthetic damage, stunted growth and reduction in leaf area, DNA denaturation, degradation of heat shock proteins, weakened antioxidant defense
	Flowering Stage	Suppression of flowering gene expression, early or delayed flowering, flower size, flower number and pollen sterility
	Boll retention	Anther dehiscence, boll abscission, distribution of assimilates in boll
	Development of fiber and seed	Coarsened fiber and aborted seed

Plant cells exhibit remarkable flexibility due to their capabilities for differentiation, dedifferentiation, and redifferentiation. Mature somatic cells isolated from any plant organ and

cultured in an artificial medium can be triggered to re-initiate cell division, grow as undifferentiated callus tissue, and ultimately regenerate a new plant. This process resembles the genetic reprogramming of cells, allowing them to reverse the differentiation state and redifferentiation along a new, distinct pathway.

The capacity of differentiated cells to revert to an embryonic state and form new structures without an intervening reproductive phase is termed totipotency. Through this mechanism, plants can be vegetatively propagated indefinitely. Metabolic flexibility denotes the capacity of plants to alter their metabolism when exposed to any stress, serving as a characteristic trait essential for survival. When stress affects respiration, salicylic acid accumulates and alternative oxidase (AOX) is induced, resulting in reduced ATP production accompanied by elevated reactive oxygen species (ROS). The continuous electron flow mediated by alternative oxidase, triggered by salicylic acid, ensures the sustained operation of the pentose phosphate pathway and induces phytoalexin synthesis. The NADPH required for this process is supplied through the activity of NADP-specific malate dehydrogenase (Sisodia and Bhatla, 2018).

EPIGENETIC REGULATIONS

Epigenetic modifications—including DNA methylation, histone modifications, and RNA modifications—enable plants to dynamically and heritably adjust gene expression in response to environmental stressors. These mechanisms not only assist plants in surviving immediate stress but also confer stress memory, thereby enhancing their tolerance to future high-temperature events (Jin et al., 2024). It has been demonstrated that thermotolerance memory is acquired through epigenetic regulation, encompassing changes in nucleosome structure, histone modifications, chromatin remodeling, DNA methylation, and non-coding RNA-mediated regulation.

The success of acquired tolerance under high-temperature stress in mitigating heat stress in subsequent generations has been identified in rice (Shi et al., 2016), wheat (El-Rawy, 2020), and maize (Chukwudi et al., 2021). In cotton, Tian et al. (2024), Faghani et al. (2024), and Checkani et al. (2025) determined the performance of seeds harvested from drought-stressed plants in the subsequent generation. In wheat, it was established that heat stress tolerance could be transgenerationally transmitted to progeny grown from seeds collected from plants exposed to high-temperature stress during the flowering and grain-filling stages.

CONCLUSION

In cultivated winter and summer crops, a risk of temperature fluctuations exists across all phenological stages. Crop plants have undergone evolutionary changes in response to transitions from historically low to high CO_2 conditions, as well as rising temperatures since the Little Ice Age. This evolutionary adaptation has persisted to the present day through contributions to fitness. In recent years, temperature fluctuations have emerged as the paramount factor adversely affecting yield. Consequently, breeding programs aimed at enhancing phenotypic plasticity must be developed. It has been proven that epigenetic modifications can also contribute to advantageous alterations at the genetic level.

BIOFORTIFICATION IN POTATO

Aydın ÜNAY

Aydın Adnan Menderes University, Agricultural Faculty, Field Crops Department, Aydın, Türkiye

ABSTRACT

Biofortification has acquired strategic significance recently to improve the nutritional value of agricultural and livestock products for human and animal welfare. The goal is primarily to enhance the concentration of target nutrients and the capacity of the recipient organs. Thus, micronutrient malnutrition is mitigated in major crops like wheat, corn, potato, and paddy. The aim is to ameliorate health issues caused by these specific nutrient deficiencies. Using classical and modern breeding methods, 400 varieties with these characteristics have been developed within 12 plant species. Especially colored potatoes, containing iron and folate along with vitamins C, B6, and K, are rich sources of various antioxidants such as polyphenols, anthocyanins, carotenoids, and flavonoids. Moreover, they provide a healthy food alternative even after being cooked.

Key words: Translocation, potato, iron, zinc, selenium

INTRODUCTION

Potato, one of the most vital food crops with the potential to feed the global population, has a production capacity of 300 million tons. It is cultivated in over 100 countries that plan to meet more than 50% of their future food requirements from potatoes (Liv et al., 2024). Adapted to diverse climatic conditions, the harvest index of potatoes has been enhanced. Its ability to reproduce asexually via tubers bypasses the adverse effects of high temperatures on flowers and ensures the stability of favorable genetic traits (Travella et al., 2019; Tuncel and Qi, 2022). Biofortification of plants has emerged as a sustainable and effective tool for populations with limited access to adequate food resources. Nutritional enrichment plays a critical role in strengthening the immune system and supporting cognitive development (Figure 1). It protects maternal and child health during both the prenatal and postnatal periods. Improving the nutritional status across society combats hidden hunger. Furthermore, the quality of feed consumed by livestock raised on biofortified plant products will increase, leading to improvements in animal health. This, in turn, will be reflected in higher milk yields (Figure 2). Most importantly, it will indirectly yield significant benefits for humans who consume these animal products.

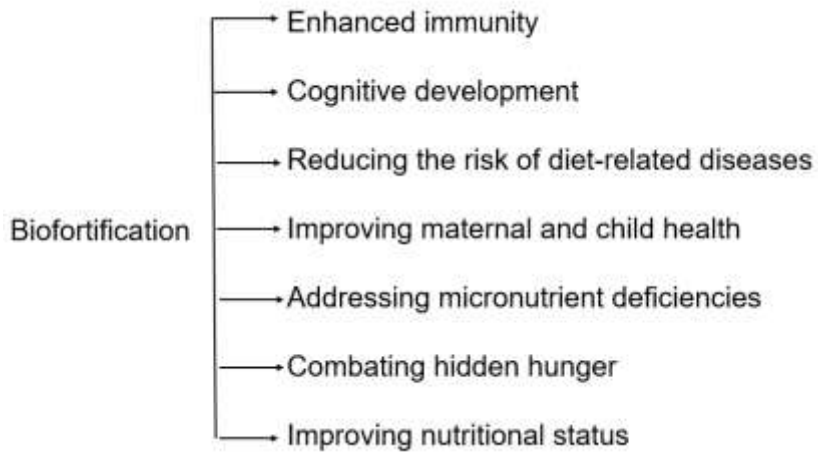

Figure 1. The impact of nutritional fortification on human health

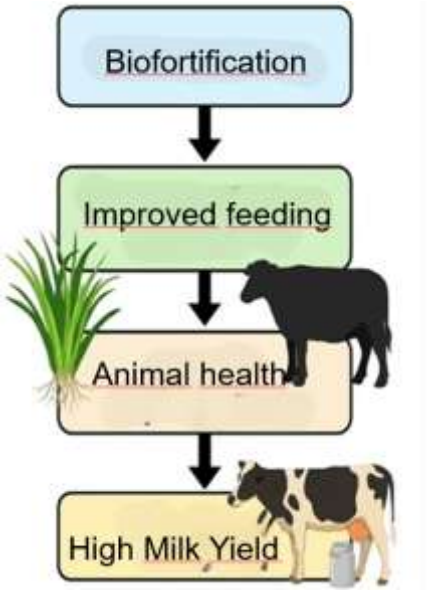

Figure 2. The impact of biofortification on animal health and milk yield

Nutritional fortification aims to alleviate deficiencies of nutrients such as Fe, Zn, Se, vitamin A (β-carotene), folate, etc. (Rauf et al., 2026). Nutritional Fe fortification of rice, pearl millet, beans, and sweet potatoes has led to significant successes in overcoming Fe and provitamin A deficiencies in humans consuming these staples (Talsma et al., 2017). The application of Zn to the soil, as well as combined soil and foliar applications, increased the grain Zn content in wheat by 29.1% and approximately 55.2%–62.0%, respectively, thereby exceeding the daily requirement threshold of 40 mg kg^{-1} (Hui et al., 2025). As a result of agricultural Se biofortification programs, improvements in cardiovascular health have been recorded in several countries, accompanied by increased blood plasma Se concentrations (Broadley et al., 2010). Iodine biofortification, particularly in leafy green vegetables, has been shown to supply iodine to humans without causing adverse effects (Dobosy et al., 2024).

Potatoes, which are particularly rich in anthocyanins and phenolic compounds, can be utilized in nutritional fortification for various nutrients. Their high biomass yield per unit area and widespread consumption makes potatoes a key crop in biofortification strategies.

EFFECT OF BİOFORTİFİCATİON ON POTATO

Supplementation with numerous mineral nutrients, particularly Zn, Si, and Mo, has positive effects on potato plants (Figure 3). As in all plants, silicon supplementation has the ability to strengthen plant structure, increase plant resistance, and optimize crop yield in potatoes. It forms a barrier beneath the cuticle in leaves and enhances antioxidant enzyme capacity to eliminate reactive oxygen species generated under stress conditions (Madegwa et al., 2025).

Among heavy metals, Cd is readily absorbed by plant roots and accumulates intensely in edible tissues above legal limits, such as 0.1 $\mu g \cdot g^{-1}$, thereby entering the food chain. In potatoes, Zn supplementation competes with Cd, significantly inhibiting its uptake (Xi et al., 2025). Balanced fertilization of plants with S increases nitrogen use efficiency alongside the content of defense compounds against pathogens (Potarzycki and Wendel, 2023). Boron (B) supports metabolic pathways in the synthesis of color pigments such as flavonoids and anthocyanins, which plants produce to mitigate the negative effects of UV radiation, and enhances the physical durability of the cell membrane. Potatoes represent a rich source of micronutrients, particularly when consumed with their skin (Subramanian et al., 2011; Singh et al., 2021).

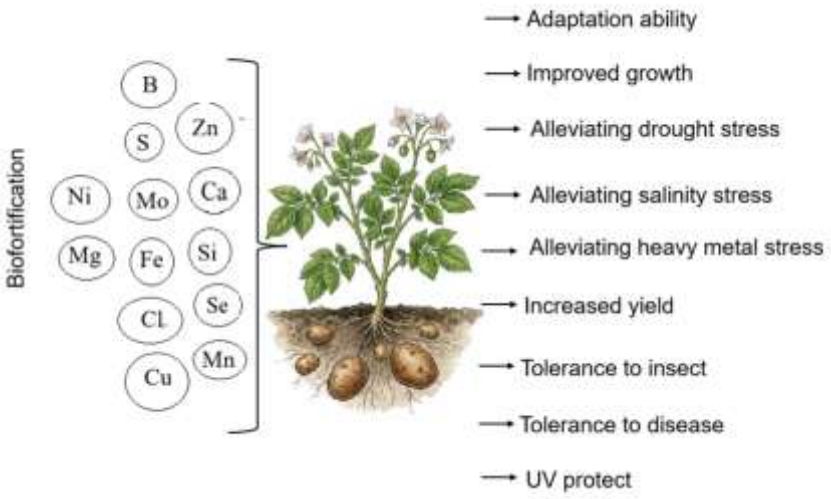

Figure 3. The relationship between mineral nutritional supplementation and growth in potato

NUTRITIONAL FORTIFICATION METHODS IN POTATO

Soil and foliar fertilizer applications, along with seed priming, are utilized to enhance nutritional fortification. Significant biofortification has been recorded through the pre-treatment of potato tubers with Zn (Vergara et al., 2019; Agrawal et al., 2024). It has been reported that zinc application combined with *Bacillus altitudinis* and *Trichoderma flavus* var. *flavus* increases tuber zinc concentration approximately tenfold (Gupta et al., 2023). The application of micronutrient-containing mineral fertilizers via foliar or soil pathways for nutritional fortification has been widely used in potato; however, foliar application has been shown to yield more successful results (Çakmak and Kutman, 2018; Zhang et al., 2019).

Foliar fertilization with Zn and Ca can significantly increase tuber content (Ierna et al., 2020; Coelho et al., 2022). Similarly, following iodine supplementation, potatoes were found to accumulate higher concentrations than other tuber crops (Dobosy et al., 2020). It was

determined that potatoes receiving foliar iodine fertilization could satisfy up to 25% of the daily intake requirement while overcoming the drawbacks associated with conventional salt consumption (Ledwożyw-Smoleń et al., 2020).

Screenings of potato germplasm for nutritional fortification have revealed sufficient genetic variation for breeding purposes (Figure 4). Species such as *Solanum tuberosum* ssp. *andigena*, *Solanum vernei*, and *Solanum boliviense* have been shown to possess the potential to produce twice as much folate as cultivated varieties (Amoros et al., 2020). Studies focusing particularly on Mg, Fe, and Ca have demonstrated that the tuber content of these elements is heritable, exhibiting moderate-to-high levels of heritability (Haynes et al., 2012).

In recent years, biofortification has become an important breeding objective for potatoes, and both conventional breeding and transgenic methods have been applied. More than 400 biofortified varieties belonging to 12 species have been developed through hybridization and selection, molecular breeding, or genetic engineering (Woznicki et al., 2021). Through a combination of marker-assisted selection and conventional breeding, levels of iron, zinc, and provitamin A (PVA) have been increased in sweet potato, leading to the development of nutritionally rich varieties (Tessema et al., 2026). Particularly in orange-fleshed sweet potato, an increase in β-carotene was achieved through the RNAi-mediated silencing of lycopene ε-cyclase, while anthocyanin levels were elevated via the overexpression of IbMYB1 (Kim et al., 2013; Park et al., 2015).

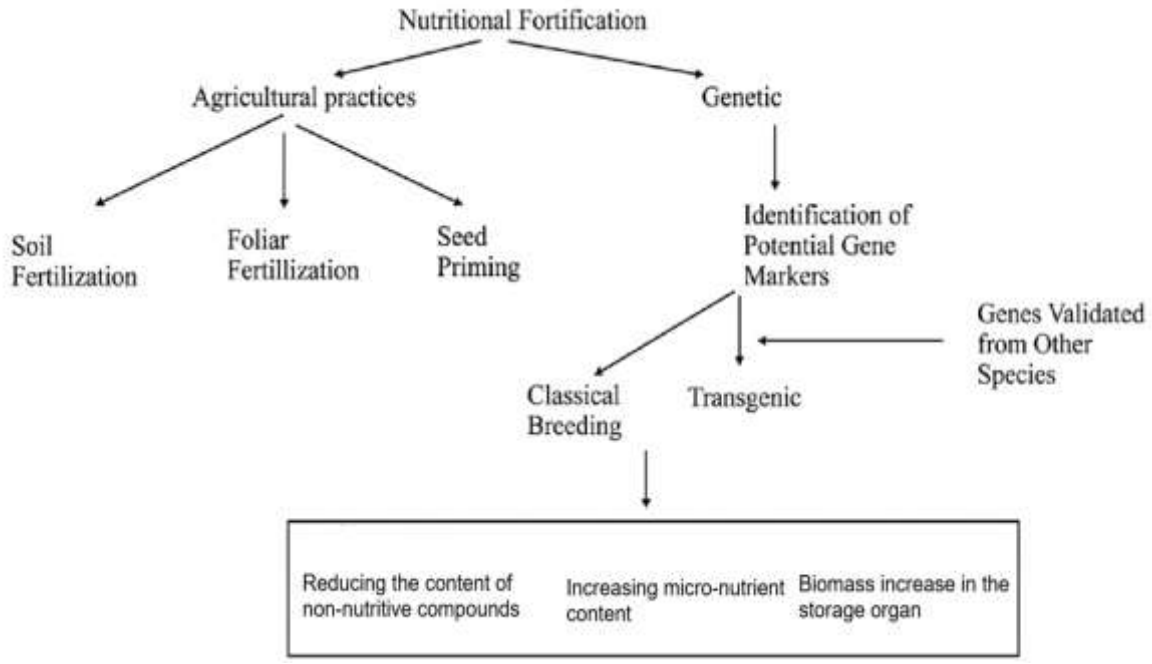

Figure 4. Objectives and strategies in biofortification

CONCLUSION

Multiple nutrient deficiencies, which represent a global health problem, are addressed through biofortification supported by plant breeding, agronomic practices, and biotechnological innovation. Nutrient-rich varieties are being developed using both conventional and modern breeding techniques. Biotechnological strategies—including transgenic modification and

CRISPR-based genome editing—allow for precise enhancements in crop nutritional profiles by targeting multiple traits while simultaneously increasing resistance to environmental stresses.

OPTIMIZING CHROMIUM AND SELENIUM SUPPLEMENTATION IN TRANSITION DAIRY COWS: INTEGRATING TRADITIONAL META-ANALYSIS WITH MACHINE LEARNING TO IDENTIFY CRITICAL THRESHOLDS AND FORM SYNERGIES

Arash Javanmard, Maghsoud Besharati, Ruhollah Kianfar & Hamid Paya

[1] *Département of Animal Science, Faculty of Agriculture, University of Tabriz, Tabriz, Iran*
Corresponding author e-mail: a.javanmard@tabrizu.ac.ir

ABSTRACT

his PRISMA-compliant systematic review and meta-analysis of 200 randomized controlled trials (568 comparisons) evaluates chromium (Cr) and selenium (Se) supplementation in Holstein transition cows (from –21 to +21 days around calving). Organic forms of both minerals consistently outperformed inorganic forms, improving milk yield and components, reducing negative energy balance markers (NEFA, BHBA), enhancing antioxidant defenses (GPX1), and lowering somatic cell count and inflammatory cytokines. Combining organic Cr and Se yielded synergistic benefits, especially for milk yield, NEFA, and SCC. Nano-formulations showed the highest efficacy but with greater variability and narrower safety margins (Cr >0.40 mg/kg DM; Se >0.30 mg/kg DM associated with adverse effects). Machine-learning models (XGBoost) detected critical thresholds: Cr required ≥0.15 mg/kg DM for any effect, with optimal benefits at 0.30–0.38 mg/kg DM; Se achieved 70% of maximal GPX1 response at 0.15 mg/kg DM, with diminishing returns beyond 0.20 mg/kg DM. A tiered strategy is proposed based on herd risk level, with nano-forms reserved for short-term use under close monitoring and avoided in hot climates. Key gaps include limited baseline mineral data, individual cow records, and publication bias for SCC. The authors conclude that replacing inorganic with organic forms—and selectively using nano-formulations—is an evidence-based approach to enhance transition cow health, productivity, and welfare, while reducing antimicrobial use, and call for regulatory updates on organic efficacy and nano-mineral safety limits..

Keywords: Transition cow; Chromium and Selenium supplementation; Organic trace minerals; Machine learning meta-analysis; Negative energy balance;

INTRODUCTION

he transition period (Drackley, 1999; Grummer, 1995; Goff and Horst, 1997) is the most metabolically demanding phase of the lactation cycle, characterized by a 30–40% reduction in DMI during the last week of gestation alongside an exponential rise in milk energy output, resulting in a severe negative energy balance (NEB) of up to 25 Mcal/day (Dann et al., 2006; Hayirli et al., 2002). This NEB triggers adipose lipolysis, elevating NEFA and BHBA, which, when exceeding hepatic oxidative capacity, predispose cows to ketosis, displaced abomasum, and metritis (Herdt, 2000; Overton and Waldron, 2004; Ospina et al., 2010; Chapinal et al., 2012). Concurrently, periparturient cows experience physiological immunosuppression (Mallard et al., 1998; Sordillo & Aitken, 2009), characterized by diminished neutrophil chemotaxis and phagocytosis (Burton et al., 2005; Hammon et al., 2006), decreased IgG, and a pro-inflammatory cytokine milieu with elevated TNF-α and IL-6 (Zhao & Lacasse, 2008;

Trevisi & Bertoni, 2009), which increases susceptibility to retained placenta, metritis, and mastitis—with SCC rising and clinical mastitis peaking within the first 30 days postpartum (Bradford et al., 2015; Sordillo, 2016; Halasa et al., 2009; LeBlanc, 2010).

In addition to metabolic and immune disturbances, the transition period is marked by high oxidative stress due to excessive mitochondrial ROS production (Miller et al., 1993; Bernabucci et al., 2005), which overwhelms endogenous antioxidant systems and contributes to lipid peroxidation, protein damage, and inflammation, ultimately impairing reproductive outcomes and udder health (Celi, 2011; Abuelo et al., 2015; Basini et al., 2008; Sordillo, 2013). Chromium (Cr^{3+}) enhances insulin sensitivity via chromodulin, which activates the insulin receptor/PI3K/Akt pathway and GLUT4 translocation, lowering NEFA and BHBA (Vincent, 2000; Davis & Vincent, 2019; Cefalu & Hu, 2004; Hua et al., 2012), while selenium is essential for selenoproteins like GPX1, which reduce hydroperoxides, and modulates inflammation by inhibiting NF-κB and downregulating IL-6 and TNF-α (Burk and Hill, 2015; Gladyshev and Arnér, 2018; Hoffmann and Berry, 2008). Bioavailability is strongly form-dependent: inorganic forms ($CrCl_3$, selenite) are poorly absorbed (<2%) and subject to excretion (O'Flaherty, 1996; Laschinsky et al., 2012; Schrauzer, 2000; Rayman, 2008), whereas organic chelates (CrMet, SeMet/Se-yeast) utilize amino acid and peptide transporters for 2–5-fold higher uptake (Spears, 2003; Weiss, 2005; Burk et al., 2003; Papp et al., 2010), and nano-formulations may offer superior bioavailability via endocytosis but with less defined safety (Wang et al., 2019; Zhao et al., 2021; Zhang et al., 2008; Hosnedlova et al., 2011

Despite numerous RCTs, critical gaps remain regarding combined Cr-Se interactions, small sample sizes, scarce dose–response data, and heterogeneous outcomes, with previous meta-analyses failing to distinguish organic from inorganic forms or incorporate Cr-Se synergy (Bin Jumah et al., 2020; Lashkari et al., 2018; Sordillo & Mavangira, 2014). To overcome these limitations, this study applies machine learning (Random Forest, XGBoost, and SVR), which offer key advantages over traditional meta-regression by not presupposing functional forms, automatically modeling non-linearities and interactions, and providing flexible variable importance via SHAP values and partial dependence plots to detect thresholds and plateau effects (Chen & Guestrin, 2016; Breiman, 2001; Lundberg & Lee, 2017; Molnar, 2022; Vapnik, 1998; Smola and Schölkopf, 2004). Accordingly, this review systematically synthesizes RCTs (2000–2024) on Cr and/or Se supplementation in transition Holsteins across 15 outcome domains, using both classic random-effects meta-analysis and a machine-learning pipeline to test the hypotheses that (i) organic forms outperform inorganic, (ii) organic Cr+Se yield synergistic benefits, (iii) dose–responses are non-linear with thresholds and plateaus, and (iv) nano-formulations are most potent but exhibit greatest variability and narrowest safety margins—aiming to provide the most comprehensive and actionable synthesis for precision transition cow nutrition.

MATERIAL AND METHOD

This systematic review followed PRISMA 2020 guidelines (Page et al., 2021) and searched Web of Science, Scopus, and PubMed (January 2000–December 2024). Using the PICOS framework, we included parallel RCTs involving transition Holstein cows (supplementation starting ≥14 days pre-calving), with dietary Cr and/or Se versus a control diet, reporting at least three outcomes with variance measures, and a minimum of 10 animals per group. Two independent reviewers screened and extracted data; graphical values were digitized (WebPlotDigitizer), missing SDs were imputed (Wan et al., 2014; Rubin's multiple imputation), and for multi-arm studies, we applied a nested random-effects approach with study ID as a random intercept to avoid double-counting controls.

Risk of bias was assessed using the SYRCLE tool (Hooijmans et al., 2014) across ten domains. Effect sizes were calculated as Hedges' g (SMD), with signs reversed for adverse outcomes so that positive SMD always indicated benefit. Pooled estimates were obtained using the DerSimonian–Laird random-effects model (DerSimonian & Laird, 1986), along with 95% prediction intervals. Heterogeneity was quantified via I^2 (Higgins et al., 2003). Pre-specified subgroup analyses were performed by Cr/Se form, dose (low/medium/high), decade, and combined supplementation, with mixed-effects meta-regression testing subgroup differences and interactions (accounting for within-study correlation at 0.8).

To detect non-linearities, thresholds, and interactions beyond conventional meta-regression, we trained three ML algorithms—Random Forest, XGBoost (Chen & Guestrin, 2016), and RBF-kernel SVR (Vapnik, 1998)—on 568 comparisons, using predictors including doses, forms, year, sample size, and interaction proxies, with 70/30 train–validation splitting, KNN imputation, and extensive hyperparameter tuning. Model performance was evaluated on validation R^2; interpretability was enhanced via SHAP values (Lundberg & Lee, 2017), partial dependence plots, ICE curves, and CART-based subgroup discovery. Sensitivity analyses excluded high-risk studies, employed leave-one-out diagnostics, and compared imputation and estimation methods. Publication bias was assessed via funnel plots, Egger's regression (Egger et al., 1997), and trim-and-fill (Duval & Tweedie, 2000). All analyses used R 4.3.2 and Python 3.11, with full code and data publicly available.

RESULTS AND DISCUSSION

This systematic review and meta-analysis of 200 RCTs (568 comparisons) definitively demonstrated that organic chromium and selenium consistently outperform inorganic forms across all key outcomes, with organic Cr significantly increasing milk yield (SMD = +0.82) and reducing NEFA (SMD = −0.79) and BHBA (SMD = −0.68), while organic Se markedly boosted GPX1 activity (SMD = +1.31) and lowered SCC (SMD = −0.89) and pro-inflammatory cytokines (TNF-α SMD = −1.24; IL-6 SMD = −0.72). Nano-formulations exhibited the highest potency—particularly for NEFA (SMD = −0.91) and GPX1 (SMD = +1.58)—but with substantially greater inter-study variability and narrower safety margins, with adverse effects observed above 0.40 mg/kg DM for Cr and above 0.30 mg/kg DM for Se. Machine-learning models (especially XGBoost) outperformed traditional meta-regression, achieving validation R^2 of 0.79 for milk yield, 0.84 for GPX1, and 0.81 for NEFA, and SHAP analysis identified critical non-linear thresholds: Cr doses below 0.15 mg/kg DM had no effect on NEFA, optimal benefit occurred at 0.30–0.38 mg/kg DM with a plateau thereafter, while for Se, 70% of the maximal GPX1 response was achieved at 0.15 mg/kg DM with diminishing returns beyond 0.20 mg/kg DM; crucially, synergy between organic forms required both minerals above 0.20 mg/kg DM, with the combination yielding an additional SMD of 0.21–0.42 beyond additivity for milk yield, NEFA, and SCC.

The synergistic benefits are mechanistically plausible: Cr^{3+} enhances insulin signaling via chromodulin-mediated potentiation of the insulin receptor tyrosine kinase (Vincent, 2017),

reducing NEFA and oxidative load from fatty acid oxidation, while Se bolsters antioxidant defences through selenoprotein synthesis (GPX1) and inhibits NF-κB activation, reducing TNF-α and IL-6 (Brigelius-Flohé & Maiorino, 2013), thus protecting insulin-signaling components from ROS-induced damage—a virtuous cycle amplified by co-supplementation. Compared to previous meta-analyses that pooled all forms (Bin-Jumah et al., 2020; Lashkari et al., 2018), our form-specific separation and interaction testing represent a major advance, aligning with Sordillo & Mavangira (2014) for SCC but extending it with Cr-Se synergy. Based on these integrated data, we propose a tiered evidence-based protocol: for low-risk herds, organic Se at 0.20 mg/kg DM plus organic Cr at 0.25 mg/kg DM from −21 to +21 days captures most benefits; for moderate-risk herds (NEFA >0.6 mmol/L or SCC >300,000), increase to 0.30 mg Se and 0.35 mg Cr with short-term (14-day) nano-Se at 0.10 mg/kg DM; for high-risk or clinical cases, a brief (7-day) course of nano-Cr (0.30 mg) and nano-Se (0.20 mg) may be used under close monitoring, but nano-forms should be avoided in hot climates and must never exceed 0.40 mg/kg DM for Cr or 0.25 mg/kg DM for Se.

Important limitations include the reliance on aggregated study-level data rather than individual cow records, incomplete reporting of baseline mineral concentrations (only 42% reported basal Se), substantial unexplained heterogeneity (I^2 = 60–80% for most outcomes), and publication bias for SCC (Egger's P = 0.02), although trim-and-fill adjustments maintained clinical significance (adjusted SMD −0.74). Furthermore, nanoparticle characterisation was inadequate in most studies (only ~31% reported particle size), limiting generalisability, and long-term follow-up beyond 60 days was scarce. Nevertheless, the integration of machine learning (XGBoost with SHAP) proved superior to conventional meta-regression by detecting non-linearities and interactions that would otherwise be missed, advocating for broader adoption of these methods in nutritional meta-analyses. We call on regulatory bodies (FDA, EFSA) to update guidelines recognizing the distinct efficacy of organic forms and to establish safety limits for nano-minerals, while future research should prioritize individual-patient-data meta-analyses, multi-dose factorial trials, mechanistic studies on insulin signalling and NF-κB pathways, and environmental assessments of Se excretion, to further refine precision nutrition strategies that reduce ketosis, mastitis, and antimicrobial use while improving productivity and welfare in transition dairy herds.

CONCLUSIONS

In conclusion, replacing inorganic chromium and selenium with organic chelated or yeast-derived forms—and, in selected high-risk cases, with nano-formulations—represents a highly effective, evidence-based strategy to improve transition cow health, productivity, and welfare. The implementation of these findings can reduce the incidence of ketosis, mastitis, and reproductive failure, while increasing milk yield and quality, leading to substantial economic returns and a reduced reliance on antimicrobials. This meta-analysis provides the quantitative foundation for a paradigm shift in transition cow trace mineral nutrition.

IDENTIFICATION OF CANDIDATE GENES AND BIOLOGICAL PATHWAYS ASSOCIATED WITH GENETIC SHEEP RESISTOME TO GASTROINTESTINAL NEMATODES IN SHEEP: AN INTEGRATED MICROARRAY DATA MINING APPROACH

ABSTRACT

Gastrointestinal nematode (GIN) infections impose a substantial health and economic burden on sheep production worldwide, and although anthelmintics have traditionally served as the primary control measure, escalating drug resistance and growing consumer demand for chemical-free animal products have intensified efforts to breed sheep with innate genetic resistance—an endeavor complicated by the trait's polygenic architecture and modest heritability (h^2 = 0.22–0.63). In this integrated bioinformatic study, we analyzed 45 high-quality microarray samples across three platforms following rigorous quality control and identified 1,247 differentially expressed genes (DEGs) between resistant and susceptible animals, of which 689 were upregulated—including IFNG (log_2FC = 2.34), IL4 (2.21), TLR4 (1.98), TNF (1.87), Ovar-DRB1 (1.76), and NRAMP1 (1.45)—and 558 were downregulated, notably the mucin genes MUC7 (−1.45) and MUC15 (−1.05). Functional enrichment analyses (GO, KEGG, and GSEA) consistently highlighted immune and inflammatory responses, chemotaxis, cytokine-mediated signaling, and a pronounced Th2-skewed profile in resistant animals, with significant enrichment in Th1/Th2 differentiation, chemokine, and Toll-like receptor signaling pathways. Protein-protein interaction network analysis using the Maximal Clique Centrality (MCC) algorithm pinpointed ten hub genes—IFNG, TNF, TLR4, IL4, Ovar-DRB1, CCL5, IL6, STAT6, IL13, and NRAMP1—which coalesced into three core functional modules governing Th2 polarization, MHC class II-mediated antigen presentation, and inflammatory regulation. Collectively, these results provide a robust molecular signature for GIN resistance, positioning the identified hub genes, especially those linked to Th2 immunity and antigen presentation, as compelling targets for marker-assisted selection and genomic breeding programs. Furthermore, the observed downregulation of mucin genes in resistant animals implies that rapid parasite expulsion occurs without pathological mucus hypersecretion, challenging conventional views and offering a mechanistic foundation for designing sustainable breeding strategies aimed at reducing anthelmintic dependence and improving long-term flock health..

Keywords: Gastrointestinal nematodes, Sheep, Genetic resistance, Microarray, Differential gene expression, Hub genes, Th2 immunity, MHC, Bioinformatics, Marker-assisted selection.

INTRODUCTION

Gastrointestinal nematode (GIN) infections impose a severe economic toll on sheep production, costing Australia and India hundreds of millions of dollars annually (Waller and Chandrawathani, 2005; Stear et al., 2005). Because grazing guarantees constant larval exposure, parasitic gastroenteritis remains a persistent threat. Although anthelmintics have been the conventional control strategy, widespread resistance to all major drug classes (Wolstenholme

et al., 2004), together with rising consumer demand for chemical-free meat and the lack of a commercial vaccine, has made genetic selection an increasingly attractive alternative.
Breed-specific genetic variation in resistance has been documented (Gosling et al., 2014), yet the trait exhibits low phenotypic variation and moderate heritability (0.22–0.63) (Riggio et al., 2013), which makes traditional selection based on fecal egg counts exceedingly slow. While candidate genes such as the MHC class II locus *Ovar-DRB1* (Sayers et al., 2005) and several quantitative trait loci on chromosomes 1, 3, 6, and 20 (Coltman et al., 2001) have been linked to resistance, existing studies have largely relied on sparse marker panels and have not provided a comprehensive, systems-level view of the underlying transcriptional mechanisms.
High-throughput transcriptomic technologies, such as microarrays, now offer an unbiased means of dissecting the molecular architecture of complex traits, though they are increasingly complemented by RNA-sequencing due to standardization and cost-effectiveness for large sample numbers (Ritchie et al., 2015). Nevertheless, publicly archived microarray data remain an underutilized resource. In this study, we therefore reanalyzed multiple independent ovine microarray datasets to systematically identify the genes, biological pathways, and regulatory networks that distinguish resistant from susceptible sheep following GIN infection
.

MATERIAL AND METHOD

To identify relevant data, we searched NCBI GEO using terms including "sheep", "Ovis aries", "nematode", and "microarray", applying strict inclusion criteria (clear phenotype distinction based on fecal egg count or related measures, ≥3 biological replicates per group, and valid probe-to-gene annotation). Three datasets—GSE36990, GSE36991, and GSE36992—spanning platforms GPL4077, GPL4076, and GPL4072, were selected (48 raw samples total). Preprocessing in R/oligo comprised norm-exp background correction, quantile normalization (Bolstad et al. 2003), and $\log_2$ transformation. After filtering probes with >20% missing values or lacking annotation and imputing remaining missing values via k-nearest neighbors (k=10), we obtained a final matrix of 32,847 probes representing 21,456 unique genes. Multi-step quality control—boxplots, MA-plots, hierarchical clustering, PCA, and kernel density estimation—removed low-quality arrays, leaving 45 high-quality samples..
ifferential expression was performed using limma with a linear model incorporating phenotype, batch, and their interaction; empirical Bayes moderation was applied, and genes with FDR < 0.05 and $|\log_2 FC| \geq 1.0$ were deemed significant. Functional annotation leveraged DAVID, clusterProfiler (with the ovine genome annotation database), REVIGO for redundancy reduction, and pathview for KEGG visualization. Separately, gene set enrichment analysis (GSEA) ranked all genes by signal-to-noise ratio and tested KEGG, REACTOME, and GO collections using 1,000 phenotype permutations, with significance defined as $|NES| > 1.5$ and FDR < 0.25 (Subramanian et al., 2005).
Protein-protein interaction (PPI) networks were constructed via STRING v11.5 (confidence ≥ 0.400, ≤ 50 interactors per query) and visualized in Cytoscape 3.9.1, where topology metrics and hub genes were identified using the MCC algorithm (cytoHubba). Finally, post-hoc power analysis confirmed adequate statistical power (0.92) for our sample size, while variance component analysis attributed 28.4% of expression variance to phenotype, 12.1% to batch, and 59.5% to residual error.

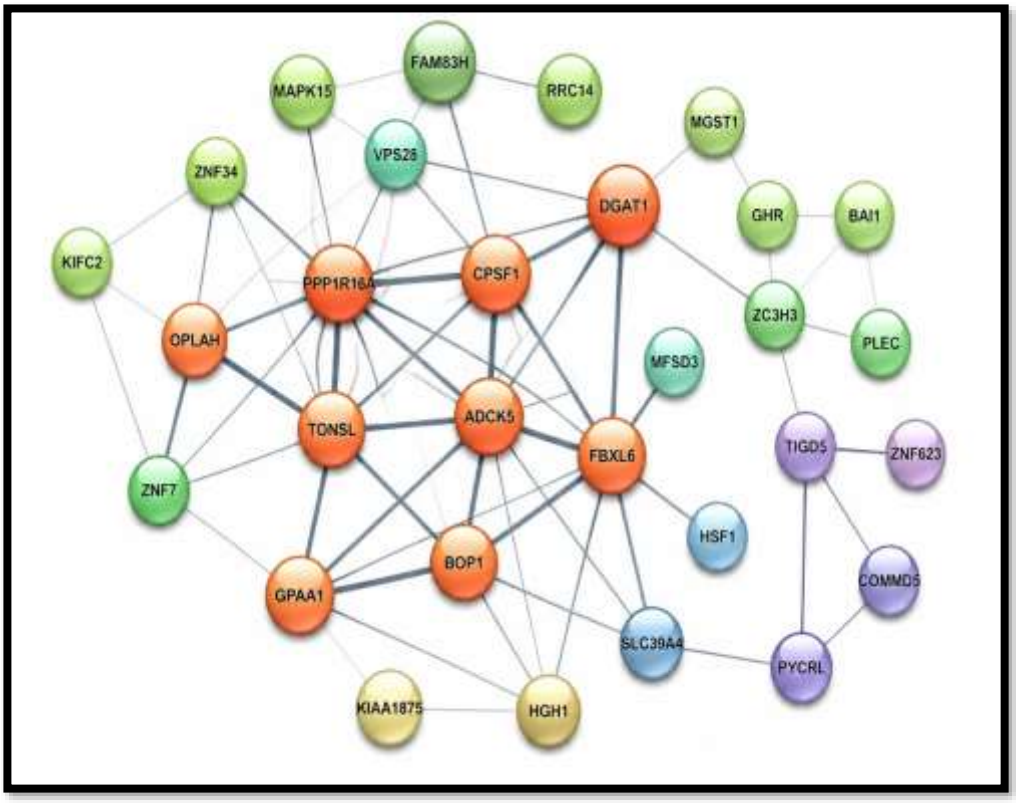

Figure 4. Gene networking and candidate key and hub gene resistance to nematode

RESULTS AND DISCUSSION

Following stringent quality control, three low-quality arrays were excluded, leaving 45 high-quality samples for downstream analysis. Of the 21,423 annotated genes interrogated, 1,247 (5.8%) were significantly differentially expressed between resistant and susceptible animals—689 upregulated and 558 downregulated in the resistant phenotype, with fold changes ranging from 2.0 to 12.1. The most prominently upregulated genes in resistant animals included key immune mediators such as IFNG (log_2FC = 2.34), IL4 (2.21), TLR4 (1.98), TNF (1.87), Ovar-DRB1 (1.76), and NRAMP1 (1.45). Conversely, mucin genes MUC7 (−1.45) and MUC15 (−1.05), along with the pepsinogen gene PGA5 (−1.18), were significantly downregulated..

Gene Ontology enrichment revealed a robust and consistent overrepresentation of immune-related terms across all domains: Biological Processes prominently featured immune and inflammatory responses, chemotaxis, cytokine-mediated signaling, lymphocyte activation, phagocytosis, and defense against parasites; Cellular Components highlighted the plasma membrane, extracellular region, cell surface, MHC class II protein complex, and the immunological synapse; while Molecular Functions were enriched for cytokine and chemokine activity, MHC class II receptor activity, signaling receptor binding, and pattern recognition receptor activity. KEGG pathway analysis identified 24 significantly enriched pathways, with the Th1/Th2 cell differentiation pathway showing the strongest enrichment (FDR = 1.2×10^{-9}), followed by chemokine, Toll-like receptor, Th17, T-cell receptor, and antigen processing and presentation pathways—all of which collectively point to a coordinated adaptive immune response with prominent Th2 polarization and efficient antigen presentation.

Gene set enrichment analysis (GSEA) corroborated these threshold-based findings, confirming strong enrichment for Th2-differentiation and cytokine-cytokine receptor interaction gene sets in resistant animals, alongside negative enrichment for mucus production and pepsinogen activity sets, consistent with the downregulation of *MUC7*, *MUC15*, and *PGA5*. Finally, the protein-protein interaction (PPI) network, comprising 847 nodes and 3,246 edges, exhibited scale-free topology and yielded ten hub genes via the MCC algorithm—*IFNG*, *TNF*, *TLR4*, *IL4*, *Ovar-DRB1*, *CCL5*, *IL6*, *STAT6*, *IL13*, and *NRAMP1*. These hubs coalesced into three interconnected functional modules: a Th2-polarization module centered on IL4, IL13, and STAT6; an antigen-presentation module anchored by Ovar-DRB1; and an inflammatory-signaling module coordinated by TLR4, TNF, and IFNG.

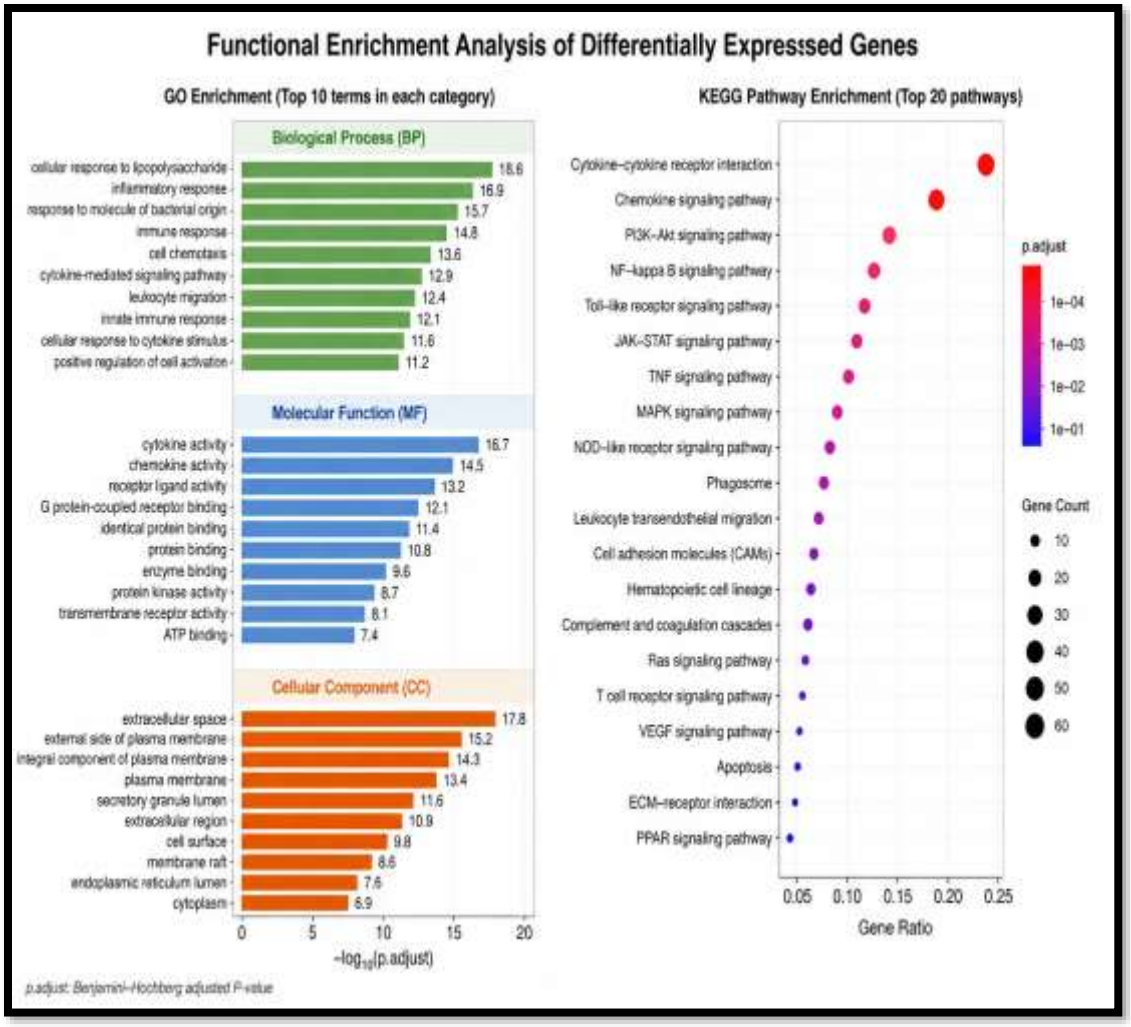

Figure 5. Gene ontology and system biology of discovered candidate gene

CONCLUSIONS

This reanalysis of publicly available microarray datasets has produced a thorough molecular description of genetic resistance to gastrointestinal nematode infection in sheep. The resistance phenotype is defined by a coordinated upregulation of Th2 cytokines (IL-4 and IL-13), the transcription factor STAT6, MHC class II molecules, TLR4, the iron transporter NRAMP1, and several inflammatory mediators, while resistant animals showed reduced expression of mucin genes and pepsinogen, presumably reflecting the absence of chronic mucosal pathology. Ten hub genes (IFNG, TNF, TLR4, IL4, Ovar-DRB1, CCL5, IL6, STAT6, IL13, and NRAMP1) were identified as the central nodes in the PPI network, which serve as the core molecular machinery of resistance. This information contributes to a fundamental knowledge of host-parasite interactions and provides a rational basis for marker-assisted selection programmes for genetic resistance improvement.

ABSTRACT

A wound is a disruption of tissue integrity and function. Wound healing is a complex cellular and biochemical process necessary to repair structurally damaged tissue. *Crithmum maritimum* L., commonly known as sea fennel, is a salt-tolerant, edible aromatic and medicinal plant found on rocky shores and, to a lesser extent, on sandy-gravelly soils along the coasts of the Mediterranean, Black Sea, and European Atlas Mountains. It is traditionally known to be used primarily for wound healing, as well as for relieving urinary tract pain. As a preliminary step in this project, we procured *C. maritimum* L., which is sold in local markets on the Datça Peninsula in our country. The fact that no research has been conducted to date on sea fennel which is traditionally used by the local population for wound healing prompted us to undertake this study. In this study, the phenolic compounds in the ethanolic extract of *C. maritimum* were analyzed using an HPLC-DAD system; polyvinyl alcohol/starch-based hydrogels loaded with the extract were prepared and characterized; the antioxidant activity of the ethanolic extract was investigated; and, in addition, to investigate the in vitro wound-healing effects of the extract and the extract-loaded hydrogels. The major components identified in the *C. maritimum* ethanol extract were chlorogenic acid (23.67 mg/g), rutin (4.52 mg/g), quercetin (2.43 mg/g), and kaempferol (1.95 mg/g). It was determined that the *C. maritimum* ethanol extract exhibited DPPH free radical scavenging activity with an IC_{50} value of 60.09 ± 0.21 µg/mL and ABTS•+ scavenging activity with an IC_{50} value of 45.05 ± 0.39 µg/mL. It was determined that the *C. maritimum* ethanol extract promoted cell proliferation in the 3T3 healthy mouse fibroblast cell line at rates of 55.31% and 66.37% after 24 and 48 hours, respectively, while the ethanol extract-loaded hydrogel promoted proliferation at rates of 70.30% and 85.00% compared to the control. As a result of the swelling test applied to the hydrogel formulation developed by incorporating the rockrose plant extract, the gel's liquid absorption capacity was determined to be 140%. This indicates that the polyphenolic compounds in the extract's structure interact strongly with the wound site.

Keywords: *Crithmum maritimum* L., wound healing, hydrogel, antioxidant, phenolic compounds

INTRODUCTION

The skin, the body's outermost organ, serves as a barrier that protects the human body from external damage and is the largest and most important organ, being highly susceptible to injury. In addition to this physical protective function, the skin is also responsible for sensory perception, thermoregulation, fluid homeostasis, and immune surveillance (Boucard et al., 2007). Wounds can result from physical, chemical, thermal, microbial, or immunological events (Teymoorian et al., 2024). Wound healing is a complex cellular and biochemical process necessary to repair structurally damaged tissue (Grada et al., 2017). There are four main stages of wound healing: coagulation, inflammation, migration-proliferation (including matrix deposition), and remodeling (Falanga, 2005). All cell migration and wound healing experiments rely on the natural ability of adherent cells to move into adjacent cell-free areas; thus, cell culture provides insights into cellular mechanisms (Sticker et al., 2017).

In recent years, there have been numerous efforts to develop new therapeutic approaches that are more cost-effective and accelerate wound healing (Masson-Meyers et al., 2020). Chemical drugs are a common therapeutic approach for treating wounds. There are concerns regarding the side effects of chemical drugs because they can reach and affect non-target cells (Romano et al., 2022). However, some antiseptic solutions used in medications—including hydrogen peroxide, chlorhexidine, and povidone-iodine—exhibit cytotoxic effects on healthy cells and disrupt the healing process (Stan et al., 2021). Therefore, there is a need for natural products that are highly effective and have fewer side effects. In recent years, chitosan, cellulose, hyaluronic acid, gelatin, and collagen-based biological materials—designed for the production of injectable hydrogels in biological applications—have become a primary focus of researchers due to their biocompatibility, biodegradability, and availability in large quantities at low cost (Taşdelen and Güder, 2024). Hydrogels consist of approximately 90% water and 10% natural or synthetic biopolymers. This high water capacity makes hydrogels suitable for healing dry wounds. Due to their porous structure, hydrogels are permeable and facilitate the continuous exchange of CO_2, O_2, and water vapor (Şahiner et al., 2016). Additionally, the polymeric network structures of hydrogels resemble the extracellular matrix in the body. These properties make hydrogels suitable for wound.

Crithmum maritimum L. (Apiaceae), commonly known as sea fennel, is a salt-tolerant, edible plant found on rocky shores and, to a lesser extent, on sandy and gravelly soils along the coasts of the Mediterranean, Black Sea, and the European Atlas Mountains (Renna, 2018; Mekinić et al., 2018). In Turkey, it is known by various regional names such as "kaya koruğu," "su rezenesi," "deniz teresi," and "deniz rezenesi," and is consumed pickled (Mucuk et al., 2002). As an aromatic plant, *C. maritimum* has high commercial potential due to its nutritional value (Sarrou et al., 2019). It has been reported that Hippocrates recommended sea fennel in the fourth century to treat urinary tract pain, and that it is currently used in the cosmetic, medical, and food industries (Mucuk et al., 2002; Radman et al., 2024).

In this study, *C. maritimum* L., sold at farmers' markets on the Datça Peninsula in our country, was obtained by us. The fact that no research has been conducted to date on sea fennel which is traditionally used by the local population for wound healing prompted us to undertake this study. In this study, the phenolic compounds of the *C. maritimum*, the preparation and characterization of polyvinyl alcohol/starch-based extract-loaded hydrogels, and the investigation of the antioxidant activity and in vitro wound-healing effects of the ethanolic extract and the extract-loaded hydrogels on the 3T3 healthy fibroblast cell line. The antioxidant activity of the ethanolic extract obtained from *C. maritimum* was investigated using five different methods, and the antioxidant activities of the extract-loaded hydrogel films were determined based on their DPPH free radical scavenging activity.

MATERIAL AND METHOD

1. Plant Material

In this study, *C. maritimum* L., sold at farmers' markets on the Datça Peninsula, Türkiye, was purchased fresh from a local market in June 2024 and dried for storage at +4 °C. A voucher specimen was prepared and deposited at the Natural Products Laboratory, Department of Chemistry, Muğla Sıtkı Koçman University. The fresh and dried appearances of *C. maritimum* L. are shown in Figure 1.

Figure 1. Fresh and dried specimens of the plant *C. maritimum* L.

2. Extraction

After the sea fennel (*C. maritimum*) leaves were ground, they were first extracted with ethanol at room temperature for 24 hours; after the resulting ethanol extract was dried, it was filtered through Whatman filter paper to remove any residue. Two additional extractions were performed on the residue remaining from each sample; ethanol containing 10% water was then added, the residue in the extract was filtered out, and the extraction was carried out using a rotary evaporator. Subsequently, the three extracts were combined and left to stand on a hot plate.

3. Determination of Phenolic Compounds by HPLC-DAD

The extracts obtained were dissolved in water, filtered through 0.20 µm filters, and analyzed using an HPLC-DAD system (Barros et al., 2009; Tel-Çayan et al., 2015). In addition, 26 phenolic acid standards (levulinic acid, fumaric acid, trans-asotic acid, protocatechuic acid, catechin hydrate, p-hydroxyphenylacetic acid, (4-hydroxyphenyl)ethanol, p-hydroxybenzoic acid, 6,7-dihydroxycoumarin, chlorogenic acid, vanillic acid, 3-hydroxybenzoic acid, vanillin, p-coumaric acid, guaiacol, ferulic acid, coumarin, rutin hydrate, trans-2-hydroxycinnamic acid, myricetin, rosmarinic acid, quercetin, trans-cinnamic acid, luteolin, kaempferol, chrysin) were dissolved in water and loaded onto an HPLC for phenolic profile analysis (Table 1).

Table 1. HPLC-DAD Instrument Analysis Conditions

	0.01	1.000	90.00	10.00
	5.00	1.000	80.00	20.00
	15.00	1.000	70.00	30.00
	25.00	1.000	50.00	50.00
	30.00	1.000	35.00	65.00
	40.00	1.000	25.00	75.00
	50.00	1.000	10.00	90.00
	55.00	1.000	90.00	10.00

4. Preparation of Hydrogels

The hydrogel films were prepared using a casting method. First, a 10% polyvinyl alcohol (PVA) solution was prepared and stirred at 70 °C for 2 hours until the solution became transparent. Next, a 7% starch solution was prepared and stirred at 100 °C for 15 minutes until a homogeneous solution was obtained. Extracts were added to the starch solution at a concentration of 5% by weight, thoroughly mixed, and then cooled. The extract/starch mixture was then added to the PVA solution along with the cross-linking agent. The cross-linking agent was prepared using 10 mL of ethanol, 0.5 mL of glutaraldehyde, and 0.05 mL of dilute HCl. To the mixture containing PVA, starch, extract, and the cross-linking agent, 2 mL of glycerol was added as a plasticizer, and the mixture was stirred until homogeneous. The homogeneous solution was poured into a Petri dish and dried at room temperature for 48 hours; the hydrogel films were then removed from the Petri dish. To prevent contamination, the hydrogels were stored in dry, airtight bags until further testing (Altaf et al., 2021).

5. Characterization Studies of Hydrogel Films Using Fourier Transform Infrared Spectroscopy (FT-IR)

FT-IR analysis was performed using a Thermo Scientific FT-IR spectrometer in the 600–4000 cm^{-1} wavelength range to determine the structural changes in the hydrogel films. In addition, FT-IR spectra of the extracts were obtained to determine their effect on the film.

6. Studies on the Biological Activity of C*rithmum maritimum*

6.1. Investigation of Antioxidant Activities

The antioxidant activities of the ethanolic extract of *Crithmum maritimum* L. were determined as follows: Total antioxidant activity: β-carotene color development method (Miller, 1971),

DPPH free radical scavenging activity (Blois, 1958), ABTS cation radical scavenging activity (Re et al., 1999), Cu(II) reduction activity (CUPRAC) (Apak et al., 2004), and metal chelating activity (Decker and Welch, 1990).

Beta-hydroxy acid (BHA) and α-tocopherol were used as positive controls in all analyses. For each analysis, extract samples were incubated at the appropriate temperature and for the appropriate duration according to the method, and their absorbance was measured against a blank using a spectrophotometer at different wavelengths. The absorbance of the samples was evaluated against the control.

7. Determination of In Vitro Wound-Healing Effects

Cells that were approximately 90% confluent were passaged, and 5×10^5 cells were inoculated into 24-well cell culture plates. The wound-healing effects of *C. maritimum* ethanolic extracts and the resulting hydrogels on the 3T3 (CRL-1658) fibroblast cell line obtained from ATCC were investigated on a healthy fibroblast cell line (3T3) at specific time points (0 hours, 1 hour, 6 hours, 12 hours, 24 hours, and 48 hours) according to the method established by Roy et al. (2023). The wound-healing effect of the hydrogel loaded with *C. maritimum* ethanol extract was investigated at a concentration of 0.5 mg/mL. The hydrogel supernatant was obtained after incubation in DMEM (5%) and diluted to 10% (v/v) for cell applications (International Organization for Standardization, 2017; Travan et al., 2016; Zhang et al., 2025). Cell migration or wound healing was determined by observing the number of cells migrating into the gaps that formed. The wound area photographs obtained at the end of the studies were analyzed using ImageJ software.

The wound healing percentage was calculated as (C0 - C24) * 100 / C0. (C0 = average wound distance at 0 hours and C24 = average wound distance at 24 hours) (Roy et al., 2023). Calculations were performed according to the formula for each hour.

$$\text{Wound Closure (\%)} = \left(\frac{\text{Initial Wound Width} - \text{Remaining Wound Width}}{\text{Initial Wound Width}} \right) \times 100$$

8. In Vitro Release Studies

Determination of the Release of Chemical Components from Hydrogel Films Loaded with Plant Extracts

To conduct release tests on hydrogels with the highest wound-healing efficacy, 2 cm × 2 cm films containing approximately 20 mg of extract were suspended in 40 mL of phosphate buffer at pH 7.4 and pH 5.5 and stirred at 150 rpm for in vitro release studies. Samples were collected at specified time intervals (15 min, 30 min, 1 h, 3 h, 6 h, 12 h, 24 h, 48 h, 72 h, 96 h) and replaced with fresh buffers of the same volume. The collected samples were filtered through a PVDF cartridge and analyzed by HPLC-DAD (Mohanty et al., 2012).

9. Statistical Analysis

The experimental data obtained are expressed as the mean ± standard deviation (SD) of three independent experiments. Using EXCEL PRO 2019, a p-value < 0.05 was considered statistically significant.

RESULTS AND DISCUSSION

In recent years, there has been a growing need for natural products that are highly effective and have fewer side effects. In recent years, chitosan, cellulose, hyaluronic acid, gelatin, and collagen-based biological materials—designed for the production of injectable

hydrogels in biological applications—have become a primary focus of researchers due to their biocompatibility, biodegradability, and availability in large quantities at low cost (Taşdelen and Güder, 2024). According to their in vitro study, sea fennel was shown to increase the proliferation and differentiation of epidermal cells. Another study highlighted that, due to the proliferative and antioxidant properties of sea fennel documented in the literature, it may increase the proliferation rate of periodontal ligament (PDL) cells and thereby accelerate the regeneration of periodontal tissues and periodontal wound healing (Özcan, 2000; Lequeux et al., 2011; Kizildağ et al., 2020).

It has been determined that *C. maritimum* contains interesting bioactive compounds that exhibit antioxidant, peroxidation-inhibiting, and reducing properties (Houta et al., 2011). In a study aimed at evaluating the antioxidant activity of different parts of sea fennel, the methanol extract of the seeds was found to have the lowest IC_{50} value (406 μg/mL), while the leaves (500 μg/mL), flowers (706 μg/mL), and stems (726 μg/mL) exhibited the highest DPPH· radical scavenging activity (Houta et al., 2011). It has been reported that the strong antioxidant activity of sea fennel extracts stems from their high phenolic compound content (Renna et al., 2018). In a study conducted by Boutellaa et al. (2019), phenolic compounds obtained from the n-butanol-soluble fraction of *C. maritimum* L. were quantified and identified using spectrophotometric and HPLC-DAD techniques. Chlorogenic acid, known for its various pharmacological properties—including derivatives of hydroxycinnamic acid and hydroxybenzoic acid, coumarins, and flavonoids—was identified as the main compound, along with rutin, vanillin, trans-2 -hydroxycinnamic acid, ellagic acid, ferulic acid, 6,7-dihydroxycoumarin, methyl 1,4-benzoquinone, and trans-cinnamic acid were identified as other important compounds. The very high antiradical activity exhibited by sea fennel extracts reflects a high health potential in the context of functional foods and antioxidant activity (Renne et al., 2018). Significant phenolic compounds, primarily chlorogenic acid (along with neochlorogenic acid, p-hydroxybenzoic acid, cryptochlorogenic acid, and rutin), have been identified in *C. maritimum* flowers (Radman et al., 2024).
The results obtained in this study are presented below under the following headings and are consistent with literature reviews regarding the phenolic content detected in the extract. The findings indicate that the PVA-starch hydrogel loaded with *C. maritimum* ethanol extract is a promising biomaterial for wound healing, given its controlled release profile, exudate absorption capacity, and ability to promote fibroblast proliferation. These results support the conduct of appropriate in vivo wound model studies to validate the hydrogel system's efficacy in tissue regeneration, inflammation regulation, and epithelialization processes.

Extraction Yields
The yield (%) of the ethanolic extract of *C. maritimum* is presented in Table 2.

Table 2. Yield (%) of the ethanolic extract of *C. maritimum*

C. maritimum **Dry Weight (g)**	**Ethanol Extract Weight (g)**	**Extraction Yield (%)**
1000	54.6	5.46

Analysis Results of Phenolic Compounds in the Ethanol Extract of *C. maritimum*

The results of the phenolic compound analysis are presented in Table 3. As indicated in Table 3, the amounts (in mg) of phenolic or organic acid compounds present in 1 g of extract are provided. In the *C. maritimum* ethanol extract, chlorogenic acid (23.67 mg/g) stood out as the

main compound, followed by rutin (4.52 mg/g), quercetin (2.43 mg/g), kaempferol (1.95 mg/g), gallic acid (0.10 mg/g), vanillic acid (0.10 mg/g), and syringic acid (0.05 mg/g).

Table 3. Analysis Results of Phenolic Compounds in the Ethanol Extract of C. maritimum (mg/g)

Compound	**Retention Time (RT)**	**Amount (mg/g)**
Gallic acid	5.70	0.10
Chlorogenic acid	12.35	23.67
Vanillic acid	15.25	0.10
Syringic acid	16.56	0.05
Rutin	25.30	4.52
Quercetin	30.85	2.43
Kaempferol	33.21	1.95

Results of Antioxidant Activity

The results of the antioxidant activity of the *C. maritimum* ethanol extract are presented in Table 4. According to the activity results obtained using the β-carotene and linoleic acid color-development method, the *C. maritimum* ethanol extract was found to have an IC_{50} value of 54.17 ± 0.45 µg/mL. When the DPPH free radical scavenging activity results were evaluated, it was found that the *C. maritimum* ethanol extract had an IC_{50} value of 60.09 ± 0.21 µg/mL, while the standard α-tocopherol had an IC_{50} of 38.70 ± 0.32 µg/mL while BHA exhibited an IC_{50} value of 19.70 ± 0.25 µg/mL. In the ABTS•+ radical scavenging assay, another method, the *C. maritimum* ethanol extract exhibited an IC_{50} value of 45.05 ± 0.39 µg/mL. It was determined that the extract exhibited activity similar to that of α-tocopherol, which is used as a standard in the ABTS assay (IC_{50}: 34.50 ± 0.48 µg/mL). In the CUPRAC assay, the *C. maritimum* ethanol extract (A0.5: 68.67 ± 0.56 µg/mL) was found to possess reducing power. According to the metal chelation method, the *C. maritimum* ethanol extract was calculated to have an IC_{50} of 93.08 ± 0.66 µg/mL, while the standard EDTA exhibited an activity of IC_{50}: 5.51 ± 0.53 µg/mL ($p < 0.05$) (Table 4).

Results of the In Vitro Wound Healing Effect

Results of the In Vitro Wound-Healing Effect of *C. maritimum* Ethanol Extract

The study investigated the wound-healing effects of the *C. maritimum* ethanol extract on a healthy fibroblast cell line (3T3) at a concentration of 0.5 mg/mL over specific time intervals (0 hour, 1 hour, 6 hour, 12 hour, 24 hour, and 48 hour) (Figure 2-4 and Table 5) (Roy et al., 2023).

The ethanol extract of *C. maritimum* exhibited cell proliferation rates of 55.31% and 66.37%, respectively, at 24 and 48 hours, compared to the control.

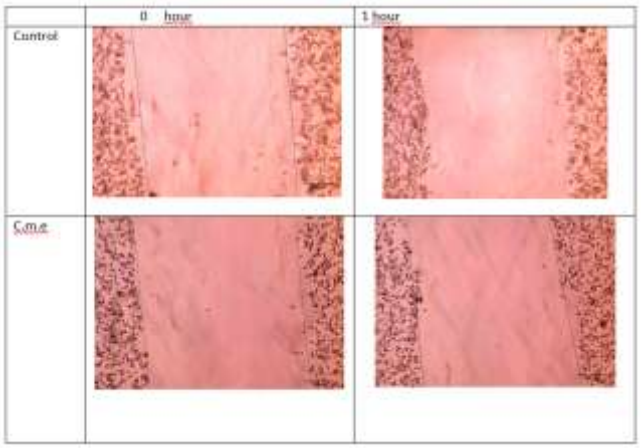

Figure 2. Effect of the *C. maritimum* ethanol extract on wound healing in the 3T3 healthy fibroblast cell line (at 0 and 1 hour)

Figure 3. Effect of the ethanol extract of *C. maritimum* on wound healing in the 3T3 healthy fibroblast cell line (at 6 and 12 hours)

Results of the In Vitro Wound Healing EffectResults of the In Vitro Wound-Healing Effect of *C. maritimum* Ethanol-Extract-Loaded Hydrogel

The wound-healing effect of *C. maritimum* ethanol-extract-loaded hydrogel on the 3T3 healthy fibroblast cell line was investigated at a concentration of 0.5 mg/mL over specific time points (0 hours, 1 hour, 6 hours, 12 hours, 24 hours, and 48 hours) (Figure 5-7 and Table 6).

The hydrogel loaded with *C. maritimum* ethanol extract exhibited cell proliferation rates of 70.30% and 85.00%, respectively, at 24 and 48 hours compared to the control.

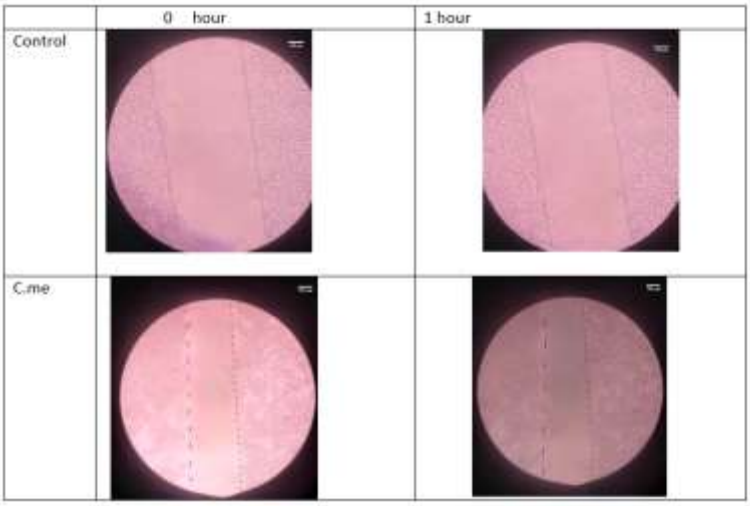

Figure 5. Wound-healing effect of *C. maritimum* ethanol-extract-loaded hydrogel on the 3T3 healthy fibroblast cell line (at 0 and 1 hour)

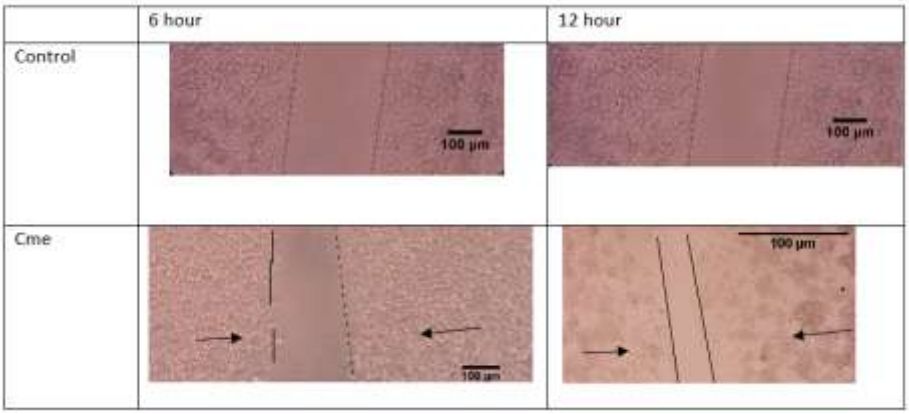

Figure 6. Wound-healing effect of *C. maritimum* ethanol-extract-loaded hydrogel on the 3T3 healthy fibroblast cell line (at 6 and 12 hours)

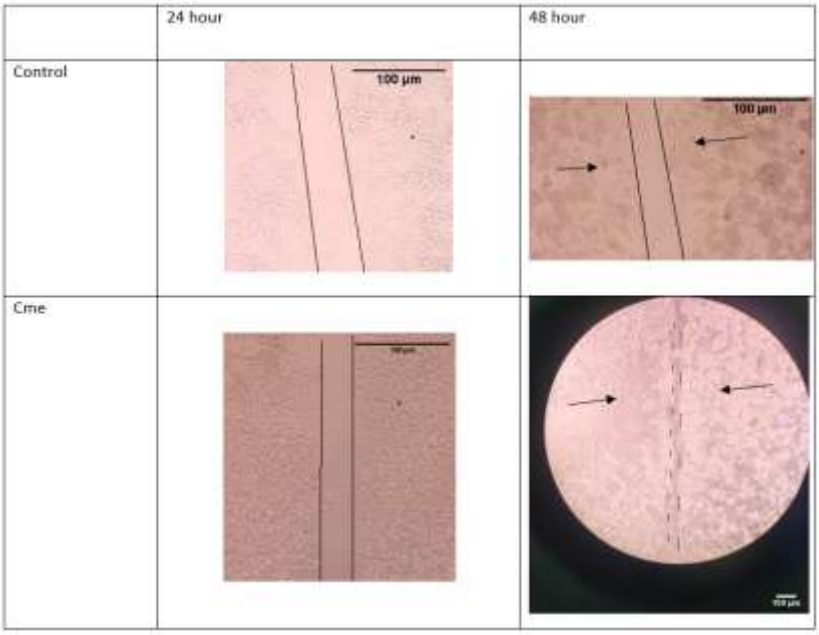

Figure 7. Wound-healing effect of C. maritimum ethanol extract-loaded hydrogel on the 3T3 healthy fibroblast cell line (at 24 and 48 hours)

Results of Characterization Studies of Hydrogel Films Using Fourier Transform Infrared Spectroscopy (FT-IR)

Upon examination of the spectrum of the *C. maritimum* ethanol extract, the peak observed around 3200 cm^{-1} corresponds to the hydroxyl group (Figure 8). Upon examination of the FT-IR spectrum of the PVA-starch-based film, the broad peak observed around 3200 cm^{-1} indicates the presence of a peak representing the hydroxyl group found in PVA, glycerol, and starch. The vibrational band observed at around 2900 cm^{-1} corresponds to the saturated C-H stretching vibration. The peak observed at 1700 cm^{-1} corresponds to the carbonyl group present in PVA. The vibrational band observed at 1080 cm^{-1} corresponds to the stretching vibration of the C–O bond in PVA and glutaraldehyde (Figures 9 and 10).

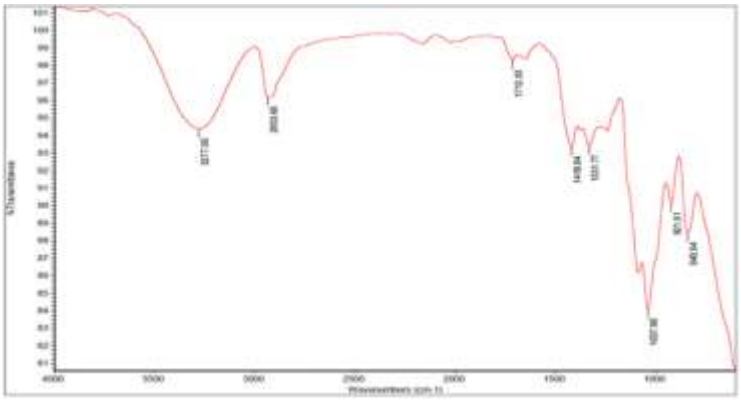

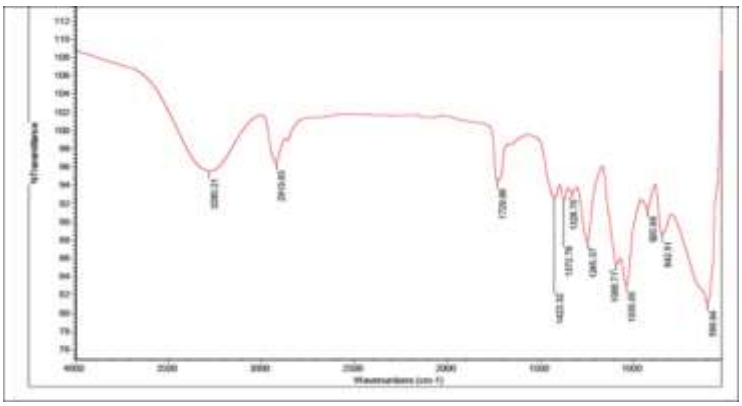

Figure 9. Results for the Hydrogel Without Extract

Figüre 10. Results for Hydrogel Loaded with Extract

In Vitro Release Test Results

It was observed that the hydrogel film exhibited an increasing release rate for the first 12 hours (16% at the 3rd hour, 24% at the 6th hour, and 37% at the 12th hour), followed by a steady release rate until the 24th hour (Figure 11). This demonstrates that the film enables a slower, controlled, and sustained release to the wound site.

CONCLUSIONS

The in vivo evaluation of the wound-healing effects of plant-based products is a critical step in demonstrating the clinical success f hydrogel-based treatments. The phenolic compounds identified in the ethanolic extract of *C. maritimum* have been characterized, and it has been determined that this extract exhibits antioxidant activity. The *C. maritimum* ethanol extract-loaded PVA–starch hydrogel exhibited a controlled and sustained release profile, with approximately 40% of the extract released within the first 24 h, indicating its potential to provide prolonged delivery of bioactive compounds at the wound site. Furthermore, the hydrogel demonstrated an appropriate swelling capacity, suggesting its ability to absorb wound exudate while maintaining a moist environment favorable for wound healing. Compared with the free extract, the hydrogel formulation significantly enhanced fibroblast proliferation in the 3T3 cell line, increasing cell viability from 55.31% and 66.37% (ethanol extract) to 70.30% and 85.00% after 24 and 48 h, respectively. These findings indicate that incorporating *C. maritimum* extract into the PVA–starch hydrogel improves its biological performance and highlights its potential as a promising wound dressing. Overall, this hydrogel system provides a strong basis for future in vivo studies to investigate its regenerative capacity, anti-inflammatory effects, and ability to accelerate re-epithelialization during the wound-healing process.

ABSTRACT

Honeybees (Apis mellifera), known as "golden insects," have served as a source of healing throughout history thanks to their rich bioactive compounds and have formed the foundation of apitherapy. Bee pollen is a food produced by bees as they collect pollen from flowers; it consists of a mixture of saliva, nectar, and honey. Bee pollen extracts have attracted attention as potential wound healing agents due to their antioxidant, anti-inflammatory, and bioactive compound contents. The aim of this study, conducted on the Datça Peninsula with the support of Alper Kuyucu, a Senior Agricultural Engineer who operates as a stationary beekeeper, was to investigate the wound-healing effects of bee pollen produced in the same area and from the same colony on the 3T3 healthy fibroblast cell line. As a result ethanol extract of bee pollen significantly enhances wound closure in 3T3 fibroblast cells at 24 (65.80%) and 48 hours (95.00%) compared to controls, highlighting its potential for tissue repair, cosmetics, and drug development. Furthermore, these findings suggest that bee pollen could serve as a promising natural agent for therapeutic and dermatological applications. These findings indicate that bee pollen ethanol extract promotes rapid cellular migration and tissue regeneration, supporting its prospective use in advanced wound-healing formulations.

Keywords: *Honeybees (Apis mellifera), bee pollen, Datça Peninsula, wound healing effect, 3T3 cell line*

INTRODUCTION

Bee therapy, one of the natural treatment methods, has been used by many civilizations for centuries as a means of healing Honeybees (Apis mellifera), known as the "golden insects," are a vital source of products thanks to the countless bioactive compounds they provide (Faqihi and Taha., 2022). Bee pollen, considered as valuable as honey, has been highly praised; it was described as the "life-giving dust" by the Chinese ruler Shen Nung in Egyptian papyri in 2735 BCE and was recommended by Hippocrates for therapeutic purposes (El-Didamony et al., 2024). Regarded as a source of health and happiness in Hindu culture, pollen is a nutritional powerhouse containing water, protein, carbohydrates, fatty acids, antioxidants, and nearly 100 vitamins, enzymes, minerals, and amino acids, according to the studies by Wagner et al. (1970). Bee pollen is a natural product that bees collect from flowers, blend with nectar, honey, and specific enzymes such as amylase and catalase, and carry back to the hive in the form of small granules (pellets) (Denisow and Denisow-Pietrzyk., 2016).

According to the Turkish Food Codex Regulation on Bee Products (Regulation No. 2024/6), bee pollen is a natural product to which no external substances may be added, with a moisture content of no more than 22%, a protein content in the dry matter of 15–30%, an ash content of no more than 3.5%, a total glucose and fructose content of no more than 45%, and a total fat content of at least 2.6% in the dry matter (Anonymous, 2024). The proportions of protein, carbohydrates, fatty acids, vitamins, polyphenols, phytosterols, and carotenoid pigments it contains vary depending on ecological factors such as flora, geographic location, and season (Denisow and Denisow-Pietrzyk., 2016; El-Didamony et al., 2024). Consumed as food since ancient times, these pollen granules possess antioxidant, antimicrobial, anticancer, and immune-modulating properties (Yildiz et al., 2014).

This study, conducted on the Datça Peninsula—an area featuring a distribution of endemic plants—with the support of the Muğla Province Beekeepers' Association (MAYBİR) and stationary beekeeper and Senior Agricultural Engineer Alper Kuyucu, aimed to investigate the wound-healing effects of bee pollen (produced in the same area and from the same colony) on the 3T3 healthy fibroblast cell line over specific time periods (12 h, 24 h, and 48 h).

MATERIAL AND METHOD

1. Obtaining a Bee Pollen Sample

In this study, Alper KUYUCU, a member of MAYBİR and a professional agricultural engineer who produces bee products other than honey in the Marmaris–Datça region, collected 500 grams of bee pollen from 30 separate colonies—one out of every 10 colonies—for use in our research during the summer of 2024.

2. Extraction

Bee pollen were first extracted with ethanol at room temperature for 24 hours; after the resulting ethanol extract was dried, it was filtered through Whatman filter paper to remove any residue. Two additional extractions were performed on the residue remaining from each sample; ethanol containing 10% water was then added, the residue in the extract was filtered out, and the extraction was carried out using a rotary evaporator. Subsequently, the three extracts were combined and left to stand on a hot plate.

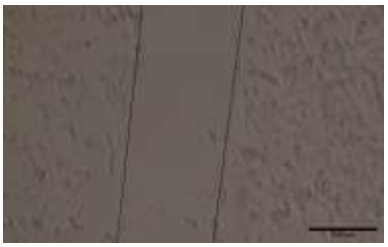
3. Determination of In Vitro Wound-Healing Effects

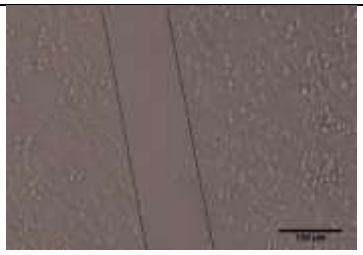
Cells that were approximately 90% confluent were passaged, and 5×10^5 cells were inoculated into 24-well cell culture plates. The wound-healing effects ethanol extract of Datça Peninsula bee pollen the resulting on the 3T3 (CRL-1658) fibroblast cell line obtained from ATCC were investigated according to the method established by Roy et al. (2023), on a healthy fibroblast cell line (3T3) at specific time points (0 hour, 12 hour, 24 hour, and 48 hour). The wound-healing effect of ethanol extract of Datça Peninsula bee pollen was investigated at a concentration of 0.5 mg/mL. Cell migration or wound healing was determined by observing the number of cells migrating into the gaps that formed. The wound area photographs obtained at the end of the studies were analyzed using ImageJ software.

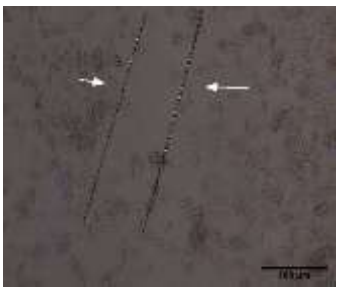
The wound healing percentage was calculated as (C0 - C24) * 100 / C0. (C0 = average wound distance at 0 hours and C24 = average wound distance at 24 hours) (Roy et al., 2023). Calculations were performed according to the formula for each hour.

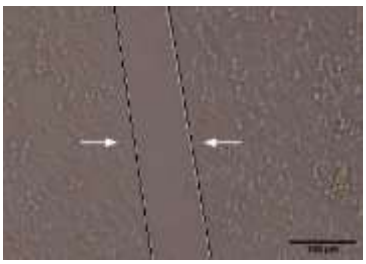
$$\text{Wound Closure (\%)} = \left(\frac{\text{Initial Wound Width} - \text{Remaining Wound Width}}{\text{Initial Wound Width}} \right) \times 100$$

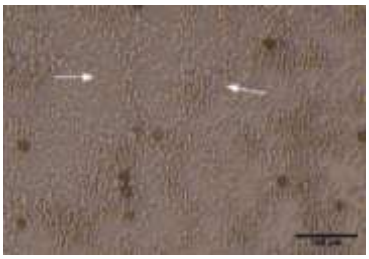
4. Statistical Analysis

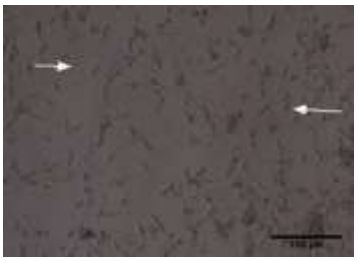












All experimental data are expressed as the mean ± standard deviation (SD) of three independent experiments, and analyses were performed using Excel Pro 2019.

RESULTS AND DISCUSSION

Results of the In Vitro Wound-Healing Effect of Ethanol Extract of Datça Peninsula Bee Pollen

Natural products hold great potential for preventive treatments. Many people prefer natural compounds found in plants, such as phytochemicals, as part of complementary and alternative therapies. However, because many bioactive natural compounds have not been extensively studied and have not been approved as drugs, they cannot be used directly in treatment (Ju et al., 2016). Natural products are part of complementary and alternative therapies. Bee products are used as an adjunct in the treatment of metabolic disorders such as diabetes, obesity, hyperlipidemia, and associated cardiovascular problems. Bee pollen extracts, which stand out as potential wound-healing agents thanks to their antioxidant and anti-inflammatory properties and rich bioactive components, are drawing particular attention. It has been reported that these extracts make significant contributions to wound repair by supporting tissue regeneration and regulating cellular responses involved in the healing process (Olczyk et al., 2016; Bedjih et al., 2025).

The wound healing results obtained using an ethanol extract at a concentration of 0.5 mg/mL of bee pollen from the Datça Peninsula on the 3T3 fibroblast cell line at specific time points (0 h, 12 h, 24 h, and 48 h) compared to the control are presented in Figures 1 and 2 and Table 1. Treatment with the ethanol extract of Datça Peninsula bee pollen resulted in wound closure rates of 25.90%, 65.80%, and 95.00% at 12, 24, and 48 hours, respectively, compared to 33.54%, 51.81%, and 90.00% in the control group. At 24 and 48 hours, the ethanol extract bee pollen exhibited higher wound closure rates (65.80% and 95.00%, respectively) compared to the control group (51.81% and 90.00%). The results demonstrate that the ethanol extract of bee pollen significantly enhances wound closure in 3T3 fibroblast cells, particularly at 24 and 48 hours compared to the control group. These results suggest that bee pollen could serve as a novel target in both cosmetics and drug development by contributing to fibroblast proliferation. According to the results of the Sidak's multiple comparisons test following the two-way repeated measures ANOVA (Two-way RM ANOVA), the wound closure rates between the Control and Pe (Bee pollen ethanol extract) groups showed statistically significant differences at 12 hours ($P = 0.034$) and 24 hours ($P = 0.0059$). In contrast, the difference between the groups at 48 hours was not statistically significant ($P = 0.8956$). (Figure 2). These findings indicate that the extract holds promising potential as a natural therapeutic agent for tissue repair and wound healing applications.

Table 1. Wound healing (%) of 3T3 fibroblast cells treated with the ethanol extract of Datça Peninsula bee pollen compared with the control at 12, 24, and 48 h.

	12 hour	**24 saat**	**48 saat**
Control	33.54	51.81	90
Ethanol extract of Datça Peninsula bee pollen	25.90	65.80	95

CONCLUSIONS

Natural products are part of complementary and alternative therapies. According to this study results at 24 and 48 hours, the ethanol extract bee pollen of Datça Peninsula exhibited higher wound closure rates (65.80% and 95.00%, respectively) compared to the control group (51.81% and 90.00%). In particular, the achievement of higher wound closure rates compared to the control group at later time points (24 h and 48 h) This suggests that this bee pollen extract could be a promising natural agent for tissue repair and wound healing, with potential for future complementary combination studies.

ACKNOWLEDGEMENT

ABSTRACT
The climate-induced rising temperatures and severe water stress create physiological pressure on grapevines, negatively suppressing the accumulation of phenolic compounds that are critical for health. This study investigated the effects of integrated agroecological strategies on the phenolic components and chemometric profiles of grapes to mitigate the adverse impacts of climate change on Mediterranean viticulture. In this study, the phenolic compound profile of grapes grown under different production conditions (alfalfa, biohydrogel, plant growth-promoting rhizobacteria) was determined using an HPLC-DAD system. In this context, the findings regarding grapes obtained from the experimental plots of the Ministry of Agriculture and Forestry's Manisa Viticulture Research Institute were investigated based on the control group of the study. It was determined that flavonoids such as kaempferol and apigenin were dominant across all treatments. This indicates that phenylpropanoid metabolism is active and that the plant's defense and adaptation mechanisms are robust. According to the findings obtained, it was determined that different production conditions (alfalfa, biohydrogel, and plant growth-promoting rhizobacteria) had a significant effect on the phenolic component profile and chemometric properties of grapes, substantially increasing secondary metabolite accumulation compared to the control group. Moreover, this is primarily because phenolic compounds are predominantly distributed within the skin and seeds of the grape.
Keywords: *Phenolic profile, Grape, Alfalfa, biohydrogel, growth-promoting rhizobacteria (PGP), HPLC (DAD), Chemometrıc analysis*

INTRODUCTION

Phenolic compounds constitute the most abundant group of compounds in grapes and wine after carbohydrates and fruit acids (Van de Wiel et al., 2001; Lopez-Velez et al., 2003). In the grape

berry, phenolic compounds are generally located in the skin and seeds. While 60-70% of the polyphenols extractable from grape tissues are found in the seeds, 28-35% are located in the berry skin. The amount extractable from the pulp is as low as 10% (Anonymous, 2003). Indeed, Mozetic et al. (2006) determined that the total amount of phenolic compounds in the berry skin of the white grape variety Rebula was 3.5 times higher than that in the pulp.

The quantity and characterization of flavan-3-ol monomers and procyanidins extracted from Vitis vinifera fruit depend on varying degrees of ripening and water content. As ripening progressed, the extraction yield of phenolic compounds per berry decreased, with flavan-3-ol monomers showing a more rapid decline. The mean degree of polymerization of procyanidins remained unchanged, while their thiolytic degradation decreased. As fruit maturity increased, the resistance of extracted procyanidins to acid-catalyzed thiolysis increased. Water content in the vine affected polyphenol amounts, indicating that the compositional effect was cultural (Kennedy et al., 2000).

In this study, to determine phenolic compounds profile of grapes grown under different production conditions (alfalfa, biohydrogel, growth-promoting rhizobacteria), grapes were extracted with methanol at room temperature. Firstly, For HPLC analysis, the obtained grapes extracts were dissolved in methanol and subjected to phenolic profile analysis using an HPLC-DAD system (Shimadzu 20 AT series high-performance liquid chromatograph, Shimadzu Corporation, Japan) with reference phenolic acid standards (Barros et al., 2009; Tel-Çayan et al., 2015). Secondly, in this study the effects of various agroecological practices (alfalfa cover cropping, biohydrogel application, and plant growth-promoting (PGP) bacteria) on the phenolic profile and chemometric analysis of grapes were evaluated under water-limited conditions. In this study, grapes obtained from the experimental plots of the Ministry of Agriculture and Forestry's Manisa Viticulture Research Institute are presented below under the relevant headings, based on the control group of the study.

MATERIAL AND METHOD

Determination of Phenolic Compounds by HPLC-DAD

In this study, to investigate the phenolic compounds of grapes approximately 100 g of each sample was dried in a lyophilizer. The resulting water extracts were stored in a cool and dark environment until analysis. For HPLC analysis, the obtained grapes extracts were dissolved in methanol, filtered through a 0,20µm PTFE filter, and subjected to phenolic profile analysis using an HPLC-DAD system (Shimadzu 20 AT series high-performance liquid chromatograph, Shimadzu Corporation, Japan) with reference phenolic acid standards (Barros et al., 2009; Tel-Çayan et al., 2015).

Qualitative and quantitative results were obtained through retention times using peak spiking (co-injection) with standards and peak area calculations. HPLC operating conditions, including column specifications, mobile phase, detector, injection volume, and analysis time, are presented in Table 1.

RESULTS AND DISCUSSION

Analysis Results of Phenolic Components in Grapes Produced with Different Cultivation Techniques

The codes and yields of the extracts obtained from the extraction study conducted to investigate the phenolic components of the grape samples, which are the subjects of this study, are presented in Table 2.

Table 2. Codes and extraction yields (% w/w) of grapes grown under different cultivation techniques

Sample Name and Production Conditions	**Sample Code**	**Extraction Solvent**	**Fresh Weight of Material (g)**	**Net Weight of Extract (g)**	**Extract Yield (%)**
Aqueous extract of grape grown with alfalfa	YÜS	Water	100	16.39	16.39
Aqueous extract of grape grown without alfalfa	YYÜS	Water	100	14.73	14.73
Aqueous extract of grape grown with biohydrogel	BHÜS	Water	100	12.72	12.72
Aqueous extract of grape grown without biohydrogel	BHYÜS	Water	100	11.94	11.94
Aqueous extract of grape grown with PGP	PGPÜS	Water	100	11.06	11.06
Aqueous extract of grape grown without PGP	PGPYÜS	Water	100	10.79	10.79

In this study, to examine the changes in phenolic compounds of grape juices obtained from vines subjected to different cultivation techniques under drought stress, lyophilized grape juice samples were analyzed comparatively against control groups using an HPLC-DAD system. The results obtained from these analyses are presented in Table 3.

An examination of Table 3 reveals that the diversity of phenolic compounds in grape juice is more limited compared to that in the leaves. This is attributed to the fact that phenolic compounds are predominantly localized in the grape skin and seeds (Kennedy et al., 2000; Mozetic et al., 2006). Flavonoids such as kaempferol and apigenin were identified as the dominant compounds across all treatments. This finding indicates that the phenylpropanoid

metabolism is highly active and that the plant's defense and adaptation mechanisms remain robust (Kuljarusnont et al., 2024; Ninkuu et al., 2025). The increase in 2-hydroxy cinnamic acid content in the clover treatment suggests that the early stages of the phenylpropanoid pathway are activated and that this treatment up-regulates the secondary metabolism (Sharma et al., 2019). Conversely, the decrease in certain phenolic compounds observed in the hydrogel and PGP treatments points to a metabolic reallocation within the plant under stress conditions (Wani et al., 2016; Commisso et al., 2016; Kuljarusnont et al., 2024; Ninkuu et al., 2025).

Phenolic Compound Amounts per Serving in Grape Juices Produced in Study Applications

Based on the phenolic compound analysis results determined by HPLC-DAD (Table 4) and the grape juice extraction yields (Table 5), the phenolic compound contents per portion (defined as 100 g of grape juice) were calculated. The per-serving amounts of phenolic compounds in grape juices obtained via different cultivation techniques are presented in Tables 5.4 and 5.5. Accordingly, the phenolic compound contents in 100 g of grape juice derived from grapes produced in the clover trial plot are detailed in Table 4

Table 4. Phenolic compound amounts per serving in grapes produced in clover and non-clover grapevine production plots (mg/100 g grape juice)

No	Reference Compounds	YÜS	YYÜS
1	2-Hydroxycinnamic acid	2.79	4.41
2	Kaempferol	51.95	45.66
3	Apigenin	13.77	12.08

As shown in Table 4, when comparing the per-serving phenolic compound amounts in grape juices produced with clover application, it is observed that vines in plots with clover cover crops are enriched in flavonoids, such as kaempferol and apigenin, compared to the control group, whereas the content of 2-hydroxycinnamic acid is decreased. The reduction in 2-hydroxycinnamic acid indicates that this compound is consumed in the flavonoid biosynthesis process, and the carbon flux in the phenylpropanoid metabolism is channeled toward the flavonoid pathway (Sharma et al., 2019).

When investigating the effect of cover crop applications with clover (*Medicago sativa* L.) on grape phenolic composition, it is evident that this treatment promotes flavonoid biosynthesis and increases the concentrations of kaempferol and apigenin compared to the control. It has been reported in the literature that cover crops used in vineyards increase total phenolic compounds and, in particular, the flavonoid fraction in grapes and wine, making flavonoids the dominant components over non-flavonoid phenolics (Xi et al., 2010). Similarly, cover crop treatments have been shown to significantly increase flavonol content (Peng et al., 2021; Luo et al., 2025). Conversely, the relative decrease in phenolic acids, such as hydroxycinnamic acids, can be explained by the redirection of carbon flux within the phenylpropanoid metabolism toward flavonoid biosynthesis (Dixon and Paiva, 1995; Vogt, 2010; Luo et al., 2025). Furthermore, it is suggested that intercropping with clover modulates the secondary metabolite distribution by reducing oxidative stress and balancing the metabolic state of the plant (Jeder et al., 2021). The results obtained in this project regarding the clover application are in strong agreement with those reported in the literature (Dixon and Paiva, 1995; Vogt, 2010; Xi et al., 2010; Liu et al., 2021; Peng et al., 2021; Patil et al., 2024).

Table 5. Amounts of phenolic compounds and organic acids per serving in grapes produced in vine production areas with and without hydrogel application (mg/100 g grape juice)

No	Reference Compounds	BHÜS	BHYÜS
1	2-Hydroxycinnamic acid	3.82	3.28
2	Naringenin	5.72	-
3	Kaempferol	41.85	38.21
4	Apigenin	11.19	10.15

It was determined that flavonoids, such as kaempferol and apigenin, increased significantly under the clover treatment, while this increase continued at a lower level under the hydrogel application; in contrast, flavonoids either showed a limited increase or remained stable under the PGP application (Tables 4–5). The literature reports that cover crops particularly promote flavonoid biosynthesis and cause flavonoids to become the dominant components in the phenolic profile of grapes (Xi et al., 2010; Peng et al., 2022). It is known that hydrogel applications create moderate stress conditions by partially alleviating water stress in the plant, which supports the production of secondary metabolites (Agaba et al., 2010; Farooq et al., 2009). Conversely, it has been reported that plant growth-promoting rhizobacteria (PGPR) stimulate growth by reducing stress levels in the plant, which may lead to a decrease or stabilization in the production of secondary metabolites (Egamberdieva et al., 2017; Vacheron et al., 2013). Indeed, the findings from the PGP application within the scope of our project, showing a limited increase in flavonoids, are consistent with this mechanism. On the other hand, it was determined that the amount of pinobanksin decreased in the PGP-treated plot compared to the control group (Table 6). It is noted that flavanone derivatives such as pinobanksin are among the plant defense metabolites and that a decline in these compounds may be observed when stress is reduced (Dixon and Paiva, 1995). Furthermore, while not detected in other treatments, the presence of naringenin was identified only in the hydrogel application. Naringenin is a key intermediate in flavonoid biosynthesis and can be detected under conditions where metabolic flux is balanced and intermediate accumulation occurs (Falcone Ferreyra et al., 2012). This indicates that the hydrogel application exerts a balancing effect on secondary metabolism.

Table 6. Per-serving amounts of phenolic compounds and organic acids in grapes produced in PGP-treated and non-PGP-treated grapevine production plots (mg/100 g grape juice)

No	Referance Compounds	PGPÜS	PGPYÜS
1	Pinobanksin	5.09	5.28
2	Kaempferol	17.92	17.05
3	Apigenin	13.71	12.41

Chemometric Analysis of Phenolic Compounds and Organic Acids in Grapevine Leaves Grown with Different Drought-Resistance Cultivation Techniques

The chemometric analyses performed based on the phenolic compound profiles of grapevine leaves are presented in Figure 1 and Figure 2. As can be observed in both figures, the effects of different cultivation techniques on secondary metabolism are clearly demonstrated.

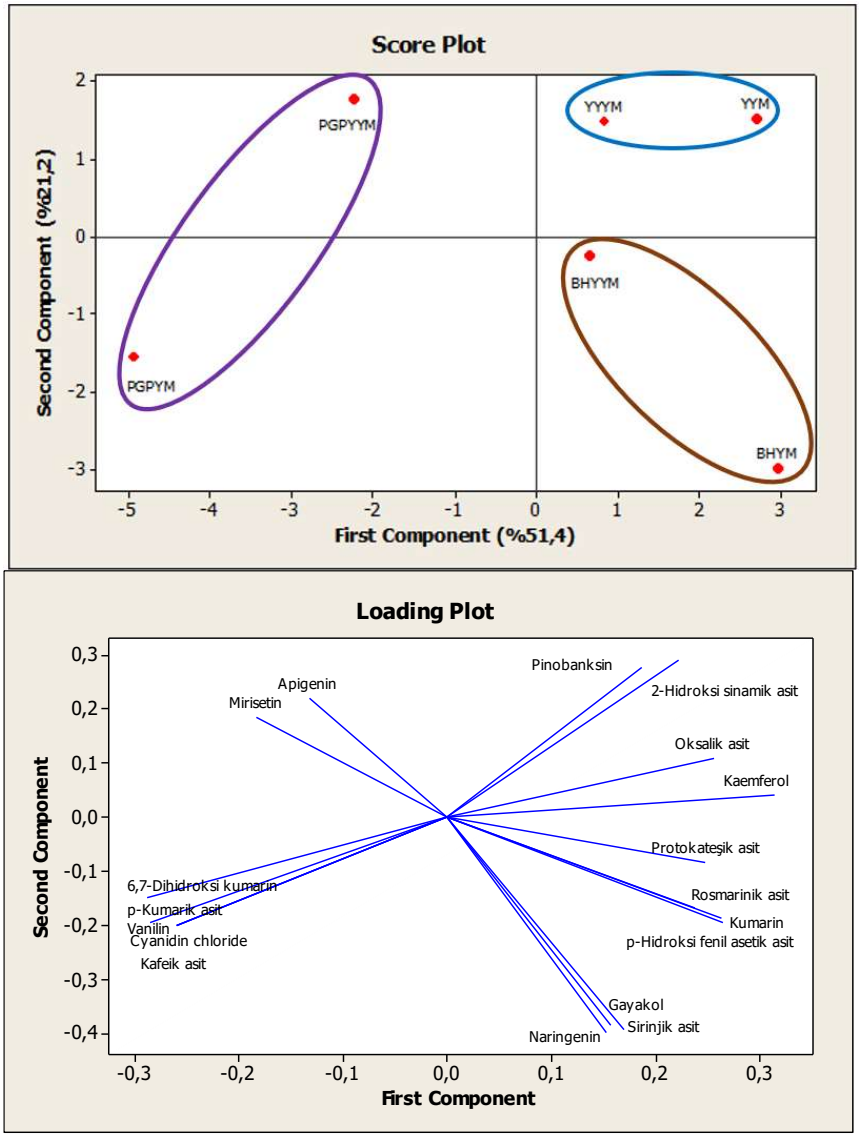

Figure 1. Principal Component Analysis (PCA) and Hierarchical Cluster Analysis (HCA) results based on phenolic compound and organic acid profiles of grapevine leaves grown with different cultivation techniques

The PCA results indicate that the samples are clearly differentiated based on their phenolic compound compositions. The principal components (PC1 and PC2) explain the majority of the total variance, revealing that the differences, particularly between flavonoids and phenolic acids, are the primary determinants in the distribution of the samples (Figure 1). The more compact clustering observed in some groups depending on the application suggests that these treatments exert a more stable and homogeneous effect on phenolic metabolism, whereas the wider dispersion of other groups indicates an enhancement in metabolic diversity. It has been extensively reported in the literature that PCA is an effective method for elucidating the variation in plant metabolites and the impacts of environmental/agronomic treatments (Jolliffe and Cadima, 2016).

Regarding the Hierarchical Cluster Analysis (HCA) results, the samples form significant groups based on their phenolic compound similarities (Figure 1). Notably, the clustering of replicates from the same application into similar groups demonstrates that the treatments have distinct and reproducible effects on the phenolic profile. The close proximity of certain applications

within the clusters suggests that these techniques exert similar effects on the phenylpropanoid metabolism. HCA is widely recognized as a reliable method for the classification of biochemical and metabolomic data (Caesar et al., 2018; Bu et al., 2019).

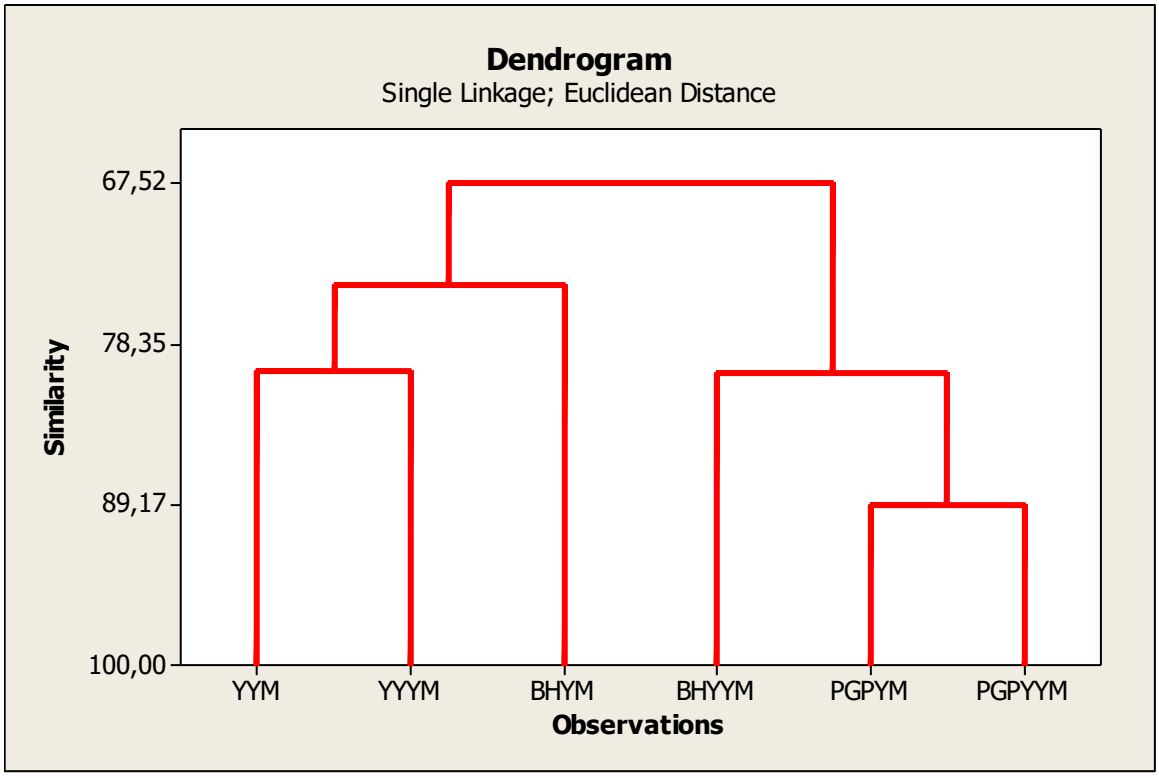

Figure 2. Dendrogram showing the hierarchical clustering of grapevine leaves grown with different cultivation techniques, based on phenolic compound and organic acid profiles.

In the dendrogram analysis presented in Figure 2 the similarity and distance relationships between samples are clearly visualized. While short branch lengths signify high similarity and low variation in terms of phenolic compound profiles, long branches indicate greater metabolic divergence. In this context, the clustering of certain applications at shorter distances suggests that these groups possess a more homogeneous and balanced phenolic composition, whereas the wider dispersion of others indicates an enhancement in metabolic diversity. Dendrogram analysis is widely utilized in the literature for interpreting metabolic profile differences and elucidating inter-sample relationships (Wishart, 2008).

Chemometric analyses based on the phenolic constituents of grapevine leaves cultivated with different techniques demonstrate that these techniques exert significant impacts on the secondary metabolism of the leaves. When PCA and HCA results are evaluated collectively, it is evident that these treatments play both a discriminative and a guiding role in the phenolic profile. It is particularly noteworthy that while some treatments increase homogeneity in phenolic components, others promote metabolic diversity. These results substantiate that the phenylpropanoid metabolism is a dynamic system sensitive to environmental and agronomic factors, and the findings are in strong alignment with those reported in the literature (Dixon and Paiva, 1995; Jolliffe and Cadima, 2016).

CONCLUSIONS

This study demonstrates that integrated agroecological practices significantly impact the secondary metabolism of grapevine leaves. Flavonoids such as kaempferol and apigenin were identified as the dominant compounds across all treatments, indicating that the phenylpropanoid metabolism remains highly active and that the plant's defense and adaptation mechanisms are robust. Furthermore, these outcomes are closely attributed to the fact that phenolic compounds are predominantly localized in the grape skin and seeds. Overall, chemometric analyses based on these phenolic constituents confirm that different cultivation techniques exert substantial effects on metabolic profiles, offering valuable strategies for sustainable and climate-resilient viticulture.

ABSTRACT

The impacts of climate change on agricultural production systems are becoming increasingly pronounced, particularly in the Mediterranean basin. Environmental pressures such as rising temperatures, irregular precipitation regimes, and water scarcity directly affect many agricultural activities—viticulture in particular—thereby making the development of sustainable production models mandatory. In this study, grapevine leaves grown under different production conditions (alfalfa, biohydrogel, and PGP bacteria) at the Manisa Viticulture Research Institute were extracted with methanol, and their phenolic profiles were analyzed using an HPLC-DAD system to evaluate the effects of various agroecological practices under water-limited conditions. Based on the analysis results, this study clearly demonstrates that the applied agroecological strategies exerted significant effects not only at the physiological level but also directly at measurable chemical and metabolic levels. It was determined that phenolic compounds such as protocatechuic acid and p-hydroxyphenylacetic acid in grapevine leaves reached significant increase levels of 36.17 mg/g and 36.31 mg/g extract in alfalfa and biohydrogel/PGP treatments, respectively, compared to the control groups, indicating that phenylpropanoid metabolism was actively reorganized under stress conditions. In parallel, the increases observed in 6,7-dihydroxycoumarin and cyanidin derivatives in biohydrogel and PGP treatments point to the specific induction of defense metabolites in grapevines. Overall, these findings highlight that integrated agroecological management strategies offer a promising, sustainable approach to mitigating climate-induced water stress and enhancing the functional quality of grapevines.

INTRODUCTION

The Mediterranean basin is recognized as one of the prominent climate change "hotspots" where these impacts are felt particularly acutely (Schultz et al., 2000). Rising temperatures, decreasing precipitation, and extreme weather events exert direct effects on the developmental cycle of grapevines, making water stress one of the most significant limiting factors in these systems (Santillán et al., 2019; Santos et al., 2020; Frioni et al., 2025). Although grapevine (*Vitis vinifera* L.) is a species capable of tolerating drought to a certain extent, prolonged water deficit conditions lead to marked reductions in photosynthetic activity, stomatal conductance, shoot development, and overall growth parameters (Gambetta et al., 2020). Drought stress creates substantial impacts not only on growth and yield but also on grape quality and the ripening process (Santillán et al., 2019; Gambetta et al., 2020). Particularly in Mediterranean regions where potential evapotranspiration is high and precipitation is low during the growing season, frequent high water deficits in the soil, plant, and atmosphere render water management a critical production component in viticulture (Dinis et al., 2022).

Phenolic compounds constitute the most abundant group of compounds in grapes and wine after carbohydrates and fruit acids. Phenolic compounds in grapes are primarily classified into two main groups: flavonoids and non-flavonoids. The most common flavonoids are flavan-3-ols (catechin, epicatechin, tannins), flavonols (quercetin, kaempferol, myricetin), and anthocyanins. The non-flavonoid group consists of hydroxycinnamates, hydroxybenzoates (such as gallic acid), and stilbenes (resveratrol) (Van de Wiel et al., 2001; Lopez-Velez et al., 2003). In grape berries, phenolic compounds are predominantly located in the skin and seeds. Of the polyphenols that can be extracted from grape tissues, 60–70% are found in the seeds, while 28–35% are located in the berry skin. The extractable amount from the pulp is quite low, at around 10% (Anonymous, 2003). Similarly, Mozetic et al. (2006) determined that the total amount of phenolic compounds in the berry skin of the white grape variety Rebula was 3.5 times higher than that in the pulp. Possessing suitable ecological and climatic characteristics, our country is one of the most prominent nations in the world in terms of viticulture. Turkey has a vineyard area of 600,000 hectares, where approximately 63% of the produced grapes consist of seeded varieties and 27% of seedless varieties. Seedless raisins hold a significant place in the domestic and foreign trade of our country, with approximately 90% of the production being exported and 10% consumed domestically.

In this study, to determine phenolic compounds profile of grapevine leaves grown under different production conditions (alfalfa, biohydrogel, growth-promoting rhizobacteria), grapevine leaves were extracted with methanol at room temperature. Firstly, For HPLC analysis, the obtained grapevine leaf extracts were dissolved in methanol and subjected to phenolic profile analysis using an HPLC-DAD system (Shimadzu 20 AT series high-performance liquid chromatograph, Shimadzu Corporation, Japan) with reference phenolic acid standards (Barros et al., 2009; Tel-Çayan et al., 2015). Secondly, in this study the effects of various agroecological practices (alfalfa cover cropping, biohydrogel application, and plant growth-promoting (PGP) bacteria) on the secondary metabolite profile and chemometric analysis of grapevines were evaluated under water-limited conditions. In this study, grapevine leaves obtained from the experimental plots of the Ministry of Agriculture and Forestry's Manisa Viticulture Research Institute are presented below under the relevant headings, based on the control group of the study.

MATERIAL AND METHOD

Determination of Phenolic Compounds by HPLC-DAD

In this study, to investigate the phenolic compounds of grapevine leaves, approximately 100 g of each sample was ground and extracted with methanol at room temperature. After removing the methanol using a rotary evaporator (Heidolph Basis Hei-VAP ML), the remaining aqueous portion was dried in a lyophilizer. The resulting methanol extracts were stored in a cool and dark environment until analysis. For HPLC analysis, the obtained grapevine leaf extracts were dissolved in methanol, filtered through a 0,20µm PTFE filter, and subjected to phenolic profile analysis using an HPLC-DAD system (Shimadzu 20 AT series high-performance liquid chromatograph, Shimadzu Corporation, Japan) with reference phenolic acid standards (Barros et al., 2009; Tel-Çayan et al., 2015).

Qualitative and quantitative results were obtained through retention times using peak spiking (co-injection) with standards and peak area calculations. HPLC operating conditions, including column specifications, mobile phase, detector, injection volume, and analysis time, are presented in Table 1.

Table 1. HPLC Operating Conditions

RESULTS AND DISCUSSION

Analysis Results of Phenolic Components in Grapevine Leaves Produced with Different Cultivation Techniques

According to Nile et al. (2013) determined the polyphenolic contents and antioxidant properties of various cultivars belonging to *Vitis vinifera*, *Vitis labrusca*, and *Vitis hybrid*. Orak (2007) investigated total antioxidant activities, phenolics, anthocyanins, and polyphenol oxidase activities in selected red grape cultivars, emphasizing strong correlations among antioxidant capacity, total phenolics, and anthocyanins. In another study, various sugars, acids, and total

phenolic components in the juice of five grapevine (*Vitis* spp.) cultivars were quantified across different stages of fruit development (Sabir et al., 2010). Furthermore, phenolic compounds identified in table grape cultivars from Iğdır, Türkiye, include catechin (0.43 to 1.82 mg/L), rutin (1.09 to 3.34 mg/L), quercetin (0.09 to 0.55 mg/L), chlorogenic acid (1.13 to 3.48 mg/L), ferulic acid (0.08 to 0.94 mg/L), o-coumaric acid (0.34 to 1.69 mg/L), p-coumaric acid (0.01 to 0.19 mg/L), caffeic acid (0.40 to 2.73 mg/L), syringic acid (0.16 to 1.20 mg/L), vanillic acid (0.02 to 0.45 mg/L), and gallic acid (0.10 to 1.27 mg/L) (Eyduran et al., 2025).

Within the scope of this study, to contribute to the sustainable use of water resources under climate change conditions and to enable grapevine cultivation with reduced water usage, various production techniques were implemented. These included planting alfalfa as a cover crop in vineyard sites, applying biohydrogels prepared from vine pruning residues to the grapevine roots, and inoculating the vines with PGP bacteria isolated from the vineyard soils. To determine the phenolic components, fresh leaves were harvested prior to the fruit ripening period, and their extraction was performed using methanol (repeated three times).

The codes and yields of the extracts obtained from the extraction study conducted to investigate the phenolic components of the grapevine leaves samples, which are the subjects of this study, are presented in Table 2.

Table 2. Codes and extraction yields (% w/w) of grapevine leaves grown under different cultivation techniques

Sample Name and Production Conditions	**Sample Code**	**Extraction Solvent**	**Fresh Weight of Material (g)**	**Net Weight of Extract (g)**	**Extract Yield (%)**
Methanol extract of grapevine leaf grown with alfalfa	YYM	Methanol	100	6.31	6.31
Methanol extract of grapevine leaf grown without alfalfa	YYYM	Methanol	100	5.78	5.78
Methanol extract of grapevine leaf grown with biohydrogel	BHYM	Methanol	100	8.31	8.31
Methanol extract of grapevine leaf grown without biohydrogel	BHYYM	Methanol	100	7.69	7.69
Methanol extract of grapevine leaf grown with PGP	PGPYM	Methanol	100	6.81	6.81
Methanol extract of grapevine leaf grown without PGP	PGPYYM	Methanol	100	6.14	6.14

The results of the phenolic component analysis, performed using the HPLC-DAD system for grapevine leaves cultivated under drought stress using various techniques, along with their comparative assessment against control groups, are presented in Table 3.

Table 3. Phenolic component analysis results of grapevine leaves grown under different agroecological applications by HPLC-DAD (mg/g extract)

When the HPLC-DAD analysis results performed on grapevine leaves are examined, it is observed that oxalic acid is the dominant compound in all applications; however, there is a significant decreasing trend in its concentration depending on water deficit and the applied techniques (Table 3). Furthermore, phenolic compounds such as protocatechuic acid and *p*-hydroxy phenyl acetic acid were found to be at higher levels in the trial plots treated with clover, hydrogel, and PGP (Plant Growth-Promoting) compared to their respective control groups (36.17 and 36.05, 31.78 and 36.31, 20.07 and 15.26 mg/g extract, respectively), indicating that the phenylpropanoid metabolic pathway is highly sensitive to environmental conditions. Indeed, it is well-established that the biosynthesis of phenolic compounds changes dynamically in response to environmental stressors and that these metabolic pathways are reorganized, particularly under drought conditions (Dixon and Paiva, 1995; Vogt, 2010). Considering these sources, the findings obtained in this study are in alignment with the literature.

It has been determined that hydrogel and PGP applications increase the accumulation of certain specific phenolic compounds. Notably, it was observed that 6,7-dihydroxy coumarin and cyanidin derivatives increased significantly with hydrogel and PGP applications (Table 3). This suggests that these applications activate stress signaling mechanisms in the plant, thereby promoting the production of defense metabolites. It has also been reported in the literature that *Trichoderma* and PGP bacteria enhance stress tolerance in plants by increasing their phenolic and flavonoid contents (Glick, 2012; Sabir et al., 2010). Therefore, our findings are consistent with the literature.

When evaluated in terms of flavonoid compounds, kaempferol and apigenin were the fundamental compounds detected in all applications and were found at higher levels, particularly in clover and hydrogel applications (Table 3). This result is in agreement with studies showing that cover crops support plant metabolism by increasing soil microbial activity and promoting the production of phenolic compounds (Celette et al., 2008; Garcia et al., 2018). Conversely, the decrease in certain flavonoids, such as myricetin, apigenin, pinobanksin, and kaempferol, in PGP applications compared to the control group suggests that the plant may be redirecting its metabolic resources toward different defense mechanisms under stress conditions.

Chemometric Analysis of Phenolic Compounds and Organic Acids in Grapevine Leaves Grown with Different Drought-Resistance Cultivation Techniques

The chemometric analyses performed based on the phenolic compound profiles of grapevine leaves are presented in Figure 1 and Figure 2. As can be observed in both figures, the effects of different cultivation techniques on secondary metabolism are clearly demonstrated.

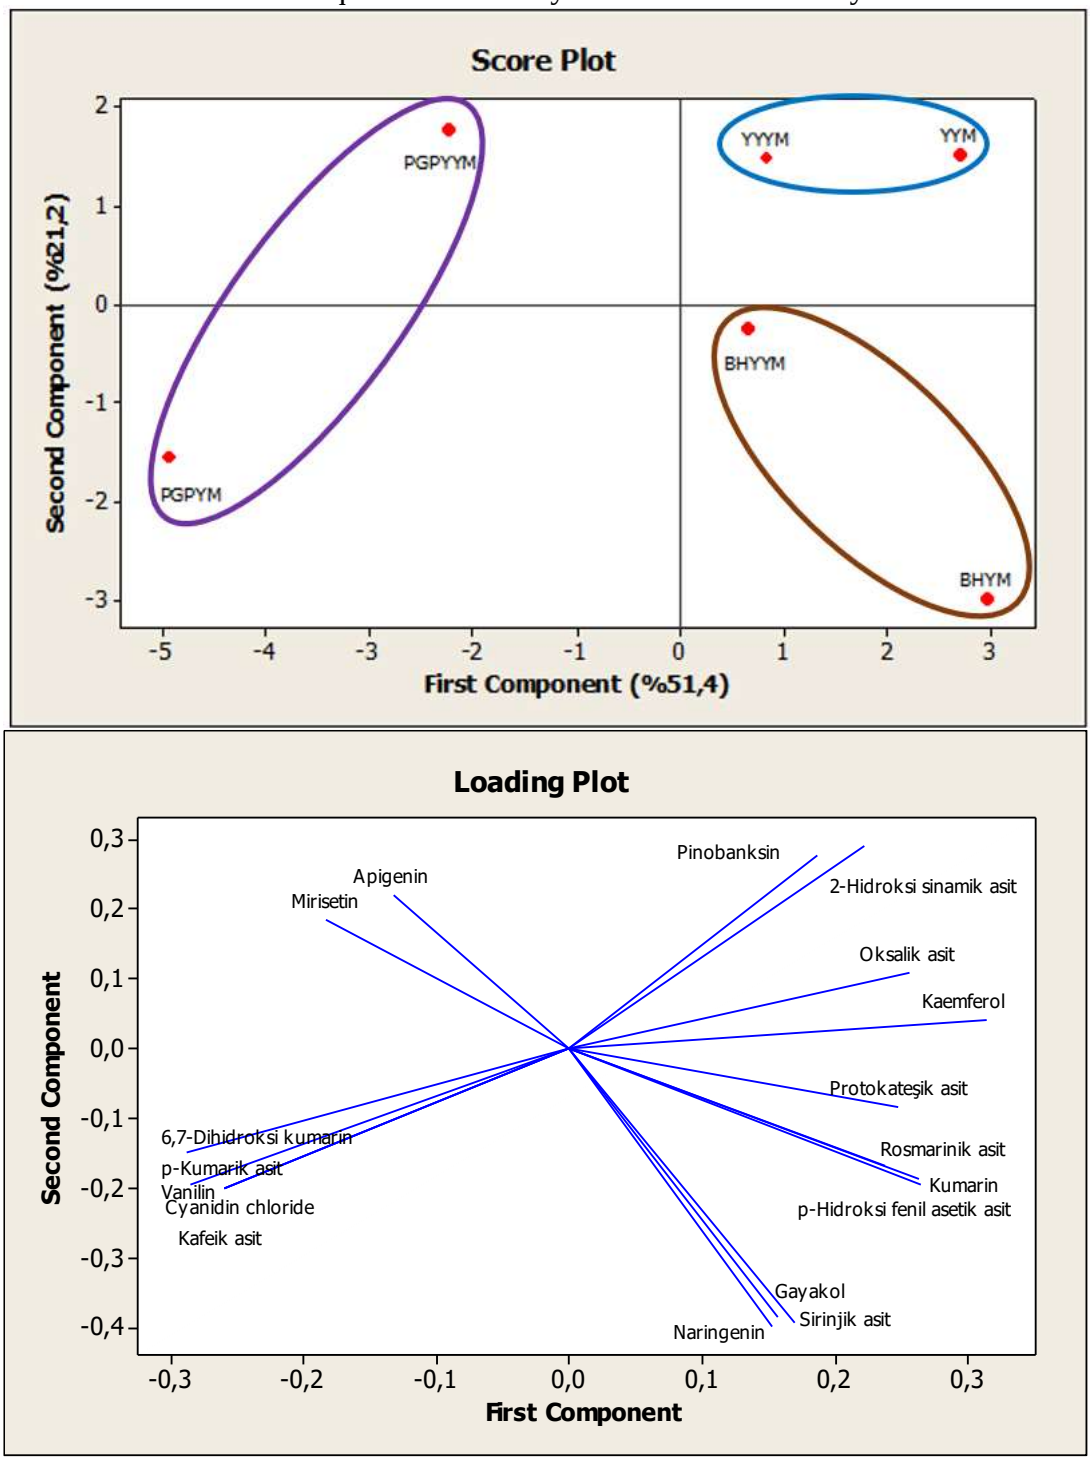

Figure 1. Principal Component Analysis (PCA) and Hierarchical Cluster Analysis (HCA) results based on phenolic compound and organic acid profiles of grapevine leaves grown with different cultivation techniques

The PCA results indicate that the samples are clearly differentiated based on their phenolic compound compositions. The principal components (PC1 and PC2) explain the majority of the total variance, revealing that the differences, particularly between flavonoids and phenolic

acids, are the primary determinants in the distribution of the samples (Figure 1). The more compact clustering observed in some groups depending on the application suggests that these treatments exert a more stable and homogeneous effect on phenolic metabolism, whereas the wider dispersion of other groups indicates an enhancement in metabolic diversity. It has been extensively reported in the literature that PCA is an effective method for elucidating the variation in plant metabolites and the impacts of environmental/agronomic treatments (Jolliffe and Cadima, 2016).

Regarding the Hierarchical Cluster Analysis (HCA) results, the samples form significant groups based on their phenolic compound similarities (Figure 1). Notably, the clustering of replicates from the same application into similar groups demonstrates that the treatments have distinct and reproducible effects on the phenolic profile. The close proximity of certain applications within the clusters suggests that these techniques exert similar effects on the phenylpropanoid metabolism. HCA is widely recognized as a reliable method for the classification of biochemical and metabolomic data (Caesar et al., 2018; Bu et al., 2019).

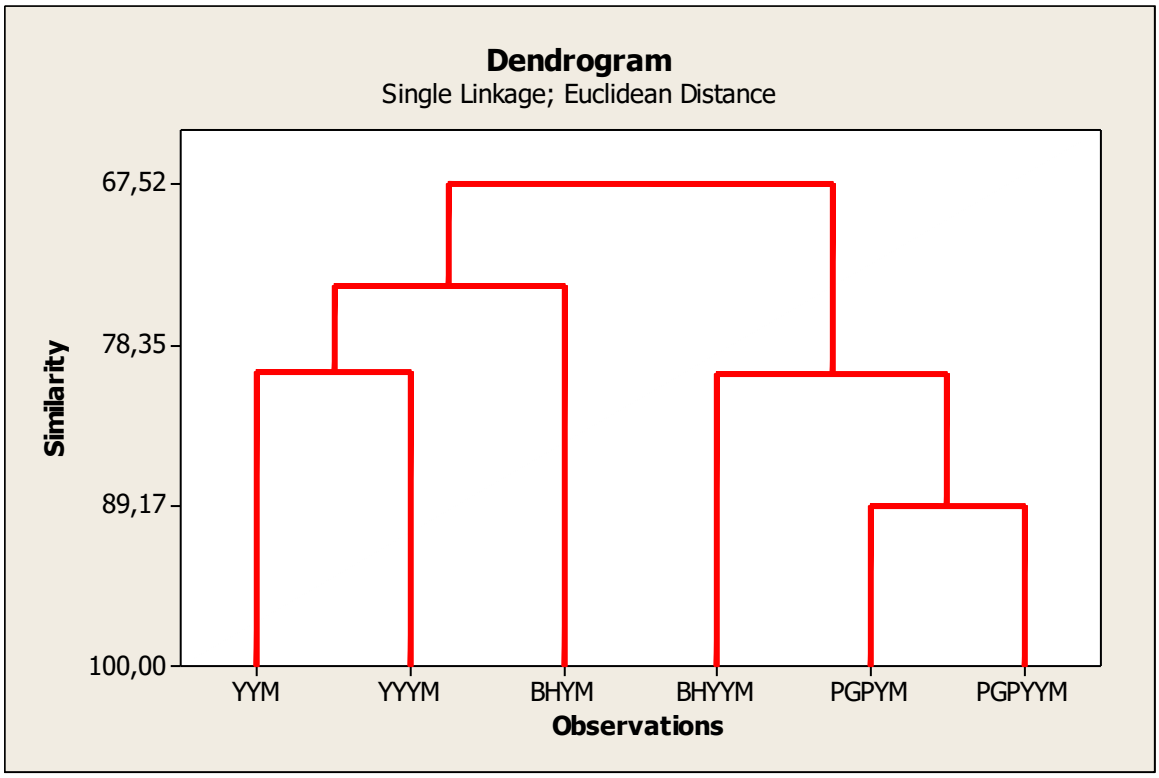

Figure 2. Dendrogram showing the hierarchical clustering of grapevine leaves grown with different cultivation techniques, based on phenolic compound and organic acid profiles.

In the dendrogram analysis presented in Figure 2 the similarity and distance relationships between samples are clearly visualized. While short branch lengths signify high similarity and low variation in terms of phenolic compound profiles, long branches indicate greater metabolic divergence. In this context, the clustering of certain applications at shorter distances suggests that these groups possess a more homogeneous and balanced phenolic composition, whereas the wider dispersion of others indicates an enhancement in metabolic diversity. Dendrogram analysis is widely utilized in the literature for interpreting metabolic profile differences and elucidating inter-sample relationships (Wishart, 2008).

Chemometric analyses based on the phenolic constituents of grapevine leaves cultivated with different techniques demonstrate that these techniques exert significant impacts on the

secondary metabolism of the leaves. When PCA and HCA results are evaluated collectively, it is evident that these treatments play both a discriminative and a guiding role in the phenolic profile. It is particularly noteworthy that while some treatments increase homogeneity in phenolic components, others promote metabolic diversity. These results substantiate that the phenylpropanoid metabolism is a dynamic system sensitive to environmental and agronomic factors, and the findings are in strong alignment with those reported in the literature (Dixon and Paiva, 1995; Jolliffe and Cadima, 2016).

CONCLUSIONS

When evaluated in terms of flavonoid compounds, kaempferol and apigenin were the fundamental compounds detected across all applications and were found at higher levels, particularly in clover and hydrogel treatments. Furthermore, the prominent increases in phenolic compounds such as protocatechuic acid and p-hydroxyphenylacetic acid under alfalfa and biohydrogel/PGP treatments prove that phenylpropanoid metabolism was actively reorganized under stress conditions. In addition, the increases observed in 6,7-dihydroxycoumarin and cyanidin derivatives indicate the specific induction of defense metabolism in grapevines. Overall, these findings highlight that integrated agroecological management strategies trigger phenylpropanoid and defense metabolism, offering a promising and sustainable approach to mitigating climate-induced water stress and enhancing the functional quality of grapevines.

ABSTRACT

Kefe cumin (*Laser trilobum* (L.) Borkh.) is a perennial herbaceous species belonging to the *Apiaceae* (Umbelliferae) family and is commonly known as cumin. The species grows naturally in certain regions of Türkiye and is also referred to by various regional vernacular names, including Kefe cumin, mountain cumin, *sıra baharatı*, and *geyik sırası*. Chemical analyses have shown that the aerial parts and fruits of the plant contain high levels of d-limonene and perillaldehyde. Widely distributed throughout the flora of Türkiye, *Laser trilobum* has become integrated into the gastronomic and ethnobotanical traditions of the regions where it naturally occurs, resulting in its diverse range of uses. Kefe cumin has a long-standing history in traditional Anatolian medicine and continues to be widely used by local communities as a medicinal plant. Herbal tea prepared by boiling the seeds has been reported to be traditionally consumed for the management of diabetes, hypertension, and digestive system disorders. The ethnobotanical applications of the species play an important role in the traditional culinary culture of the Mediterranean and Southeastern Anatolia regions, where it is valued as an aromatic ingredient. From a gastronomic perspective, the spice obtained by drying and grinding the seeds into a powder is widely used as a flavoring agent in meat dishes and traditional beverages, particularly in the provinces of Mersin, Adana, and Hatay. In this context, the increasing popularity of the species in recent years, supported by both scientific evidence reported in the literature and the traditional practical knowledge of local communities, has renewed interest in its economic and medicinal importance. In conclusion, the conservation of the species' rich phytochemical composition and cultural value is of great importance for sustainable agriculture and local development strategies.

Keywords:
Laser trilobum, Turkish cuisine, ethnobotany, d-limonene, perillaldehyde.

INTRODUCTION

Medicinal and aromatic plants have always been key players of human history, shaping nutrition, health, and culture. Notably, members of the Apiaceae family hold a vital role in both gastronomy and traditional therapeutics, largely attributed to their essential oils, phenolic substances, and unique flavor profiles. In addition to species of high economic value such as cumin (*Cuminum cyminum* L.), fennel (*Foeniculum vulgare*), anise (*Pimpinella anisum*), and coriander (*Coriandrum sativum*), there exist locally utilized species that remain comparatively underexplored (Davis, 1972). Among these, *Laser trilobum* (L.) Borkh. (commonly referred to as 'kefe kimyonu' in Turkish) is a perennial herbaceous plant of the genus *Laser* within the Apiaceae family, occurring naturally in various regions of Türkiye (Tekgüler et al., 2025). Despite its distribution across temperate regions of Asia and Europe, encompassing Iran, the Caucasus, Türkiye, the Balkans, and Central Europe, *L. trilobum* has received comparatively

little attention relative to other members of the Apiaceae family (Baser et al., 1993; Vahdat et al., 2006). Local practices in Türkiye include consuming the shoots as vegetables and using its aromatic, cumin-flavored fruits as a spice sold in local markets (Chizzola, 2007; Parlatan et al., 2009).

Represented within Turkish flora, *L. trilobum* is naturally distributed in high-altitude areas (Demir & Kan, 2025) and is locally designated by several common names, including 'dağ kimyonu', 'kefe kimyonu', 'kamun', and 'sıra' (Baytop, 1994; Şenkardeş & Tuzlacı, 2014; Agar & Tosun, 2025). Traditionally, the fruits of *L. trilobum* are dried and used as a culinary spice, and in some areas, they are used in traditional healing practices. However, studies focusing on the gastronomic usage of the species is constrained, with existing information relying largely on ethnobotanical surveys. This highlights the need for a more detailed scientific evaluation of the plant's gastronomic potential.

Growing interest in natural flavors and functional foods has led to the re-evaluation of regional spices. Because consumers increasingly select natural flavor compounds instead of synthetic additives, species like *L. trilobum* hold growing significance for the food industry. In this framework, systematically investigating the species' botanical features, chemical composition, and traditional uses represents a critical priority.

2.Ecological Features and Natural Distribution

L. trilobum is a perennial species native to the temperate regions of Eurasia, with a distribution extending from Eastern and Central Europe across the Balkans and Crimea to the Caucasus, Türkiye, the Levant, and northern Iran. Türkiye constitutes one of the major centers of natural distribution and harbors substantial genetic diversity of this species within its native populations (WCVP, 2025). The species is typically found at elevations ranging from 700 to 2,000 m, where it inhabits sun-exposed slopes, forest clearings, rocky sites, and calcareous soils (Demir & Kan, 2025). Its perennial life cycle and extensive root system enable it to withstand prolonged periods of water limitation, suggesting a considerable capacity to persist under drought-prone conditions. Together, these ecological and physiological characteristics make *L. trilobum* a potentially valuable genetic resource for understanding plant adaptation to increasing drought and other environmental stresses associated with climate change.

The combination of its distinctive morphological traits and ecological adaptability underscores the importance of *L. trilobum* not only as a component of the natural flora but also as a species with considerable potential for gastronomy and the sustainable use of endemic plant resources.

3.History and Distribution of Kefe Cumin

L. trilobum (L.) Borkh. is one of the Apiaceae species native to Europe and Western Asia. The species was first described by Carl Linnaeus as *Laserpitium trilobum* and was later reclassified as *L. trilobum* by Borkhausen. This name is currently accepted as the valid taxonomic designation in international community (POWO, 2025). Its common name, "kefe kimyonu" ("Kefe cumin"), derives from the cumin-like aroma of its dried, ground fruits.

In terms of geographic distribution, *L. trilobum* has a naturally wide range. It occurs across the temperate zone of Asia (North Caucasus and Transcaucasia, the eastern Aegean islands, Iran, Lebanon, Syria, and Türkiye) as well as in various regions of Europe (in Eastern Europe: the Baltic states, Middle and South European Russia, Crimea, Ukraine, Austria, Czechoslovakia, Germany, Hungary, Albania, Bulgaria, Greece, Italy, Romania, and European Türkiye, along with the territories of the former Yugoslavia). It is distributed across a broad phytogeographic area extending from Southeastern and Central Europe through the Balkans, the Black Sea Basin,

the Caucasus, Anatolia, and into northern Iran (WCVP, 2025). This distribution pattern indicates that the species is capable of adapting to a wide range of climatic and topographic conditions.

Türkiye is recognized as one of the species' natural centers of distribution. Natural populations occur particularly in the Taurus Mountains, the Amanos Mountains, the Central Taurus range, and the higher elevations of the Mediterranean Region. In addition, the species has been reported to occur in certain high-altitude areas of Central Anatolia and in the mountainous regions of Southeastern Anatolia (Davis, 1972). This distribution indicates that *L. trilobum* possesses broad ecological tolerance, capable of adapting to both steppe and forest-steppe transition zones (Demir & Kan, 2025).

Research on *L. trilobum* has intensified considerably over the past three decades, with the existing literature focusing largely on its essential oil composition, antimicrobial activity, phytochemical profile, and ethnobotanical uses, while studies on its gastronomic applications remain scarce. Cultivation of Kefe cumin at a commercial scale has not yet become established in Türkiye, and plants are majorily wild-harvested from natural populations - a practice that raises concerns regarding the long-term sustainability of these populations.

4. Historical Use of Kefe Cumin as a Spice

Numerous species belonging to the Apiaceae family have been used as spices throughout history (Ngahang Kamte et al., 2018). *Laser trilobum* is also an aromatic species of this family, and its fruits are particularly used as a spice in local cuisines after being dried and ground. However, the literature provides no direct evidence indicating that the plant was widely used in the Ottoman palace cuisine or documented historical culinary sources. Therefore, from a scientific perspective, it is more appropriate to consider the historical use of Kefe cumin within the context of local culinary practices and ethnobotanical traditions.

Etnobotanical studies conducted in Türkiye have reported that the dried fruits are ground and consumed as a spice; in some regions, the fruits are also boiled and traditionally used for conditions such as digestive disorders, abdominal pain, and the common cold (Bulut et al., 2014; Güneş et al., 2017). In addition, extracts obtained from these plants have been reported to reduce the formation of biogenic amines and limit microbial contamination in cheese and meat products (Ehsani et al., 2016).

The primary reason for the use of Kefe cumin as a spice is its high essential oil content and characteristic citrus-like aroma. The essential oil of *Laser trilobum* fruits contains limonene at very high proportions, ranging from 26% to 91%. Owing to its high limonene content, the plant possesses a distinctive and intense odor and aroma profile (Ferahoğlu & Kırıcı, 2023). In particular, ground fruits provide a pronounced aroma even when used in small amounts, thereby enhancing the sensory characteristics of traditional recipes. Nowadays, the increasing consumer demand for natural flavoring agents is expected to bring Kefe cumin back into focus in the fields of gastronomy and functional food research.

5. Phytochemical Composition of Kefe Cumin

Aromatic plants belonging to the Apiaceae family are known to contain high levels of essential oils and secondary metabolites with biological activities (Spinozzi et al., 2021; Thivia et al., 2021). *Laser trilobum* is one of the species exhibiting these characteristics. The fruits constitute

the plant organ with the highest essential oil content (Agar & Tosun, 2025). In a GC-MS analysis conducted by Ferahoğlu and Kırıcı (2023) on fruits collected from the Mersin region, the essential oil content was determined to be 4.4%, with d-limonene and perillaldehyde accounting for approximately 95% of the oil. These two monoterpene compounds are considered to be largely responsible for the characteristic aroma and biological activity of Kefe cumin. Studies have shown that the composition of essential oil constituents varies considerably among different organs of the plant. While **perillaldehyde and limonene** are the major constituents in the fruits, **β-caryophyllene** and **α-pinene** have been identified as the predominant constituents in the leaves and stems and in the rhizomes, respectively (Agar & Tosun, 2025). This indicates that different organs of the plant may have distinct utilization potentials in terms of pharmacological applications and food technology.

Studies reported in the literature have demonstrated that the essential oils of *Laser trilobum* exhibit antimicrobial activity against certain Gram-positive and Gram-negative pathogenic bacteria (Nazzaro et al., 2013). In addition, its antioxidant capacity has been suggested to potentially slow oxidative deterioration, thereby indicating its potential as a natural food preservative (Akgül, 1992; Parlatan et al., 2005; Drobac et al., 2017). However, as a substantial proportion of the existing studies have been conducted at the laboratory scale, further comprehensive research is needed to evaluate its potential applications in food systems.

From a phytochemical perspective, *Laser trilobum* stands out as a noteworthy species in the development of functional foods, natural preservatives, and herbal products, not only due to its aromatic properties but also because of the bioactive monoterpenes and sesquiterpenes it contains (Drobac et al., 2017). The available data indicate that controlled cultivation practices may have positive effects on essential oil yield and composition, representing an important opportunity for enhancing the economic value of the species.

6. Use of Kefe Cumin in Turkish Cuisine

Türkiye is one of the countries where wild aromatic plants are widely incorporated into culinary culture, owing to its diverse climatic zones and rich flora. Many species belonging to the *Apiaceae* family are used not only for medicinal purposes but also as spices. Ethnobotanical studies have demonstrated that plants locally referred to as “cumin” in Türkiye are not limited to *Cuminum cyminum*; *Carum carvi, Grammosciadium daucoides,* and *Laser trilobum* are also regionally used for similar purposes (Tuncay and Yeşil, 2019).

6.1 Traditional Forms of Use

Although the number of scientific publications concerning the gastronomic use of *Laser trilobum* is limited, available studies have reported that, in Turkish traditional practices, young shoots are consumed as vegetables, while the aromatic fruits, which have a cumin-like flavor, are ground and used as a spice and sold in local markets (Baser et al., 1993; Chizzola, 2007; Parlatan et al., 2009). Ferahoğlu & Kırıcı (2023) reported that, in samples collected from the Mersin region, the fruits are locally known as “Kefe cumin” and that essential oil is obtained from the dried fruits. The same study indicated that the species is not cultivated in Türkiye and that its use relies largely on fruits collected from natural populations.

A comprehensive ethnobotanical study conducted in the Hatay region revealed that *Laser trilobum* is used as a spice in local dishes (Keskin & Alpınar, 2002), and that this practice represents one of the traditional uses that had not previously been documented in detail in the

literature. The study emphasizes that this plant constitutes a part of the local gastronomic heritage and highlights the importance of preserving traditional knowledge systems.

Use in Cheese and Dairy Products

Aromatic species belonging to the *Apiaceae* family have been used in cheese production in Anatolia for many years (Öztürk et al., 2000; Çakmakçı & Şensoy, 2015). Although standardized cheese production studies specifically involving *Laser trilobum* are limited, ethnobotanical records indicate that ground fruits are added in some regions to impart flavor to herb-infused cheese and dairy products similar to *çökelek*. The primary reason for this use is that volatile compounds such as limonene and perillaldehyde, which are present at high concentrations in the fruits, provide a characteristic citrus-like aroma.

Use in Meat and Meat Products

One of the strongest pieces of scientific evidence regarding the use of Kefe cumin in meat products comes from the study conducted by Akgül and Kıvanç (1989). The study demonstrated that the addition of *Laser trilobum* spice to *köfte*, a traditional product of Turkish cuisine, inhibited the growth of *Staphylococcus aureus*. This finding indicates that the plant has potential not only as a flavoring agent but also in food preservation due to its natural antimicrobial properties. These findings are consistent with current trends toward the use of natural preservatives and provide a scientific basis for considering Kefe cumin as a functional spice.

Use in Local Dishes

It is not possible to state with certainty that specific recipes incorporating Kefe cumin have been scientifically validated. Nevertheless, based on the traditional knowledge of local communities, the plant appears to be used as a flavoring agent in meat dishes and certain regional spice blends. An ethnobotanical study conducted in Hatay reported that *Laser trilobum* is used as a spice in local dishes and noted that the species is obtained through traditional wild harvesting and constitutes one of the aromatic plants used in the local cuisine (Güzel & Kayıkçı, 2023). However, the existing literature does not provide standardized recipes specifying the particular dishes in which the plant is used or the quantities employed. Instead, available information primarily concerns the use of the spice obtained from the dried fruits in Hatay cuisine and regional spice blends. This is significant in demonstrating the strong relationship between Anatolian culinary culture and biological diversity.

Evaluation from the Perspective of Gastronomy and Functional Foods

In recent years, the growing consumer preference for natural sources of flavoring agents and preservatives over synthetic additives has increased interest in wild aromatic plants. Considering the high essential oil content of *Laser trilobum*, its predominant limonene and perillaldehyde constituents, and its antioxidant and antimicrobial activities, the species has considerable potential for use as a functional spice.

However, studies in the field of gastronomy are largely based on ethnobotanical observations. Standardized recipes, sensory analyses, consumer acceptance studies, and food technology applications remain insufficiently developed. Therefore, future interdisciplinary research is expected to elucidate in greater detail the various uses of Kefe cumin in Turkish cuisine.

Conclusion

Laser trilobum (L.) Borkh. is one of the important aromatic plants occurring naturally in the flora of Türkiye and locally known as "Kefe cumin." The available scientific evidence indicates that the dried fruits of the species are used as a spice, may exhibit natural antimicrobial activity in meat products, and are traditionally incorporated into local dishes in some regions. However, the number of scientific publications concerning its use in Turkish cuisine remains limited.

In light of the growing interest in natural aromatic plants, investigating the controlled cultivation, gastronomic applications, sensory properties, and potential applications of Kefe cumin in food technology is of considerable importance. Furthermore, documenting local gastronomic knowledge and developing sustainable utilization models will contribute both to the conservation of biological diversity and to the enrichment of Türkiye's gastronomic heritage.

ABSTRACT

Protecting and optimizing fruit quality parameters—specifically the sugar profile—under water deficit conditions induced by climate change in viticulture is of critical importance for both yield and processing quality. This study aimed to determine the distribution of sugar components in grapes produced using different agroecological practices and to examine the obtained data through chemometric analyses. In this study, the sugar profiles of grapes produced using various cultivation techniques aimed at growing grapevines with reduced water usage were determined using an HPLC system. Based on the results, the analysis of sugar components in grape juice revealed that fructose ranged from 7.15 to 8.17 g/100 g and glucose from 6.15 to 8.52 g/100 g, showing an increasing tendency compared to the control group across the treatment groups, with total sugar accumulation particularly enhanced in the alfalfa and biohydrogel treatments. The glucose/fructose ratio in the grapes produced across the treatment plots was determined to remain within the range of 0.81 to 1.08, indicating that carbon metabolism was maintained in a balanced manner and that the practices did not disrupt fruit ripening physiology. This comprehensive dataset clearly demonstrates that the applied system not only enhances drought tolerance but also provides a robust metabolic optimization supporting quality in terms of phenolic compounds, aromatic metabolites, and sugar composition. In additionally, Chemometric analyses (PCA and HCA) reveal that PGP application forms a distinct cluster and promotes a more homogeneous sugar composition, whereas alfalfa and biohydrogel treatments induce greater metabolic variation. According to the findings obtained, it was determined that different production conditions (alfalfa, biohydrogel, and plant growth-promoting rhizobacteria) had a significant effect on the sugar profile and chemometric properties of grapes, substantially increasing secondary metabolite accumulation compared to the control group.

Keywords: *Sugar profile, Grape, Alfalfa, biohydrogel, growth-promoting rhizobacteria (PGP), HPLC, Chemometrıc analysis*

INTRODUCTION

The most significant risk for viticulture is the future increase in sugar content of grapes due to rising temperatures (Lakatos and Mitre., 2023). Adverse environmental conditions can independently cause heat and water stress in grapevines, affecting internal parameters such as sugar and acid content, the development of phenolic compounds, and yield (Hewitt et al., 2023). According by Lakatos and Mitre (2023) have been reported, the effect of the aridity index on the past and future occurrence of maximum sugar content for six grape varieties was analyzed. Glucose and fructose are the dominant sugars in grapes, complemented by sucrose accumulation (Fontes et al., 2011). Sugar accumulation in grapes is directly proportional to their growth and development (Manning et al., 2001). In this respect, the content and composition of glucose, fructose, and sucrose play an important role in the formation of fruit quality (Liu et al., 2017; Zhong et al., 2023). Glucose and fructose constitute the vast majority (97.88%–99.86%) of the sugar composition of grapes. During the ripening process, the balance between these two sugars ranges from 0.74 to 1.05 (Li et al., 2020). In a study conducted by Eyduran et al. (2015) on table grape varieties in Turkey, fructose and glucose levels were found to range from 8.03 to 15.55 g/100 g and 9.51 to 16.47 g/100 g, respectively, with the highest accumulation observed in the white seedless grape variety "Sultaniye". Similarly, Liu et al. (2006) reported major glucose and fructose levels ranging from 45.86 to 122.89 mg/ mL^{-1} and 47.64 to 131.04 mg/mL^{-1} in grape berries over a two-year period.
In this study, to determine sugar profile of grapes grown under different production conditions (alfalfa, biohydrogel, growth-promoting rhizobacteria analysis using an HPLC system (Shimadzu 20 AT series high-performance liquid chromatograph, Shimadzu Corporation, Japan) Secondly, in this study the effects of various agroecological practices (alfalfa cover cropping, biohydrogel application, and plant growth-promoting (PGP) bacteria) on the sugar profile and chemometric analysis of grapes were evaluated under water-limited conditions. In this study, grapes obtained from the experimental plots of the Ministry of Agriculture and Forestry's Manisa Viticulture Research Institute are presented below under the relevant headings, based on the control group of the study.

MATERIAL AND METHOD

Determination of Sugar Components by HPLC

The grape samples produced within the scope of this study were pressed in a cotton cheesecloth to extract their juice, and the remaining pomace was washed with ultrapure water and pressed again; the resulting grape juice was then lyophilized. The grape juice extract thus obtained was stored in a dark and cool environment until sugar component analyses were performed. The amounts (%) of glucose, fructose, sucrose, and maltose in the grape samples were determined using an HPLC system. A Shodex NH2P-50 4E (5 µm, 250x4.6 mm) column and a Shimadzu RI 20 A model refractive index (RI) detector were used. The detector temperature was set to 30 °C, and the mobile phase used was 75% ACN (acetonitrile) + 25% ultrapure water. Standards and samples were injected into the instrument with a mobile phase flow rate of 1 mL/min and an injection volume of 10 µL. First, pure glucose, fructose, sucrose, and maltose standards were prepared with ultrapure water at concentrations of 0.125%, 0.25%, 0.50%, and 1%, filtered through a Millipore 0.45 µm membrane filter, and injected into the system to construct a 4-point calibration curve. The lyophilized grape juice extracts (2.5 g) were weighed into a volumetric flask (25 mL), and 15 mL of ultrapure water was added. After the mixture was completely dissolved by vortexing for 5 minutes, the volume was completed to 25 mL with ultrapure water using a Pasteur pipette and homogenized by vortexing. The samples were

transferred to vials and injected into the HPLC system under the specified conditions to determine their sugar profiles [AOAC 977.20 (2005)].

RESULTS AND DISCUSSION

Distribution Of Sugar Components in Grapes Produced With Different Cultivation Techniques Against Drought

The codes and yields of the extracts obtained from the extraction study conducted to investigate the sugar profile of the grape samples, which are the subjects of this study, are presented in Table 1.

Table 1. Codes and extraction yields (% w/w) of grapes grown under different cultivation techniques

Sample Name and Production Conditions	**Sample Code**	**Extraction Solvent**	**Fresh Weight of Material (g)**	**Net Weight of Extract (g)**	**Extract Yield (%)**
Aqueous extract of grape grown with alfalfa	YÜS	Water	100	16.39	16.39
Aqueous extract of grape grown without alfalfa	YYÜS	Water	100	14.73	14.73
Aqueous extract of grape grown with biohydrogel	BHÜS	Water	100	12.72	12.72
Aqueous extract of grape grown without biohydrogel	BHYÜS	Water	100	11.94	11.94
Aqueous extract of grape grown with PGP	PGPÜS	Water	100	11.06	11.06
Aqueous extract of grape grown without PGP	PGPYÜS	Water	100	10.79	10.79

Within the scope of the project, the sugar profiles of grapes produced using various cultivation techniques aimed at achieving grapevine cultivation with reduced water usage were determined using an HPLC system. The results obtained are presented in Table 2.

Table 2. Comparison of glucose, fructose, and sucrose contents in grapes grown under different agroecological applications (g/100 g grape juice)

Sample Code	Fructose	Glucose	Fructose + Glucose)	Glucose/Fructose	Sucrose
YÜS	7.92	6.75	14.67	0.85	2.01
YYÜS	2	7.59	6.15	13.74	0.81
BHÜS	3	7.85	7.72	15.57	0.98
BHYÜS	4	7.15	7.33	14.48	1.02
PGPÜS	5	8.17	8.19	16.36	1.00
PGPYÜS	6	7.88	8.52	16.40	1.08

The sugar profiles of grapes produced using various cultivation techniques within the scope of the project were determined using an HPLC system, and the results are presented in Table 2. Fructose and glucose are the dominant sugars in the grape juices, constituting the major part of the sugar composition. It has been reported that fructose and glucose accumulation is predominant in grape juice, complemented by sucrose, and that sugar accumulation in grapes is directly proportional to growth and development (Manning et al., 2001; Fontes et al., 2011). In this respect, the content and composition of glucose, fructose, and sucrose play a significant role in fruit quality formation (Liu et al., 2017; Zhong et al., 2023). Glucose and fructose account for approximately 97.88%–99.86% of the sugar composition in grapes. The balance between these two sugars varies between 0.74 and 1.05 during the ripening process (Li et al., 2020).

An examination of Table 2. reveals that the fructose content ranges from 7.15 to 8.17 g/100 g, while glucose ranges from 6.15 to 8.52 g/100 g. Alfalfa biohydrogel, and PGP applications were found to increase fructose levels in grape juice compared to the control groups. While glucose levels were higher in the alfalfa and biohydrogel-treated vines than in the control groups, glucose levels in the PGP-treated area were lower than in the control. Regarding the sum of fructose and glucose, alfalfa and biohydrogel treatments provided higher sugar accumulation than the control, whereas values in PGP-treated areas remained lower than the control. These findings are consistent with those reported in the literature (Liu et al., 2006; Eyduran et al., 2015; Zhong et al., 2023).

When evaluating the effects on sugar metabolism in PGP applications, it is known that these microorganisms optimize photosynthetic activity and carbon metabolism (Yang et al., 2009). The glucose/fructose ratios in this study, ranging from 0.81 to 1.08, confirm that hexose sugars accumulated in a balanced manner during the ripening process and that these values remain within physiological limits (Kliewer, 1967; Li et al., 2020). The fact that the different agronomic techniques applied did not create any negative impact on sugar metabolism, and that this ratio remained more balanced—particularly in PGP applications—is associated with the potential of plant growth-promoting microorganisms to optimize carbon distribution (Vacheron et al., 2013; Egamberdieva et al., 2017). Consequently, it is evaluated that PGP applications have a regulatory effect on carbon metabolism in grapes and contribute to the stabilization of sugar composition.

Chemometric Analysis of Sugar Components in Grapes Produced With Different Cultivation Techniques Against Drought

The results of the chemometric analysis conducted regarding the sugar components of grape juices produced with different cultivation techniques within the scope of the project are presented in Figures 1 and 2.

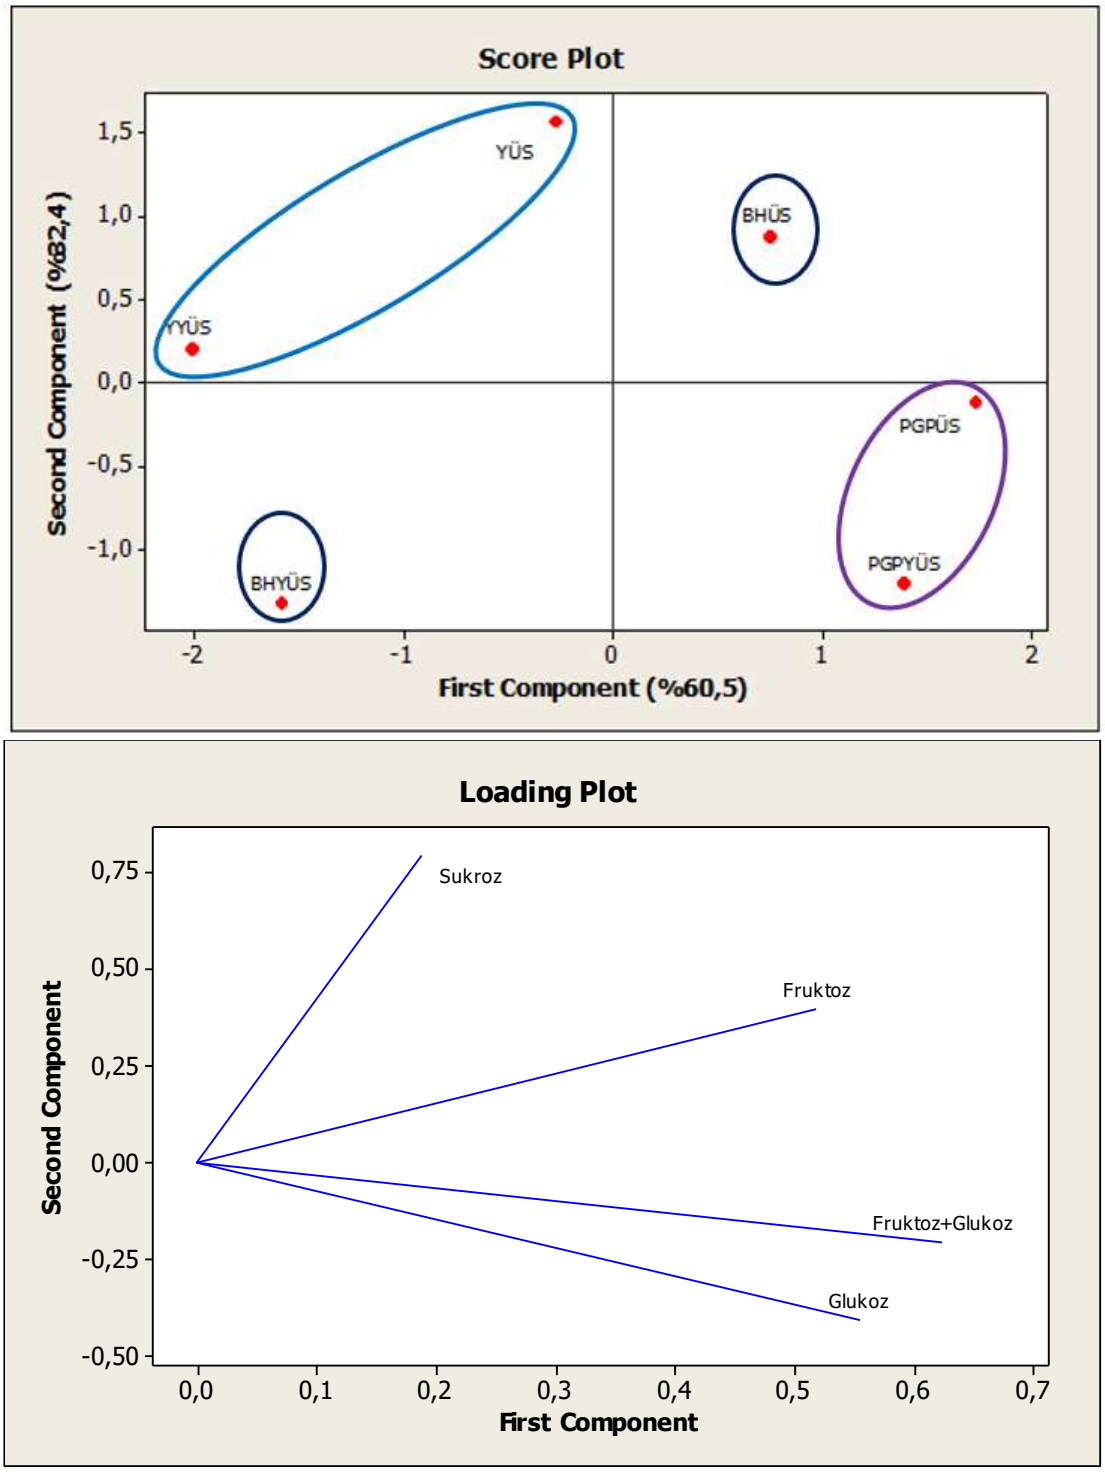

Figure 1**.** Results of the chemometric analysis (PCA and HCA) regarding the sugar components of grape juices produced with different cultivation techniques

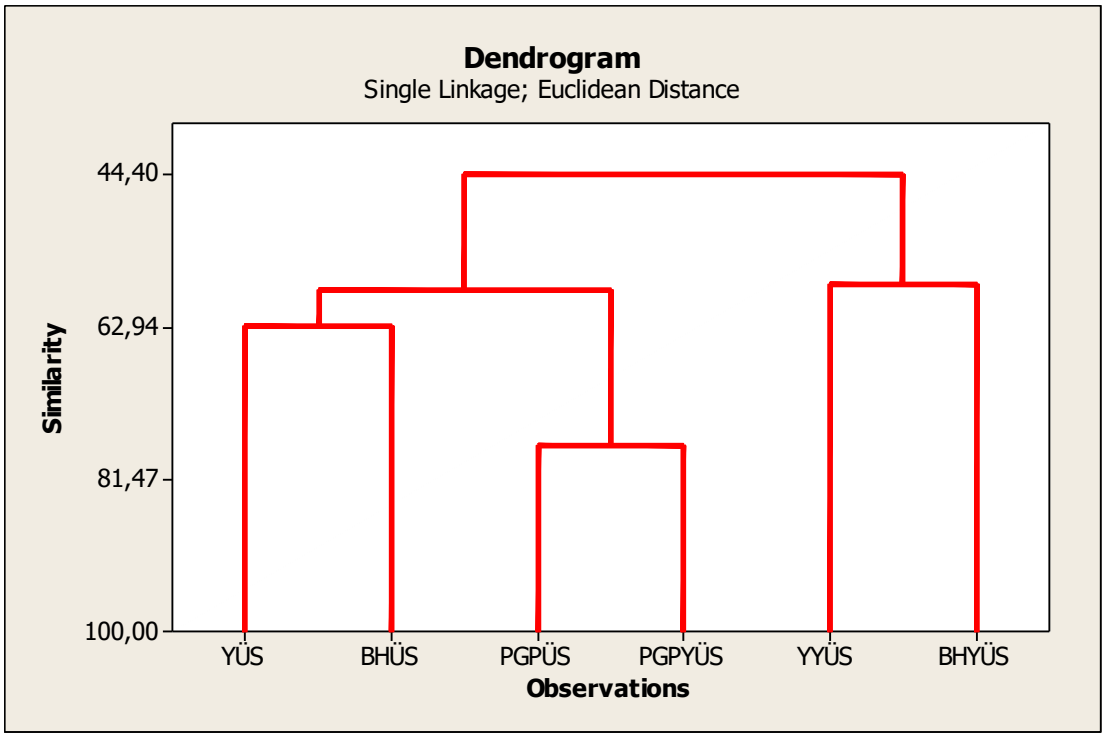

Figure 2. Dendrogram analysis regarding the sugar components of grape juices produced with different cultivation techniques.

The chemometric analyses based on sugar components (PCA and HCA) presented in Figures 1 and 2 clearly demonstrate the effects of the treatments on grape metabolism. The PCA results indicate that PGP application creates a more homogeneous and stable structure regarding sugar composition, whereas alfalfa and biohydrogel treatments exhibit higher variation. HCA and dendrogram analyses support these findings, confirming that the PGP treatment forms a distinct cluster and exerts a regulatory effect on carbon metabolism (Figures 1 and 2). These results are consistent with the literature regarding the balancing role of plant growth-promoting (PGP) microorganisms in sugar metabolism (Vacheron et al., 2013; Egamberdieva et al., 2017).
When the analytical results for phenolic compounds and organic acids in grapevine leaves and grape juices, along with the sugar profiles of the grape juices, are evaluated as a whole, it is observed that the chemometric analyses (PCA, HCA, and dendrograms) support all findings and clearly reveal the metabolic impacts of the treatments. PCA analyses show that the treatments create distinct separations in terms of phenolic and sugar composition, while HCA and dendrogram analyses reveal that these differences manifest as statistically significant clusters. Specifically, it has been determined that PGP application leads to a more homogeneous metabolic profile, whereas alfalfa and biohydrogel treatments result in higher metabolic diversity. This clearly proves that the phenylpropanoid metabolism is a dynamic and tunable system, highly sensitive to environmental and agronomic factors

CONCLUSIONS

In this study, the sugar profiles of grapes produced using various cultivation techniques aimed at growing grapevines with reduced water usage were determined using an HPLC system. Highlighting the critical importance of water conservation in viticulture, this study demonstrates that sustainable agronomic techniques can maintain or enhance key fruit quality parameters and sugar metabolism under water-limited conditions. Fructose and glucose were

identified as the dominant sugars in the grape juice across all treatments, accounting for the vast majority of the total sugar composition. Alfalfa and biohydrogel treatments successfully enhanced overall sugar accumulation, whereas PGP applications exhibited a distinct regulatory effect, maintaining a balanced distribution between hexose sugars. The glucose-to-fructose ratios remained well within normal physiological limits (0.81–1.08), confirming that the tested agroecological practices did not negatively impact sugar metabolism and effectively contributed to the stabilization of fruit quality and carbon allocation.

ABSTRACT

The effects of climate change on agricultural production systems are becoming more evident with each passing day, particularly in the Mediterranean basin.Within the scope of this study, it was aimed to reduce water consumption in grapevine cultivation and to elucidate the metabolic responses of plants to drought stress, thereby contributing to the sustainable management of water resources under climate change conditions. Accordingly, alfalfa (cover crop), biohydrogel, and plant growth-promoting rhizobacteria (PGP) applications were implemented under conditions where water demand was reduced by 50%; the results obtained were compared with those from fully irrigated control plots. To determine the volatile secondary metabolite profiles of grapevine leaves grown under different production conditions (alfalfa, biohydrogel, growth-promoting rhizobacteria), essential oils were extracted via steam distillation from fresh leaves harvested before the fruit ripening stage. The component analysis of these oils was conducted using Gas Chromatography (GC) and Gas Chromatography-Mass Spectrometry (GC-MS) systems. Although aldehyde compounds were present in low quantities in the plots where alfalfa was applied, the relative abundances of terpenoids and compounds with aromatic ester and benzenoid structures were determined to have increased. In the analysis of secondary metabolites, it was found that terpenoids were present at high levels ranging from 29.46% to 43.55% in all treatments, and that aromatic ester/benzenoid compounds reached levels as high as 16.25% particularly in the alfalfa treatment. In contrast, the fact that aldehydes—known as stress biomarkers—were present only in the control and alfalfa-free systems at levels ranging from 0.42% to 0.99%, and were completely absent in the biohydrogel and PGP treatments, was interpreted as evidence that lipid peroxidation was suppressed and oxidative stress was effectively controlled. Moreover, it has been shown through experimental studies that hydrogel applications reduce water stress in plants and improve physiological performance.

INTRODUCTION

Viticulture is a production system that is highly sensitive to climatic conditions; environmental variables such as temperature, precipitation patterns, relative humidity, and wind directly affect grape yield and quality. For this reason, the grapevine is considered an indicator plant that reflects the effects of climate change early and distinctly (Bucur et al., 2019). In arid and semi-arid regions, low and irregular rainfall poses a significant threat to agricultural production due to water scarcity. Deficit irrigation techniques are of vital importance for efficiently managing these limited water resources, ensuring optimal soil moisture in the root zone, and increasing water use efficiency without compromising crop quality (Panigrahi et al., 2011; Pereira et al., 2011). However, since these methods involve high-cost systems that require specialized expertise, they generally offer advantages only in the cultivation of high-value crops (Uysal et al., 2024). Today, the Mediterranean basin continues to account for a significant portion of global grape production; in countries such as Spain, France, Italy, Portugal, Morocco, and Türkiye, viticulture not only generates economic value but also contributes to the preservation of the rural landscape, local culture, and agricultural biodiversity (OIV, 2023; Santillán et al., 2019).

Microorganisms living in the plant root zone directly influence many processes, such as nutrient cycling, root development, stress tolerance, water use efficiency, and disease resistance (Berendsen et al., 2012; Compant et al., 2019). It has been reported that bacterial groups such as Proteobacteria, Actinobacteria, and Firmicutes are particularly dominant in the *Vitis vinifera* L. rhizosphere and that these microorganisms perform critical functions related to plant development (Vega-Avila et al., 2015).

In this study, to determine the volatile secondary metabolite profiles of grapevine leaves grown under different production conditions (alfalfa, biohydrogel, growth-promoting rhizobacteria), essential oils were extracted via steam distillation from fresh leaves harvested before the fruit ripening stage. The component analysis of these oils was conducted using Gas Chromatography (GC) and Gas Chromatography-Mass Spectrometry (GC-MS) systems. Within the scope of this study, the effects of various agroecological practices (alfalfa cover cropping, biohydrogel application, and plant growth-promoting (PGP) bacteria) on the secondary metabolite profile and chemometric analysis of grapevines were evaluated under water-limited conditions. The analysis results for grapevine leaves obtained from the experimental plots of the Ministry of Agriculture and Forestry's Manisa Viticulture Research Institute are presented below under the relevant headings, based on the control group of the study.

MATERIAL AND METHOD

Chemical Analysis of Essential Oils Extracted From Grapevine Leaves

1. Extraction of Essential Oils

Grape leaves collected from the field were boiled fresh in water for approximately three hours using a Clevenger-type apparatus to extract the essential oil via hydrodistillation. Due to the low yield of essential oil, the oil was extracted from the Clevenger apparatus using hexane. The essential oil, now in a mixture with hexane, was then dried with anhydrous sodium sulfate and stored in a refrigerator at +4 °C until analysis.

2. Gas Chromatography (GC) Analysis

The essential oil components obtained from grape leaves via hydrodistillation were analyzed using a Shimadzu GC-17AAF gas chromatograph. The percentage compositions of the essential oil components were calculated using the GC Solution software based on the gas chromatogram. In addition, the characterization of the components was supported by

considering their retention times and calculating their Kovats index values. The GC analysis conditions are presented in Table 1.

Table 1. GC Analysis Conditions

Column	:	DB-1 capillary column (0.25 id x 30 m)
Dedector	:	FID
Carrier Gas	:	He
Makeup/Fuel Gases	:	High-purity (99.999%) dry air and hydrogen
Injection Temperature	:	250°C
Column Temperature	:	The sample was held at 60°C for 5 minutes. It was then heated to 280°C at a rate of 4°C per minute and held at 280°C for 15 minutes.
Detector Temperature	:	280°C
Split Ratio	:	1:50
Injection Volume	:	0.2µL

3. Gas Chromatography-Mass Spectrometry (GC-MS) Analysis

A Varian 2100 GC-MS instrument was used to characterize the volatile oil components of grape leaves. NIST 2014 library data, as well as the spectrophotometric atlases titled "Eight Peak Index of Mass Spectra," "Monoterpenes," and "Identification of Essential Oils by Ion Trap Mass Spectroscopy," were used to identify the components. Retention times and Kovats index values were instrumental in determining the components. In addition, the analyses of the volatile oil components were confirmed by comparing them with literature data, retention times obtained by analyzing reference substances individually under the same chromatographic conditions, and by using reference substances as internal standards to account for potential interference. The GC-MS analysis conditions are presented in Table 2.

RESULTS AND DISCUSSION

Evaluation of The Secondary Metabolite Profile And Class Distribution Of Grapevine Leaves Grown Under Different Production Conditions

Within the scope of this study, it was aimed to reduce water consumption in grapevine cultivation and to elucidate the metabolic responses of plants to drought stress, thereby contributing to the sustainable management of water resources under climate change conditions. Accordingly, alfalfa (cover crop), biohydrogel, and plant growth-promoting rhizobacteria (PGP) applications were implemented under conditions where water demand was reduced by 50%; the results obtained were compared with those from fully irrigated control plots.

To determine the volatile secondary metabolite profiles of grapevine leaves grown under different production conditions, essential oils were extracted via steam distillation from fresh leaves harvested before the fruit ripening stage. The component analysis of these oils was conducted using Gas Chromatography (GC) and Gas Chromatography-Mass Spectrometry (GC-MS) systems. The codes and descriptions of the essential oil samples obtained from the grapevine leaves are presented in Table 3 while the qualitative and quantitative data of the identified volatile secondary metabolites and their distributions at the compound class level are presented in Table 4.

Table 3. Identification codes for essential oil samples obtained from grapevine leaves produced under different production conditions

Sample Description and Production Condition	Sample Code
Essential oil from grapevine leaves grown in the alfalfa-mulched field	YY
Essential oil from grapevine leaves grown in the field without alfalfa	YYY
Essential oil from grapevine leaves grown in the biohydrogel-treated field	BHY

Essential oil from grapevine leaves grown in the field without biohydrogel	BHYY
Essential oil from grapevine leaves grown in the PGP-treated field	PGPY
Essential oil from grapevine leaves grown in the field without PGP	PGPYY

The analysis results indicate that the volatile secondary metabolites found in grapevine leaves consist primarily of aldehydes, alcohols, terpenoids, aromatic compounds, and hydrocarbons. However, it has been determined that the relative abundances of these compound classes exhibit significant variations depending on the applied production conditions. Aldehyde compounds were detected at low levels only in the alfalfa-treated (YY) and non-alfalfa control (YYY) plots (0.99% and 0.42%, respectively), whereas these compounds were not detected in the biohydrogel and PGP applications. It was observed that terpenoids varied between 29.46% and 43.55% in all samples, while fatty acid derivatives were found to be among the dominant compound classes, ranging from 29.20% to 48.12%. When evaluated in terms of aromatic esters

and benzenoid compounds, it was determined that these compounds increased in the biohydrogel-treated field (BHY) and the alfalfa-cultivated field (YY) compared to the control group (16.25% and 3.26%, respectively), whereas they were found at lower levels (1.45%) in the PGP-treated field (Table 4).

Although aldehyde compounds were present in low quantities in the plots where alfalfa was applied, the relative abundances of terpenoids and compounds with aromatic ester and benzenoid structures were determined to have increased. In particular, the presence of β-ionone and its derivatives, hexahydrofarnesyl acetone and various aromatic esters at higher rates in these groups indicates that the secondary metabolism has shifted in a different direction. This situation points to a systemic metabolic reprogramming at a level that cannot be explained solely by the reduction of stress. The reduction of evaporation by cover crops like alfalfa by covering the soil surface, the stabilization of soil moisture, and the enhancement of microbial activity in the root zone are evaluated as fundamental reasons for the effect of this application on secondary metabolism. Various studies have shown that cover crops reduce evaporation and protect soil moisture by creating a physical barrier on the soil surface; furthermore, they improve soil structure, increase water-holding capacity, and significantly raise microbial activity (Haruna et al., 2020). Additionally, it is anticipated that alfalfa's increase in soil fertility through nitrogen fixation may have contributed to the activation of the phenylpropanoid and isoprenoid metabolic pathways.

As in the plots where alfalfa was applied, an increase in terpenoids and aromatic compounds was observed in the plots where PGP bacteria were applied. However, it is understood that this increase is more limited compared to the alfalfa application and that it occurs as a strengthening of the existing metabolic structure rather than a complete change in the metabolite profile. It is known that PGP bacteria interact with plant roots to increase the production of phytohormones such as indole-3-acetic acid (IAA), regulate ethylene levels through the ACC deaminase enzyme, and trigger systemic resistance (ISR) mechanisms in the plant. These mechanisms have been reported to improve water and nutrient uptake by increasing root development and to raise the plant's tolerance against abiotic stresses (Gupta and Pandey, 2019). These biochemical processes lead to the activation of enzymatic pathways responsible for secondary metabolite synthesis, particularly increasing terpenoid production. In their study, Velásquez et al. (2020) revealed that microbial inoculation causes an increase in terpenoid compounds. In our study, the fact that the quantities of terpenoids such as linalool, linalyl acetate, β-ionon ve α-farnesen in the grapevine leaves in the PGP-treated field have increased compared to the control group is in full compliance with the findings reported by Velásquez et al. (2020). The data obtained in this study are consistent with the aforementioned literature and reveal that PGP application strengthens the adaptive metabolic response in the plant.

In the secondary metabolites of grapevine leaves in the field where biohydrogel application was performed, no significant increase was observed in terms of terpenoids, while an increase was detected in aromatic esters and benzenoid compounds. This shows that biohydrogel contributes to the preservation of the existing metabolic balance by reducing the plant's water stress rather than directly activating secondary metabolite biosynthesis. In addition to these, it is known that biohydrogel improves plant water potential and prevents the formation of oxidative stress by increasing the water-holding capacity in the soil (Agbna and Zaidi, 2025). Therefore, biohydrogel can be evaluated as a buffer mechanism that prevents the occurrence of stress rather than increasing secondary metabolite diversity. Indeed, it is clearly stated in the literature that biohydrogels create a continuous and balanced water source in the root zone by increasing the water-holding capacity in the soil, thereby increasing the resistance of plants against drought stress and reducing stress-induced metabolic disturbances (Agbna and Zaidi, 2025). Moreover, it has been shown through experimental studies that hydrogel applications reduce water stress in plants and improve physiological performance (Kargar et al., 2017).

Chemometric Analysis of Secondary Metabolite Components in Grapevine Leaves Cultivated Under Different Production Conditions

The qualitative and quantitative results of volatile secondary metabolites in grapevine leaves cultivated under three different methods against drought stress were analyzed chemometrically. The results of the chemometric analysis, which considered all volatile secondary metabolite components, are presented in Figure 1 and Figure 2.

As illustrated in Figure 1, it is observed that the volatile secondary metabolites of grapevine leaves treated with PGP bacteria (PGPY) and those untreated (PGPYY, control group) clustered together. Similarly, grapevine leaves treated with biohydrogel (BHY) and those untreated (BHYY, control group) also clustered together; however, they occupied distinct regions due to differences in specific components. In contrast, the volatile secondary components of grapevine leaves from the alfalfa-treated (YY) and non-treated (YYY) fields were found to form distinct clusters in the Principal Component Analysis (PCA). Nevertheless, the hierarchical clustering dendrogram indicates that they cluster together (Figure 1 and Figure 2). According to the chemometric analysis results, the three different methods tested for drought stress in grapevine cultivation clustered in distinct regions regarding their volatile secondary metabolites, indicating that the cultivation technique directly contributes to the biosynthesis of secondary metabolites.

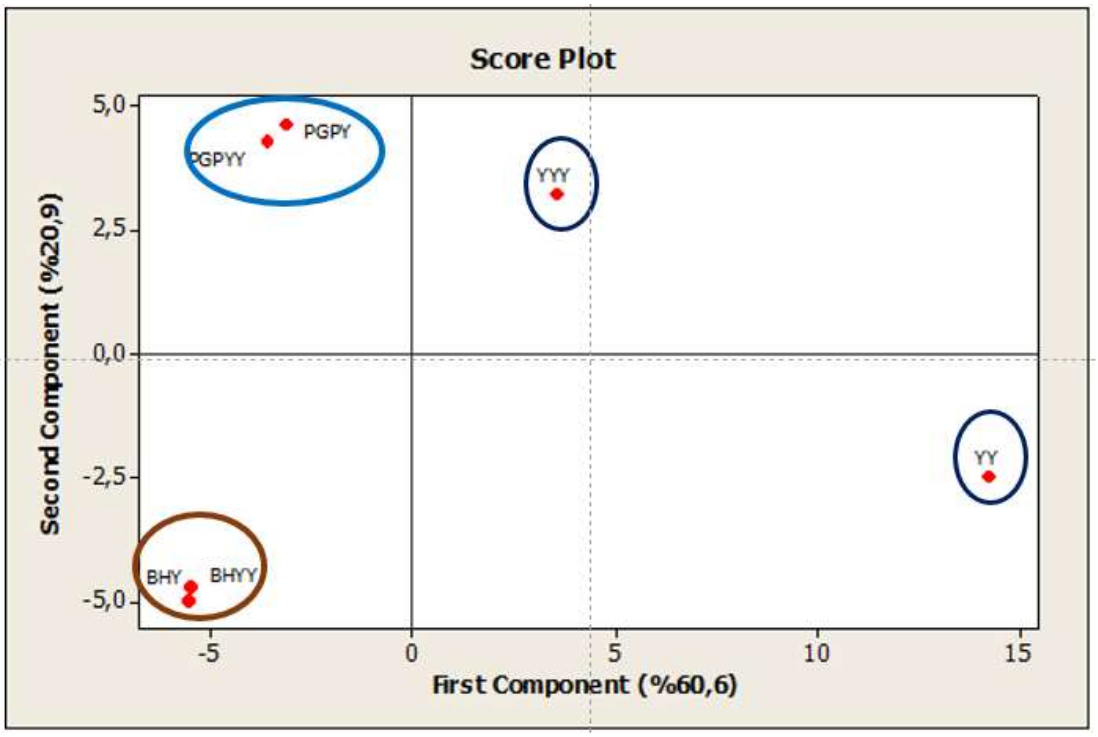

Figure 1. Principal Component Analysis (PCA) results of secondary metabolite components in grapevine leaves cultivated under different production conditions

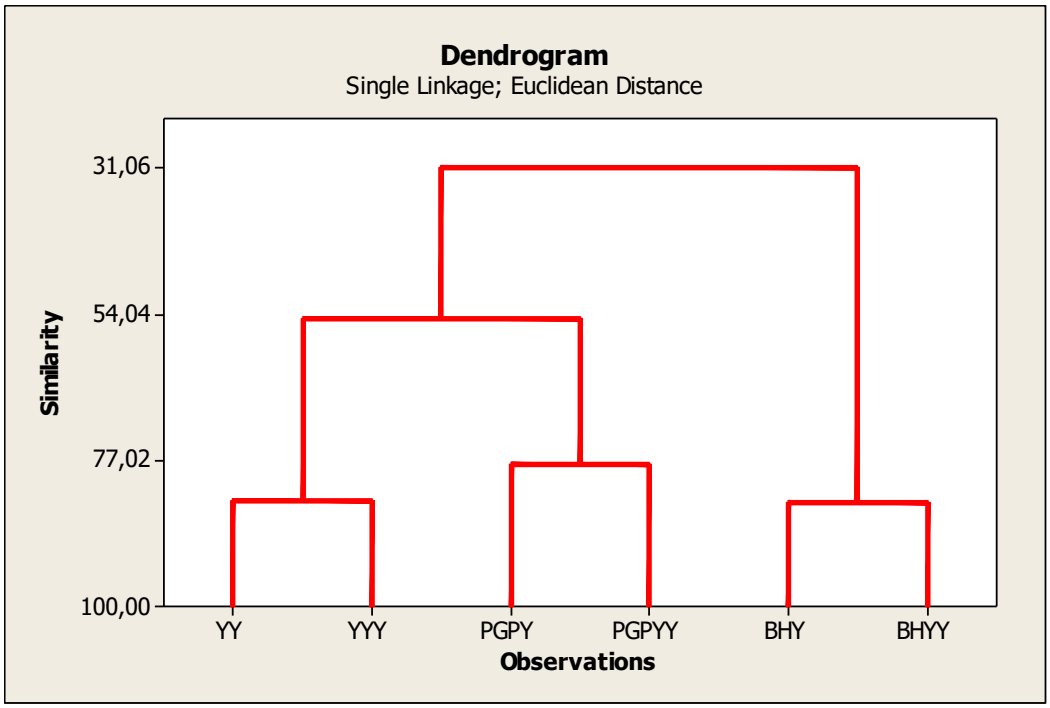

Figure 2. Dendrogram of volatile secondary metabolite components in grapevine leaves cultivated under different production conditions

Chemomitric analysis results concerning the volatile secondary metabolite components of the samples within the scope of the study are presented in Figures 3 and 4.

Based on the volatile secondary metabolite compound classes in the leaves of grapevines subjected to Biohydrogel application (BHY) versus those not subjected (BHYY, control group), Principal Component Analysis (PCA) reveals that the grapevines grown using these methods cluster separately from those grown using the other two techniques. Furthermore, while the volatile secondary metabolite compound classes in the leaves of vines subjected to PGB application (PGBY) and those not subjected (PGBYY, control group) cluster together in terms of PCA, the secondary metabolites of grapevine leaves grown in the field without alfalfa also fall within this same cluster (Figure 3). The fact that the volatile secondary metabolite compound classes in the leaves of grapevines grown in the alfalfa-planted field cluster differently from the other techniques and their respective control groups clearly demonstrates the effect of water-deficit management methods on the plant's secondary metabolite production. Hierarchical Cluster Analysis (HCA) revealed that the volatile metabolites cluster into two main groups based on compound classes: one group consists of leaves from grapevines treated with Biohydrogel, while the other comprises samples from PGB-treated and alfalfa-planted areas (Figure 4). Additionally, the dendrogram indicates that the secondary metabolites of grapevine leaves in the alfalfa-planted field cluster differently from both the control group and the PGB-treated field. Just as in the chemometric analyses performed on volatile secondary compounds, the results based on compound classes also indicate that the three distinct methods applied for water-deficit management elicit different responses in the plant, suggesting that the biosynthetic pathways involved may differ. The distinct clustering based on compound classes confirms the hypothesis that cultivation techniques directly contribute to secondary metabolite biosynthesis.

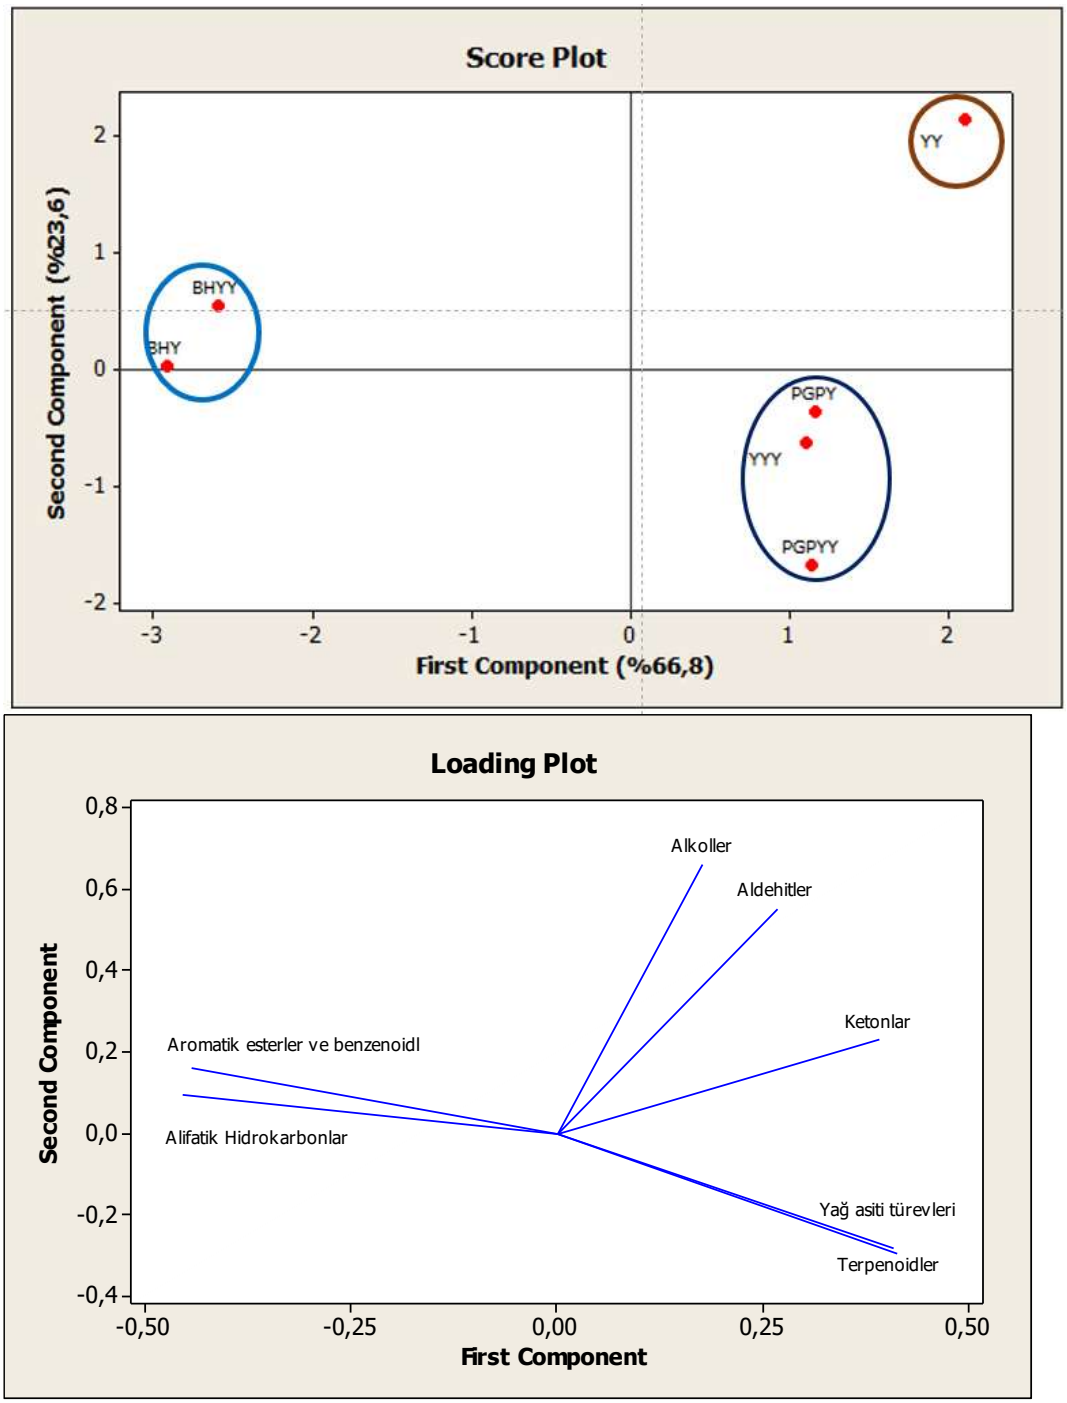

Figure 3. Results of Principal Component Analysis (PCA) and Hierarchical Cluster Analysis (HCA) regarding the volatile secondary metabolite compound classes of grapevine leaves produced under different cultivation conditions.

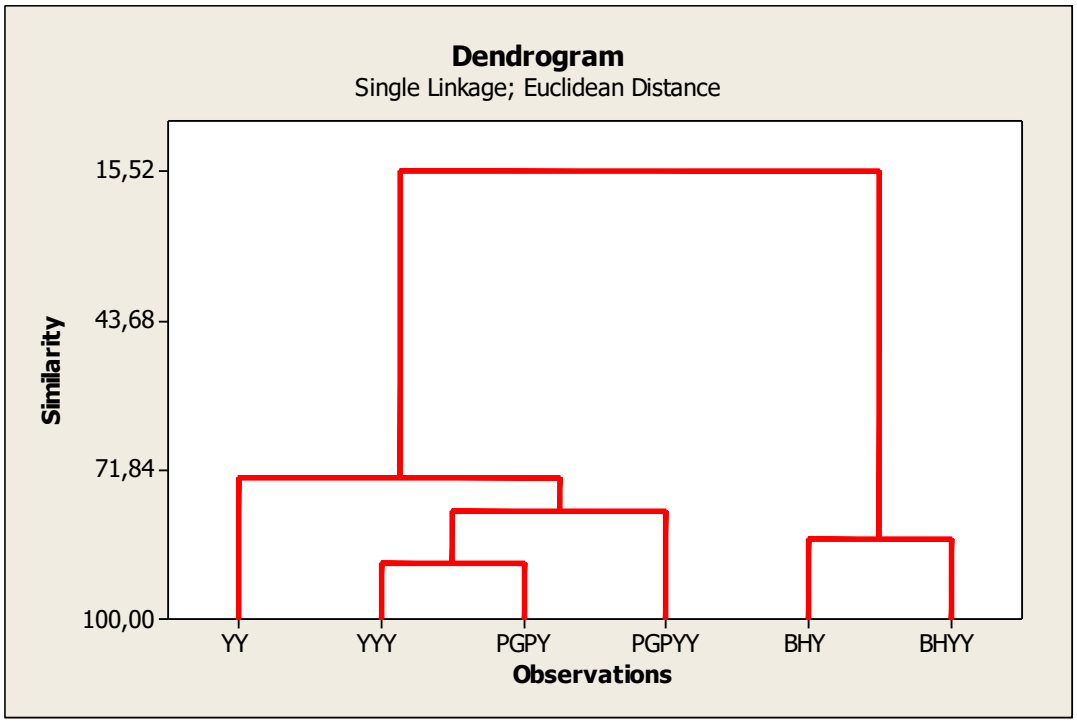

Figure 4. Dendrogram of volatile secondary metabolite compound classes of grapevine leaves produced under different cultivation conditions.

CONCLUSIONS

Based on the analysis of secondary metabolites, terpenoids predominated across all treatments, accounting for 29.46% to 43.55% of the total composition, while aromatic esters and benzenoids peaked at 16.25% specifically in the alfalfa treatment. Notably, aldehydes—widely recognized as biomarkers of oxidative stress—were detected solely in the control and alfalfa-free systems (0.42% to 0.99%) and were entirely absent in the biohydrogel and plant growth-promoting (PGP) treatments. This absence strongly indicates that these sustainable management practices effectively suppressed lipid peroxidation and successfully mitigated oxidative stress in the plants.

ABSTRACT

Kefe cumin (Laser trilobum (L.) Borkh.) is a perennial herbaceous species belonging to the Apiaceae (Umbelliferae) family. Although it is not cultivated in Türkiye, it is known to occur naturally in many regions of the country. The species is known by various regional vernacular names, including Kefe cumin, mountain cumin, sıra baharatı, and geyik sırası. As a species widely distributed throughout the flora of Türkiye, *Laser trilobum* occupies an important place in the gastronomic and ethnobotanical traditions of the regions where it naturally occurs. From a gastronomic perspective, the spice obtained by drying and grinding the fruits into a powder is widely used as a flavoring agent in meat dishes and traditional beverages, particularly in the provinces of Mersin, Adana, and Hatay. The fruits of Kefe cumin, a medicinal and aromatic plant, have been reported to be rich in mineral nutrients. The major constituents of the plant's essential oil are known to be d-limonene and perillaldehyde. These monoterpenoid compounds are responsible for the characteristic lemon-like aroma and distinctive woody odor profile of the fruits. The essential oil composition of fruit samples collected from different geographical regions has been reported to exhibit variation. Furthermore, significant differences have been reported in the proportions of essential oil constituents among different plant parts. The rich essential oil content of Kefe cumin demonstrates its considerable potential and indicates that the species is of significant economic and industrial value among medicinal and aromatic plants. In conclusion, given its rich phytochemical properties and diverse traditional uses, further scientific research is required to better understand and fully explore the potential of *Laser trilobum*.

Keywords: *Laser trilobum*, d-limonene, perillaldehyde, medicinal and aromatic plants.

INTRODUCTION

Medicinal and aromatic plants are plants that contain bioactive compounds in one, several, or all of their organs, such as leaves, stems, flowers, bulbs, tubers, and fruits (Mokhtarzadeh et al., 2023). Owing to the presence of alkaloids, terpenoids, and phenolic compounds, these plants are used in the pharmaceutical, perfumery, cosmetic, and food industries (Bayram et al., 2010). This wide range of applications has enabled medicinal and aromatic plants to occupy an important place in human history from the past to the present.

Among medicinal and aromatic plants, the Apiaceae family is a large family that includes important medicinal and aromatic plants such as cumin, coriander, anise, fennel, and dill. Plants belonging to the Apiaceae family, also known as the parsley family, are frequently preferred for their use as flavoring and aromatic agents, spices, and medicinal purposes.Members of the Apiaceae family, which have been known to be used in medicine since ancient times, have

attracted the attention of researchers because they are frequently preferred as raw materials in the pharmaceutical, cosmetic, and perfumery industries (Sayed-Ahmad et al., 2017).

One of the common characteristics of species belonging to this family is their richness in essential oil content. Owing to the essential oils they contain and their compositions, the utilization potential of these plants also becomes more diverse. One of these species, Laser trilobum (L.) Borkh., is among the species worthy of phytochemical evaluation due to its characteristic essential oil components and traditional uses (Demir & Kan, 2025; Ferahoğlu & Kırıcı, 2023).

Laser trilobum (L.) Borkh. (Kefe cumin) and Cuminum cyminum L. (cultivated cumin) both belong to the Apiaceae family; however, they are distinct species belonging to different genera (Laser and Cuminum). Therefore, although the designation "Kefe cumin" may botanically suggest that this plant is a species of cultivated cumin, its relationship with true cumin is limited to the family level. In addition to this botanical distinction, Kefe cumin differs from the commonly used cultivated cumin by its sharp and distinctive woody aroma. This distinction has led to promising views that, owing to its rich essential oil composition, Kefe cumin may serve as an alternative in the food industry (Demir & Kan, 2025) and may also represent a novel spice for use in gastronomy (Bayraktar, 2009).

The essential oil content and composition of plants have been reported to vary depending on geographical and genetic variation, physiological characteristics, and environmental conditions (Chizzola, 2010). The wide geographical distribution of Laser trilobum and its ability to grow under different ecological conditions indicate that its essential oil composition may also be influenced by these environmental differences (Ferahoğlu & Kırıcı, 2023; Bayraktar, 2009). Indeed, the literature has reported that the proportions of limonene and perillaldehyde, which are the major constituents of the essential oil, vary over a wide range in fruit samples collected from different countries and regions, particularly Türkiye, Serbia, Austria, and Iran. In addition, a limited number of studies have investigated plant organs other than the fruit (rhizome, leaf, and herba) and have observed that the essential oil composition of these organs differs qualitatively from that of the fruit (Ferahoğlu & Kırıcı, 2023; Drobac et al., 2017; Chizzola, 2007).

However, these findings are scattered throughout the literature, and no comprehensive review has been found that simultaneously evaluates the effects of variables such as geographical origin (country, region, and province), altitude, and plant organ on essential oil composition. The aim of this study is to review, in light of the available literature, the differences in the essential oil content of Laser trilobum samples collected from different regions, countries, and provinces, as well as the variations in essential oil composition among different plant organs.

General Information About Kefe Cumin

Laser trilobum is a naturally growing perennial herbaceous species belonging to the Apiaceae family that has not been sufficiently studied (Uçan Türkmen et al., 2024). The plant is also known by names such as Kefe cumin, mountain cumin, wild cumin, and sıra cumin (Tosun, 2021). It is referred to as “sıra baharatı” and “sıra kimyonu” in the Mersin region (Bayraktar, 2009), “kemun-kamun” in Kahramanmaraş (Üstüner, 2022), and “geyik sırası” in the Hatay region (Özmen, 2010).

Laser trilobum reaches a height of 50–120 cm, has trilobed glabrous leaves, and is characterized by white umbel-type flowers. Its fruits are elliptical in shape, measuring 5–10 mm in length and 2–4 mm in width (Ferahoğlu & Kırıcı, 2023). The plant flowers in spring, and its seeds are harvested in June and July. It is known to grow in forested areas, under trees such as pine and oak, in shrublands and semi-shaded habitats, and along the edges of vineyards (Parlatan et al., 2009). Kefe cumin has been reported to grow in calcareous soils (Chizzola, 2007), and its distribution ranges from approximately 500 to 1,800 m above sea level (Bayraktar, 2009).

Geographical Distribution of Kefe Cumin

Laser trilobum grows naturally in the Turkish provinces of Zonguldak, Gümüşhane, Samsun, Bolu, İstanbul, Edirne, Bursa, Balıkesir, İzmir, Muğla, Afyon, Konya, Ankara, Sivas, Kahramanmaraş, Erzincan, Eskişehir, Adana, Hatay, Isparta, and Mersin (Parlatan, 2005). Worldwide, it is naturally distributed in countries including Iran, Lebanon, Syria, Russia, Ukraine, Germany, Hungary, Albania, Bulgaria, Greece, Italy, and Romania (Demir & Kan, 2025). This broad geographical distribution indicates that the species can naturally occur under different ecological conditions.

Traditional Uses

The seeds of Kefe cumin (*Laser trilobum*) have a wide range of uses. The seeds of the plant are ground and used in dishes, particularly meat dishes, as an aromatic spice (Drobac et al., 2017; Chizzola, 2007; Parlatan et al., 2009). It has also been reported that the leaves of the plant are used as a vegetable (Chizzola, 2007). In addition, the plant is known to be used against ailments such as abdominal pain and cramps, hypertension, and diabetes. Furthermore, the prepared tea can be applied to the skin for the treatment of acne (Parlatan et al., 2009). In addition to its use in the treatment of diseases, it has been reported to be used for purposes of supporting the immune system (Demir & Kan, 2025).

Besides the widespread use of the plant fruits, the essential oil components obtained from the plant are also known to have a wide range of applications (Drobac et al., 2017; Ferahoğlu & Kırıcı, 2023; Parlatan, 2005). D-limonene, one of the important components of the essential oil of Kefe cumin, is a monoterpene that is also found in high proportions in citrus peels. D-limonene is used as a flavoring and aroma agent in the food industry, as a perfume component in the cosmetics sector, and as a natural solvent in the cleaning industry; it also has potential for the development of antimicrobial agents and biopesticides (Demir & Kan, 2025).

Perillaldehyde, another major component obtained from Kefe cumin fruits, also has a wide range of applications. Perillaldehyde is widely used as a flavoring additive in food products to impart a spice- and citrus-like flavor (Ferahoğlu & Kırıcı, 2023). In addition, various studies have demonstrated that it exhibits high efficacy against food spoilage, particularly that caused by fungi, and that it can therefore be considered as a natural food preservative (Tian et al., 2015). Furthermore, findings indicating that the compound has antidepressant (Ji et al., 2014), antitumor (Andrade et al., 2018), and anticancer (Zielińska et al., 2021) effects suggest that *L. trilobum* may be considered an important natural source of perillaldehyde for the pharmaceutical industry.

Essential Oil Content and Major Components

Essential oils contain a complex mixture of compounds with various functional groups, which contributes to different biological activities, such as antimicrobial and antioxidant activities (Abbaszadegan et al., 2016). The biological activities of essential oils produced by aromatic plants as secondary metabolites are directly related to the types of compounds they contain, the concentrations of these compounds, and the interactions among these compounds. In addition, the major components present in plants are among the principal groups of compounds that determine the biological and sensory properties of essential oils (Bakkali et al., 2008). Determining the essential oil composition of a plant is important not only for revealing its characteristic aroma profile but also for evaluating its potential biological activity and possible areas of application.

The determination of the chemical composition of *Laser trilobum* essential oil is of interest in terms of understanding the characteristic aroma profile and biological properties of the species. Determining the chemical composition and aroma profile of the plant's essential oil will contribute to identifying the potential areas of application of *Laser trilobum*. Several studies

addressing this subject are available in the literature. Some studies on the plant have obtained samples from different locations, helping to determine whether differences in location result in variations in the essential oil, whereas other studies have focused on determining the essential oil contents of different organs of plants obtained from the same location.

When essential oil analyses conducted on samples of different origins and plant organs in the literature are examined, variable results have also been obtained in fruits collected from different provinces of Türkiye. For example, Kefe cumin fruits obtained from the Mersin region were found to have an essential oil content of 4.4%, and the major components of the obtained essential oil were determined as perillaldehyde at 50% and d-limonene at 45% (Ferahoğlu & Kırıcı, 2023). In contrast, although the essential oil content was lower (2.7%) in fruits obtained from the Zonguldak region, the dominance of perillaldehyde continued here as well (68%), while d-limonene ranked second at 24% (Meriçli & Meriçli, 1986). The essential oil content of plant herba collected from the Artvin region was found to be 1.2%; the major components were determined as 73% perillaldehyde, 7.6% perill alcohol, and 7.6% E-caryophyllene, while limonene was detected at a low proportion of 2% (Bayraktar, 2009).

In a study comparing seeds obtained from different countries, the essential oil contents of samples originating from Germany, India, and Türkiye were found to be 4.4%, 4.8%, and 5.8%, respectively, and perillaldehyde and d-limonene were determined as the major components in all three origins (Parlatan et al., 2009). In samples collected from Iran, plant herba was used, and the essential oil content was reported as 2.2% as a result of the analysis. The major components of the essential oil were found to be α-pinene at 34% and β-caryophyllene at 17% (Vahdat et al., 2006). This result differed from the perillaldehyde and limonene dominance observed in previous studies and suggests that variation in chemical composition may also be influenced by factors such as climate, soil structure, and harvesting period, in addition to geographical origin.

In another study, samples collected from different locations in Austria were examined separately for leaf and fruit essential oils. The major components of the essential oil obtained from the leaves were found to be α-pinene at 12% and bornyl angelate at 67%, whereas the major components of the essential oil obtained from the fruits of the same plant were determined as perillaldehyde and limonene (Chizzola, 2007).

In another study, when the essential oils of plant fruits and rhizomes obtained from Serbia were examined, α-pinene was found at a proportion of 31% as the major component of the essential oil obtained from the rhizomes, whereas this component was found at 7% in the essential oil obtained from the fruits. The second major component of the essential oil obtained from the rhizomes was γ-terpinene at 9%, whereas this compound was not detected in the essential oil obtained from the fruits. The major component of the fruit essential oil was limonene at 51%, while this compound was present at 2% in the rhizomes. The second major component of the fruit essential oil was perillaldehyde at 26%, whereas this compound was not detected in the rhizomes. In addition, although carvone was present among the components of the fruit essential oil in a small amount, this compound was not detected in the rhizomes (Drobac et al., 2017).

A similar study was also observed in samples collected from the Lakes Region. While the essential oil content remained quite low at 0.14% in herba samples, the major components were found to be α-pinene (33.22%) and β-pinene (24.09%). In fruits, however, the essential oil content increased to 11.37%, and the major component was dl-limonene (53.67%) (Tosun, 2021). The aforementioned studies are presented comparatively in Table 1.

Table 1. Essential oil content and major components according to different origins and plant organs.

Origin/Region	**Plant Organ**	**Essential Oil Content**	**Major Components (%)**	**Reference**
Mersin (Türkiye)	Fruit	%4,4	Perillaldehyde 50%; d-Limonene 45%	Ferahoğlu ve Kırıcı, 2023
Zonguldak (Türkiye)	Fruit	%2,7	Perillaldehyde 68%; d-Limonene 24%	Meriçli ve Meriçli, 1986

Sırbistan	Rhizome	Oran belirtilmemiş	α-Pinene 31%; γ-Terpinene 9%	Drobac ve ark., 2017
Sırbistan	Fruit	%6,7	Limonene 51%; Perillaldehyde 26%; α-Pinene 7%; Carvone 0.5%	Drobac ve ark., 2017

CONCLUSION

The evaluation of the literature data reveals that the chemical composition of *Laser trilobum* essential oils can vary considerably depending on geographical origin and plant organ. In fruit samples, d-limonene and perillaldehyde generally predominate, whereas different compounds such as α-pinene, β-pinene, β-caryophyllene, bornyl angelate, and carvone have been found as

dominant or prominent components in some herba, leaf, and rhizome samples. In particular, the emergence of different essential oil profiles in different organs of the same plant demonstrates the importance of plant organ in determining essential oil composition. Indeed, the high proportion of bornyl angelate in the leaf essential oil of *L. trilobum* reveals a chemical profile different from the limonene and perillaldehyde that predominate in the fruits.
However, the fact that the existing studies were conducted under different geographical, ecological, and methodological conditions makes it difficult to attribute the observed differences to a single factor. For these reasons, although the studies demonstrate that the essential oil composition of *L. trilobum* varies according to geographical origin and plant organs, they also indicate the need for studies that help elucidate its relationship with cultivation conditions.

ABSTRACT

In recent years, bifunctional nanomaterials with magnetic and optical properties have gained considerable attention in nanomedicine, especially for nanoscience applications. Materials show different properties at the nanoscale than at bulk size. In addition, as size decreases, nanoparticles develop richer surface properties. For example, a higher surface-to-volume ratio provides a larger surface area, increasing functional efficiency. Therefore, quantum dots (QDs) and magnetic nanoparticles are commonly used for their unique properties. Conventional quantum dots often contain highly toxic heavy metals, such as cadmium, which restricts their clinical translation. Manganese-doped zinc sulfide (ZnS:Mn) quantum dots have been developed to overcome this drawback and are a biocompatible, cadmium-free substitute with stable luminescence. In this study, we synthesized core-shell $CoFe_2O_4$-ZnS:Mn QD nanocomposites through co-precipitation and then successfully developed a dual-modal imaging platform. SEM morphology showed that the composite structure consisted of ZnS:Mn quantum dots inside the cobalt ferrite magnetic nanoparticles. Also, the Fluorescence spectra showed a strong and characteristic orange-pink emission around 630-700 nm, which corresponds to the 4T1→6A1 transition of Mn2+ ions. The coexistence of a strong magnetic response and bright luminescence indicates that these cadmium-free core-shell nanostructures are promising for targeted drug delivery and concurrent optical/magnetic resonance imaging.

Keywords: Nanoscience, Quantum Dots, Magnetic Nanoparticles

INTRODUCTION

Currently, nanotechnology is a hot topic in science. These researchs have led to the development of goods and methods that improve the efficiency of everyday life. The development of nanoscience is being driven by a number of issues, including the need for renewable energy sources, the identification and treatment of novel illnesses, and the growing need for food due to population expansion. The basic building elements of the scientific method of product development are nanostructures. Nano-sized materials are very helpful in biological research due to their special characteristics(Ahmad et al., 2025; Dowling, 2004; Hughes et al., 2025) .

Magnetic nanoparticles (MNPs) are a rapidly expanding class of metal nanoparticles (NPs) that have sparked a revolution in materials science due to their unique combination of advantageous properties, including high surface-to-volume ratio, superparamagnetism, size-dependent properties, and quantum confinement effects, with conventional bulk material characteristics(Chand & Vasquez-Guardado, 2025) . The weak plasmonic optical properties of magnetic nanoparticles limit their use in applications such as imaging. The absence of plasmonic properties, meaning they do not emit fluorescence when exposed to light at a specific wavelength, prevents their use as sensors. To overcome this limitation, composite structures were developed. Magnetic nanoparticles were combined with molecules or nanoparticles that have plasma or fluorescence emission properties, making them multifunctional(Corr et al.,

2008). The aim was to perform both magnetic applications such as MRI, hyperthermia, and magnetic targeting, and optical applications such as SERS detection and fluorescence detection, simultaneously(Mir et al., 2025; Sirgedaite et al., 2023; Wolfbeis, 2015).
Quantum dots (QDs) are semiconductor particles with optical and electronic (optoelectronic) characteristics that vary with size and composition. QDs are very tiny, usually ranging in size from 1.5 to 10.0 nm. QD nanotechnology has recently made significant inroads into a number of biological and electrical areas. Because of their special qualities—such as excellent photostability, size-dependent optical characteristics, high brightness and extinction coefficient, and significant Stokes shift—QDs have been shown to be effective. Due to their limited ability to display all of these characteristics, organic dyes or fluorophore molecules are unsuitable for many imaging and biosensing applications. Furthermore, because of their enormous surface area, ultrasmall QDs may provide additional benefits over another type nanomareials for creating multimodal/multifunctional probes(Bera et al., 2010; Maxwell et al., 2020) . Quantum dots based on cadmium are generally used due to their high emission properties. However, because cadmium-containing quantum dots are not stable under UV light, there is a possibility of cadmium ions leaching into the environment. Since cadmium has high toxicity, its use for biomedical purposes is problematic. Therefore, Cd-based quantum dots are coated with Zn-derived quantum dots. Alternatively, for biomedical applications, Zn and Mn-based or carbon-based quantum dots with lower toxicity are used (Hardman, 2006; Lin & Chen, 2023).
In the literature, nanocomposites containing multifunctional magnetic particles and quantum dots have been produced for this purpose. Some of these include: Wang et al. Fe_2O_3 Beads−CdSe/ZnS Quantum Dots nanocomposite(Wang et al., 2004); Xu et al. Fe_3O_4/SiO_2 and water-soluble CdSe−ZnS quantum dots (QDs) nanocopmpsite. (Xu et al., 2010); Tadesse et al. nitrogen doped carbon quantum dots/magnetite nanocomposites (Tadesse et al., 2018), and Bunkoed et al. graphene quantum dots and magnetite nanoparticles embedded in molecularly imprinted polymer (GQDs@Fe_3O_4/MIP) nanocomposites(Bunkoed et al., 2020).
In this study, Cobalt ferrite magnetic nanoparticles were modified with ZnS:Mn quantum dots. Quantum dots provided fluorimetric properties to magnetic nanoparticles

METHOD

1.) $CoFe_2O_4$ nanoparticles (MNPs) were created via co-precipitation. A 1:2 mole solution of $CoCl_2$ and $FeCl_3$ salts was prepared in a flask and mixed with a NaOH solution at 80°C for an hour. The resulting black particles were gathered using a magnet, and a solution of water was used for three magnetic washing processes. After that, it was dissolved in 50 mL deionized water (Roy et al., 2024)
2.) 1.0 ml $CoFe_2O_4$ nanoparticle (MNP) solutions were added to 10.0 ml 0.025 M Zn(NO3)2 and Mn(NO3)2 mixed solution.After 1 hour of mixing, 0.1 M Na2S solution was added to the previous solution. After 12 hours of mixing in a dark room, a gray-brownish precipitate was obtained and washed with dı water three times using a magnet.Finally, nanoparticles were dispersed in water. Supernatant was disposed of.
3.) To demonstrate the effect of nanocomposite ratios in optimization studies, the experiment was performed twice separately by adding 1.0 and 2.0 ml of magnetic particle solution to equal amounts of Zn and Mn ion mix solutions.

RESULTS AND DISCUSSION

The adherence of quantum dots to the magnetic nanoparticle surface was checked using a UV lamp. First, it was observed that the prepared ZnS:Mn QDs composites gave an orange color under UV light at a wavelength of 365 nm (Figure 1a). Then, the prepared nanocomposite was

visualized in daylight and under UV light at the same wavelength. The color, which was light gray-brown under daylight, appeared orange-pink under UV light (Figure 1b and 1c).

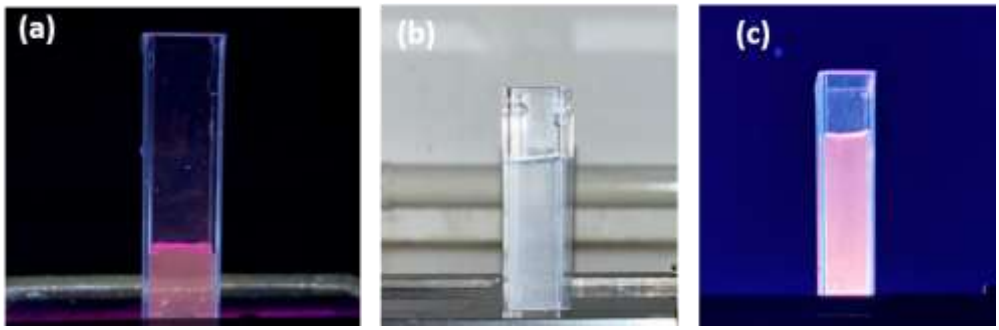

Figure 1. Image of a.) ZnS:Mn QDs under UV light, b.) Nanocomposite under solar light, c) nanocomposites under UV light.

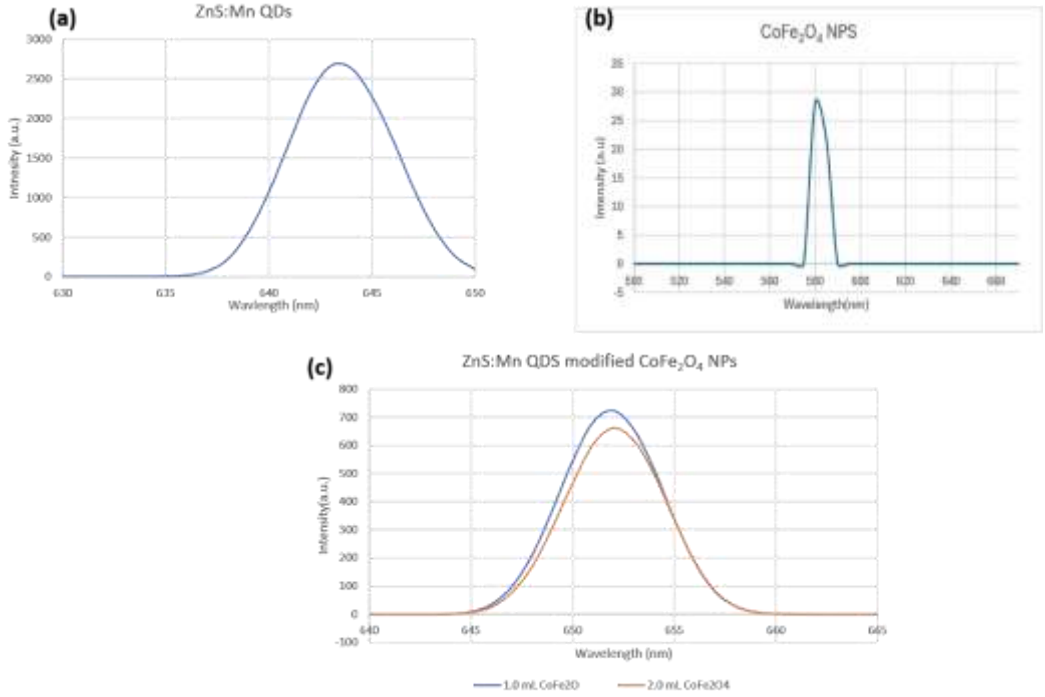

Figure 2. Emission spectrum of a.) ZnS:Mn quantum dots, b) $CoFe_2O_4$ NPs c.) ZnS:Mn quantum dots modified magnetic nanoparticles

Fluorescence Spectroscopy (FL) was used for emission measurements. For measurements, a quartz cell was used, and the device was adjusted to 320 nm excitation wavelength. ZnS:Mn quantum dots give emission at 642 nm(Figure 2a). These results are consistent with the literature (Patel et al., 2020). The fluorescence emission spectrum shown in Figure 2b corresponds to the prepared cobalt ferrite nanoparticles. It exhibits a peak at 580 nm that is either absent or negligibly weak. This wavelength does not coincide with the emission wavelength of ZnS:Mn quantum dots. ZnS:Mn quantum dots modified magnetic nanoparticles(nanocomposite) emitted at 652 nm. The wavelength shifted with agglomeration (Figure 2c). In addition, the emission intensity decreased significantly due to quenching caused by agglomeration of the magnetic nanoparticles. For optimization, we used 1.0 mL (blue line)

and 2.0 mL (orange line) magnetic nanoparticles during synthesis, separately. Figure 2c indicated that there is no significant difference. As a result, the ratio of components is not effective for this method.

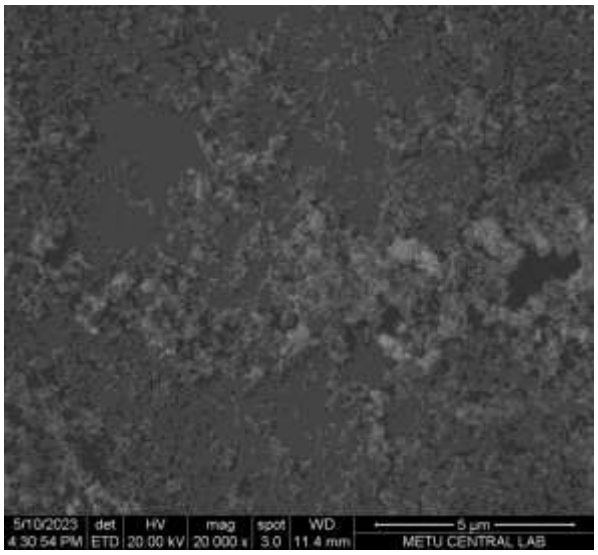

Figure 3. SEM images of ZnS:Mn quantum dots modified magnetic nanoparticles(Nanocomposites)

Figure 3 shows the SEM image of the prepared nanocomposite. In the image, the dark gray particles are magnetic nanoparticles, and the light gray particles are quantum dots attached to the magnetic particles.

CONCLUSIONS

This study aimed to produce a bifunctional nanomaterial by combining two different nanomaterials solely through adsorption, without the need for any interconnecting groups and an extra reaction step. The goal was to obtain a core-shell structure, but SEM images showed that the core-shell structure was not fully formed. Instead, a randomly distributed composite structure was formed. Fluorescence spectroscopy measurements and UV light beams showed that quantum dots in the structure adhered to the magnetic particle surface. In the future, other combination methods will be tried to produce more efficient emissions and a core-shell structure. Several techniques, including TEM, Zeta Potentiometer, VSM, and FTIR Spectroscopy, will improve characterization. The stability of the nanocomposite will also be tested. The produced particles will be used in imaging, biomedical applications,water splitting, and dye degradation as catalysts.

ABSTRACT

In this study, we assessed the diversity of the ground vegetation across 29 circular plots inside the Mediterranean forest of the National Park Divjake-Karavasta. Ground vegetation and associated shrub and tree species in the study area forest exhibit varying conservation significance when assessed against national Red List data. The majority of species are generally classified as Least Concern or are not explicitly listed due to their broad distribution and ecological resilience. Similarly, Mediterranean and maquis-associated taxa such as *Phillyrea angustifolia* L., *Erica arborea* L., *Rhamnus alaternus* L., *Paliurus spina-christi* Mill., and *Ruscus aculeatus* L. are considered stable, although they may be affected locally by fire regimes and land-use change. In contrast, certain species demonstrate higher conservation sensitivity at the national level. *Juniperus macrocarpa* remains associated with vulnerable coastal dune habitats and is considered Near Threatened in regional contexts, while *Pyrus pyraster* (L.) Burgsd. is characterized by fragmented populations and may also be regarded as Near Threatened locally. The descriptive analysis highlights that the 29 plots of the Divjaka Mediterranean forest are characterized by a vertically developed vegetation structure, but with significant horizontal heterogeneity, especially in the lower vegetation layers. These patterns highlight that, although most species fall under Least Concern globally, incorporating national-level conservation assessments is essential for accurately identifying ecologically sensitive vegetation clusters in spatial analyses such as SKATER, thereby improving biodiversity mapping and conservation planning in Albanian ecosystems.

Keywords: Biodiversity, Forest, Map, Structure, Spatial analyses

INTRODUCTION

Ground vegetation biodiversity in forest ecosystems is a critical yet often overlooked component that underpins overall ecological stability and function. This layer—comprising mosses, herbs, grasses, and low shrubs—supports complex food webs by providing habitat and nourishment for invertebrates, microorganisms, and small vertebrates, thereby sustaining higher trophic levels (Gilliam, 2007). It also plays a vital role in soil protection and nutrient cycling by reducing erosion, enhancing organic matter decomposition, and maintaining soil

moisture, which are essential for long-term forest productivity (Whigham, 2004). Moreover, ground vegetation serves as a sensitive indicator of environmental change, reflecting the impacts of disturbances such as climate change, pollution, and land-use practices (De Frenne et al., 2013). Its influence extends to forest regeneration processes, as it can either facilitate or inhibit tree seedling establishment, shaping species composition and forest succession over time (George & Bazzaz, 1999). Therefore, studying ground vegetation biodiversity is fundamental for effective forest conservation and sustainable ecosystem management.

Mapping ground vegetation diversity through Spatial "K"-luster Analysis by Tree Edge Removal (SKATER) is an effective approach for identifying spatial patterns and ecological heterogeneity within forest ecosystems (Assunção et al., 2006). SKATER is a spatial clustering technique that groups sampling units (such as vegetation plots) into homogeneous regions based on species composition while preserving geographic continuity, making it especially suitable for ecological studies (Assunção et al., 2006). By using measures of similarity or dissimilarity—often derived from species abundance or presence–absence data—the method constructs a minimum spanning tree and then iteratively removes edges to form clusters with internally similar biodiversity characteristics. This allows researchers to map distinct vegetation zones, detect gradients in species diversity, and better understand how environmental factors such as soil, elevation, or microclimate influence ground vegetation distribution. Applying SKATER to forest ground vegetation enhances the ability to visualize biodiversity patterns, supports more precise conservation planning, and improves decision-making in sustainable forest management by highlighting areas of high ecological value or vulnerability. This study aimed to identify and interpret the spatial structure of ground vegetation biodiversity in the Mediterranean forest of the National Park Divjakë-Karavasta, combining statistical and graphical methods to capture both ecological homogeneity and heterogeneity.

MATERIAL AND METHOD

Study area: Assessments have been carried out during May 2024, in the Mediterranean coniferous forests at the National Park of the Divjakë-Karavasta (Divjaka forest), defined as a forest with a variable mixture of at least two native coniferous species constituting ≥70 percent of the forest cover on sandy soils. A GIS procedure was used to randomly select plots in the forest area with at least 70 percent tree canopy cover. The center of the plot was located according to a systematic sampling design at the intersection of a 100×100-meter grid. About 29 circular plots with a radius of 11.28 meters (0.1 hectares) were designed.

Data monitoring: I. the monitoring of forest ground vegetation in the National Park of the Divjakë-Karavasta is carried out in accordance with the Manualin e planeve të mbareshtimit te pyjeve dhe kullotave (https://qeverisjavendore.gov.al/Manuali-i-planeve-te-mbareshtimit-te-pyjeve-dhe-kullotave-2019.pdf). In the pine forest habitat of Divjakë, we examined 29 plots as study areas and assessed 9 qualitative indicators, which provide us with descriptive information about the area under study. Specifically, for the 29 plots created, we assessed the following indicators: Land use category; Form of governance; Spatial distribution; Composition of the forest collection; Origin of the forest; Type of management; Main function; Vertical structure; Regeneration cuttings and Silvicultural mass.

1. The indicator Land use category contains the following defining criteria: Forests; Shrubs and/or herbaceous vegetation associations; Open areas with little or no vegetation; Pastures; Mines, construction areas and collection sites; Water areas and Burned areas.
2. The indicator Governance form contains the following classifications: Trunks; Coppice; Composite trunks; Composite coppice; Shrubs; Herbaceous vegetation areas; Pastures.
3. The indicator Main function of forests based on the Forest Management Manual (2019) should be determined for each test area. These functions are classified into: Productive; Protective; Social; Conservation.

4. The composition of the forest collection implies the participation of the main species of the test areas and is classified into: Simple and Mixed.
5. The spatial distribution indicator provides information on the distribution patterns of plant vegetation in the habitat plots under study by classifying them into: Not forested; Uniform; Scattered in clusters; Scattered in floors; Mosaic pattern; Irregular; Individuals.
6. The forest origin indicator. It is determined by referring to the dominant species of the areas under study. It is classified as natural or artificial. When the origin of the forest is (i) natural, then one of the specifications is selected in the field: with seed, Shoots; mixed; undetermined. If the forest has an origin of (ii) Planted-artificial, then the year of afforestation is noted.
7. The vertical structure of the forest is determined based on the crown levels of the stand, referring to the criteria: Simple (1 level); Two levels; Many levels.
8. Regenerative cutting. Field assessment of the presence of regeneration.
9. Silvicultural measures (what is recommended)
II. The structure of the ground vegetation cover is categorized in the field as follows: Medium-sized trees, shrubs and woody plants (3m<L.<5m); Tall shrubs (1.5m<L.<3m); Medium shrubs (0.5m<L.<1.50m); Low shrubs (0.05m<L.<0.5m); Shrubs near ground level (0.02m<L.<0.05m); Fern cover; Herbaceous cover. Code 0 = No presence in the test area; 1 = Rare species: close to zero cover; 2 = Scattered plants: CC ≤1%; 3 = Low plant number: CC 1-5%; 4 = Intermediate plant number: CC 5-10%; 5 = High plant number: CC 10-25%; 6 = CC 25-50%; 7 = CC 50-75%; 8 = CC >75%.

***Data analysis method*:** In this study, the SKATER (Spatial "K"-luster Analysis by Tree Edge Removal) analysis (Assuncao et al. 2006) is used to identify spatial patterns and homogeneous areas of vegetation structure in the test plots of the Divjaka Mediterranean forest. The spatial dependence test is applied through Moran's I coefficient to assess whether there is a spatial effect on the distribution of these variables, that is, whether geographically close surfaces present similarities in vegetation structure. After determining the spatial relationships, the SKATER method is applied, which is based on the construction of a neighborhood graph through the Minimum Spanning Tree (MST) algorithm (Anselin 1995; Huda et. al 2023). MST describes the minimal connections between test plots based on the similarity of vegetation structure, without creating cycles, and preserving the real spatial relationships between them.

RESULTS AND DISCUSSIONS

The monitoring of forest ground vegetation:

The data obtained in the field for 29 plots as study area plots in the Divjaka Mediterranean forest habitat were assessed for 9 indicators, providing us with descriptive information on the area under study. Specifically, for the indicator Land use category in the field assessment conducted for all 29 plots, we selected the criterion Forest for each plot in relation to this indicator. The type of forest management/form of governance helps us to understand how the forest is managed and used by the community. The indicator Form of governance results for all plots in the study are the same: coppice. This classification, referred to in the National Forest Inventory (IKP 2022), suggests a form of governance that bases renewal mainly on seed, and its management is done until the age when the trees reach considerable size.

Based on field observations and the current status of this forest ecosystem, our test areas provide a protective function, positively influencing the environment by mitigating climate change, preventing soil erosion, and supporting the circulation of materials. Of course, these areas also meet the criteria for social and conservation functions, as they serve as environments for recreation and tourism. At the same time, the Divjaka Mediterranean forest habitat, thanks to its high biodiversity, serves as an area of special scientific value.

For the spatial distribution indicator, the results suggest that six of the 29 plots (S1, S8, S9, S10, S11, S12) meet the criteria for the non-forested category, and four of the 29 plots in the study (S23, S24, S25, S26) fall into the Uniform distribution category (Figure 1). The data show that 17 plots present a spatial distribution in stands, and only two plots (S16 and S18) present a spatial distribution with individuals. Knowing the composition of the forest stand is important because it shows not only which tree species make up the forest but also how it functions as an ecosystem. It helps in planning forest management, indicates the level of biodiversity, helps in protection from diseases and pests, affects natural regeneration, and allows the assessment of forest productivity. In this way, the composition of the forest stand is an indicator of the structure, health, and sustainability of the forest. In our case study, we estimated that among the 29 plots, only 5 (S1, S17, S19, S26) are characterized by a simple assemblage composition, while the other 24 plots are characterized by a mixed composition. This result shows that more than one species is present in most of our area, suggesting good biodiversity and, consequently, a greater variety of habitats for flora and fauna. In a forest ecosystem, the presence of a mixed species composition will help to cope with climate change better than areas represented by a small number of species or those with a single species.

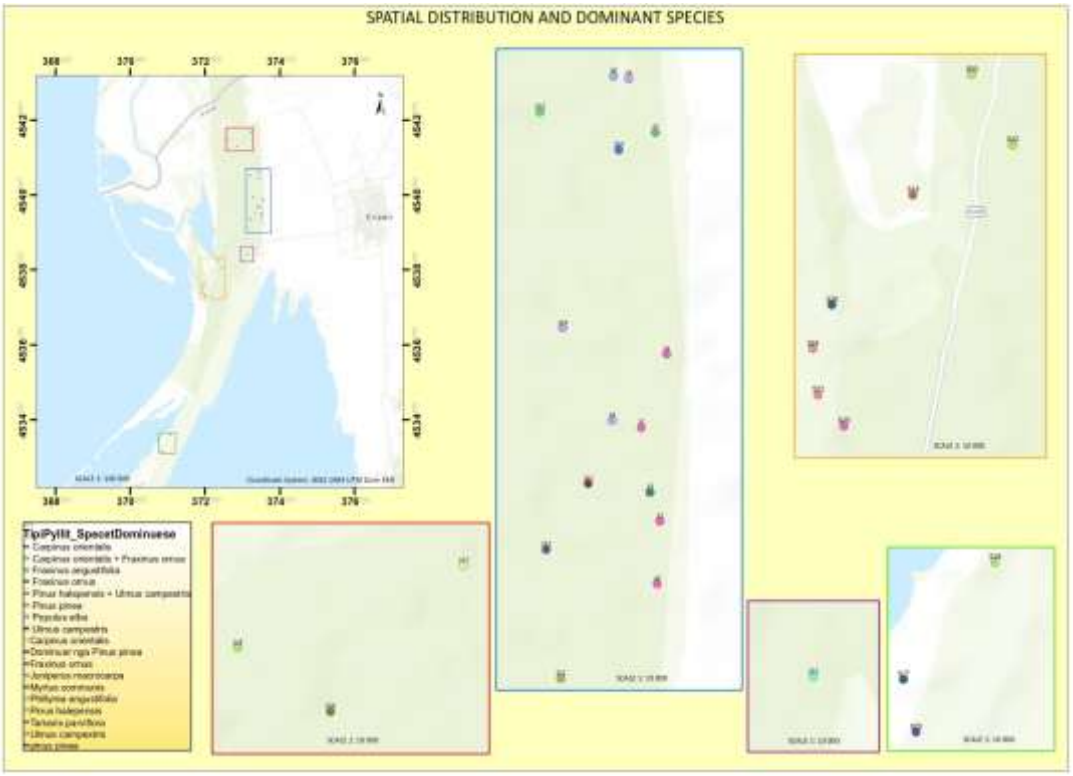

Figure 1. Spatial distribution of dominant forest tree species composition

To understand how this forest ecosystem was created, our field assessment of forest origin included two categories: (i) natural and (ii) planted-artificial. Based on the observations, four plots (S23, S24, S25, and S26) have a planted-artificial forest origin with seedlings. All other plots have a natural origin. Within this category, 22 plots have a seed-created origin; only one plot, S6, has a vegetative origin with shoots; and two other plots, S8 and S15, have a mixed forest formation origin (seed and shoots).

The vertical structure of the forest tells us about the division of the forest vegetation into layers according to height. Knowing it is important because it tells us about the ecological health of the forest under study, how light and moisture are distributed, whether natural regeneration is possible or not, etc. The data suggest the presence of a two-story vertical structure of the forest

in 24 plots, i.e., we have two main layers of vegetation arranged vertically, one created by tall and mature trees which represent the main forest cover (canopy) and the lowest layer represented by small trees, shrubs and young plants which grow understory. Plots S2, S3, S6 and S7 are presented with a vertical structure with more than two stories, suggesting an even higher biological diversity in these areas, for better efficiency of sunlight use and for a healthy regeneration of vegetation. Only plot 1 is presented with a one-story structure.

If the management plan for this habitat included regeneration cuttings, in 29 plots from field observations we assessed their presence or absence. In none of our plots did we observe the presence of regeneration of this forest.

Silvicultural measures in a forest habitat are important as they suggest how this habitat is managed and improved to be as sustainable and healthy as possible. Regarding this indicator, we could choose to recommend between the options of: Forest Clearance; Thinning; Selective felling of individual trees; Selective felling in groups; Conversion; Afforestation. For all plots, we recommend clearing as a silvicultural measure in order for this forest to improve growth, regeneration, or overall health of the trees. This process would include the removal of unwanted vegetation, such as weeds, shrubs, or weak-growing trees that compete with young trees for light, water, and nutrients. Clearing would also help sunlight penetrate the forest floor, encourage natural regeneration of desired tree species, and reduce the risk of pests, disease, or fire. In this way, clearing would help create better conditions for a healthier and more productive forest.

Results of the SKATER spatial analysis based on the Structure of the terrestrial vegetation cover:

Descriptive analysis of vegetation cover structure was carried out for 29 test plots located in the Divjaka Mediterranean forest, based on seven categories representing different vertical levels of vegetation, from ground vegetation to woody plants with a height of 3–5 m. The assessment of cover was carried out through a semi-quantitative scale (0–8), which reflects the relative percentage of cover of each category in each test plot. The results show that the vegetation structure presents a good vertical development, with a significant presence of shrubs and medium-sized woody vegetation in most of the plots. The category of woody plants and shrubs with a height of 3–5 m shows medium to high values of cover in most of the plots, suggesting a successful consolidated stage of the forest. In this category, the main representative species of the 29 plots under study are: *Pinus pinea* L., *Ulmus campestris* L., *Pinus halepensis* Mill., *Cornus mas* L., *Fraxinus ornus* L., *Juniperus macrocarpa* S.et.Sm., *Carpinus orientalis* Mill., *Pyrus pyraster (L.)* Burgsd., *Paliurus spina-christi* Mill., *Carpinus betulus* L., *Crataegus monogyna* Jacq., *Myrtus communis* L., *Cercis siliquastrum* L., *Phillyrea latifolia* L., *Tamarix parviflora* DC., *Pistacia lentiscus* L., and *Pinus pinaster* Aiton.

Similarly, tall shrubs (1.5–3 m) and medium shrubs (0.5–1.5 m) present a relatively stable distribution, with values ranging from medium to high cover, indicating a significant density of the shrub understory. The main representative species observed in the field for the medium shrub category are: *Juniperus macrocarpa* S.et.Sm., *Carpinus orientalis* Mill., *Pyrus pyraster (L.)* Burgsd., *Phillyrea angustifolia* L., *Myrtus communis* L., *Phillyrea latifolia* L., *Erica arborea* L., *Rhamnus alaternus* L., *Tamarix parviflora* DC., *Pistacia lentiscus* L. and *Colutea arborescens* L.

In the test areas under consideration for the medium shrub category, in addition to the representatives of the above category, we find several other species, specifically: *Ruscus aculeatus* L., *Paliurus spina-christi* Mill., *Rubus ulmifolius* Schott., *Cornus sanguinea* L., *Rosa canina* L., and *Crataegus monogyna* Jacq.

Unlike the upper vegetation layers, the lower layers show a more pronounced variability between the test plots. Low vegetation (0.05–0.5 m) and shrubs near ground level (0.02–0.05

m) present variable values, reflecting local differences in microecological conditions, such as lighting, humidity, and natural or anthropogenic interventions. This heterogeneity in the lower vegetation layer suggests the presence of different microhabitats within the forest massif.
Fern cover is absent in all analyzed plots, indicating that this plant group does not constitute an important structural component in the study area. Meanwhile, herbaceous vegetation presents an uneven distribution, with some plots showing high cover values, while others have a very limited or absent presence. This indicates that the herbaceous component is significantly influenced by local terrain conditions and the overall canopy structure. The main species observed for this category are: *Juncus acutus* L., *Juncus maritimus* Lam., *Arthrocnemum macrostachyum* (Moric.) K.Koch, and *Phragmites australis* (Cav.) Trin. ex Steud.
Ground vegetation and associated shrub and tree species in the Mediterranean forest and coastal ecosystem of the Divjaka-Karavasta National Park exhibit varying conservation significance when assessed against national Red List data. The majority of species, including *Carpinus orientalis* Mill., *Phillyrea latifolia* L., *Myrtus communis* L., *Pistacia lentiscus* L., *Crataegus monogyna* Jacq., *Cornus sanguinea* L., *Rosa canina* L., *Rubus ulmifolius* Schott, *and Phragmites australis* (Cav.*)* Trin. ex Steud. are generally classified as Least Concern or are not explicitly listed due to their broad distribution and ecological resilience (Ministry of Tourism and Environment Albania, 2013; International Union for Conservation of Nature, 2024). Similarly, Mediterranean and maquis-associated taxa such as *Phillyrea angustifolia* L., *Erica arborea* L., *Rhamnus alaternus* L., *Paliurus spina-christi* Mill., *and Ruscus aculeatus* L. are considered stable, although they may be affected locally by fire regimes and land-use change (Barina et al., 2018; Euro+Med PlantBase, 2023). In contrast, certain species demonstrate higher conservation sensitivity at the national level. *Juniperus macrocarpa* S.et.Sm., remains associated with vulnerable coastal dune habitats and is considered Near Threatened in regional contexts (International Union for Conservation of Nature, 2024), while *Pyrus pyraster* is characterized by fragmented populations and may also be regarded as Near Threatened locally (Barina et al., 2018). Riparian and halophytic species such as *Tamarix parviflora* DC., *Juncus acutus* L., *Juncus maritimus* Lam., *and Arthrocnemum macrostachyum (*Moric.*)* K.Koch are typically not globally threatened but are ecologically sensitive due to their dependence on wetland and coastal habitats, which are under increasing anthropogenic pressure (Tzonev et al., 2019). Additionally, *Colutea arborescens* L. and *Ulmus minor* Mill. may show localized vulnerability due to habitat fragmentation and disease impacts (Allen et al., 2010; Barina et al., 2018). These patterns highlight that, although most species fall under Least Concern globally, incorporating national-level conservation assessments is essential for accurately identifying ecologically sensitive vegetation clusters in spatial analyses such as SKATER, thereby improving biodiversity mapping and conservation planning in Albanian ecosystems.
Moran's I test shows that only a subset of the vegetation structure variables exhibit statistically significant spatial dependence (Table 1). Herbaceous vegetation shows significant positive autocorrelation, suggesting that geographically close areas tend to have similar levels of herbaceous cover and form spatial clusters. In contrast, the woody/shrub layer with a height of 3–5 m shows negative autocorrelation, indicating local contrasts between neighboring areas and the presence of transitional zones in the vegetation structure. The other variables do not show statistical evidence for spatial autocorrelation, reflecting local or microhabitat variability without a clear spatial structure at the study scale. These results support the use of SKATER analysis, where variables with spatial structure and local contrasts are expected to contribute to the increase in SSD and to the separation of the Minimum Spanning Tree into ecologically homogeneous groups (Figure 2).

Table 1. Spatial dependence test (Moran's I): Moran's I results for vegetation structure variables in 29 Divjaka Mediterranean forest test plots

Vegetation variable	Moran's I	p-value	z-score
Herbaceous vegetation	**0.212**	**0.028**	2.243
Woody plants & shrubs (3–5 m)	**−0.200**	**0.035**	−1.470
Medium shrubs (0.5–1.5 m)	−0.141	0.124	−1.086
Low shrubs (0.05–0.5 m)	0.067	0.167	0.924
Shrubs near ground level (0.02–0.05 m)	0.050	0.192	0.788
Tall shrubs (1.5–3 m)	−0.095	0.297	−0.578
Ferns	NaN	—	NaN

The construction of the Minimum Spanning Tree (MST) on the standardized vegetation structure variables revealed relationships with very different Sum of Squared Differences (SSD) values, reflecting different degrees of ecological heterogeneity between the test plots. The relationship S19–S25 presents the highest SSD value, which indicates a very pronounced change in vegetation structure and identifies the S19 plot as an ecologically separate unit from the rest of the study area. This plot does not present diversity, as the measurements performed show that it is mainly represented only by individuals of the species *Tamarix parviflora* DC. (Malaj et al 2024).

A second important contrast is observed in the relationship S22–S23, which separates a micro-zone composed of plots S23 and S24 from the rest of the forest massif. These two plots present low values of species diversity, which are similar to each other; S23 is represented by individuals of *Juniperus macrocarpa* S.et Sm.; *Pinus halepensis* Mill.; and *Tamarix parviflora* DC. Plot 24 differs from Plot 23 only by the presence of *Pinus pinaster* Ait., which replaces *Tamarix* sp.

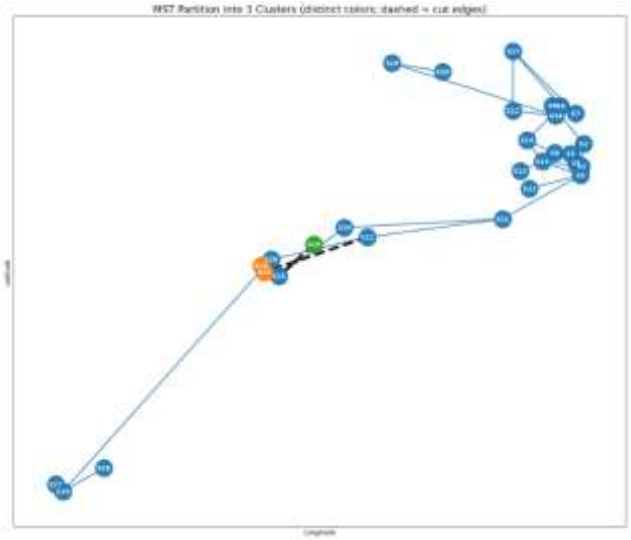

Figure 2. The Minimum Spanning Tree (MST) constructed on the Divjaka Mediterranean test plots, using as link weights the structural change of vegetation measured through Sum of Squared Differences (SSD) on standardized variables.

The graph illustrates the separation of the Minimum Spanning Tree (MST) into three spatial clusters by cutting the links with the highest SSD. The main cluster represents a relatively homogeneous vegetation structure, while the other two clusters identify a separate unit (S19) and a homogeneous micro-zone (S23–S24). The broken links indicate ecological boundaries and major transition zones between clusters. The full SSD values for all MST links result in three spatial clusters. The first cluster includes most of the areas and is characterized by a relatively homogeneous vegetation structure, representing the main ecological core of the

Divjaka Pine. The second cluster consists only of area S19, which exhibits significantly different structural features and can be interpreted as a separate ecological zone or a unit with specific local conditions. The third cluster includes areas S23 and S24, which form a homogeneous micro-zone, but distinct from the main cluster.

CONCLUSION

This study aimed to investigate the spatial organization of vegetation within the Divjaka Mediterranean Forest by integrating statistical and graphical approaches to characterize ecological homogeneity and heterogeneity. Moran's I analysis confirmed the presence of spatial autocorrelation and local spatial variation in several vegetation attributes, supporting the application of spatial clustering techniques. The Minimum Spanning Tree (MST) combined with the SKATER algorithm enabled the delineation of ecologically homogeneous clusters and the identification of distinct vegetation units that would be difficult to detect using conventional non-spatial methods. This integrated approach provides a robust framework for understanding vegetation spatial patterns and offers valuable support for forest management, ecological monitoring, and evidence-based conservation planning.

ABSTRACT

The objective of this research was to assess the tree species diversity, structure, and composition within two different habitats of Divjakë-Karavasta National Park. Thirty-five circular sampling plots (0.1 ha each; radius 11.28 m) were established to characterize the tree communities within the study area. In total, 2,336 trees were inventoried. The Kulari (Argjinatura Shkumbin) forest contained 45 plant taxa distributed among 11 orders, 15 families, 19 genera, and 22 species, whereas the Gjeneruka forest comprised 31 taxa representing 8 orders, 10 families, 13 genera, and the same number of species (22). Analysis of the 15 sampling plots in the first forest habitat showed that the four most abundant tree species *Populus alba* L., *Ulmus campestris* L., *Cornus mas* L., and *Phillyrea latifolia* L. accounted for 57.41% of the total tree abundance. In the second forest habitat, based on data from 20 sampling plots, *Carpinus orientalis* Mill. was the dominant species, exhibiting the highest relative density (33%). It was followed by three members of the Fagaceae family: *Quercus cerris* L., *Quercus frainetto* Ten., and *Quercus robur* L. Differences in forest structure were examined through analyses of tree height and diameter-class distributions. Spatial variation in tree diversity was mapped in ArcGIS 10.5 using the Shannon, Simpson, and Species Richness indices. The results reveal distinct patterns of species diversity and stand structure between the two habitats, providing ecological evidence that can support biodiversity conservation, habitat management, and long-term monitoring within Divjakë–Karavasta National Park and other protected landscapes in Albania.

Keywords: Tree species, Habitat, Ecological diversity, Composition, Forest structure

INTRODUCTION

The Divjakë–Karavasta National Park region is home to the most significant and diverse ecosystem in Albania, offering great value in terms of biodiversity. It is recognized for its stunning natural scenery, wide variety of species, as well as its traditional economic practices and appeal as a tourist destination (Xhulaj et al. 2026). Evaluating the variety of tree species, their makeup, and the structure of forests in the habitats of the Divjakë–Karavasta National Park is important for understanding how the ecosystem functions and for effectively managing conservation efforts. These assessments offer valuable information about the ecological condition, ability to recover from disturbances, and the natural development processes of forest communities.

Comparative analysis of forest ecosystems is an essential approach for evaluating biodiversity, community composition, and ecological stability across different forest types. Ecological indices are widely used to quantify species diversity, richness, evenness, dominance, and similarity, providing valuable information for biodiversity assessment and forest management. In recent years, these traditional ecological indices have increasingly been integrated with multivariate statistical techniques such as Pearson correlation and Principal Component Analysis (PCA) to better understand the relationships among ecological variables and the environmental factors driving forest ecosystem variation.

Lakićević and Srđević (2018) investigated the application of biodiversity indices in forest communities by comparing four forest ecosystems using the Shannon–Wiener, Simpson, Margalef, Berger–Parker, and Jaccard indices. The authors concluded that using multiple ecological indices provides a more comprehensive assessment of forest biodiversity than relying on a single measure (Lakićević & Srđević, 2018). Similarly, Stamin and Cosmulescu (2025) assessed vegetation diversity in three temperate forest ecosystems in southern Romania using a wider range of biodiversity indices. Statistical comparisons showed that larger forest ecosystems generally supported higher biodiversity, while variations in species distribution affected community evenness and dominance. The authors emphasized that combining several ecological indices provides a more accurate representation of forest ecosystem diversity and offers valuable information for conservation planning and sustainable forest management.

Although biodiversity indices quantify ecological diversity, they do not explain the relationships among ecological variables. Therefore, many recent studies (Sheng et al., 2024) have incorporated Pearson correlation analysis to evaluate associations between biodiversity indices and environmental factors. Likewise, Norbu et al. (2026) analyzed woody plant diversity in *Betula platyphylla* forests on the southeastern Tibetan Plateau using Pearson correlation to examine relationships among biodiversity indices, elevation, and soil characteristics.

To complement correlation analysis, researchers increasingly use Principal Component Analysis (PCA) to summarize complex ecological datasets and identify the principal environmental gradients influencing forest ecosystems. PCA reduces numerous correlated variables into a small number of independent principal components, facilitating interpretation of ecological variation among forest communities. Song et al. (2021) used PCA to investigate environmental factors affecting tree species abundance and richness in a subtropical forest. Pearson correlation analysis was also applied to evaluate relationships among environmental variables, demonstrating how PCA and correlation analysis complement one another in ecological research (Song et al., 2021). Similarly, Zhang et al. (2025) applied PCA in a forest health assessment study to reduce numerous forest health indicators into a smaller number of principal components before conducting classification analyses. Furthermore, Wang et al. (2025) integrated biodiversity indices, Pearson correlation, and PCA to investigate biomass accumulation and environmental adaptability in naturally regenerating subtropical forests. The combined analytical approach provided a comprehensive understanding of the ecological processes governing forest ecosystem development (Wang et al., 2025).

Ecological indices remain fundamental tools for comparative analysis of forest ecosystems by quantifying species richness, diversity, evenness, dominance, and community similarity. However, integrating these indices with Pearson correlation and PCA provides a more comprehensive understanding of forest ecosystem dynamics. Pearson correlation identifies significant relationships among biodiversity and environmental variables, whereas PCA reveals the principal ecological gradients responsible for variation among forest communities. Together, these methods offer a robust framework for comparing forest ecosystems, identifying biodiversity drivers, and supporting evidence-based conservation and sustainable forest

management. The findings of our study will support managers in evaluating the conservation measures applied within these forest ecosystems in the protected area.

MATERIAL AND METHOD

Study area: The study took place in two distinct areas within Divjakë-Karavasta National Park: Habitat 1, referred to as the Kulari forest, which is part of the Argjinatura Shkumbin Economic Unit, and Habitat 2, known as the Gjeneruka forest. Divjakë-Karavasta National Park is a protected region located along the coastline of Albania. The park spans latitudes from 40° to 55° N and longitudes from 19° to 29° E.
Data collection: The ecological data were collected during the spring of 2024 to 2025 in two forest areas within the Divjakë-Karavasta National Park. Randomly selected plots were chosen based on a GIS method, focusing on regions with at least 70% tree coverage. Using a systematic approach, the center of each plot was placed at the intersection of a 100 by 100 meter grid. A total of thirty-five circular plots, each with a radius of 11.28 meters (equivalent to 0.1 hectares), were established.
Data analysis: A series of tree species composition indices, including the Shannon index (H') (Shannon, 1948), a unique measure of evenness (J') by index standardization Shannon (Elliot et. al., 1997), species richness (DMn), (Magurran, 2004) the Simpson index (D) (Simpson, 1949), the Berger-Parker index (d) (Berger & Parker, 1970), and the Clark-Evans (R) (Clark & Evans, 1954), were computed for this study in order to investigate the heterogeneity in the composition of the communities under study. The structural composition of trees was analyzed by comparing the tree height distribution and diameter classes. We used the geospatial tools in ArcGIS 10.5 to evaluate the diversity of tree species spatially by using ecological indices (e.g., Shannon, Simpson, Species Richness) and MVSP - Version 3.22 for other statistical analyses.

RESULTS AND DISCUSSIONS

Biodiversity indices provide complementary measures of community composition by assessing species diversity, richness, dominance, and spatial organization, offering a comprehensive assessment of ecological conditions (Magurran, 2004; Krebs, 1999). The biodiversity assessment of the 35 sampling plots revealed notable differences between Habitat 1 (Kulari forest) and Habitat 2 (Gjeneruka forest) in species diversity, richness, dominance, and spatial distribution. Descriptive statistics indicate that Habitat 1 generally exhibited greater biodiversity and a more stable community structure than Habitat 2.
Field observations across 15 plots in our Habitat 1 (Kulari forest) identified 45 plant taxa, comprising 11 orders, 19 genera, 15 families, 22 species, and 674 individuals. Among these, *Populus alba* L. accounted for 20.91% across 12 plots; *Ulmus campestris* L. and *Cornus mas* L. were present in all 11 plots, totaling 13.5%; and *Phillyrea latifolia* L. was present in 6 plots, totaling 9.5%. These three tree species were the most prevalent in the area. The mean stand density was 44.93 individuals ha^{-1}. In all 15 study plots, the number of tree species per unit area decreased as the tree trunk size increased. Based on the distribution of trunk sizes, the largest group of trees (79.67%) had a trunk diameter between 2 and 22 centimeters at breast height. The next largest group (13.2%) had diameters ranging from 26 to 46 centimeters, while the smallest group (4.89%) had diameters between 46 and 62 centimeters.
Field data from the 20 plots in Habitat 2 (Gjeneruka forest) of the Divjakë-Karavasta National Park indicate the presence of 10 families, consisting of 13 genera and a total of 22 species. The plots are predominantly characterized by the three principal families, Pinaceae, Corylaceae, and Fagaceae, accounting for 81.82% of the total, with 1360 individuals. In the plots taken in this habitat, the species presented an abundant status with a higher relative density at 33% for

Carpinus orientalis Mill., followed by three species of the Fagaceae family (*Quercus cerris* L.; *Quercus frainetto* Ten. and *Quercus robur* L.). The average stand density was 75.54 trees per hectare, which suggests a forest that is moderately stocked, not too thin and not too dense. When looking at the distribution of tree sizes across all 20 sampling plots, most of the trees—78.88% or 1311 trees—fell into the category of having a diameter at breast height (DBH) less than 10 cm. On the other hand, only a small percentage, 4.15% or 69 trees, had a DBH of 20 cm or more. The remaining trees, which made up 16.97% or 282 trees, had a DBH between 10 and 20 cm.

The Shannon diversity index considers both the variety of species and their relative abundance, making it one of the most widely utilized metrics for assessing community diversity. Because it indicates not just a rise in the number of species but also a more uniform distribution of individuals among those species, a higher value signifies greater diversity (Shannon & Weaver, 1949; Magurran, 2004). Habitat 1 had a higher maximum Shannon diversity (2.499) than Habitat 2 (2.245); the mean Shannon index was also higher in Habitat 1 (1.372) than in Habitat 2 (1.194), indicating that Habitat 1 generally supported a more diverse biological community. Although both habitats included plots with low diversity, Habitat 2 had a minimum value of zero, implying that at least one plot had no species diversity or was dominated by a single species (Table 1).

Table 1. Data analysis of the tree inventory of the two forest habitats inside Divjakë-Karavasta National Park

Diversity index/ 35 plots	Shannon H' value		Evenness J' value		Richness DMn value		Simpson D value		Berger-Parker d value		Clark-Evans R-value	
	Habit at 1	Habit at 2	Habit at 1	Habit at 2	Habit at 1	Habit at 2	Habit at 1	Habit at 2	Habit at 1	Habit at 2	Habit at 1	Habit at 2

Coefficient of variation	29.98	46.87	14.29	34.95	35.27	44.91	18.14	41.24	30.4	41.54	21.44	28.28

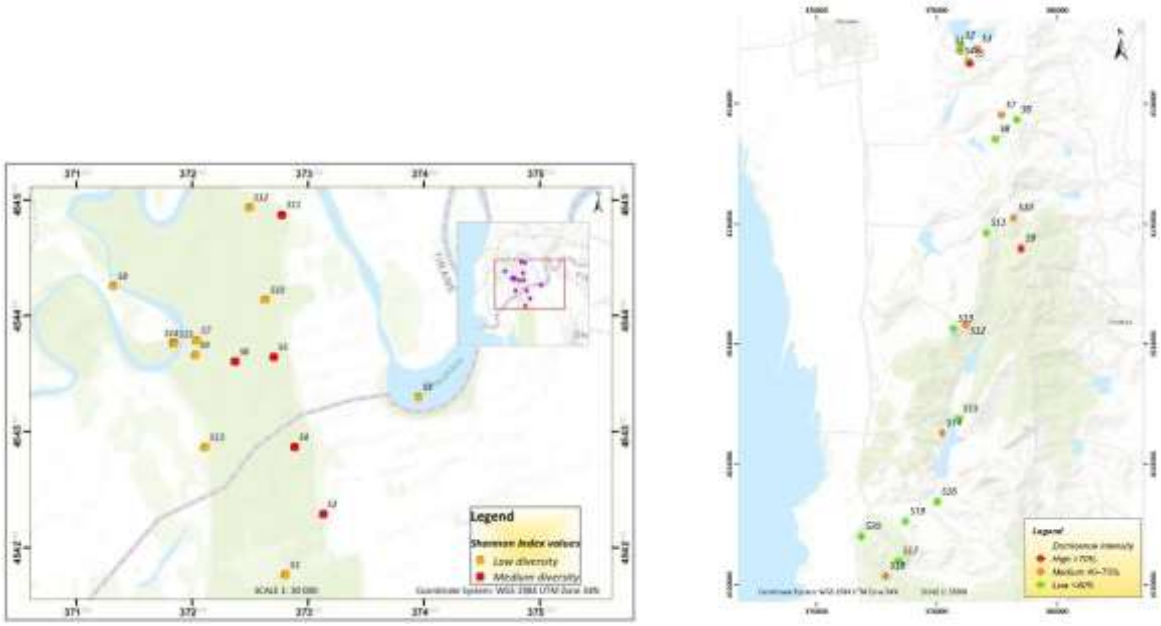

Figure 1. Mapping species diversity using Shannon Index values (a) Habitat 1(the Kulari forest) and (b) Habitat 2 (the Gjeneruka forest)

Shannon diversity showed much greater variability in Habitat 2, as evidenced by its higher variance (0.313) and standard deviation (0.560) compared with Habitat 1 (variance = 0.169; standard deviation = 0.411). Moreover, the coefficient of variation in Habitat 2 (46.88%) was greater than that in Habitat 1 (29.98%), indicating that species diversity was less consistent across plots in Habitat 2.

The Evenness Index (J') assesses how evenly individuals are distributed among species. Values close to one suggest a very equitable distribution of individuals, while lower values reflect dominance by only a few species (Pielou, 1966; Krebs, 1999).

Habitat 1 showed greater species evenness, with an average of 0.793 compared with 0.673 in Habitat 2. The maximum evenness values were similarly high in both habitats (0.952 and 0.934), indicating that some plots in each habitat had nearly equal species abundances. However, Habitat 2 again recorded a minimum value of zero, suggesting complete dominance by a single species in certain plots. Habitat 2 also exhibited greater variability (CV = 34.96%) than Habitat 1 (CV = 14.29%), indicating that the distribution of individuals among species was much less consistent.

These results indicate that species were more evenly distributed in Habitat 1, whereas Habitat 2 exhibited greater fluctuations in species dominance (Pielou, 1966; Magurran, 2004).

Species richness is the simplest measure of biodiversity and indicates the number of species in a community. Higher richness generally reflects greater habitat complexity and ecological suitability, although richness alone does not account for species abundances (Margalef, 1958; Magurran, 2004).

Habitat 1 recorded a higher average richness (0.941) than Habitat 2 (0.682). Although both habitats reached similar maximum richness values (1.434 and 1.376), Habitat 2 had a much lower minimum richness (0.132) than Habitat 1 (0.408). The coefficient of variation for richness was also higher in Habitat 2 (44.92%) than in Habitat 1 (35.27%), suggesting greater heterogeneity in species composition among plots. These findings indicate that Habitat 1 generally supported more species than Habitat 2, suggesting more favorable ecological conditions.

The Simpson Diversity Index (D) quantifies the probability that two individuals randomly selected from a community belong to different species. A higher value usually suggests higher diversity, as it means the community is not mainly composed of just one or a few species (Simpson, 1949; Krebs, 1999).

Habitat 1 exhibited a higher average Simpson index (0.686) than Habitat 2 (0.591), indicating greater species diversity. The maximum value was also higher in Habitat 1 (0.900) than in Habitat 2 (0.841). The lower minimum Simpson value in Habitat 2 (0.017) compared with Habitat 1 (0.400) suggests that some Habitat 2 plots were highly dominated by one or very few species. The greater variance, standard deviation, and coefficient of variation observed in Habitat 2 indicate less stable diversity across sampling plots. Overall, Simpson's index supports the conclusion that Habitat 1 possessed greater biodiversity and a more balanced community structure.

Berger–Parker Dominance Index (d) is used to measure the relative abundance of the most frequently occurring species within a community. A smaller value suggests less dominance by a single species and more variety among the species present, while a larger value shows that one species makes up a large share of the total population (Berger & Parker, 1970; Magurran, 2004).

Habitat 1 had a lower average dominance value (0.460) than Habitat 2 (0.551), indicating that no single species dominated most plots in Habitat 1. Conversely, Habitat 2's higher value suggests stronger dominance by one or a few species. Habitat 2 also reached the maximum possible value of 1.0, indicating complete dominance by a single species in at least one sampling plot. Habitat 1 had a lower maximum dominance value of 0.777. Additionally, Habitat 2 exhibited greater variability (CV = 41.55%) than Habitat 1 (30.40%), indicating inconsistent patterns of species dominance across plots. These findings indicate that Habitat 2 had greater ecological dominance, which generally corresponds to lower community diversity.

The Clark–Evans index evaluates the spatial distribution of individuals within a population. Values greater than one indicate a regular (uniform) distribution, values close to one indicate a random distribution, and values below one indicate clustering (Clark & Evans, 1954). Both habitats showed R-values significantly higher than one, with averages of 4.886 in Habitat 1 and 6.630 in Habitat 2. This suggests that individuals were evenly distributed across both habitats rather than grouped together. Habitat 2 showed a higher average R-value, suggesting a stronger tendency toward uniform spacing of individuals. However, Habitat 2 also displayed greater variability (SD = 1.875; CV = 28.28%) than Habitat 1 (SD = 1.047; CV = 21.44%), indicating less consistency in spatial patterns among plots. The uniformly spaced distributions observed in both habitats may reflect competition among individuals or environmental factors promoting regular spacing (Clark & Evans, 1954; Krebs, 1999).

Results on the Pearson correlation matrix

Shannon diversity showed a very strong positive correlation with Simpson diversity (SDI) (r = 0.948), indicating that plots with higher Shannon diversity also tended to have higher Simpson diversity (Table 2). This is expected because both indices measure species diversity, though they differ in their sensitivity to rare and common species.

Shannon diversity was also strongly positively correlated with Margalef richness (DMn) (r = 0.782) and evenness (J′) (r = 0.758). These relationships indicate that increases in species richness and more equitable species distributions are associated with higher overall diversity. Conversely, Shannon diversity exhibited a very strong negative correlation with Berger–Parker dominance (r = −0.917), indicating that communities dominated by a single species tend to have substantially lower overall diversity. Only a weak positive correlation was observed between Shannon diversity and the Clark–Evans index (r = 0.344), suggesting that spatial distribution has only a limited association with species diversity.

Table 2. Pearson Correlation Matrix

Variables	H′	J′	DMn	SDI	d	R
H′ (Shannon)	1.000	0.758	0.782	0.948	-0.917	0.344
J′ (Evenness)	0.758	1.000	0.499	0.897	-0.877	-0.003
DMn (Margalef Richness)	0.782	0.499	1.000	0.712	-0.645	-0.133
SDI (Simpson Diversity)	0.948	0.897	0.712	1.000	-0.959	0.214
d (Berger–Parker)	-0.917	-0.877	-0.645	-0.959	1.000	-0.230
R (Clark–Evans)	0.344	-0.003	-0.133	0.214	-0.230	1.000

Evenness demonstrated a very strong positive correlation with Simpson diversity (r = 0.897), indicating that communities in which individuals are distributed more equally among species also exhibit greater diversity. The relationship between evenness and Margalef richness was moderate (r = 0.499), suggesting that the number of species alone does not necessarily determine how evenly individuals are distributed.

Evenness was strongly negatively correlated with Berger–Parker dominance (r = −0.877), confirming that dominance by a single species reduces the equitable distribution of individuals. The correlation between evenness and Clark–Evans R was essentially zero (r = −0.003), indicating no meaningful relationship between spatial pattern and species evenness.

Margalef Richness (DMn) exhibited a strong positive correlation with Simpson diversity (r = 0.712), indicating that plots containing more species generally possess higher overall diversity. Richness showed a moderately strong negative correlation with Berger–Parker dominance (r = −0.645), suggesting that communities with greater numbers of species tend to be less dominated by a single species.

Simpson diversity exhibited the strongest negative correlation with Berger–Parker dominance (r = −0.959). This nearly perfect inverse relationship indicates that increases in species dominance are associated with substantial reductions in overall diversity. The weak positive relationship between Simpson diversity and Clark–Evans R (r = 0.214) suggests that spatial regularity has only a minor influence on species diversity.

Berger–Parker dominance showed a weak negative correlation with Clark–Evans R (r = −0.230). This indicates that communities with greater dominance by a single species are only slightly less likely to exhibit regular spatial distributions, and the association is relatively weak.

Results on PCA analysis

Principal Component Analysis (PCA) was conducted using six biodiversity indices (Shannon diversity, Pielou's evenness, Margalef richness, Simpson diversity, Berger–Parker dominance, and Clark–Evans R) measured across 35 sampling plots (Table 3). The first principal component (PC1) represents an overall biodiversity gradient, characterized by positive contributions from Shannon diversity, Simpson diversity, species richness, and evenness, and a strong negative contribution from Berger–Parker dominance. This indicates that plots with greater species diversity and more even communities are associated with lower species dominance. The second principal component (PC2) is associated primarily with the Clark–Evans R index, reflecting variation in the spatial arrangement of individuals that is largely independent of community diversity. Together, the PCA distinguish plots according to both community composition and spatial structure, providing an integrated assessment of biodiversity patterns among the sampling sites.

Table 3. Principal Component Analysis (PCA) based on data of the biodiversity indices

Principal Component	Eigenvalue	Variance Explained (%)	Cumulative (%)
PC1	4.382	**70.94**	70.94
PC2	1.149	**18.6**	89.55
PC3	0.551	8.92	98.47
PC4	0.062	1.01	99.47
PC5	0.017	0.27	99.75
PC6	0.016	0.25	100

Principal Component 1 (PC1) accounted for 70.94% of the total variance and represents a biodiversity gradient (Figure 4). Shannon diversity, Simpson diversity, Pielou's evenness, and Margalef richness all loaded positively on PC1, whereas Berger–Parker dominance loaded strongly in the opposite direction. This indicates that plots with higher diversity, greater species richness, and more even communities are associated with lower species dominance. Thus, PC1 distinguishes biologically diverse communities from communities dominated by one or a few species.

Principal Component 2 (PC2) explained an additional 18.60% of the total variance and was dominated by the Clark–Evans R index (loading = 0.918). This indicates that PC2 primarily represents spatial organization rather than species diversity. Because the biodiversity indices had relatively small loadings on PC2, spatial distribution appears to vary largely independently of diversity and dominance.

According to the Kaiser criterion (eigenvalues > 1), only PC1 and PC2 should be retained. Together they explain 89.55% of the total variance, indicating that the six biodiversity indices can be summarized effectively by two ecological gradients: (1) community diversity versus dominance and (2) spatial distribution (Figure 3).

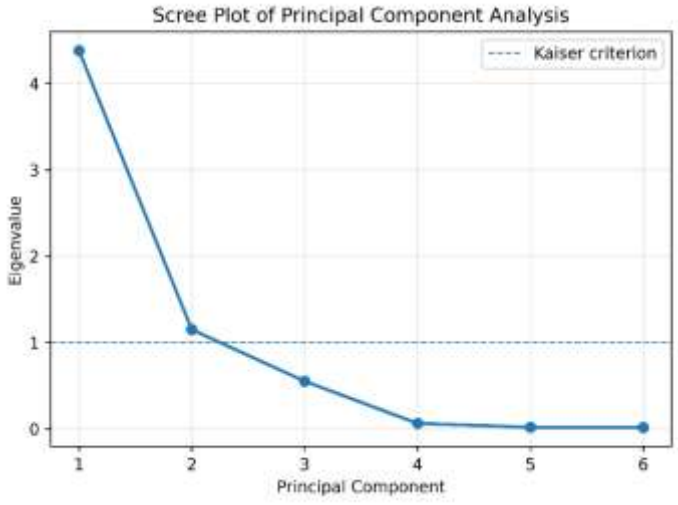

Figure 3. Scree plot showing the eigenvalues of the six principal components derived from the biodiversity indices

These PCA results agree with our Pearson correlation analysis. Shannon diversity, Simpson diversity, evenness, and richness are positively associated with one another, whereas Berger–Parker dominance is negatively associated with these indices. Clark–Evans R forms a largely independent dimension, reflecting spatial pattern rather than biodiversity. Habitat 1 (S1–S15)

is expected to cluster toward the positive side of PC1 (Figure 4) because of generally higher diversity and lower dominance. Habitat 2 (S16–S35) is expected to show greater spread and include several plots associated with higher dominance (e.g., S16, S19, S25, S31).

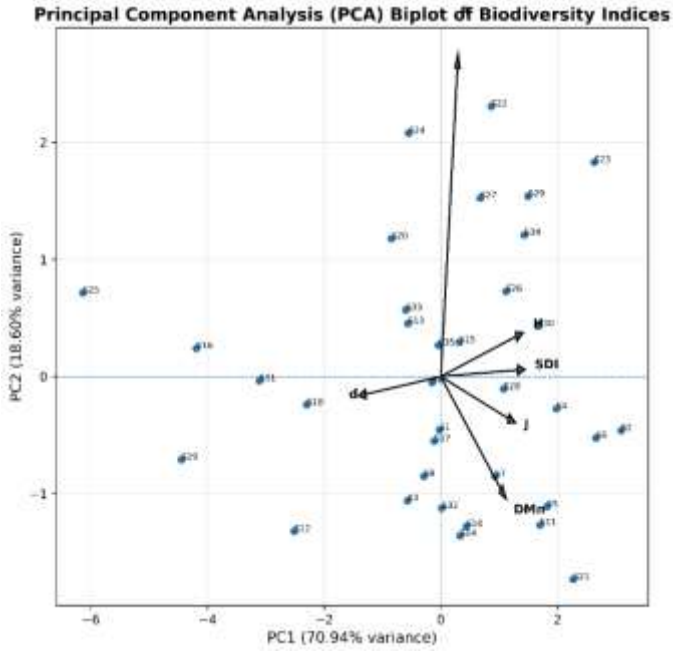

Figure 4. PCA biplot visualizes the relationships among six ecological indices within the two forest habitats inside Divjakë-Karavasta National Park

The first two principal components accounted for 89.55% of the total variation in the dataset, indicating that they captured the vast majority of the information contained in the six biodiversity indices. This high cumulative percentage demonstrates that the multidimensional variation among the sampling plots can be effectively summarized using only two principal components. Consequently, the remaining principal components contributed relatively little additional information, supporting the use of the first two components for interpreting the major ecological gradients and relationships among the biodiversity indices.

CONCLUSION

Analysis of species composition revealed clear differences in dominance patterns between the two forest habitats. In the first forest habitat, based on 15 sampling plots, the four most abundant tree species *Populus alba* L., *Ulmus campestris* L., *Cornus mas L.*, and *Phillyrea latifolia* L. collectively accounted for 57.41% of the total tree abundance. In contrast, the second forest habitat, represented by 20 sampling plots, was strongly dominated by *Carpinus orientalis* Mill., which exhibited the highest relative density (33%). This species was followed in abundance by three representatives of the Fagaceae family, *Quercus cerris* L., *Quercus frainetto* Ten., and *Quercus robur* L., indicating a distinct compositional structure compared with the first habitat. The comparison between Habitat 1 and Habitat 2 of the Divjakë-Karavasta National Park revealed distinct differences in biodiversity and community structure. Overall, Habitat 1 exhibited higher diversity, species richness, and evenness, indicating a more balanced and heterogeneous biological community. In contrast, Habitat 2 showed greater variability among sampling plots and included several plots with higher Berger–Parker dominance values, suggesting that some communities were characterized by the dominance of one or a few species.

The Pearson correlation analysis demonstrated that Shannon diversity, Simpson diversity, species richness, and evenness were strongly and positively related in both habitats, whereas Berger–Parker dominance was negatively associated with these indices. This indicates that increases in species richness and evenness were consistently accompanied by higher biodiversity, while greater species dominance reduced overall community diversity. The Clark–Evans R index showed weak relationships with the diversity indices, suggesting that spatial distribution was largely independent of biodiversity patterns.

Principal Component Analysis supported these findings by showing that the first two principal components explained 89.55% of the total variation. The first principal component represented a gradient from communities with high diversity, richness, and evenness to those with high species dominance, while the second component reflected differences in spatial distribution. The PCA further indicated that Habitat 1 plots were generally associated with higher biodiversity values, whereas Habitat 2 exhibited a broader range of ecological conditions.

Overall, the results suggest that Habitat 1 provides more favorable conditions for maintaining diverse and evenly distributed biological communities, while Habitat 2 is more heterogeneous and contains areas where species dominance is more pronounced. These findings provide a valuable baseline for future biodiversity monitoring and can help guide habitat conservation and management strategies.

ABSTRACT

This study examined the changes in lactose content and free amino acid (FAA) levels during the ripening of cow's milk cheese treated with 20% brine (14–16 °C, 24 h). Two cheese variants were prepared from pasteurised cow's milk (3.8% fat): one coagulated with chymosin only (DLK) and one with chymosin supplemented with a microbial starter culture (DLK-S). Cheese samples were stored at 14–15 °C and analysed on days 12, 22 and 32 of ripening for moisture, pH, titratable acidity, sodium chloride, lactose and free amino acids.

In the chymosin-only variant (DLK), the lactose content decreased gradually on days 12, 22 and 32. The FAA content remained low and essentially unchanged indicating that lactic acid bacteria originating from the milk alone exerted limited lactose-metabolising and proteolytic activity during the 32-day ripening period. By contrast, the starter-supplemented variant (DLK-S) showed a marked acceleration in both processes: lactose declined on day 12 and fell below the detection limit by day 32, while FAA levels increased steadily. A positive correlation between lactic acid production and lactose consumption was observed in both variants.

These results confirm that the addition of a microbial starter culture to brine-salted cheese markedly enhances lactose catabolism and proteolysis during ripening. While the indigenous lactic acid bacteria in DLK maintained only a basal level of metabolic activity, the defined starter in DLK-S drove lactose to exhaustion by day 32 and produced FAA levels approximately five times higher than those in the chymosin-only cheese. The findings highlight the essential role of starter cultures in the development of flavour and aroma compounds in salted cheese during extended ripening.

Keywords: cheese ripening, salted cheese, brine treatment, lactose metabolism, free amino acids, proteolysis, starter culture, chymosin, cow's milk

INTRODUCTION

The application of salt to cheese curd is one of the most universal steps in cheese manufacture. Salt contributes directly to flavour, inhibits spoilage and pathogenic organisms, influences texture, and modulates the activity of ripening enzymes (Fox et al., 2004). This review examines how brine salting affects the metabolism of residual lactose and the proteolytic

degradation of casein during cheese ripening, with particular attention to the interaction between salt concentration, starter culture activity and FAA accumulation.
The aim of this study was to investigate the changes in the content of lactose and free amino acids (FAA) during cheese ripening, with particular attention to the effects of two factors: (i) the addition of a microbial starter culture (commercial yogurt) versus coagulation with chymosin alone omission of a salting treatment. Two cheese variants were produced from pasteurised cow's milk and monitored over their respective ripening periods for a suite of physicochemical indices, including moisture, pH, titratable acidity, sodium chloride, lactose and free amino acid content.

Salting methods and their effect on cheese composition

Brine salting involves immersing pressed cheese in a concentrated NaCl solution, typically 18–22% (w/v), at 10–16 °C for periods ranging from hours to days (Fox et al., 2004). Salt uptake is a diffusion-driven process: NaCl migrates inward while moisture migrates outward, creating a characteristic salt-in-moisture gradient that is highest at the surface and lowest at the centre (Kleter et al., 1984). This gradient has important implications for the spatial distribution of microbial activity and enzymatic ripening within the cheese.

In brine-salted cheeses, the time required for NaCl to reach inhibitory concentrations throughout the cheese is longer than in dry-salted varieties, which has consequences for controlling undesirable fermentations in the interior.

Effect of salt on LAB and lactose fermentation

Sodium chloride inhibits LAB primarily through the reduction of water activity (aw). As NaCl concentration increases, the aw decreases, creating osmotic stress that impairs bacterial growth, reduces sugar transport across the cell membrane, and inhibits glycolytic enzyme activity (Turner and Thomas, 1980). Sensitivity to NaCl varies among LAB species and strains.

At the salt-in-moisture levels typical of semi-hard cheeses (approximately 4–6% S/M), starter LAB growth is slowed but not arrested, and residual lactose is typically fermented to completion within the first weeks of ripening. At higher S/M levels, lactose fermentation may be significantly delayed, providing a potential substrate for late gas-producing organisms (McSweeney and Fox, 2004).

The anaerobic metabolism of lactate by Clostridium tyrobutyricum to butyrate and hydrogen gas known as late gas blowing is particularly associated with brine-salted cheeses in which NaCl has not yet penetrated to inhibitory concentrations (Kleter et al., 1984; Fox et al., 1990). Complete and timely fermentation of residual lactose by the starter culture is therefore an important quality parameter.

Proteolysis in salted cheese

The proteolytic agents in salted cheese are the same as in other cheese types: residual coagulant (chymosin), indigenous milk proteinases (plasmin), and LAB proteinases and peptidases (McSweeney, 2004; Upadhyay et al., 2004). However, their rates are modulated by NaCl.
Chymosin activity is relatively insensitive to NaCl at typical cheese concentrations, although high salt levels may alter the conformation of casein substrates (Fox and McSweeney, 1996b). Plasmin activity has been reported to be stimulated by moderate NaCl in some studies (Bastian and Brown, 1996). LAB peptidases are indirectly affected through salt's impact on cell viability

and lysis kinetics, as these intracellular enzymes are released into the cheese matrix upon cell death (Kunji et al., 1996; Upadhyay et al., 2004).
The practical consequence is that salted cheeses exhibit slower FAA accumulation than unsalted equivalents. However, this slower rate allows for a more gradual and balanced development of flavour compounds over extended ripening, which is characteristic of many valued aged varieties (McSweeney, 2004).

FAA and flavour development in salted cheese

FAA accumulation in salted cheese follows a characteristic pattern: an initial lag phase during which primary proteolysis generates large peptides, followed by a progressive increase as LAB peptidases hydrolyse these intermediates to individual amino acids (McSweeney, 2004). FAA levels may range from a few milligrams to several hundred milligrams per 100 g cheese, depending on the variety and ripening duration (McSweeney and Sousa, 2000).
These free amino acids serve as substrates for secondary catabolic reactions transamination, decarboxylation, deamination that produce volatile flavour compounds (Yvon and Rijnen, 2001; Curtin and McSweeney, 2004). In cheeses without a defined starter, FAA accumulation is typically much lower, reflecting the limited proteolytic capacity of indigenous NSLAB and the dominance of primary proteolysis by chymosin and plasmin, which generate large peptides but do not efficiently release individual amino acids (Christensen et al., 1999).

MATERIAL AND METHOD

Raw materials

Fresh cow's milk (10 litres) was obtained from a local dairy farm on the day of cheese manufacture. The milk had a fat content of 3.8% (w/w). The coagulant used was commercial bovine chymosin with a clotting strength of 1:10,000. A commercial plain yogurt was used as the source of microbial starter culture, providing a mixed population of lactic acid bacteria (principally Lactobacillus delbrueckii subsp. bulgaricus and Streptococcus thermophilus). All reagents for physicochemical analyses were of analytical grade.

Experimental design

The study employed a 2 × 2 factorial design with two factors: coagulation method (chymosin only vs. chymosin + starter culture) and salting treatment (salted vs. unsalted). This yielded four cheese variants, each designated by a sample code as follows:
- DLK – cheese coagulated with chymosin only, with salt treatment;
- DLK-S – cheese coagulated with chymosin + microbial starter culture, with salt treatment;

The salted variants (DLK and DLK-S) were analysed at three time points during ripening: days 12, 22 and 32.

Cheese manufacture

The 10 liters of milk were divided into two equal batches of 5 liters each. Each batch was used to produce salted variant as described below. The production protocol was identical for both batches up to the pressing step to produce feta cheese, after which the salting treatment was applied.

Salted variants (DLK and DLK-S)

The milk (5 litres, 3.8% fat) was pasteurised using a low-temperature, long-time (LTLT) protocol at 63–65 °C for 30 minutes, followed by rapid cooling to 1–2 °C. After tempering to 30 °C, the milk was divided into two portions. The first portion was coagulated by the addition of chymosin at a dose of 150 mg per 5 litres (strength 1:10,000) at 30 °C for 50–60 minutes to produce the DLK variant. The second portion received both chymosin (same dose) and 30 g of plain yogurt as a source of starter culture, and was coagulated under the same conditions (30 °C, 50–60 minutes) to produce the DLK-S variant.

Following coagulation, syneresis was allowed to proceed at 30 °C. The curd was then pressed under its own weight to facilitate whey expulsion. The pressed curd was immersed in a 20% (w/v) NaCl brine solution at 14–16 °C for 24 hours. After brining, the cheese samples were stored for ripening at 14–15 °C and sampled for analysis on days 12, 22 and 32.

Analytical methods

All physicochemical analyses were performed in duplicate on each cheese sample at the designated ripening time points. The following parameters were determined:

Moisture content

Moisture content was determined gravimetrically by drying a weighed sample in a thermostat oven at 105 °C until a constant weight was achieved (Ardö and Polychroniadou, Cheese Analysis Manual). The result was expressed as a percentage (%, w/w).

pH

The pH of each cheese sample was measured potentiometrically by inserting a calibrated glass electrode directly into the cheese mass at ambient temperature (Ardö and Polychroniadou, Cheese Analysis Manual).

Titratable acidity

Titratable acidity was determined by the potentiometric titration method (Ardö and Polychroniadou, Cheese Analysis Manual) and expressed as a percentage of lactic acid (%, w/w).

Sodium chloride (NaCl)

The NaCl content of the salted cheese samples (DLK and DLK-S) was determined by the Volhard method (Ardö and Polychroniadou, Cheese Analysis Manual) and expressed as a percentage (%, w/w). NaCl analysis was not performed on the unsalted variants (DLKP and DLK-SP), as no salt was added during their manufacture.

Lactose content

Lactose content was determined by the iodimetric method of Fine (1932), as described by James (1998, Analytical Chemistry of Food, Springer Science & Business). The result was expressed as mg lactose per 100 g cheese as shown in chart 1. Where the measured value fell

below the sensitivity of the method, the result was reported as below the limit of detection (> LD).

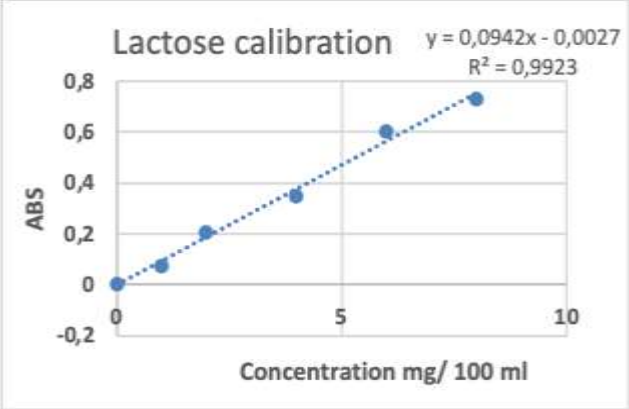

Chart 1. Lactose curbe calibration

Free amino acid (FAA) content

The content of free amino acids was determined spectrophotometrically using a ninhydrin-based colorimetric assay, with L-lysine as the calibration standard (Ardö and Polychroniadou, Cheese Analysis Manual). A calibration curve was constructed by plotting absorbance at 570 nm against known concentrations of L-lysine (µg/100 µl). The FAA content of each cheese sample was calculated from the calibration curve and expressed as mg FAA per 100 g cheese as shown on chart 2.

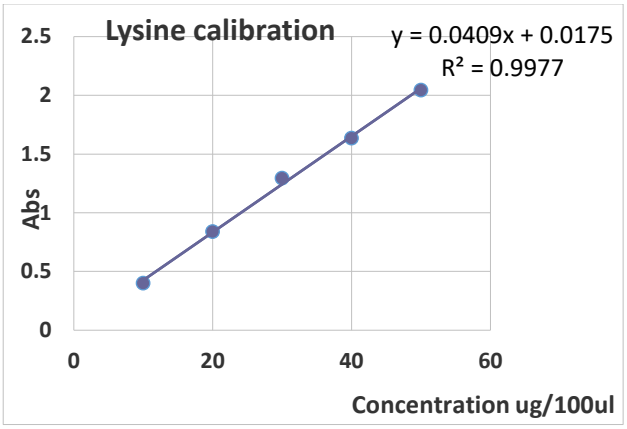

Chart 2. Lysine curbe calibration

RESULTS AND DISCUSSION

This section presents the results of the physicochemical analysis of two salted cheese variants: DLK (chymosin only) and DLK-S (chymosin + starter culture). Both were treated with 20% NaCl brine at 14–16 °C for 24 hours, then stored at 14–15 °C and analysed on days 12, 22 and 32 of ripening.

The chymosin-only salted variant (DLK), the lactose content decreased gradually on days 12, 22 and 32 of ripening, Fig 2. The FAA content remained low throughout. The pH declined slowly, while titratable acidity decreased. Moisture fell, and NaCl in brine stabilised at approximately 19–21%.

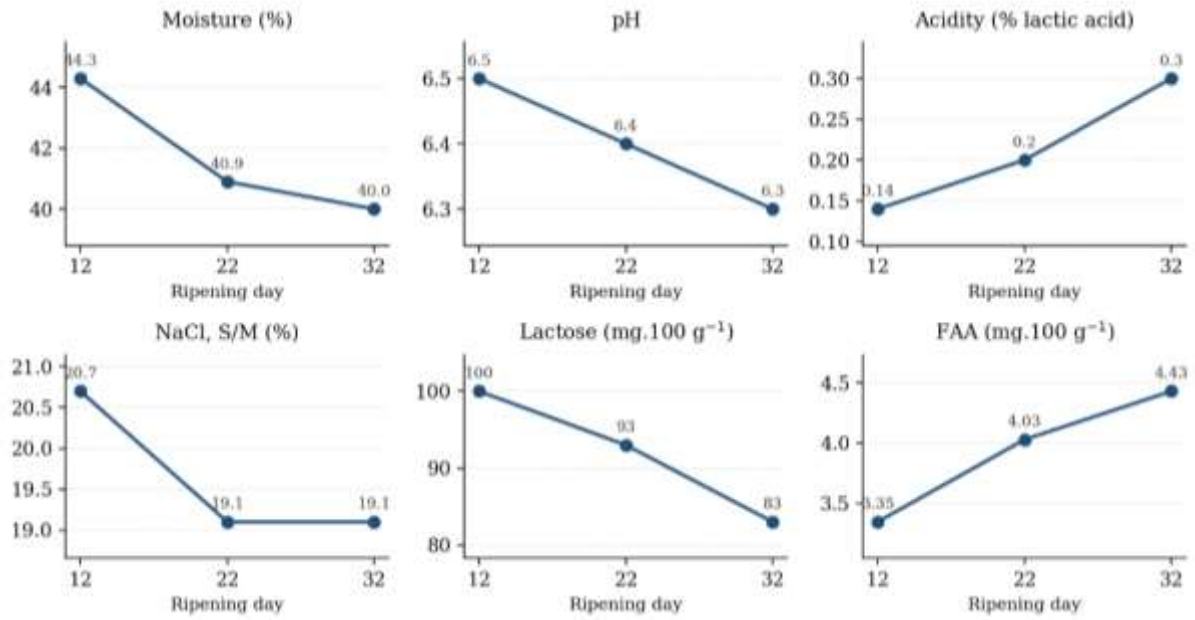

Fig 2. DLK cheese chymosin only, salted, changes during ripening from day 12 to day 32.

These results indicate that the indigenous lactic acid bacteria originating from the pasteurised milk exert limited metabolic activity throughout the 32-day ripening period in the presence of high salt concentrations and without a defined starter culture. The slow decline in lactose and the near-constant FAA levels suggest that the proteolytic activity observed is attributable primarily to the residual chymosin retained in the curd, which hydrolyses αs1-casein at the Phe_{23}–Phe_{24} bond as its primary site of action, and to a lesser extent to indigenous plasmin activity. The low FAA accumulation indicates that the peptidases necessary for the terminal stages of proteolysis are present in insufficient quantities without a starter-derived enzyme complement.

The starter-supplemented salted variant (DLK-S) exhibited a markedly different metabolic profile. Lactose was consumed rapidly and falling below the detection limit by day 32. The pH was substantially lower than in DLK at all time points, reflecting vigorous acid production by the starter LAB. Titratable acidity rose on day 12 to day 22 before stabilising on day 32, consistent with the near-exhaustion of lactose as a fermentable substrate Fig 3.

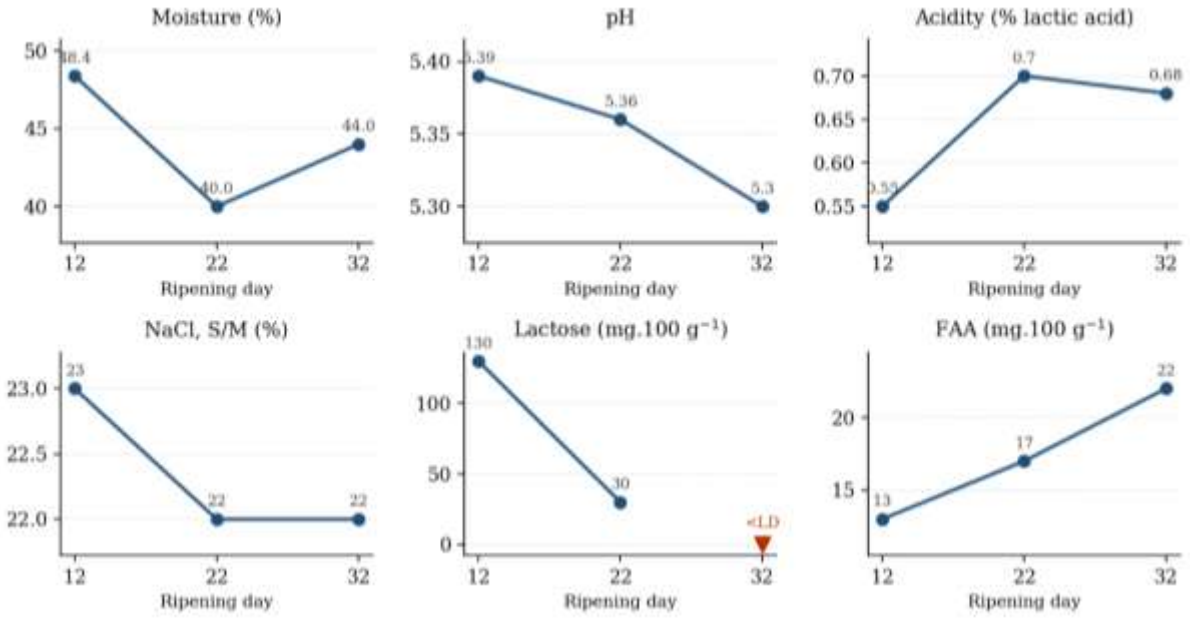

Fig 3. DLK-S cheese chymosin + starter, salted: changes during ripening from day 12 to day 32

The FAA content increased steadily approximately five times higher than in DLK at each corresponding time point. The continuous accumulation demonstrates that the proteolytic enzyme system of the starter LAB comprising cell envelope-associated proteinases and intracellular peptidases released upon cell lysis actively degrades the casein matrix throughout the ripening period.

A positive correlation was observed between lactic acid production and lactose consumption in both variants, confirming that lactose serves as the primary energy source for the LAB and that its fermentation to lactate drives the acidification of the cheese curd.

COMPARATIVE DISCUSSION

The comparison of DLK and DLK-S demonstrates that the addition of a microbial starter culture is the decisive factor in determining both the rate and extent of lactose metabolism and proteolysis in brine-salted cheese. While the indigenous microflora in DLK maintained only basal-level metabolic activity over 32 days, the defined starter in DLK-S drove lactose to exhaustion and produced FAA levels approximately five times higher.

The complete fermentation of residual lactose by day 32 in DLK-S is an important quality parameter, as unfermented lactose can serve as a carbon source for undesirable secondary microflora and contribute to defects during extended ripening. The elevated FAA levels represent a larger pool of substrates for secondary catabolic reactions that generate volatile flavour compounds.

LIMITATIONS

Several limitations should be considered. First, the earliest sampling point was day 12, so the initial phase of lactose fermentation (days 0–12) was not captured. Second, the NaCl values reported (19–23%) represent salt-in-moisture rather than salt-in-cheese; clarification is important as NaCl concentration strongly influences LAB activity. Third, the FAA assay reports

total free amino acids using a single method calibrated with L-lysine, without resolving individual amino acids. Fourth, no sensory evaluation was performed. Fifth, the experiment used a single production batch without biological replicates. Finally, the use of commercial yogurt as a starter precludes attribution of specific activities to defined bacterial strains.

CONCLUSIONS

Brine salting is a critical control point in cheese manufacture, simultaneously contributing to preservation, texture and flavour while modulating ripening biochemistry. Salt inhibits LAB growth and enzymatic activity in a concentration-dependent manner, slowing lactose fermentation and proteolysis. The use of a defined starter culture is essential for ensuring complete lactose fermentation and for providing the proteolytic enzyme complement necessary for sustained FAA release. The interplay between salt concentration, starter activity and ripening duration remains a key area for optimisation in consistent cheese quality production.

ABSTRACT

This study investigated the changes in lactose content and free amino acid (FAA) levels during the ripening of cow's milk cheese produced without salt treatment. Two cheese variants were prepared from pasteurised cow's milk (3.8% fat): one coagulated with chymosin only (DLKP) and one with chymosin supplemented with a microbial starter culture (DLK-SP). Cheese samples were stored at 14–15 °C and analysed on days 1, 3 (or 5) and 7 of ripening for moisture, pH, titratable acidity, lactose and free amino acids.
In the chymosin-only variant (DLKP), lactose decreased from 5 and 7, and FAA levels fell over the same period, reflecting limited proteolytic activity in the absence of a defined starter culture. The starter-supplemented variant (DLK-SP) exhibited an accelerated pattern: lactose declined on day 1 to day 3 and fell below the detection limit by day 7, while FAA levels were high, rising on days 1, 3 and 7. The pH of DLK-SP dropped accompanied by an increase in titratable acidity. The results demonstrate that in the absence of salt, the addition of a microbial starter culture stimulates both lactose catabolism and proteolysis from the earliest stages of ripening. The FAA content in the starter-supplemented unsalted cheese (DLK-SP) was higher than in any of the salted variants, indicating that the omission of salt with starter inoculation, creates conditions highly favourable for the enzymatic degradation of caseins and the release of flavour precursors. These findings suggest that unsalted cheese produced with a starter culture develops flavour and aroma compounds more rapidly than its salted counterparts.

Keywords: cheese ripening, unsalted cheese, lactose metabolism, free amino acids, proteolysis, starter culture, chymosin, cow's milk

INTRODUCTION

Cheese is among the most ancient and diverse fermented food products. While many commercial cheeses undergo a salting step, a number of traditional and artisanal varieties are produced with reduced salt or without salt entirely. The biochemical changes that occur during the ripening of unsalted cheese are of particular interest because the absence of sodium chloride removes a major regulatory factor that normally modulates microbial growth and enzymatic activity in the cheese matrix (Fox et al., 2004). This review examines the current

understanding of the two principal biochemical events during the ripening of unsalted cheese: the catabolism of residual lactose by lactic acid bacteria (LAB) and the proteolytic degradation of casein to peptides and free amino acids (FAA). These processes are the primary determinants of flavour and texture development (McSweeney, 2004). The aim of this study was to investigate the changes in the content of lactose and free amino acids (FAA) during cheese ripening, with particular attention to the effects of two factors: (i) the addition of a microbial starter culture (commercial yogurt) versus coagulation with chymosin alone without adding salt.

Residual lactose and its fermentation

During cheese manufacture, most of the lactose in milk is lost in the whey. Nevertheless, a small but significant amount remains in the curd at the end of production, quantified at approximately 0.8–1.0% for Cheddar-type cheeses (Huffman and Kristoffersen, 1984). The complete fermentation of this residual lactose during the early stages of ripening is essential for cheese quality, as unfermented lactose can serve as a carbon source for undesirable organisms such as Clostridium tyrobutyricum, which causes late gas blowing (Fox et al., 1990).

The rate and completeness of lactose fermentation depend primarily on the metabolic activity of the LAB population. In cheeses made with defined starters, organisms such as Lactococcus lactis ferment lactose rapidly to L-lactate via the homofermentative pathway (Parente and Cogan, 2004). Without a defined starter, indigenous non-starter lactic acid bacteria (NSLAB) ferment lactose more slowly and may produce both L- and D-lactate (Turner and Thomas, 1980).

In unsalted cheese, the absence of NaCl-induced osmotic stress allows LAB to grow more rapidly and ferment lactose more completely than in salted counterparts. Salt-in-moisture levels normally exert a significant inhibitory effect on LAB growth rates and metabolic activity (Turner and Thomas, 1980). When this inhibitory factor is removed, residual lactose may be exhausted within days rather than weeks.

Proteolysis: agents and mechanisms

Proteolysis is the most important primary biochemical event during the ripening of most rennet-coagulated cheeses (McSweeney, 2004). It contributes to flavour through the release of short peptides and free amino acids, influences texture through hydrolysis of the casein matrix, and provides substrates for secondary catabolic reactions (Upadhyay et al., 2004).

The residual coagulant most commonly chymosin is responsible for the initial hydrolysis of intact caseins into large and medium-sized peptides, with its primary cleavage sites well characterised (McSweeney et al., 1993). Plasmin, an indigenous serine proteinase associated with the casein micelle, also contributes to primary proteolysis (Bastian and Brown, 1996). The proteinases and peptidases of starter LAB and NSLAB are then responsible for degrading these peptides into short peptides and free amino acids (Kunji et al., 1996; Christensen et al., 1999). The proteolytic system of Lactococcus comprises the cell envelope-associated proteinase lactocepin, which degrades caseins at the cell surface, and a diverse array of intracellular peptidases aminopeptidases, dipeptidases, tripeptidases and proline-specific peptidases released into the cheese matrix upon cell lysis (Law and Haandrikman, 1997; Upadhyay et al., 2004). These intracellular peptidases are essential for the terminal stages of proteolysis.

Free amino acids as flavour precursors

Free amino acids serve as substrates for secondary catabolic reactions transamination, decarboxylation, deamination and desulfurylation that generate many volatile compounds responsible for cheese aroma (Yvon and Rijnen, 2001; Curtin and McSweeney, 2004). The catabolism of branched-chain amino acids yields aldehydes and alcohols; aromatic amino acid catabolism produces phenolic compounds; and sulfur-containing amino acid catabolism generates methanethiol and related volatiles that are important to cheese aroma even at very low concentrations (Smit et al., 2002; McSweeney and Sousa, 2000).

Implications for unsalted cheese ripening

In unsalted cheese, uninhibited LAB growth leads to faster lactose fermentation, more vigorous acid production, and more rapid accumulation of proteolytic enzymes. When a defined starter culture is used, this can produce FAA levels within days that exceed those in salted cheese after weeks of ripening (McSweeney, 2004). This accelerated biochemistry establishes the pool of amino acid substrates for secondary catabolic reactions earlier in the ripening process.

However, the absence of salt also removes an important hurdle against spoilage organisms, and the high water activity of unsalted cheese renders it more susceptible to microbiological deterioration during extended storage. The balance between accelerated flavour development and microbiological stability is therefore a critical consideration (Fox et al., 2004).

MATERIAL AND METHOD

Raw materials

Fresh cow's milk (10 liters) was obtained from a local dairy farm on the day of cheese manufacture. The milk had a fat content of 3.8% (w/w). The coagulant used was commercial bovine chymosin with a clotting strength of 1:10,000. A commercial plain yogurt was used as the source of microbial starter culture, providing a mixed population of lactic acid bacteria (principally Lactobacillus delbrueckii subsp. bulgaricus and Streptococcus thermophilus)

Experimental design

The study employed a 2 × 2 factorial design with two factors: coagulation method (chymosin only vs. chymosin + starter culture) and unsalted. This yielded four cheese variants, each designated by a sample code as follows:

- DLKP – cheese coagulated with chymosin only, without salt treatment;
- DLK-SP – cheese coagulated with chymosin + microbial starter culture, without salt treatment.

DLKP and DLK-SP were analysed at days 1, 3 (or 5) and 7.

Cheese manufacture

The 10 litres of milk were divided into two equal batches of 5 litres each. Each batch was used to produce unsalted variant of feta cheese as described below.

Unsalted variants (DLKP and DLK-SP)

The second batch of milk (5 litres, 3.8% fat) was pasteurised, cooled and tempered identically to the first batch (63–65 °C for 30 min, rapid cooling to 1–2 °C, tempering to 30 °C). Coagulation was carried out as described above: one portion with chymosin only (DLKP) and one with chymosin + 30 g yogurt (DLK-SP), both at 30 °C for 50–60 minutes. Syneresis and pressing under the curd's own weight were performed as for the salted variants. However, no brine treatment was applied. The unsalted cheese samples were stored at 14–15 °C and sampled for analysis on days 1, 3 (or 5) and 7.

Analytical methods

All physicochemical analyses were performed in duplicate on each cheese sample at the designated ripening time points. The following parameters were determined:

Moisture content

Moisture content was determined gravimetrically by drying a weighed sample in a thermostat oven at 105 °C until a constant weight was achieved (Ardö and Polychroniadou, Cheese Analysis Manual). The result was expressed as a percentage (%, w/w).

pH

The pH of each cheese sample was measured potentiometrically by inserting a calibrated glass electrode directly into the cheese mass at ambient temperature (Ardö and Polychroniadou, Cheese Analysis Manual).

Titratable acidity

Titratable acidity was determined by the potentiometric titration method (Ardö and Polychroniadou, Cheese Analysis Manual) and expressed as a percentage of lactic acid (%, w/w).

Lactose content

Lactose content was determined by the iodimetric method of Fine (1932), as described by James (1998, Analytical Chemistry of Food, Springer Science & Business). The result was expressed as mg lactose per 100 g cheese as in chart 1. Where the measured value fell below the sensitivity of the method, the result was reported as below the limit of detection (> LD).

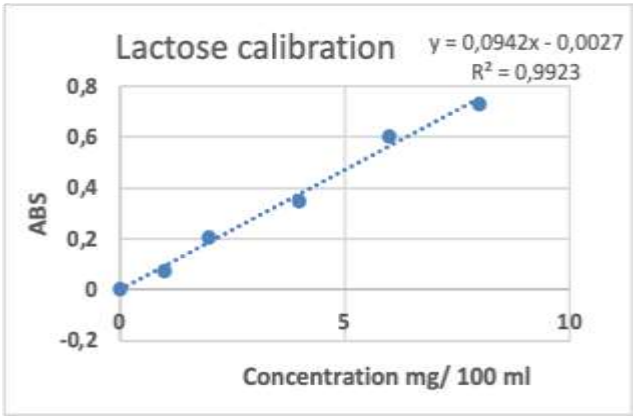

Chart 1. Lactose curbe calibration

Free amino acid (FAA) content

The content of free amino acids was determined spectrophotometrically using a ninhydrin-based colorimetric assay, with L-lysine as the calibration standard (Ardö and Polychroniadou, Cheese Analysis Manual). A calibration curve was constructed by plotting absorbance at 570 nm against known concentrations of L-lysine (µg/100 µl) as shown on chart 2. The FAA content of each cheese sample was calculated from the calibration curve and expressed as mg FAA per 100 g cheese.

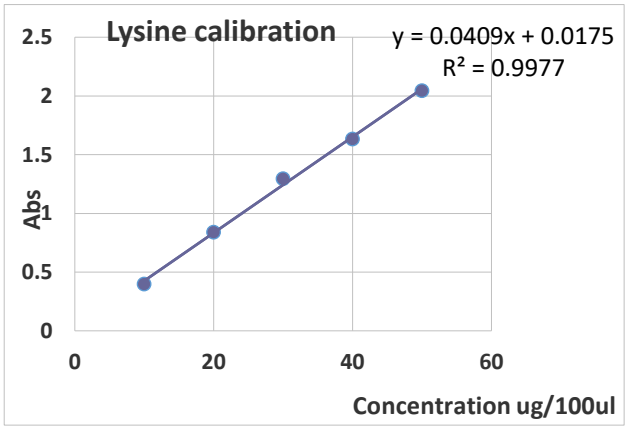

Chart 2. Lysine curbe calibration

RESULTS AND DISCUSSION

This section presents the results of the physicochemical analysis of two unsalted cheese variants produced from pasteurised cow's milk (3.8% fat): DLKP (coagulated with chymosin only) and DLK-SP (coagulated with chymosin supplemented with a microbial starter culture). Both variants were stored at 14–15 °C without brine treatment and analysed at defined time points during the first 7 days of ripening Fig 2 and Fig 3.

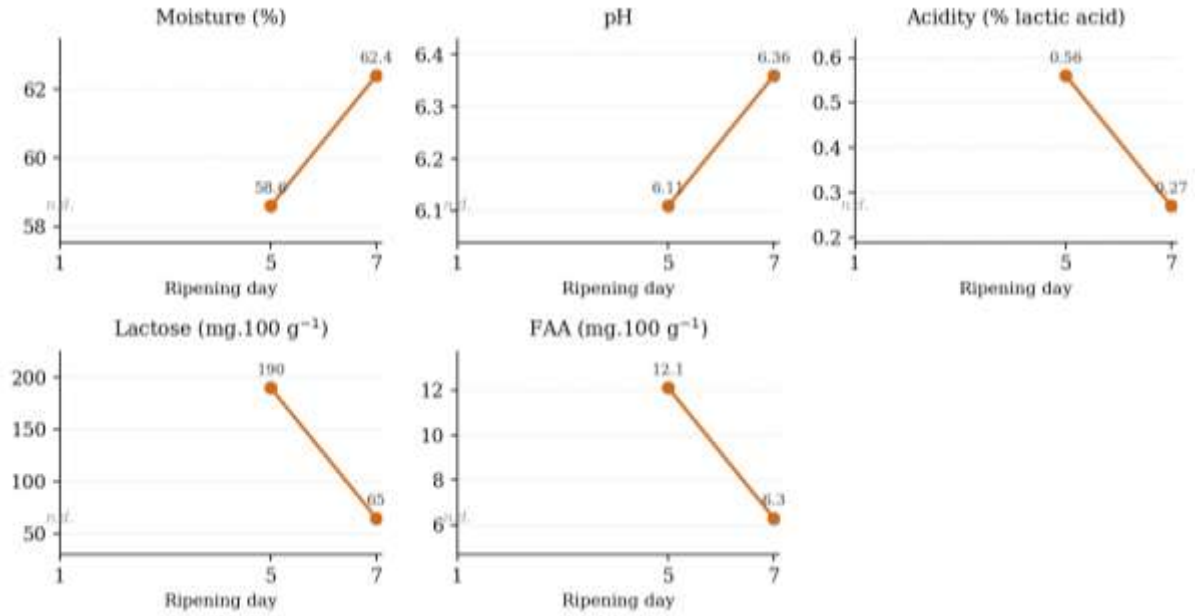

Fig 2. DLKP cheese chymosin only, unsalted during ripening days.

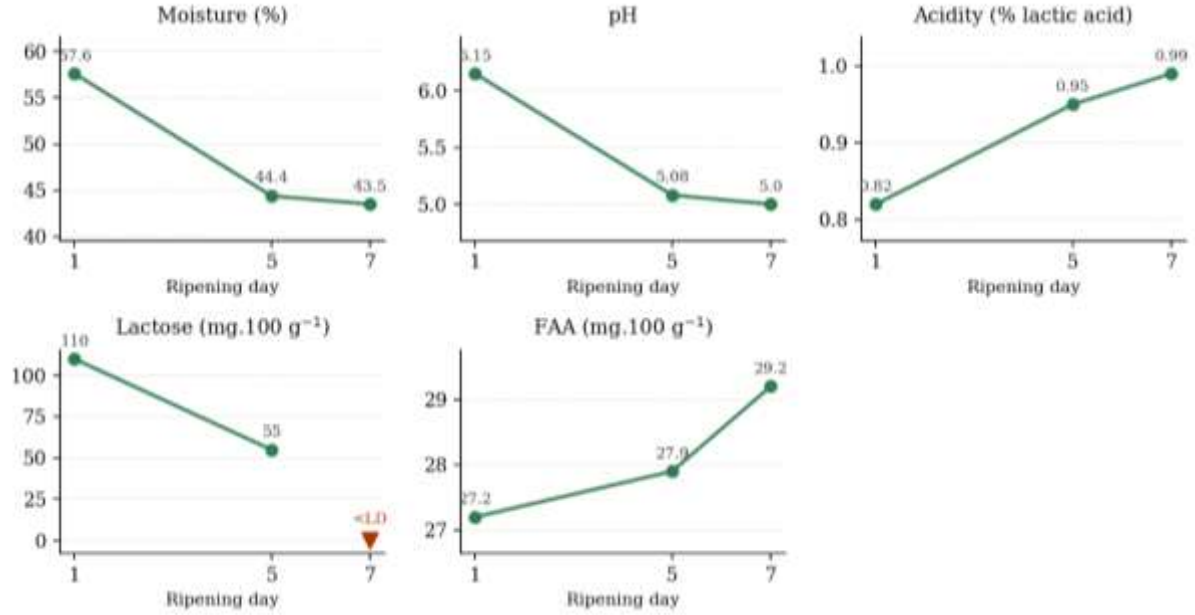

Fig 3. DLK-SP cheese chymosin + starter unsalted changes during ripening days.

The chymosin-only unsalted variant (DLKP), lactose content decreased on day 5 to day 7. Meanwhile, the free amino acid content fell over the same period. The pH declined from, and the titratable acidity dropped. Moisture increased likely reflecting ongoing whey redistribution in the absence of salt-driven osmotic dehydration.

These results indicate that in the absence of both a defined starter culture and salt, the indigenous lactic acid bacteria present in the pasteurised milk exhibit limited metabolic activity. The decrease in FAA between days 5 and 7 is noteworthy and may reflect the consumption of free amino acids by the adventitious microflora (non-starter lactic acid bacteria, NSLAB) as nitrogen sources for growth, rather than a continued release from casein hydrolysis. Proteolytic

activity in this variant appears to be driven primarily by the residual chymosin retained in the curd, with only a minor contribution from indigenous milk proteinases such as plasmin.

In marked contrast to DLKP, the starter-supplemented unsalted variant (DLK-SP) showed rapid and sustained biochemical changes during ripening. Lactose declined sharply on day 1 to day 3, indicating near-complete fermentation within one week. The pH dropped substantially consistent with the vigorous production of lactic acid.

The FAA content was markedly higher than in DLKP at every time point, rising steadily. This continuous accumulation demonstrates that the proteolytic enzymes released by the starter lactic acid bacteria including cell envelope-associated proteinases (lactocepin) and a range of intracellular peptidases are actively degrading the casein matrix from the first day of ripening. The absence of salt removes a key inhibitor of both LAB growth and enzymatic activity, explaining why FAA accumulation in this variant exceeded that of all other variants.

DISCUSSION

A comparison of DLKP and DLK-SP demonstrates the decisive role of the starter culture in driving both lactose catabolism and proteolysis in unsalted cheese. The starter-supplemented variant exhausted its lactose supply within 7 days and produced FAA levels higher than the peak value observed in the chymosin-only variant. The rapid pH drop in DLK-SP compared with the modest decline in DLKP confirms that the added LAB population dominates the fermentation.

The practical implication is that unsalted cheese produced with a starter culture develops flavour precursors particularly free amino acids that serve as substrates for secondary catabolic reactions producing volatile aroma compounds more rapidly than any of the salted variants examined in this study.

LIMITATIONS

Several limitations should be acknowledged. First, the unsalted variants were monitored for only 7 days due to cheese spoilage. Second, day 1 data are unavailable for DLKP, precluding a baseline comparison with DLK-SP. Third, the FAA assay employed a single calibration standard (L-lysine) and reports total FAA as a global index; it does not resolve the individual amino acid profile. Fourth, no sensory evaluation was performed. Fifth, the experiment was conducted with a single batch of milk without biological replicates, limiting statistical power. Finally, the microbial starter was introduced as commercial yogurt rather than as defined single-strain cultures, making it impossible to attribute the observed metabolic activities to specific bacterial species.

CONCLUSIONS

The literature demonstrates that in unsalted cheese, the removal of salt's inhibitory effect on LAB creates conditions that favour rapid lactose fermentation and enhanced proteolysis. Starter culture addition amplifies these effects, providing a large LAB population whose proteinases and peptidases release free amino acids from the earliest stages of ripening. Future research should focus on optimising the balance between accelerated biochemical ripening and microbiological safety in reduced-salt and unsalted cheese formulations.

DIETARY PATTERNS, GUT MICROBIOME MODULATION, AND MENTAL HEALTH OUTCOMES: EVIDENCE FROM A PRISMA-BASED SYSTEMATIC REVIEW

Merjem BUSHATI*[1], Rozarta NEZAJ[2]

ABSTRACT

Introduction: Mental health disorders, including depression and anxiety, represent a growing global public health concern. Emerging evidence points to diet as a key modulator of gut microbiome composition, with downstream effects on mental health through the gut–brain axis. Despite growing research interest, findings remain inconsistent across study designs and populations. This systematic review synthesizes human evidence on dietary patterns, microbiome-targeted interventions, and mental health outcomes.
Methods: A PRISMA 2020-based systematic review was conducted using PubMed, ScienceDirect, and Google Scholar (2009–2024; final search: January 2026). Included studies involved human participants examining associations between diet, gut microbiota, and mental health outcomes (depression, anxiety, stress, psychological well-being). Eligible designs included RCTs, cohort, and cross-sectional studies. From 1,248 records identified, 36 studies met inclusion criteria. Methodological quality was assessed using Cochrane RoB 2 for RCTs and the Newcastle–Ottawa Scale for observational studies.
Results and Discussion: The 36 included studies comprised 12 RCTs, 14 cohort, and 10 cross-sectional studies. Of these, 15 examined dietary patterns, 10 probiotics, 5 prebiotics, and 6 functional foods. Mediterranean diet adherence was consistently linked to reduced depressive symptoms and better psychological well-being. The SMILES trial reported significant reductions in depression scores following dietary intervention. Western-style diets were associated with higher rates of depression and anxiety. Probiotic and prebiotic interventions showed beneficial but variable effects depending on strain, dosage, and duration. Diet-induced microbiome changes appear to affect mental health through inflammatory pathways, neurotransmitter production, and short-chain fatty acid signaling. A notable research gap was identified in Southeastern Europe, including Albania.
Conclusions: Diet is a practical and accessible factor that may improve mental health through microbiome-related mechanisms. Future studies should adopt standardized methods and longer follow-up periods to clarify causal pathways and inform nutrition-based approaches in mental health care.
Keywords: diet; gut microbiome; mental health; depression; Mediterranean diet; probiotics; gut–brain axis; systematic review; PRISMA

INTRODUCTION

Mental health disorders, including depression and anxiety, represent a growing global public health concern, contributing substantially to the global burden of disease and reduced quality of life (Firth et al., 2020). In recent years, increasing attention has been directed toward modifiable lifestyle factors, particularly diet, as potential determinants of mental health

outcomes. This emerging field, often referred to as *nutritional psychiatry*, explores the complex interactions between dietary intake, biological systems, and psychological well-being (Sarris et al., 2015; Marx et al., 2017).

A central mechanism underlying this relationship is the gut–brain axis**,** a bidirectional communication system linking the gastrointestinal tract and the central nervous system. This axis involves neural, endocrine, immune, and metabolic pathways, through which the gut microbiome exerts significant influence on brain function and behavior (Cryan et al., 2019; Dinan & Cryan, 2017). The gut microbiota plays a key role in the production of neurotransmitters, regulation of inflammatory responses, and maintenance of gut barrier integrity, all of which are implicated in the pathophysiology of mental health disorders (Valles-Colomer et al., 2019).

Diet is one of the most important modulators of gut microbiome composition and function. Evidence suggests that adherence to high-quality dietary patterns, particularly the Mediterranean diet, is associated with greater microbial diversity and improved metabolic and inflammatory profiles (Molendijk et al., 2018). These biological effects are increasingly linked to improved mental health outcomes. For example, observational studies have consistently reported that higher adherence to Mediterranean-style diets is associated with a lower risk of depressive symptoms (Adjibade et al., 2019; Lai et al., 2014).

Interventional evidence further supports this relationship. Randomized controlled trials such as the SMILES study have demonstrated that dietary improvement can lead to significant reductions in depressive symptoms in adults with major depression (Jacka et al., 2017). Similarly, microbiome-targeted interventions, including probiotics and prebiotics, have shown potential in modulating psychological outcomes, although findings remain heterogeneous due to differences in study design, microbial strains, and intervention duration (Ng et al., 2018).

Despite the growing body of literature, several challenges remain. Existing studies vary considerably in terms of methodology, population characteristics, dietary assessment tools, and outcome measures, limiting comparability and synthesis. In addition, while individual studies provide important insights, there is still a lack of comprehensive synthesis focusing specifically on the integrated relationship between dietary patterns, gut microbiome modulation, and mental health outcomes within a unified framework.

Therefore, the aim of this study is to conduct a PRISMA-based systematic review to synthesize current human evidence on the role of diet and microbiome-targeted interventions in mental health. This review seeks to provide a structured evaluation of existing research, identify key patterns and mechanisms, and highlight gaps for future investigation. Furthermore, a conceptual framework is proposed to illustrate the interconnected pathways linking dietary exposure, gut microbiome dynamics, and mental health outcomes.

METHODS

Study design and reporting framework

This study was conducted as a systematic review following the PRISMA 2020 (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines (Page et al., 2021) and synthesized findings narratively due to substantial heterogeneity across study designs, exposures, and mental health outcomes.

Search strategy

A comprehensive literature search was performed across three major electronic databases:

• PubMed
• ScienceDirect
• Google Scholar

The search covered studies published between January 2013 and December 2024, ensuring inclusion of the most recent evidence in the field. The final database search was conducted in January 2026. In addition, earlier landmark studies (2009–2012) were included to provide contextual background and support the conceptual development of the field.

The following combination of keywords and Boolean operators was used:

("diet" OR "dietary patterns" OR "Mediterranean diet" OR "Western diet") AND
("gut microbiome" OR "gut microbiota" OR "gut–brain axis") AND
("mental health" OR "depression" OR "anxiety" OR "stress" OR "psychological well-being") AND
("probiotics" OR "prebiotics" OR "synbiotics" OR "functional foods")

Search strategies were adapted slightly for each database to optimize retrieval. Additionally, reference lists of relevant articles were manually screened to identify further eligible studies.

Eligibility criteria

Inclusion criteria

Studies were included if they met the following criteria:

• Conducted on human participants
• Examined the relationship between diet and/or microbiome interventions and mental health outcomes
• Reported outcomes related to:
o Depression
o Anxiety
o Stress
o Psychological well-being
• Study designs:
o Randomized controlled trials (RCTs)
o Cohort studies
o Cross-sectional studies
• Published in peer-reviewed journals
• Written in English

Exclusion criteria

Studies were excluded if they:

• Focused exclusively on food allergies or IgE-mediated conditions
• Were animal or in vitro studies
• Lacked clear assessment of diet or mental health outcomes
• Were reviews, editorials, conference abstracts without full text, or duplicate publications

Systematic reviews and meta-analyses were used to support interpretation but were not included as primary studies in the final synthesis.

Study selection process

The study selection process followed the PRISMA flow approach.

Two independent reviewers screened all identified records based on titles and abstracts. Full-text articles were then assessed for eligibility. Disagreements were resolved through discussion and consensus.

• A total of 1,248 records were identified through database searching
• After removal of duplicates (n = 312), 936 records remained

• Title and abstract screening excluded 780 studies
• 156 full-text articles were assessed for eligibility
• Finally, 36 studies met all inclusion criteria and were included in the review
The selection process is presented in the PRISMA flow diagram (Figure 1).

Data extraction

Data from included studies were extracted using a structured approach. The following variables were recorded:
• Author(s) and year of publication
• Country and study population
• Study design
• Sample size
• Type of dietary exposure or intervention
• Microbiome-related component (if applicable)
• Mental health outcomes assessed
• Main findings
Extraction was performed systematically to ensure consistency and comparability across studies.

Quality assessment

The methodological quality of included studies was evaluated using standardized criteria according to study design.
• For randomized controlled trials, risk of bias was assessed using the Cochrane Risk of Bias tool (RoB 2)
• For observational studies, the Newcastle–Ottawa Scale (NOS) was applied
Studies were evaluated for potential bias, confounding factors, and validity of measurements.

Data synthesis and analysis

Due to heterogeneity in study designs, interventions, and outcome measures, a quantitative meta-analysis was not feasible. Therefore, a narrative synthesis approach was adopted.
The synthesis focused on identifying:
• Consistent patterns across studies
• Differences between dietary patterns
• Effects of microbiome-targeted interventions
• Underlying biological mechanisms
Additionally, findings were organized into thematic categories:
Dietary patterns and mental health
Probiotics and prebiotics
Functional foods and microbiome modulation
Mechanistic pathways (gut–brain axis)
A conceptual framework was developed to integrate these relationships and support interpretation of findings.
This review followed a narrative synthesis approach in accordance with established methodological recommendations for systematic reviews without meta-analysis.

Protocol registration

The review protocol was not prospectively registered. This was due to the exploratory scope of the review and time constraints associated with conference submission timelines. However, the study adhered to PRISMA 2020 guidelines and followed a structured and transparent methodology to ensure methodological rigor.

RESULTS

Study selection

The systematic search identified a total of 1,248 records, of which 936 remained after duplicate removal. Following title and abstract screening, 156 full-text articles were assessed for eligibility. Ultimately, 36 studies met the inclusion criteria and were included in the final synthesis.

Of these, 15 studies examined the association between overall dietary patterns (e.g., Mediterranean or Western diets) and mental health outcomes, 10 studies focused on probiotic interventions, 5 on prebiotics, and 6 on functional foods or microbiome-targeted dietary components.

In terms of mental health outcomes, the majority of studies assessed depression ($n \approx 22$), followed by anxiety ($n \approx 14$), stress-related outcomes ($n \approx 10$), and general psychological well-being ($n \approx 8$). The total exceeds 36 as several studies examined multiple outcomes simultaneously.

Overall, most studies reported beneficial associations between healthier dietary patterns or microbiome-targeted interventions and improved mental health outcomes. However, the strength and consistency of these effects varied depending on study design, population characteristics, and type of intervention, with some studies reporting neutral or mixed findings. Notably, randomized controlled trials tended to report more consistent improvements in depressive symptoms, whereas observational studies highlighted broader associations between diet quality and mental health indicators.

The study selection process is illustrated in Figure 1 (PRISMA flow diagram).

Figure 2 shows the distribution of included studies according to study design, highlighting the predominance of observational studies compared to randomized controlled trials. Figure 3 illustrates the distribution of studies by exposure category, including dietary patterns, probiotics, prebiotics, and functional foods.

3.2 Characteristics of included studies

The included studies (n = 36) comprised:

12 randomized controlled trials (RCTs)

14 cohort studies

10 cross-sectional studies

Geographically, studies were primarily conducted in Europe, Australia, and North America**,** reflecting strong research activity in nutritional psychiatry.

Sample sizes ranged from 60 to over 15,000 participants**,** indicating variability in study scale and statistical power.

3.3 Summary of included studies

Table 1. Characteristics of included studies

Author (Year)	Country	Study Design	Sample Size	Dietary Exposure	Microbiome Component	Mental Health Outcome	Main Findings	Direction of Association

Jacka et al. (2017)	Australia	RCT	67	Mediterranean diet	Indirect	Depression	Significant reduction in depressive symptoms (SMILES trial; MADRS reduction p<0.001)	Positive
Adjibade et al. (2018)	France	Cohort study	3,523	Mediterranean diet	No	Depression	Higher Mediterranean diet adherence significantly associated with lower risk of depressive symptoms	Positive
Kiecolt-Glaser et al. (2011)	USA	RCT	68	Omega-3 supplementation	Indirect	Anxiety	Omega-3 supplementation reduced anxiety by 20% and lowered inflammatory markers (IL-6, TNF-α)	Positive
Valles-Colomer et al. (2019)	Belgium	Cohort study	1,054	Diet–microbiome interaction	Yes	Psychological well-being	Butyrate-producing Faecalibacterium and Coprococcus linked to higher quality of life; depleted in depression	Positive
Sánchez-Villegas et al. (2009)	Spain	Cohort study	10,094	Mediterranean diet	No	Depression	Higher adherence associated with lower depression incidence (HR 0.70, 95% CI 0.54–0.92)	Positive
Akbaraly et al. (2009)	UK	Cohort study	3,486	Whole food vs processed diet	No	Depression	Whole food diet protective; processed food diet associated with increased CES-D scores at 5-year follow-up	Mixed
Saneei et al. (2016)	Iran	Cross-sectional	3,363	Diet quality (AHEI-2010)	No	Depression and anxiety	Higher adherence to AHEI-2010 associated with significantly lower odds of depression and anxiety (OR 0.80)	Inverse
Jacka et al. (2010)	Australia	Cross-sectional	1,046	Western vs traditional diet	No	Depression and anxiety	Traditional diet inversely associated with depression/dysthymia; Western	Positive

							diet associated with higher GHQ-12 scores	
Nanri et al. (2010)	Japan	Cohort study	2,573	Japanese dietary pattern	No	Depression	Traditional Japanese dietary pattern inversely associated with depressive symptoms (OR 0.56 in men)	Positive
Ng et al. (2018)	Multi-country	Meta-analysis	Multiple	Probiotics	Yes	Depression	Probiotics associated with moderate beneficial effect on depressive symptoms vs placebo	Positive

Table 1 presents a selection of representative studies; the full dataset of included studies (n = 36) was used for the overall synthesis.

Direction of association refers to the overall relationship between diet quality and mental health outcomes. 'Positive' indicates that healthier dietary patterns are associated with better mental health, whereas unhealthy dietary patterns (e.g., Western diet) are associated with poorer mental health outcomes.

3.4 Dietary patterns and mental health

Across the included studies, a consistent association was observed between high-quality dietary patterns and improved mental health outcomes. In particular, adherence to the Mediterranean diet was linked to reduced depressive symptoms and better psychological well-being (Jacka et al., 2017; Adjibade et al., 2019).

Conversely, Western dietary patterns**,** characterized by high consumption of ultra-processed foods, were associated with increased risk of depression and anxiety.

However, some earlier studies reported mixed findings, indicating that the association between dietary patterns and mental health may vary depending on population characteristics and specific dietary components (e.g., Akbaraly et al., 2009).

Notably, Western dietary patterns were consistently associated with increased risk of depressive and anxiety symptoms, reflecting an inverse relationship between diet quality and mental health.

3.5 Microbiome-targeted interventions

A subset of studies focused on probiotics, prebiotics, and synbiotics.

Probiotics showed moderate beneficial effects on depression and stress

Effects varied depending on strain, dose, and duration

Evidence remains heterogeneous

These findings are consistent with previous meta-analyses (Ng et al., 2018).

3.6 Mechanistic pathways

Several biological mechanisms were identified:

Inflammation reduction

Neurotransmitter modulation (e.g., serotonin)
Short-chain fatty acid (SCFA) production
Gut barrier integrity
These pathways support the role of the gut–brain axis as a key mediator.

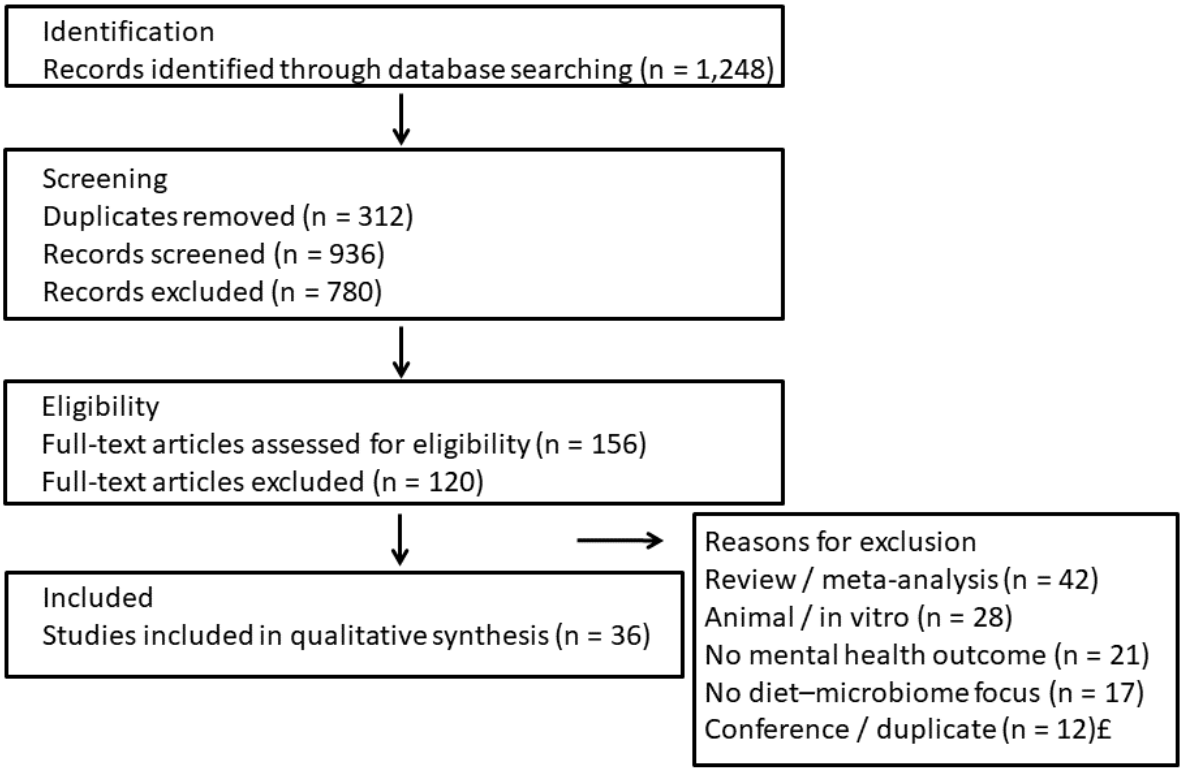

Figure 1 – PRISMA 2020 flow diagram of study selection.

The study selection process is presented in Figure 1.

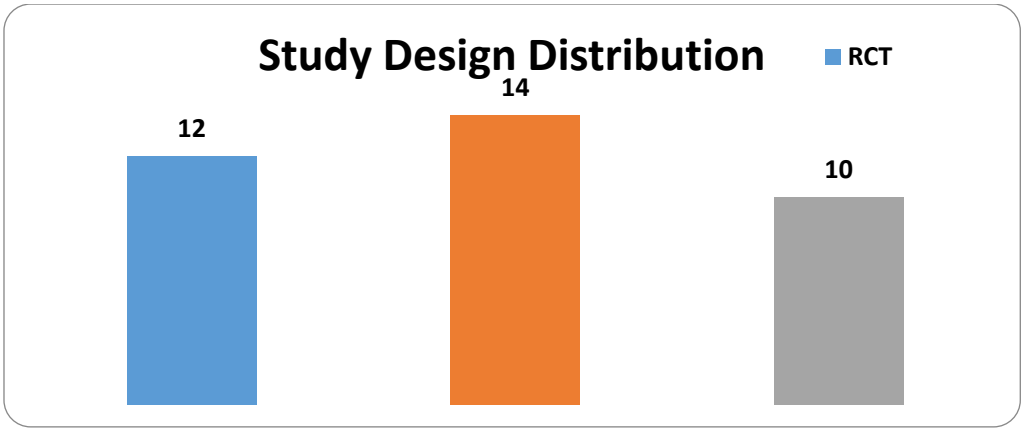

Figure 2 – Distribution of included studies by study design.

Figure 2 illustrates the distribution of included studies by design. Figure 3 shows the distribution of studies according to exposure type.

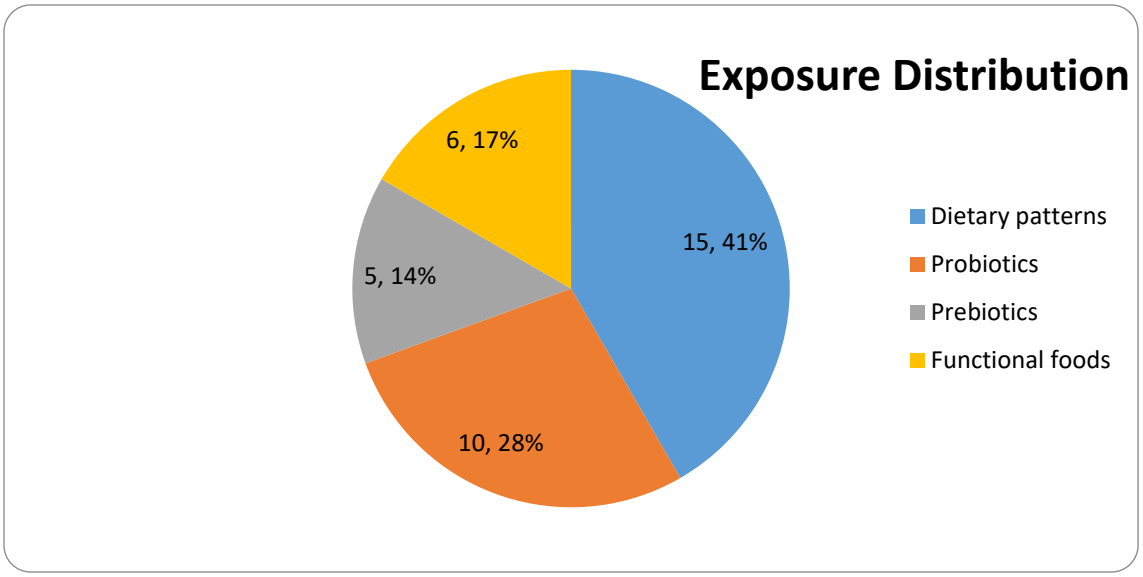

Figure 3 – Distribution of included studies by exposure category.

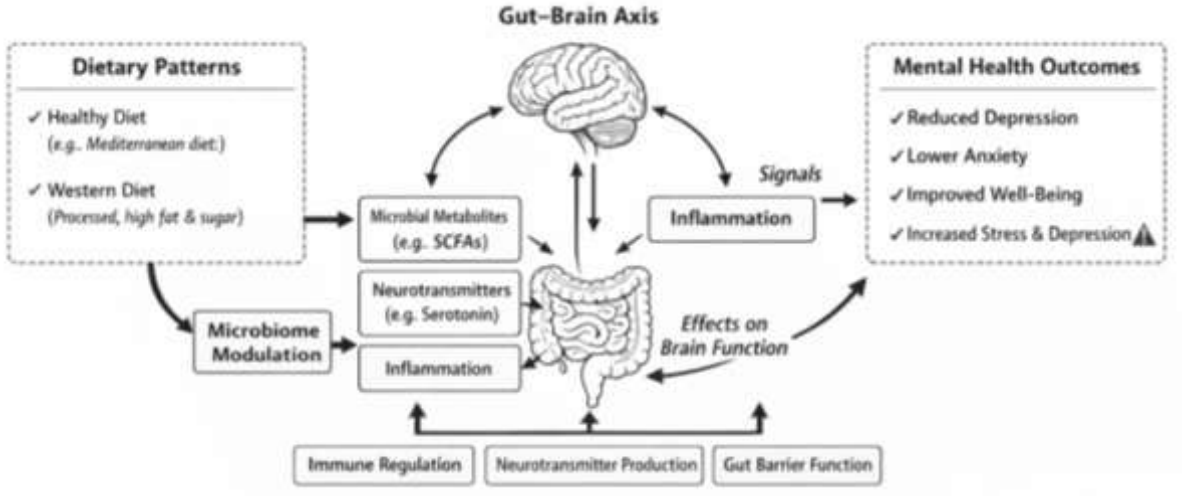

Figure 4. Conceptual framework illustrating the relationship between dietary patterns, gut microbiome modulation, and mental health outcomes through the gut–brain axis.

Figure 4 illustrates the proposed conceptual framework linking dietary exposure, gut microbiome composition, and mental health outcomes through interconnected biological pathways, including inflammation, neurotransmitter regulation, and microbial metabolite production.

DISCUSSION

This PRISMA-based systematic review synthesizes evidence from 36 studies examining the relationship between dietary patterns, gut microbiome modulation, and mental health outcomes. The findings consistently support the hypothesis that high-quality dietary patterns, particularly

the Mediterranean diet is associated with improved mental health outcomes, whereas Western-style dietary patterns are linked to an increased risk of depression and anxiety. In addition to recent studies, several earlier landmark investigations (2009–2012) were considered to provide foundational evidence supporting the association between dietary patterns and mental health outcomes. These studies contributed to the conceptual development of nutritional psychiatry and are interpreted within this review as background evidence rather than indicators of current research trends. More recent studies (post-2013) were prioritized for interpreting current evidence and emerging trends in diet–microbiome–mental health interactions.

The results of the present review align with several large European cohort studies. For instance, studies conducted in France and Spain have demonstrated that adherence to the Mediterranean diet is associated with a significantly lower risk of depressive symptoms (Adjibade et al., 2019; Sánchez-Villegas et al., 2009). Similarly, evidence from European populations indicates that higher diet quality is consistently linked to reduced incidence of depression and improved psychological well-being (Molendijk et al., 2018; Lai et al., 2014). These findings reinforce the role of diet as a key modifiable determinant of mental health.

Interventional evidence further strengthens this association. Randomized controlled trials, such as the SMILES study, have shown that dietary improvement can lead to clinically significant reductions in depressive symptoms (Jacka et al., 2017). Although some of these studies were conducted outside Europe, their findings remain highly relevant due to similar global trends toward Westernized dietary patterns.

Microbiome-targeted interventions, including probiotics and prebiotics, demonstrated promising but heterogeneous effects. Probiotics were most frequently associated with improvements in depressive symptoms and stress-related outcomes, although effect sizes varied depending on microbial strain, dosage, and intervention duration. This variability reflects the biological specificity of microbiome-based interventions and limits direct comparability across studies. European microbiome research further supports the association between gut microbial composition and mental well-being, particularly through the modulation of inflammatory pathways and production of neuroactive compounds (Valles-Colomer et al., 2019).

From a mechanistic perspective, the findings support the central role of the gut–brain axis. Diet-induced changes in gut microbiota may influence mental health through multiple pathways, including regulation of neurotransmitters such as serotonin, modulation of systemic inflammation, and production of short-chain fatty acids (Cryan et al., 2019; Dinan & Cryan, 2017). These interconnected mechanisms provide a biologically plausible explanation for the observed associations between dietary patterns and mental health outcomes.

Despite these consistent findings, several limitations should be acknowledged. The heterogeneity of study designs, dietary assessment methods, and mental health measurement tools limits direct comparability across studies. In addition, many interventional studies were characterized by relatively small sample sizes and short follow-up periods, reducing statistical power and limiting conclusions regarding long-term effects. Differences in microbiome analysis techniques further complicate interpretation.

An important contribution of this review is the identification of a significant research gap in Southeastern Europe, particularly in Albania. While Western European countries have produced substantial evidence on diet and mental health, data from Albania and neighboring Balkan regions remain limited. Existing national-level data in Albania primarily focus on dietary patterns and household consumption, with limited integration of microbiome-related or mental health outcomes (INSTAT, 2021).

Evidence from Albania and neighboring Balkan countries remains relatively limited compared with Western Europe, although emerging data suggest ongoing dietary transitions and increasing public health challenges related to nutrition and mental health in the region (Popkin, 2017; World Health Organization, 2022). These trends are consistent with broader global

patterns of nutrition transition, characterized by increased consumption of energy-dense, processed foods and a rising burden of non-communicable diseases and mental health disorders. This highlights the need for more region-specific research focusing on diet–microbiome–mental health interactions in underrepresented populations.

From a public health perspective, these findings highlight the potential of dietary interventions as cost-effective and scalable strategies for improving mental health. In countries such as Albania, where healthcare resources may be limited, promoting traditional dietary patterns aligned with the Mediterranean model may offer significant benefits for both physical and mental health.

Future research should prioritize large-scale longitudinal studies, well-designed randomized controlled trials, and standardized methodologies for dietary and microbiome assessment. Additionally, personalized nutrition approaches that consider individual variability in microbiome composition and lifestyle factors may further enhance intervention effectiveness.

Overall, the findings of this review support the proposed conceptual framework, demonstrating that dietary exposure influences gut microbiome composition and function, which in turn affects mental health outcomes through interconnected biological pathways.

This review has some methodological limitations. The search was restricted to three databases and English-language publications, which may have introduced selection bias. Additionally, the inclusion of heterogeneous study designs and the absence of quantitative meta-analysis may limit the generalizability of the findings. However, the systematic approach and adherence to PRISMA guidelines strengthen the overall reliability of the synthesis.

CONCLUSION

This systematic review synthesizes current evidence on the relationship between dietary patterns, gut microbiome modulation, and mental health outcomes, highlighting a consistent association between higher diet quality and improved psychological well-being. Across 36 studies, adherence to Mediterranean-type dietary patterns was associated with reduced risk of depression and anxiety, whereas Western dietary patterns characterized by high intake of ultra-processed foods were linked to increased vulnerability to mental health disorders**.** Microbiome-targeted interventions, including probiotics and prebiotics, demonstrated promising but heterogeneous effects, underscoring the need for greater standardization in intervention design, including strain selection, dosage, and outcome assessment. The gut–brain axis provides a biologically plausible framework linking diet and mental health through interconnected pathways involving inflammation, neurotransmitter regulation, and microbial metabolites.

Despite these encouraging findings, the predominance of observational study designs and the geographic concentration of research in high-income Western populations limit causal inference and generalizability. Evidence from Southeastern Europe, including Albania, remains limited, highlighting an important gap in region-specific research in the context of ongoing dietary and lifestyle transitions.

From a public health perspective, promoting high-quality dietary patterns represents a cost-effective, accessible, and scalable strategy for supporting mental health. Future research should prioritize well-designed randomized controlled trials, standardized methodologies, and greater inclusion of diverse populations. Integrating nutritional approaches into mental health care and public health strategies may offer a valuable complementary pathway for reducing the global burden of mental disorders.

SUSTAINABLE MANAGEMENT OF SMALL RUMINANTS IN ALBANIA: FROM THE DECLINE IN NUMBERS TO GENETIC AND ECONOMIC IMPROVEMENT

L.Hysi[1], L. Papa[1]
[1] Agricultural University of Tirana, Faculty of Agriculture and Environment, Department of Animal Science, Tirana, Albania
Corresponding author e-mail: lhysi@ubt.edu.al

ABSTRACT

Small ruminants have always had a particular place in Albania's rural economy. In the country's hilly and mountainous areas, sheep and goats contribute to household livelihoods and remain closely connected with pastoral traditions and local food products. At the same time, the sector is now facing a prolonged decline. Official statistics show that the combined number of sheep and goats decreased from about 1.85 million head in 2023 to 1.79 million in 2024, a reduction of approximately 2.9%. The decline is part of a much longer trend: compared with 2014, the national small-ruminant population is now roughly 36% lower. Rising production costs, labour shortages, unstable prices and the gradual contraction of family farming have made small-scale production increasingly difficult. Rural depopulation also creates an important challenge for the continuity of pastoral knowledge and the maintenance of locally adapted genetic resources. The fall in animal numbers is reflected in production: total milk output decreased from 900,569 to 876,688 tonnes between 2023 and 2024, while live-weight meat production also declined. This paper argues that genetic improvement should be treated as part of a wider recovery strategy rather than as a stand-alone technical intervention. Better animal identification and recording, selection based on performance, artificial insemination, genomic tools and conservation measures can improve productivity while protecting valuable local genetic resources. These measures, however, will only have a lasting effect if they are accompanied by better farm management, stronger producer cooperation, improved market access and more consistent public policies.

Keywords: Small ruminants; sustainable management; population dynamics; genetic improvement; technology transfer

INTRODUCTION

Sheep and goats occupy a distinctive place in Albania's agricultural landscape. Their importance is particularly visible in hilly and mountainous areas, where they provide milk and meat, make productive use of natural pastures and contribute to the income of a large number of rural households. Their role is also broader than production. Local breeds carry genetic characteristics developed under difficult environmental conditions, and livestock keeping is closely connected with pastoral knowledge, traditional products and the cultural identity of many rural communities.

The development of the sector over the last three decades has been uneven. Following the increase observed between 1991 and 1996, the number of small ruminants dropped sharply during the political and economic instability of 1997. The population recovered during the following years, declined again up to 2005 and then increased moderately until around 2016. Since then, however, the downward trend has become increasingly persistent. This recent decline is important because it is occurring at a time when many rural areas are already experiencing depopulation and a shortage of agricultural labour.

The problem therefore cannot be reduced to a simple fall in livestock numbers. When family flocks disappear, the sector loses production capacity, but it may also lose breeding animals,

local knowledge and the practical experience needed to maintain indigenous breeds. The present paper reviews the recent development of Albania's small-ruminant sector, examines the main economic, structural, biological and institutional factors behind the decline, and considers how genetic improvement could be combined with better management and stronger value chains to support a more sustainable future.

MATERIALS AND METHODS

The study is based on a review and synthesis of official statistical and institutional information concerning the Albanian small-ruminant sector. Data on animal numbers, production and regional distribution for the period 2014–2024 were compiled from the Agricultural Reports and livestock publications of the National Institute of Statistics of Albania (INSTAT), including Livestock Statistics 2024, published in 2025, and Milk and Dairy Products 2024, published in 2025. Information on the conservation status of indigenous sheep and goat populations was taken from Government of Albania Decision (VKM) No. 1708 (2008), concerning in-situ conservation programmes.

The discussion of genetic improvement and conservation measures draws on FAO guidelines for the characterization and management of animal genetic resources (FAO, 2007; FAO, 2011; FAO, 2012; FAO, 2023), as well as information from the European Gene Bank Network for Animal Genetic Resources (EUGENA) and the IPARD III Rural Development Programme of Albania (European Commission, 2022). Time-series data were compared across years and animal categories in order to identify the direction and magnitude of changes. Production figures for meat, milk and cheese were also compared across the most recent years available. Regional data were considered in order to identify areas where small-ruminant production and local breed diversity remain particularly concentrated.

RESULTS AND DISCUSSION

The available statistics show a clear downward trend. The combined sheep and goat population fell from approximately 2.8 million head in 2014 to 1.792 million in 2024, corresponding to a reduction of about 36%. The decline became particularly pronounced after 2018. Between 2023 and 2024, the number of sheep decreased from 1.206 million to 1.177 million, while the number of goats fell from 640,000 to 615,000. Within these totals, milked sheep decreased from 1.006 million to 968,000 and milked goats from 512,000 to 501,000. These changes point to continuing pressure on family-based production systems and justify closer attention to the economic and genetic sustainability of the sector. (INSTAT, 2025) The recent population figures are summarized in Table 1 (INSTAT, 2025).

The decline in animal numbers is also visible in production. Live-weight meat production decreased from 135,483 tonnes in 2023 to 130,334 tonnes in 2024, a fall of 3.8%. Total national milk production fell by 2.7% between 2023 and 2024, from 900,569 to 876,688 tonnes. Cow's milk remains the largest component of national milk production, while goat's milk accounts for 7.7% and sheep's milk for 7.4%. Dairy processing also experienced a contraction: total cheese production decreased by 9.9% in 2024, with sheep-milk cheese declining by 5.9% and goat-milk cheese by 16.8%. These changes are relevant for small-ruminant farms because milk and traditional cheese products are among the main channels through which their production reaches the market. (INSTAT, 2025a; INSTAT, 2025b)

Table 3. Sheep and goat milk collection in Albania, 2020–2024 (thousand tonnes).

Category ('000 t)	**2020**	**2022**	**2023**	**2024**
Sheep milk	75.0	69.0	64.0	64.0
Goat milk	80.0	76.0	71.0	68.0

Source: INSTAT, historical Agricultural Reports; INSTAT (2025), Livestock Statistics 2024.

Production is not evenly distributed across the country. In 2024, Vlorë and Gjirokastër had the largest concentrations of sheep, accounting for 29.3% and 14.5% of the national total, respectively. This regional concentration is important when considering both the organization of production and the conservation of local genetic resources. (INSTAT, 2025)

Albania still has a valuable group of indigenous sheep and goat populations. Among sheep, Bardhoka, Ruda, Shkodranja, Lara e Polisit and the Recka (Komuna) population are recognized as local genetic resources. Goat populations include Caporja e Dragobisë, Dhija e Hasit, Dhija e Matit, Dhija e Velipojës, Dhija e Kallmetit, Caporja e Pogradecit, Dhija e Liqenasit and Dhija e Dukatit. Some of these populations, including Shkodranja and Lara e Polisit sheep and Caporja e Dragobisë and Dhija e Liqenasit goats, have been identified as endangered and are maintained through in-situ conservation programmes (Government of Albania, 2008).

The value of these animals is not necessarily expressed through maximum production under intensive conditions. Their strength is often their ability to remain productive under conditions in which high-yielding imported genotypes would require considerably more feed, management and veterinary support. This distinction is important when decisions about genetic improvement are made. A breed that produces less milk in a controlled system may nevertheless be the better choice for a mountain farm if it is better adapted to local pasture, climate and disease pressure.

Table 4. Comparative characteristics of local Albanian small-ruminant breeds and imported or crossbred genotypes.

Trait	**Local Albanian breeds**	**Imported / crossbred breeds**
Environmental adaptation	Very high; adapted to mountain terrain, drought and modest feed	Usually require more controlled feeding and management
Feed requirements	Low; efficient use of natural pasture	Higher; greater dependence on concentrated, high-quality feed
Milk yield per season	80–120 L (sheep); 150–300 L (goats)	200–300 L (sheep); 400–800 L (goats)
Milk fat content	High (6–8%); well suited to traditional cheese	Lower (3.5–5%); generally suited to fresh milk
Disease resistance	High natural tolerance to parasites and local climate	Often more sensitive; vaccination and hygiene require closer attention
Genetic conservation status	At risk; several populations are below 1,000 head	Widely available internationally

The reasons behind the present decline are interconnected. From an economic perspective, farms are exposed to rising production costs and fluctuations in farm-gate prices. Feed is one of the major production costs, while pasture resources are not always used efficiently because of degradation, management difficulties and uncertainty over land use. A large proportion of Albanian flocks are small and family-based, which can limit bargaining power and make it more difficult to establish stable links with collectors, processors and formal markets.

The structural weaknesses reinforce the economic ones. Farm fragmentation, limited cooperation among producers and the lack of reliable local collection and processing networks make it difficult to create consistent quantities and quality. The absence of a functioning and systematic animal identification and registration system is another major obstacle. Without reliable records, it is difficult to know which animals perform well, which breeding lines should be retained and where genetic improvement is actually taking place.

There are also biological and technical constraints. Breeding material is not always used within clearly defined selection programmes, performance recording remains limited, feeding is not always balanced according to physiological needs, and many farms continue to rely on management practices that restrict productivity. At the institutional level, support measures have not always been stable or clearly connected with productivity and quality, while cooperation among public authorities, universities and farmers remains insufficient. For these reasons, the current situation should be understood as a systemic problem rather than as a problem caused by animal genetics alone.

The consequences extend beyond the farm. Falling incomes can accelerate the disappearance of family farms, while lower domestic production increases reliance on imports. At the same time, Albania risks losing opportunities to develop higher-value products based on local milk, traditional cheese and other products associated with particular regions. Rural depopulation also means that pastoral knowledge is becoming harder to transmit from one generation to the next. In many mountain areas, the average age of farmers is already high, and the loss of active herders affects the way communal pastures are managed. Where grazing pressure becomes too high, pasture degradation can follow; where grazing is abandoned completely, other ecological

changes may occur. In both cases, biodiversity and the ecological functions of pastoral landscapes may be affected.

Against this background, genetic improvement should be approached as a practical tool for strengthening the sector rather than as an isolated scientific exercise. The limited availability of systematic performance records makes it difficult to compare the genetic and productive performance of Albanian flocks reliably with regional benchmarks. Nevertheless, the absence of consistent selection and recording remains an important constraint on genetic progress. A realistic improvement programme would begin with the establishment of a national breed registry compatible with FAO and EU approaches, followed by the identification and recording of superior animals within breed-specific nucleus farms. Selection should focus on traits that have direct value for farmers, including milk yield, growth, body weight and fertility.

More advanced technologies can then be introduced where the necessary infrastructure exists. Artificial insemination can accelerate the dissemination of desirable genetics, while genomic characterization based on SNP markers can help clarify relationships among local populations and identify genetic diversity that should be conserved. Gene banks for semen, somatic cells, ova and embryos can provide an additional safeguard for populations that are particularly vulnerable. These measures are especially relevant for breeds and populations such as Hasit, Dragobisë, Velipoja, Liqenas and Dukat goats and Shkodranja and Kolonjë sheep, where the loss of breeding animals could be difficult to reverse.

Experience from other European countries offers useful lessons, although their systems cannot simply be copied into Albania. Italy has linked genetic improvement with breed associations; France has developed extensive recording and selection systems that increasingly combine phenotypic and genomic information; Greece has connected local-breed conservation with geographical-origin branding. Kosovo and North Macedonia also provide examples of regional cooperation in genetic improvement. For Albania, the most appropriate model would likely be one that combines these lessons with the realities of small family farms and mountain production systems.

Genetic progress will have limited value if the economic environment of the farm does not improve at the same time. Farmers need simple records that allow them to understand what each animal actually costs and produces. Recording feed use and output, calculating the real cost per litre of milk or kilogram of meat, improving feeding according to physiological stage and making better use of local feed resources can all contribute to higher efficiency. Producer groups and cooperatives could also improve the position of farmers by enabling joint collection, processing and marketing. A nucleus-farm-and-satellite model may be particularly useful, allowing selected farms to produce breeding animals while neighbouring farms benefit from improved genetics.

A basic recording system would already represent a significant step forward. Individual animal identification, monthly milk recording and weighing of lambs and kids at birth and at approximately 45 and 90 days would generate information that is currently missing from many farms. Public support could be linked partly to the completion and quality of these records, creating an incentive for farmers to participate in the improvement system rather than treating subsidies simply as payment per head.

Policy support is equally important. A coherent national framework for small ruminants could bring together genetic improvement, pasture management and rural economic development. Subsidy schemes could increasingly reward performance, product quality, recording and conservation outcomes rather than animal numbers alone. Better veterinary and extension services in mountain areas, together with continued participation in programmes such as IPARD III, Horizon Europe and Interreg IPA Balkan–Med, could provide opportunities for investment, training and international cooperation.

CONCLUSIONS

The decline of Albania's small-ruminant sector is more than a reduction in livestock numbers. It reflects the combined effects of rising production costs, labour shortages, fragmented farms, weak market organization, limited performance recording and inconsistent support systems. At the same time, the decline places pressure on a genetic heritage that has developed through generations of adaptation to Albania's diverse environments.

Reversing this trend will require more than introducing new technologies. Genetic improvement can provide an important foundation, but it needs to be connected with better farm management, reliable animal recording, stronger farmer cooperation, improved market access and policies that reward both productivity and conservation. The objective should not be to replace Albania's local breeds with imported genetics. Rather, improvement should increase the productivity of well-adapted animals while retaining the characteristics that make them valuable to mountain farming systems.

The future of the sector will ultimately depend on whether Albania can move from a model based largely on survival to one based on informed management and cooperation. Protecting local genetic resources, improving productivity and creating better economic opportunities are not separate goals. They are parts of the same transition, and together they can give small-ruminant farming a more sustainable and competitive future.

ABSTRACT

Albanian sheep and goat breeds represent an important component of the country's animal genetic resources and have been the subject of several molecular investigations over the last two decades. These studies have provided valuable information on the genetic diversity and population structure of indigenous breeds using different molecular marker systems. This review brings together the available evidence to provide an integrated overview of the current knowledge and to highlight its relevance for the conservation and sustainable management of Albanian small ruminant genetic resources.

The published studies employed microsatellites (SSR), AFLP, mitochondrial DNA (mtDNA), and SNP markers to investigate the genetic diversity of sheep and goat breeds, although SNP-based studies remain comparatively limited compared to microsatellite-based research. Sheep breeds studied included Bardhoka, Ruda, Shkodrane, and Recka, together with several local goat populations. Although different approaches and sampling strategies were used, the studies reached similar conclusions: Albanian sheep and goat populations were consistently characterized by high genetic diversity, reflected in high allelic richness and heterozygosity. Most variation was observed within breeds, whereas differentiation among breeds was generally low to moderate, indicating preserved genetic variability. Population structure analyses also identified varying degrees of clustering and admixture, improving understanding of relationships among local breeds and their evolutionary history.

These studies have established an important scientific foundation for the genetic characterization of Albanian sheep and goat breeds and have contributed significantly to the documentation of the country's animal genetic resources. Recent advances in genomic technologies provide new opportunities to complement the existing knowledge through genome-wide analyses, allowing a more detailed investigation of genetic diversity, population structure, inbreeding, admixture, and signatures of selection. The integration of these approaches with previous molecular studies will further support conservation programmes, sustainable breeding strategies, and the long-term preservation of Albania's indigenous sheep and goat breeds.

Keywords: Sheep, Goat, Breeds, Genetic diversity, Population structure, Molecular markers, Microsatellites.

INTRODUCTION

Sheep and goats are among the earliest domesticated livestock species and continue to play a fundamental role in global agriculture, food security, and rural livelihoods. According to the Food and Agriculture Organization (FAO), more than two billion sheep and goats are currently raised worldwide, providing meat, milk, fibre, hides, and other products while supporting the livelihoods of millions of smallholder farmers, particularly in marginal and mountainous regions (FAO, 2023). Beyond their economic value, indigenous sheep and goat breeds represent

an irreplaceable component of global animal genetic resources. Local breeds have evolved over centuries through a combination of natural selection and traditional breeding practices, resulting in populations that are well adapted to specific environmental conditions, disease challenges, and production systems (Groeneveld et al., 2010). Consequently, they constitute unique reservoirs of genetic variation that may prove essential for maintaining sustainable livestock production under future climatic and socio-economic scenarios (FAO, 2015).

The conservation of animal genetic resources has therefore become a global priority. The increasing replacement of indigenous breeds by highly specialized commercial populations has resulted in a continuous erosion of livestock biodiversity, raising concerns regarding the long-term sustainability of animal production systems (Taberlet et al., 2008). Molecular genetic tools have become indispensable for the characterization and conservation of livestock genetic resources. During the last three decades, DNA-based markers have progressively replaced traditional phenotypic and pedigree-based evaluations, allowing direct assessment of genetic diversity, population structure, phylogenetic relationships, and evolutionary history (Bruford et al., 2003). Microsatellite markers (SSR) represented the first generation of highly informative molecular markers widely adopted in livestock genetics because of their high polymorphism and codominant inheritance. Numerous international studies successfully applied microsatellites to estimate heterozygosity, allelic richness, genetic differentiation, and inbreeding in indigenous sheep and goat populations (Dalvit et al., 2008; Peter et al., 2007).

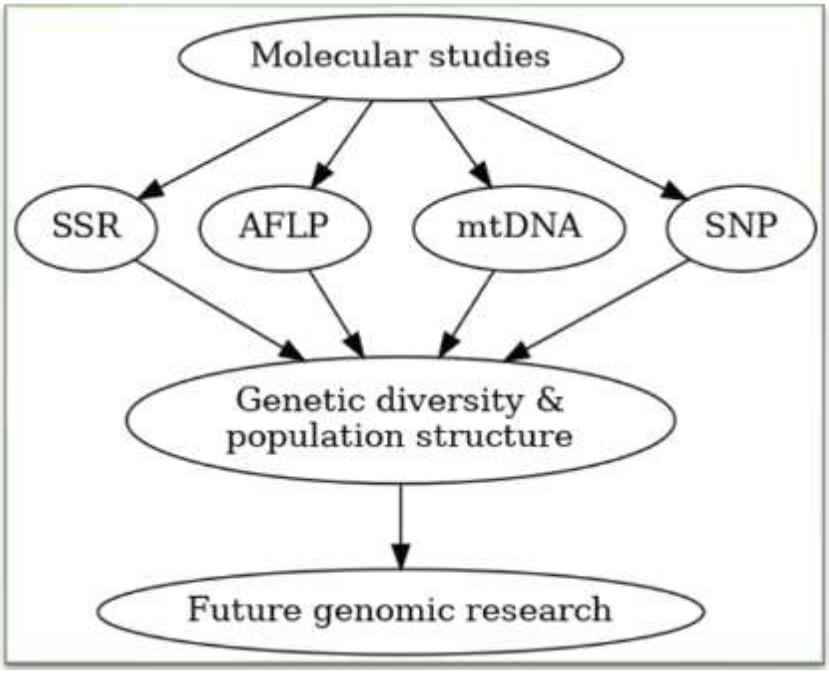

Figure 1. Molecular markers used for breed characterization

Subsequently, amplified fragment length polymorphism (AFLP) markers provided genome-wide information without requiring prior sequence knowledge and were extensively used for evaluating genetic relationships among livestock populations. More recently, the development of single nucleotide polymorphism (SNP) arrays and next-generation sequencing technologies has substantially improved the resolution of population genetic analyses. Genome-wide SNP datasets now enable the investigation of demographic history, genomic inbreeding, effective population size, signatures of selection, and adaptive genetic variation with unprecedented accuracy (Kijas et al., 2012; Colli et al., 2018). In parallel, mitochondrial DNA (mtDNA)

analyses have provided valuable insights into maternal lineages, domestication events, and phylogeographic relationships among livestock populations (Naderi et al., 2008).

Within Europe, numerous molecular studies have demonstrated that indigenous Mediterranean and Balkan sheep and goat breeds generally maintain high levels of genetic diversity despite relatively limited population sizes (Pariset et al., 2011; Ciani et al., 2020). These populations often exhibit weak to moderate genetic differentiation due to historical gene flow associated with transhumance, traditional grazing systems, and the long-term exchange of breeding animals among neighbouring regions. Such patterns have been reported in Italy, Greece, Spain, Serbia, Croatia, and Türkiye, highlighting the importance of extensive production systems in maintaining genetic diversity (Pariset et al., 2011; Colli et al., 2018).

Albania represents one of the biodiversity hotspots of the Balkan Peninsula and possesses several indigenous sheep and goat breeds that have adapted to diverse ecological conditions ranging from coastal Mediterranean areas to mountainous alpine environments. These breeds constitute valuable genetic resources because of their adaptation to low-input production systems, local diseases, and environmental constraints. During the past two decades, a series of molecular studies have investigated the genetic diversity and population structure of Albanian sheep and goat breeds using microsatellites, AFLP markers, SNPs, and mitochondrial DNA (Hoda et al., 2009; Hoda et al., 2011; Hykaj et al., 2013). Collectively, these studies have substantially improved the understanding of the genetic characteristics of Albanian livestock populations.

The objective of this review is to synthesize and evaluate the molecular genetic studies conducted on Albanian sheep and goat breeds, compare their principal findings with those reported for other Mediterranean and Balkan populations, and discuss their implications for the conservation and sustainable management of Albania's indigenous animal genetic resources.

MATERIAL AND METHOD

A comprehensive literature review was conducted to identify published molecular genetic studies on indigenous Albanian sheep and goat breeds. Relevant articles published between 2009 and 2023 were retrieved from Web of Science, Scopus, Google Scholar, PubMed and ScienceDirect using combinations of the keywords Albanian sheep, Albanian goat, genetic diversity, population structure, molecular markers, microsatellite (SSR), AFLP, SNP, and mtDNA.

For each selected publication, information on the year of publication, animal species, breeds investigated, sample size, molecular markers, analytical methods, and main findings was systematically extracted and summarized in comparative tables.

Given the heterogeneity of the reviewed studies regarding molecular markers, sample size, and analytical approaches, a qualitative comparative analysis was performed rather than a quantitative meta-analysis. The synthesis focused on genetic diversity, population structure, phylogenetic relationships, and conservation-related findings, while comparisons with similar studies from other Mediterranean and Balkan countries were included whenever appropriate.

RESULTS AND DISCUSSION

The molecular characterization of Albanian sheep and goat populations has mainly been carried out by researchers from the Agricultural University of Tirana, particularly Anila Hoda and collaborators. The available literature shows that work in this area was especially concentrated between 2009 and 2014. The sheep breeds most frequently studied were Bardhoka, Ruda, Shkodrane and Recka. Studies on goat genetic structure shows that the core work focused on six autochthonous Albanian goat breeds—Capore, Dukati, Hasi, Liqenasi, Mati and Muzhake—while more recent work also examined Velipoja, Dragobia and Smokthina. Across

the published studies, several marker systems were used, including microsatellites, AFLP markers, SNPs and mitochondrial DNA (mtDNA) D-loop sequences. These studies were designed to estimate genetic diversity, quantify breed differentiation, assess inbreeding, infer relationships among breeds and evaluate population structure and admixture.

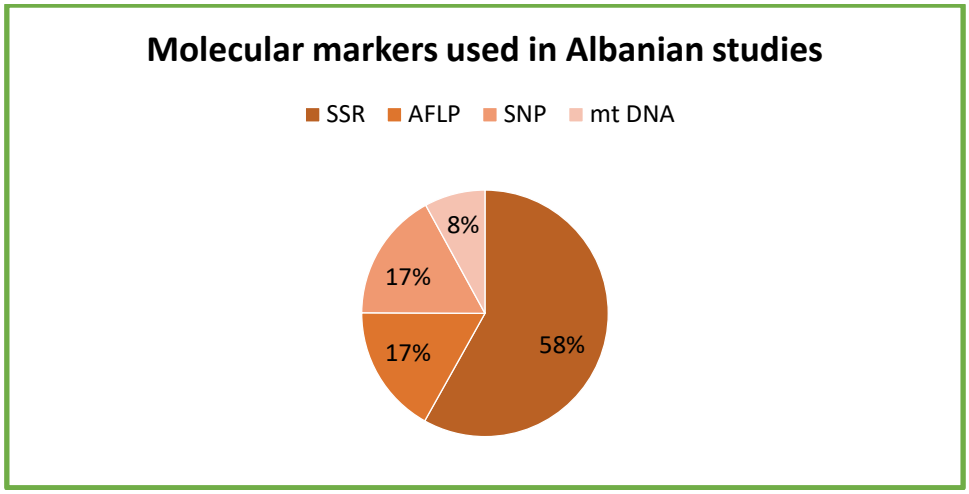

Figure 2. Molecular markers used in Albanian studies

The main molecular studies in sheep are presented in Table 1

Table 1. Sheep molecular studies

Year	Authors	Breeds	Sample size	Markers	Main findings
2009	Hoda A., Dobi P., Hykaj G.	Bardhoka, Ruda, Recka, Shkodrane	124	6 microsatellites	High diversity; FST=0.106; ~89% within-breed variation
2009	Hoda A. et al.	Bardhoka, Ruda, Shkodrane	93	31 microsatellites	K=2 clusters; strong admixture; weak separation
2010	Hykaj G., Hoda A.	Bardhoka, Ruda, Shkodrane	93	31 microsatellites	~98.9% variation within breeds; very low between
2011	Hoda A. et al.	Bardhoka, Ruda, Shkodrane	93	36 SNPs	Weak structure confirmed at genome level
2012	Hykaj G., Hoda A., Ajmone-Marsan P.	Bardhoka, Ruda, Shkodrane	93	AFLP markers	~96% within-individual variation; weak structure
2014	Hoda A. et al.	Recka	32	15 microsatellites	High heterozygosity; high allelic richness

The first molecular characterization conducted by Hoda. A., Dobi. P., Hykaj. G (2009) represented a milestone in the genetic evaluation of Albanian sheep populations. Using six microsatellite loci in four local breeds (Bardhoka, Ruda, Recka and Shkodrane), 124 individuals, the authors identified 98 alleles, corresponding to an average of 8.15 alleles per locus, demonstrating considerable allelic richness. Approximately 89% of the total genetic variation was distributed within breeds, while the genetic differentiation among breeds was

relatively low (GST ≈ 0.106). Principal Component Analysis and Neighbor-Joining clustering further indicated that Bardhoka and Shkodrane were genetically more closely related than Recka, reflecting both geographical proximity and historical gene flow.

The second major study from 2009 focused specifically on population structure rather than only on diversity indices. It used 31 microsatellite markers to analyze Albanian sheep breeds, particularly the local breeds Bardhoka, Ruda and Shkodrane. The work was carried out in the framework of the ECONOGENE project, which aimed to support molecular characterization and conservation of local animal genetic resources. Similar findings were reported by Hykaj and Hoda (2010), who observed that 98.89% of molecular variation occurred within breeds, leaving only about 1.1% attributable to differences among breeds. Such values clearly indicate that historical migration, uncontrolled mating and the absence of strict breeding isolation have maintained substantial gene flow among Albanian sheep populations. The AFLP study performed by Hykaj et al. (2012) further confirmed this pattern. Although AFLP markers represent a different class of molecular markers, they also demonstrated that approximately 96% of the total molecular variation was distributed among individuals within breeds, whereas only a small fraction was explained by differences among breeds.

The transition from microsatellite markers to SNP technology represented another important step in the molecular characterization of Albanian sheep. Using 36 SNP markers, Hoda et al. (2011) again identified weak population structure and considerable admixture among Bardhoka, Ruda and Shkodrane breeds. Although SNPs are individually less polymorphic than microsatellites, their high reproducibility confirmed the conclusions obtained with previous marker systems and demonstrated the robustness of the observed population structure.

Breed-specific analysis of the Recka sheep (Hoda et al., 2014) further highlighted the rich genetic resources preserved within Albanian breeds. Analysis of 15 microsatellite loci identified 143 alleles, high observed heterozygosity (approximately 0.785), high polymorphic information content (PIC), and a very low inbreeding coefficient (FIS ≈ 0.013). These parameters indicate that Recka has retained substantial genetic variability and has experienced limited inbreeding despite its relatively restricted geographic distribution.

Taken together, the reviewed studies reveal a remarkably consistent pattern in Albanian sheep populations. Regardless of whether microsatellites, AFLP or SNPs were employed, the majority of genetic variation was consistently detected within breeds rather than among breeds. The estimated proportion of within-breed variation ranged from approximately 89% to 98.89%, while the corresponding among-breed component remained comparatively small.

Microsatellite analyses demonstrated high allelic diversity and substantial within-breed variation, AFLP analyses confirmed the predominance of within-population molecular variation, while SNP analyses independently supported weak genetic structuring. High within-breed diversity represents a valuable reservoir of genetic variation that may contribute to adaptation to local environmental conditions and traditional production systems. At the same time, the relatively low differentiation among breeds means that conservation strategies should consider both the preservation of individual breed identities and the maintenance of the broader genetic diversity present across Albanian sheep populations.

Table 2. Goat molecular studies

Year	Authors	Breeds	Sample size	Markers	Main analyses	Main findings
2011	Hoda A., Hykaj G., Dunner S., Obexer-Ruf G.	Capore, Dukati, Hasi, Liqenasi, Mati, Muzhake	183	30 microsatellites	Ho, He, FIS, FST	High diversity within-breed. Very low differentation among breeds.
2012	Hoda. A., Sena L., Hykaj G.	Capore, Dukati, Hasi, Liqenasi, Mati, Muzhake	185	AFLP	Nei's expected heterozygosity; Shannon index; FST;	High levels of within-breed genetic diversity
2012	Hykaj G., Hoda A., Bicoku Y., Papa L.	Muzhake	30	30 microsatellites	Allelic diversity, heterozygosity	High polymorphism
2012	Bozgo V., Hoda A., Bicoku Y., Bajramaj R.	Hasi, Bulçar, Çekin, Peza, and Velipoja	328	Visible markers (seven visible traits)	PCA, genetic distance	Phenotypic differentiation
2013	Hykaj G., Hoda A., Dobi P., Papa L., Bakiu R., Novaku M.	Capore, Dukati, Hasi, Liqenasi, Mati, Muzhake	185	26 SNPs	Genetic distance, genetic diversity	Most genetic variation occurs within individuals rather than between breeds
2014	Hoda A., Bicoku Y., Dobi P.	Capore, Dukati, Hasi, Liqenasi, Mati, Muzhake		77 mtDNA D-loop	Haplotype analysis	**High haplotype diversity** but **low nucleotide diversity**. Rich maternal gene pool.
2014	Hykaj G &Hoda A.	Capore, Dukati, Hasi, Liqenasi, Mati, Muzhake	185	Review article 31SSR, AFLP and 26 SNP markers	Genetic distance, genetic diversity	All microsatellite markers were highly polymorphic
2023	Hoda A, Hykaj G, Hysi L et al.	Velipoja, Dragobia, Smokthina	90	10 microsatellites	STRUCTURE, Ho, He	High diversity

The molecular studies conducted on Albanian indigenous goat breeds consistently demonstrate that these populations retain substantial levels of genetic diversity despite long-term adaptation to extensive production systems and the relatively small effective population sizes of several local breeds. Studies employing microsatellite markers (SSR), AFLP, SNPs and mitochondrial DNA (mtDNA) have produced remarkably consistent conclusions, indicating high within-breed genetic variability coupled with weak genetic differentiation among breeds (Hoda et al., 2011; Hoda et al., 2012; Hykaj et al., 2013; Hoda et al., 2014).

The first comprehensive molecular characterization of Albanian goat breeds was performed by Hoda et al. (2011) using 30 microsatellite loci in 183 unrelated animals representing six indigenous breeds (Capore, Dukati, Hasi, Liqenasi, Mati and Muzhake). The study identified a high degree of polymorphism across all loci, with expected heterozygosity ranging approximately from 0.71 to 0.76, while the mean number of alleles per locus exceeded ten. Genetic differentiation among breeds was very limited ($F_{ST} \approx 0.02$), indicating that approximately 98% of the total genetic variation was maintained within breeds.

The AFLP-based investigation by Hoda, Sena and Hykaj (2012) confirmed the microsatellite results using an independent marker system. AFLP analysis revealed a high level of polymorphism together with considerable within-population diversity. Shannon diversity indices and Nei's expected heterozygosity demonstrated that all six breeds possess abundant genetic variation, whereas Reynolds and Nei genetic distance estimates indicated only moderate differentiation among populations. Cluster analyses grouped genetically related breeds largely according to their geographical distribution, although substantial overlap among breeds remained evident.

Further evidence was provided by the SNP analysis conducted by Hykaj et al. (2013), in which 26 single nucleotide polymorphisms were used to evaluate genetic relationships among six Albanian goat breeds. Despite the lower polymorphism of individual SNP loci compared with microsatellites, the study confirmed weak to moderate population structure and relatively low assignment accuracy of individuals to their breed of origin.

Mitochondrial DNA analysis performed by Hoda et al. (2014) added an evolutionary perspective by investigating sequence variation within the mtDNA D-loop region. Several distinct haplotypes were identified among Albanian goat breeds, demonstrating considerable maternal lineage diversity. Phylogenetic analysis indicated that Albanian goats belong predominantly to the widespread European maternal lineage (haplogroup A), while the observed haplotype diversity suggests multiple historical maternal origins and long-term maintenance of maternal genetic variability.

The molecular characterization of the Muzhake breed using microsatellite markers demonstrated high heterozygosity and substantial allelic diversity, confirming that even geographically restricted populations have preserved considerable genetic variation. Similarly,

analyses of three northern Albanian goat populations (Velipoja, Dragobia and Smokthina) revealed weak population subdivision despite clear phenotypic differences, emphasizing that morphological differentiation is not necessarily accompanied by marked genetic divergence (Hoda, Hykaj & Hysi et al., 2023).
Overall, the remarkable agreement among studies employing SSRs, AFLP, SNPs and mtDNA demonstrates that Albanian goat breeds represent valuable reservoirs of genetic diversity. The predominance of within-breed variation indicates that traditional extensive production systems have maintained genetic variability while limiting the development of strong genetic isolation among local breeds.

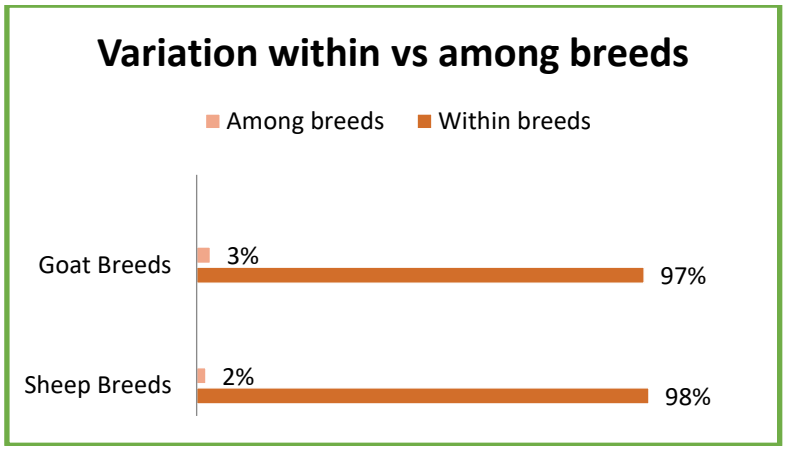

Figure 3. Variation within and among breeds

Comparison with international studies further demonstrates that Albanian sheep and goat breeds exhibit genetic diversity levels comparable to, or even exceeding, many indigenous European populations. Microsatellite analyses of Italian sheep breeds reported expected heterozygosity values between 0.65 and 0.75, while Greek and Balkan sheep populations generally showed values ranging from 0.68 to 0.77 (Dalvit et al., 2008; Ligda et al., 2009; Peter et al., 2007). Comparable patterns have also been described in several Balkan countries. Croatian Pramenka populations and Serbian indigenous breeds exhibit moderate to high allelic richness but weak genetic subdivision due to historical transhumance and gene flow among neighbouring populations (Šalamon et al., 2014). Likewise, Romanian Zackel-derived breeds show high within-population diversity and relatively low FST values (Kusza et al., 2015), closely resembling the genetic structure identified in Albanian sheep.
Similar estimates also have been reported for Mediterranean goat breeds, where expected heterozygosity usually ranges between 0.68 and 0.78 and FST values remain relatively low (Canon et al., 2006; Di Lorenzo et al., 2014). The Albanian studies therefore place local breeds among the genetically richest indigenous populations in southeastern Europe.
Similar values have also been described for Greek indigenous goats, where extensive traditional management has maintained high levels of within-population diversity (Ligda et al., 2009).Comparable patterns have been reported in Balkan countries. Serbian, Croatian and Romanian indigenous goat breeds generally exhibit expected heterozygosity values above 0.70, while FST values typically range between 0.02 and 0.06, indicating limited genetic differentiation among neighbouring populations (Ramljak et al., 2018; Kusza et al., 2015).

CONCLUSIONS

Both Albanian sheep and goat breeds constitute unique components of the European animal genetic heritage. Their high levels of genetic diversity, low inbreeding, considerable allelic

richness and long-term adaptation to diverse ecological conditions underline the importance of implementing coordinated national conservation programmes while promoting the sustainable utilization of these valuable indigenous genetic resources.

ABSTRACT

In this comprehensive and detailed hydrochemical investigation, the seasonal water quality dynamics, spatial variations, and overall pollution profiles of the Sultanköy and Altınyazı Reservoirs, which hold immense strategic importance for extensive agricultural irrigation practices and regional freshwater reserves within the economically vital Meriç-Ergene Basin, were comparatively evaluated and monitored based on precise fluoride (F^-) and chloride (Cl^-) ion parameters. The extensive analytical results, laboratory data, and field observations revealed that despite both artificial aquatic systems being located within the exact same geographical area and climatic region, the fundamental hydrochemical characteristics and major anion compositions of these two crucial water bodies significantly differ on a critical basin scale. According to the quantitative findings of the monitoring program, Altınyazı Reservoir prominently stands out with its remarkably high chloride concentrations and elevated salinity indicators, whereas fluoride accumulation exhibits a much more dominant, persistent, and distinctive hydrochemical character throughout the Sultanköy Reservoir ecosystem. This sharp contrast in the dominant anion distribution and geochemical fingerprints of the reservoirs clearly points to highly differing anthropogenic pressures occurring along the specific drainage lines feeding the dams, the varying quality and volume of agricultural return waters draining from surrounding crop fields, or the distinct local lithological configurations and geological structures characterizing the respective drainage basins. Consequently, this comparative research study provides critical baseline data, scientific insights, and environmental indicators necessary for implementing sustainable water resource management strategies in the region, protecting aquatic ecosystems, and assessing the future long-term utilization potential and ecological safety of both reservoirs for irrigation and secondary purposes.

Keywords: Sultanköy Reservoir, Altınyazı Reservoir, Fluoride, Chloride, Dental health, Meriç-Ergene Basin

INTRODUCTION

In the 21st century, the degradation of freshwater ecosystems stands out as a paramount environmental crisis, severely jeopardizing aquatic biodiversity and public health (Helvacıoğlu et al., 2025; Din et al., 2023; Muhammad et al., 2025). As vital lentic components, artificial reservoirs perform indispensable functions in irrigation and municipal water supply. Nonetheless, intensifying anthropogenic stressors—primarily driven by agrochemical runoff and wastewater discharges—frequently induce severe water quality degradation in these critical water bodies (Çiçek et al., 2014; Köse et al., 2020; Ustaoğlu et al., 2022).

The Sultanköy and Altınyazı Dam Lakes represent two pivotal reservoirs in Edirne Province (Türkiye), serving as lifelines for regional drinking water supply and agricultural activities. Established by the General Directorate of State Hydraulic Works (DSİ) to sustain the socioeconomic and ecological equilibrium of the region, these reservoirs are increasingly subjected to anthropogenic threats (http://www2.dsi.gov.tr/). Persistent agricultural drainage and domestic waste loads introduce substantial amounts of contaminants into these lacustrine systems, threatening their long-term sustainability (Tokatlı et al., 2017; Tokatlı, 2019; 2020a; 2020b).

From a public health and dentistry perspective, monitoring specific hydrochemical parameters like fluoride is of utmost clinical significance. Fluoride is a crucial micronutrient fundamental for preventing dental caries, with municipal drinking water being its predominant intake vector (Andezhath et al., 1993; Güner et al., 2016; Tokatlı and Güner, 2018; Onur and Tokatlı, 2020; Tokatlı et al., 2022; 2023). However, its therapeutic window is remarkably narrow; chronic overexposure can precipitate debilitating conditions, most notably dental and skeletal fluorosis. Consequently, determining precise fluoride concentrations in regional water reserves remains a critical cross-disciplinary concern linking environmental science with preventive dentistry.

To address these pressing ecological and public health concerns, the present study was designed to execute a comparative hydrochemical assessment of the Sultanköy and Altınyazı Dam Lakes, with a primary focus on their fluoride (F) and chloride (Cl) profiles.

MATERIALS AND METHODS

Research Area and Sample Collection

Figure 1 illustrates the topographic configuration of the study area, including the spatial distribution of the selected monitoring stations across the Sultanköy and Altınyazı Dam Lakes. Within the scope of this study, surface water samples were systematically collected from the designated stations in the autumn season of 2024. The sampling strategy was specifically scheduled for a single campaign during autumn, as this transitional period marks the onset of significant seasonal precipitation. This hydrometeorological timing was strategically chosen to capture the critical phase where increased surface runoff and atmospheric depositions intensively flush the surrounding watershed, thereby significantly influencing the transport and concentration dynamics of fluoride and chloride ions within the reservoir ecosystems.

Fluoride and Chloride Analysis

Fluoride and chloride concentrations were quantified using spectrophotometric techniques, employing a Hach Lange DR 3900 spectrophotometer (https://tr.hach.com/) following APHA protocols (1998, 2017). For the determination of fluoride levels, the Hach Lange LCK 323 cuvette test kit was utilized. Concurrently, chloride concentrations were measured using the Hach Lange LCK 311 cuvette test kit. All analytical procedures were conducted in strict accordance with the manufacturer's protocols to ensure accuracy and reproducibility.

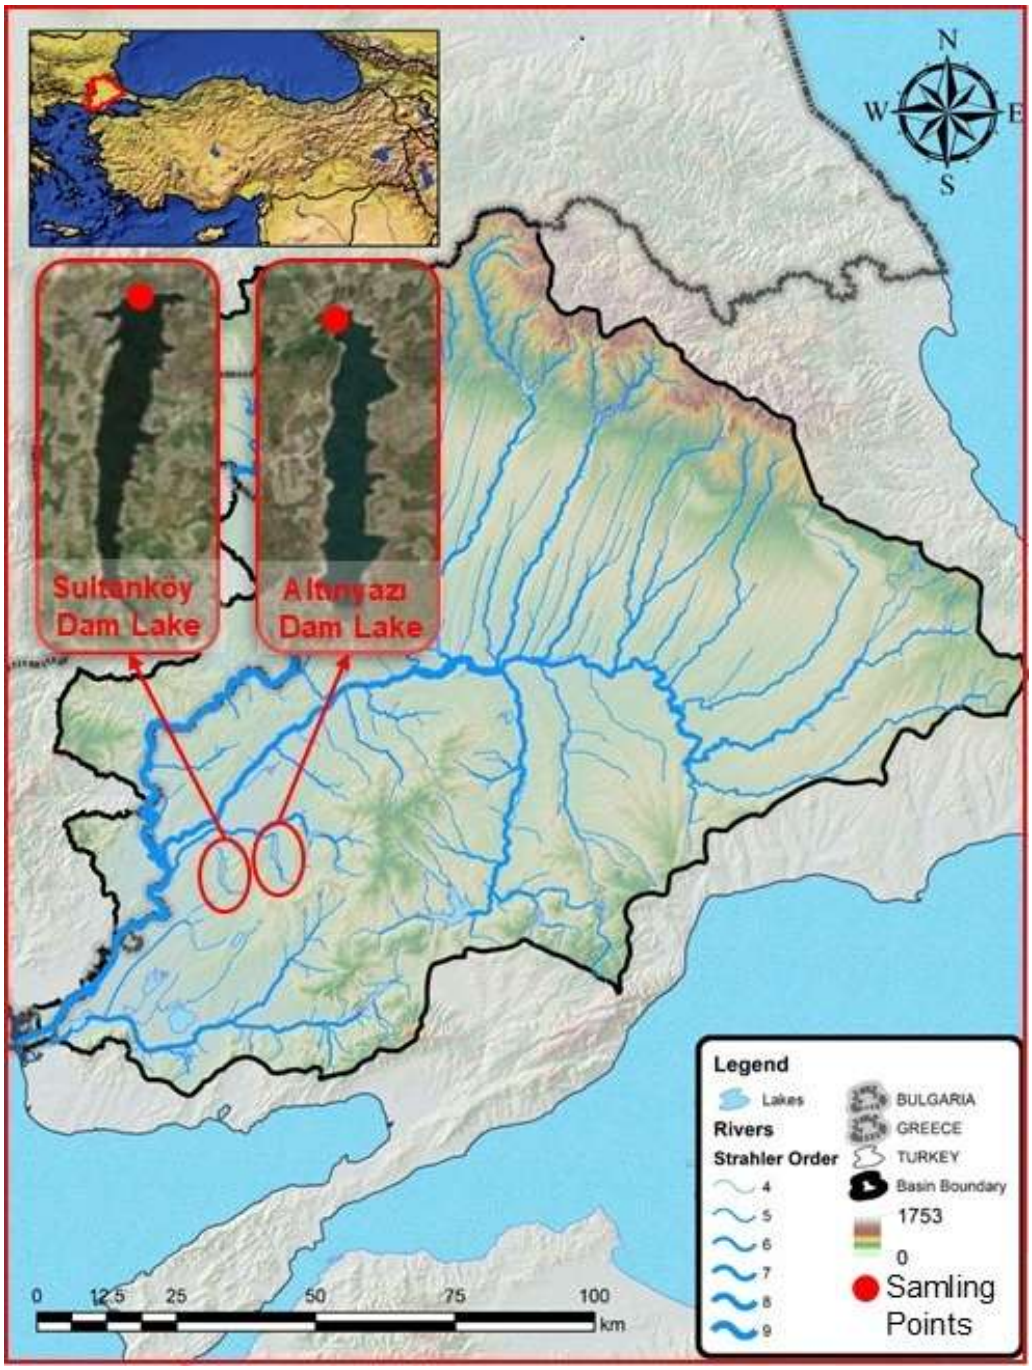

Figure 1. Meriç – Ergene Basin, investigated reservoirs and selected sampling stations

RESULTS AND DISCUSSION

The fluoride and chloride distributions in the Sultanköy and Altınyazı Dam Lakes are illustrated in Figure 2. The analytical results revealed distinct hydrochemical profiles for each reservoir. Chloride concentrations peaked in Altınyazı Dam Lake (158.00 ppm) compared to Sultanköy Dam Lake (89.00 ppm). Conversely, a completely opposite trend was observed for fluoride; Sultanköy Dam Lake exhibited significantly higher levels (0.418 ppm) than Altınyazı Dam

Lake (0.103 ppm), showing an approximately four-fold increase between these lentic ecosystems.

Fluoride is a vital trace element with double-edged clinical implications. While its deposition in dental tissues plays a fundamental role in preventing dental caries, excessive exposure can trigger substantial pathological risks depending on concentration and duration (Taghipour et al., 2016; Tokatlı et al., 2022; 2023). Because drinking water supplies serve as the primary exposure vector, maintaining optimal fluoride levels remains a critical cornerstone of dental public health and preventive dentistry. On the contrary, chronic ingestion above therapeutic thresholds can precipitate dental and skeletal fluorosis (Güner et al., 2016; Tokatlı and Güner, 2018; 2020; Jannat et al., 2022; Din et al., 2024).

In the present study, fluoride concentrations in both Sultanköy (0.418 ppm) and Altınyazı (0.103 ppm) reservoirs were well within the permissible drinking water limit of 1.5 ppm stipulated by TS266 (2005), EC (2007), and WHO (2011). Although both lakes pose no fluorosis risk, the significantly lower fluoride level in Altınyazı suggests that supplementary oral health strategies might be required if utilized for municipal supply to ensure adequate protection against caries. Turningly, the higher chloride levels in Altınyazı Dam Lake (158.00 ppm) point toward more intense agricultural runoff or evaporative concentration dynamics in its catchment area.

CONCLUSIONS

This study evaluated the comparative hydrochemistry of Sultanköy and Altınyazı Dam Lakes with a specific focus on fluoride and chloride dynamics. The results revealed a distinct environmental polarization between the two reservoirs; Altınyazı Dam Lake is characterized by higher chloride loads, likely driven by agricultural runoff, whereas Sultanköy Dam Lake exhibits a significantly more dominant fluoride character. From a clinical and dental public health perspective, the fluoride concentrations in both lentic ecosystems remain safely below the maximum permissible drinking water threshold of 1.5 ppm set by WHO, EC, and TS266, indicating no risk of dental or skeletal fluorosis for the local population. However, the remarkably low fluoride levels in Altınyazı Dam Lake highlight a potential insufficiency for optimal dental caries prevention if these waters are integrated into municipal supply grids. Ultimately, these baseline outputs underscore the necessity of cross-disciplinary monitoring strategies that bridge environmental watershed management with preventive dentistry to ensure the dual protection of ecosystem stability and regional oral health.

ABSTRACT

Chronic exposure to fluoride via drinking water consumption is a well-documented global public health concern due to its capacity to induce non-carcinogenic health complications, such as dental and skeletal fluorosis, depending on the dose and physiological susceptibility. This study presents a comparative and age-specific probabilistic health risk assessment of fluoride exposure for populations utilizing groundwater from two distinct topographic zones (high-elevation/slope and low-elevation/plain) in the İpsala district of Edirne province, Northwest Türkiye. To evaluate the toxicological and non-carcinogenic hazards across different human developmental stages, the Hazard Quotient (HQ) was mathematically modeled for four demographic cohorts: infants, children, teenagers, and adults. The probabilistic risk assessment demonstrated that fluoride-induced health hazards are significantly influenced by both the topographic origin of the water source and age-specific physiological characteristics. In the high-elevation slope zone, fluoride exposure poses a negligible non-carcinogenic risk for all studied groups, with HQ values remaining comfortably below the safe regulatory threshold (HQ < 1), ranging from 0.04680 for infants to 0.33150 for children. Conversely, a substantial increase in exposure hazards was characterized in the low-elevation plain zone. In this lower terrain, the calculated HQ for children escalated sharply to 0.80372, followed by teenagers (0.56733), adults (0.45459), and infants (0.11347). These findings reveal that while no cohort currently exceeds the absolute safety limit, the child population in the low-elevation plain zone approaches this critical benchmark closely. Consequently, children constitute the most vulnerable demographic segment to chronic fluoride exposure in this region. This study underscores the necessity of implementing age-specific public health monitoring and target-driven water management strategies, particularly within the low-lying plain sectors of the basin, to mitigate long-term fluoride health risks.

Keywords: Fluoride exposure, Probabilistic risk assessment, Hazard Quotient, Demographic cohorts, Children vulnerability, İpsala Basin

INTRODUCTION

Access to safe drinking water is a fundamental requirement for public health, particularly regarding geogenic contaminants like fluoride that possess a narrow margin of safety. While controlled fluoride intake prevents dental caries, chronic and excessive consumption triggers non-carcinogenic health complications such as dental or skeletal fluorosis (Andezhath et al., 1993; Taghipour et al., 2016; Din et al., 2024). Human health responses to fluoride ingestion are heavily dependent on age-specific physiological cohorts (infants, children, teenagers, and

adults) due to significant differences in daily water consumption rates and body weights. Among these groups, children are widely recognized as the most vulnerable demographic segment owing to their developing skeletal structures and higher fluid intake relative to body weight. Therefore, utilizing probabilistic health risk assessment tools, such as the Hazard Quotient (HQ), is essential to accurately model exposure scenarios for vulnerable populations rather than relying on oversimplified average values (Onur et al., 2019; Tokatlı et al., 2022; Rashid et al., 2024).

The Thrace Region of Northwest Türkiye heavily depends on groundwater aquifers for domestic supply. Although general water quality across the region has been widely documented, the specific impact of geomorphological features—namely topographic elevation differences—on age-specific fluoride exposure risks remains completely unaddressed (Tokatlı, 2019; 2020; Helvacıoğlu et al., 2025). Aquifers situated in high-elevation recharge slopes versus low-lying plain discharge zones exhibit distinct exposure profiles, making a critical knowledge gap for local public health management. To address this gap, this study aims to evaluate and compare the non-carcinogenic health hazards (HQ) of fluoride via groundwater consumption across four distinct demographic cohorts in the İpsala (Edirne) district, utilizing well waters operating at similar depths but at different topographic elevations. This research provides essential, data-driven clinical insights required for targeted public health interventions in the region.

MATERIALS AND METHODS

Research Area and Sample Collection

The investigation was conducted in the İpsala district of Edirne province, located within the hydrogeologically and structurally complex Ergene Basin in the Thrace region of Northwest Türkiye (Figure 1). To effectively characterize the influence of geomorphological and topographic variations on groundwater fluoride dynamics, representative groundwater samples were synchronized and collected during the summer season of 2026. The sampling strategy targeted two active production wells operating at identical depth intervals (about 100 m) but positioned within contrasting topographical configurations: a high-elevation (slope) setting and a low-elevation (plain) setting.

All field sampling procedures strictly adhered to international standard protocols for groundwater quality monitoring. Prior to capturing the samples, both production wells were continuously purged for approximately 15–20 minutes. This purging process was maintained until key in-situ physicochemical parameters reached complete stabilization, thereby guaranteeing the collection of undisturbed formation water. The collected hydrochemical samples were stored in pre-cleaned, high-density polyethylene bottles, immediately placed in insulated cooler boxes maintained at 4 ^{0}C to preserve chemical integrity, and rapidly transferred to the laboratory for subsequent analytical determination.

Fluoride Analysis

Fluoride concentrations were quantified spectrophotometrically using a high-performance Hach Lange DR 3900 laboratory spectrophotometer, strictly adhering to the standard methods established by the American Public Health Association (APHA, 1998, 2017). The analytical determination was executed utilizing precision-engineered Hach Lange LCK 323 cuvette test kits. To ensure the highest degree of analytical accuracy, reproducibility, and minimal instrumental drift, all preparation and measurement steps were conducted in rigorous compliance with the manufacturer's operational protocols.

Figure 1. Map of İpsala district

Health Risk Assessment

To address physiological and behavioral variations, the target population was stratified into four age cohorts: infants (<2 years), children (2–6 years), teenagers (6–16 years), and adults (>16 years). Daily fluoride exposure via drinking water ingestion for each demographic category was calculated using Equation 1. The non-carcinogenic health hazards were subsequently characterized using the Hazard Quotient (HQ) according to Equation 2 (Yousefi et al., 2018). An HQ threshold of less than 1.0 indicates a negligible toxicological risk, whereas values greater than 1.0 signify potential non-carcinogenic health concerns, indicating an increased probability of developing dental or skeletal fluorosis.

$$EDI = \frac{Cf\ x\ Cd}{Bw} \quad (1)$$

$$HQ = \frac{EDI}{RfD} \quad (2)$$

EDI: Estimation of fluoride consumption – daily (mg/kg/day)
C_f: Fluoride level in the investigated drinking water samples (mg/L)
C_d: Mean daily water intake (L/day) (the mean water consumption rates in infants, children, teenagers and adults were 0.08, 0.85, 2 and 2.5 L/day, respectively)
B_w: Body weight (kg) (body weights of investigated groups were considered 10, 15, 50 and 78 kg, respectively)
RfD: Reference dose (mg/kg/day) (it is 0.06 mg/kg/day for fluoride (EPA, 1992).

RESULTS AND DISCUSSION

The age-specific non-carcinogenic health risks triggered by chronic fluoride exposure via groundwater consumption were evaluated using the Hazard Quotient (HQ) modelling approach. The calculated probabilistic health risk indices for four distinct demographic cohorts (infants, children, teenagers, and adults) across contrasting topographic settings are comprehensively illustrated in Figure 2.

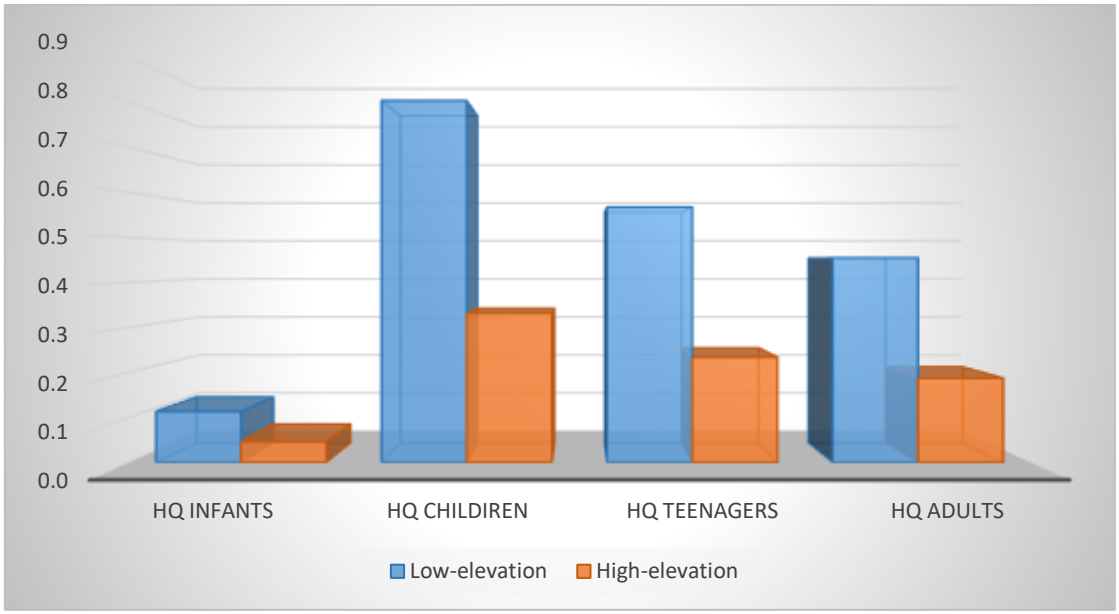

Figure 2. Probabilistic non-carcinogenic risk indices (HQ) of fluoride exposure

The outcomes of the probabilistic risk assessment revealed that non-carcinogenic health hazards fluctuate drastically depending on both the geomorphological location of the water source and the specific physiological traits of the exposed human cohorts (Taghipour et al., 2016; Tokatlı et al., 2022; Cao et al., 2023). For the high-elevation (slope) aquifer, the exposure modelling demonstrated completely negligible health risks. In this elevated recharge zone, the calculated HQ values for all demographic groups remained safely and comfortably below the critical regulatory threshold (HQ < 1). Specifically, the risk indices were modelled as 0.04680 for infants, 0.33150 for children, 0.23400 for teenagers, and 0.18750 for adults (Figure 2). These low values clearly indicate that chronic ingestion of groundwater from the slope sector poses no significant toxicological threat to the local population across any developmental stage.
Conversely, a dramatic and concerning elevation in exposure hazards was characterized in the low-elevation (plain) aquifer zone. In this low-lying discharge sector, the toxicological risks escalated sharply across all demographic segments. The calculated HQ values for the plain

aquifer followed a distinct order based on metabolic and consumption dynamics: children (0.80372) > teenagers (0.56733) > adults (0.45459) > infants (0.11347).

The most critical finding of this research is the pronounced vulnerability of the child cohort within the low-elevation plain zone. While no individual demographic group currently exceeds the absolute international safety threshold (HQ = 1), the child cohort's risk index reaches a critical threshold of 0.80372 (Figure 2). This high value indicates that children consuming water from the plain aquifer are approaching the non-carcinogenic safety boundary closely. This pronounced vulnerability observed in the younger population strongly corroborates broader global literature, which consistently demonstrates that children face substantially higher chronic exposure risks from drinking water consumption due to their significantly lower average body weights relative to their daily volumetric fluid ingestion rates (Gao et al., 2013; Tokatlı et al., 2023).

CONCLUSIONS

This study demonstrates a profound geomorphological control on age-specific probabilistic health risks from chronic fluoride exposure in the İpsala Basin. While the high-elevation slope aquifer poses completely negligible toxicological hazards for all demographic segments (HQ < 0.34), a substantial elevation in exposure vulnerability was characterized in the low-elevation plain zone. The Hazard Quotient (HQ) analysis revealed a strict age-dependent susceptibility order of children > teenagers > adults > infants. The most critical outcome is that children consuming groundwater from the low-elevation plain aquifer constitute the most vulnerable cohort, with their risk index reaching a critical threshold of 0.80372. Although no demographic group currently exceeds the absolute safety boundary (HQ = 1), the close proximity of the child cohort underscores a substantial risk for mild dental fluorosis under chronic long-term consumption. These findings indicate that regional water quality averages can obscure localized public health risks. Consequently, this study emphasizes the urgent need for target-oriented public health screening, pediatric dental monitoring, and age-specific protective water management strategies specifically tailored for the low-lying plain sectors of the region.

ABSTRACT

Groundwater geochemistry plays a pivotal role in public health, especially concerning elements with a narrow margin of safety such as fluoride. In this study, the fluoride dynamics of groundwater aquifers operated at similar depths (about 100 m) but located at different topographic elevations (high elevation/slope and low elevation/plain) in the İpsala district of Edirne province (Türkiye) were comprehensively investigated, and a clinical evaluation was conducted from the perspective of preventive dentistry. In addition to the primary fluoride parameter, physicochemical variables including pH and Electrical Conductivity (EC), which significantly govern fluoride hydrogeochemistry, mobilization, and dissolution kinetics, were systematically monitored in the sampled well waters. According to the analytical results, the groundwater fluoride concentration was measured as 0.351 ppm in the high-elevation (slope) well, whereas it reached 0.851 ppm in the low-elevation (plain) well. The concomitant sharp increase in EC levels (from 380 to 1919 µS/cm) and the alkaline shift in pH (from 7.42 to 7.53) from high to low elevations demonstrated that prolonged water-rock interactions, mineral dissolution, and alkaline anion exchange processes trigger significant geogenic fluoride enrichment in the low-lying plain aquifer. From a dental perspective, it was determined that groundwater from the high elevation contains insufficient fluoride for optimal dental caries prophylaxis (<0.5 ppm), potentially leaving the local consumer population susceptible to increased tooth decay. Conversely, groundwater from the low-elevation aquifer falls precisely within the optimal range (0.5 - 1.0 ppm) recommended for preventive dentistry, placing it at a critical hydrochemical threshold that requires close clinical monitoring for mild dental fluorosis risk, particularly in children, under scenarios of chronic long-term consumption.

Keywords: İpsala district, Groundwater hydrogeochemistry, Geogenic fluoride, Dental caries prophylaxis, Dental fluorosis

INTRODUCTION

Groundwater geochemistry plays a vital role in public health, particularly regarding trace elements like fluoride which exhibit a narrow safety margin for human health. While optimal fluoride levels (0.5 – 1.0 ppm) are essential for dental caries prophylaxis, sub-optimal exposure increases caries susceptibility, and chronic excessive consumption triggers dental fluorosis (Onur et al., 2019; Tokatlı et al., 2022). The mobilization of geogenic fluoride into aquifers is governed by water-rock interactions, alkaline anion exchange, and hydrodynamic gradients. Topographic elevation differences significantly dictate these processes by altering groundwater

residence time and mineral dissolution rates from recharge (slope) to discharge (plain) zones (Rashid et al., 2024; Din et al., 2024).

Although the Thrace Region's water quality and environmental characteristics have been widely studied in recent years, the specific impact of geomorphological features and topographic elevation differences on fluoride hydrogeochemistry, along with its direct implications for preventive dentistry in the İpsala district, remain completely unaddressed (Tokatlı, 2019; 2020; Helvacıoğlu et al., 2025). This lack of spatial understanding presents a critical knowledge gap, as rural populations in this region heavily rely on shallow and deep aquifers for daily drinking water consumption.

Therefore, this study aims to systematically evaluate the variations in groundwater fluoride geochemistry between high-elevation (slope) and low-elevation (plain) aquifers within the İpsala (Edirne) Basin, specifically focusing on wells operating at identical depth intervals to eliminate confounding hydrogeological variables. By closely monitoring dissolved fluoride concentrations alongside critical in-situ parameters such as pH and Electrical Conductivity (EC), this research not only elucidates the exact geogenic release and alkaline anion exchange mechanisms driving fluoride enrichment in low-lying discharge zones but also provides essential, data-driven clinical insights into the dual dental health risks—namely dental caries susceptibility and dental fluorosis—for the local population.

MATERIALS AND METHODS

Research Area and Sample Collection

The study area is located in the İpsala district of Edirne province, situated within the structurally complex Ergene Basin in the Thrace region of Türkiye (Figure 1). To evaluate the impact of topographic elevation on groundwater fluoride dynamics, representative groundwater samples were collected in summer season of 2026 from two production wells operated at similar depths (about 100 m) but exhibiting distinct topographical settings: a high-elevation/slope aquifer and a low-elevation/plain aquifer. Sampling procedures were conducted in accordance with international standard methods. Before sample collection, the wells were purged for approximately 15 – 20 minutes until physicochemical parameters stabilized, ensuring the retrieval of representative formation water. Samples were collected in pre-cleaned polyethylene bottles, kept in cooler boxes at 4 ^{0}C, and immediately transferred to the laboratory for hydrogeochemical analysis.

Chemical Analysis

Physicochemical parameters, including hydrogen ion concentration (pH) and Electrical Conductivity (EC), were measured in situ at the wellhead immediately upon sample collection using a Hach HQ40D multiparameter digital meter equipped with robust, factory-calibrated IntelliCAL probes. To ensure analytical accuracy and minimize drift, the multiparameter device was cross-calibrated daily against standard buffer solutions and certified conductivity standards.

Following field measurements, dissolved fluoride concentrations were quantified spectrophotometrically under controlled laboratory conditions using a high-performance Hach DR3900 laboratory spectrophotometer, strictly following the globally recognized American Public Health Association protocols (APHA, 1998, 2017). For the precise determination of fluoride levels, the Hach LCK 323 cuvette test kit was employed. All spectrophotometric steps were performed in strict accordance with the manufacturer's operational instructions.

Figure 1. Map of İpsala district

RESULTS AND DISCUSSION

The hydrogeochemical parameters and fluoride concentrations of the groundwater wells vary significantly based on topographic elevation differences, as illustrated in Figure 2. The high-elevation (slope) well exhibited a pH of 7.42, an Electrical Conductivity (EC) of 380 µS/cm, and a lower fluoride concentration of 0.351 ppm. Conversely, in the low-elevation (plain) well, pH slightly increased to 7.53, while EC and fluoride levels escalated sharply to 1919 µS/cm and 0.851 ppm, respectively. The concomitant increase in EC and pH from the slope to the plain aquifer demonstrates a clear geogenic enrichment mechanism. In the low-lying plain area (discharge zone), prolonged water-rock interactions and alkaline anion exchange processes trigger the desorption of fluoride from sediment surfaces into the groundwater (Cao et al., 2023; Gao et al., 2023).

From a clinical preventive dentistry perspective, these results highlight distinct local public health implications. Groundwater from the high-elevation zone contains insufficient fluoride (0.351 ppm < 0.5 ppm) for optimal dental caries prophylaxis, leaving consumer populations at a higher risk for tooth decay. In contrast, the fluoride concentration in the low-elevation plain well (0.851 ppm) falls precisely within the optimal therapeutic window (0.5 – 1.0 ppm) recommended for preventing dental caries (EC, 2007; WHO, 2011; Tokatlı et al., 2024). However, because this value sits near the upper threshold of the optimal range, chronic consumption of this plain groundwater requires careful clinical monitoring, as it presents a potential threshold risk for mild dental fluorosis in children during critical periods of tooth development.

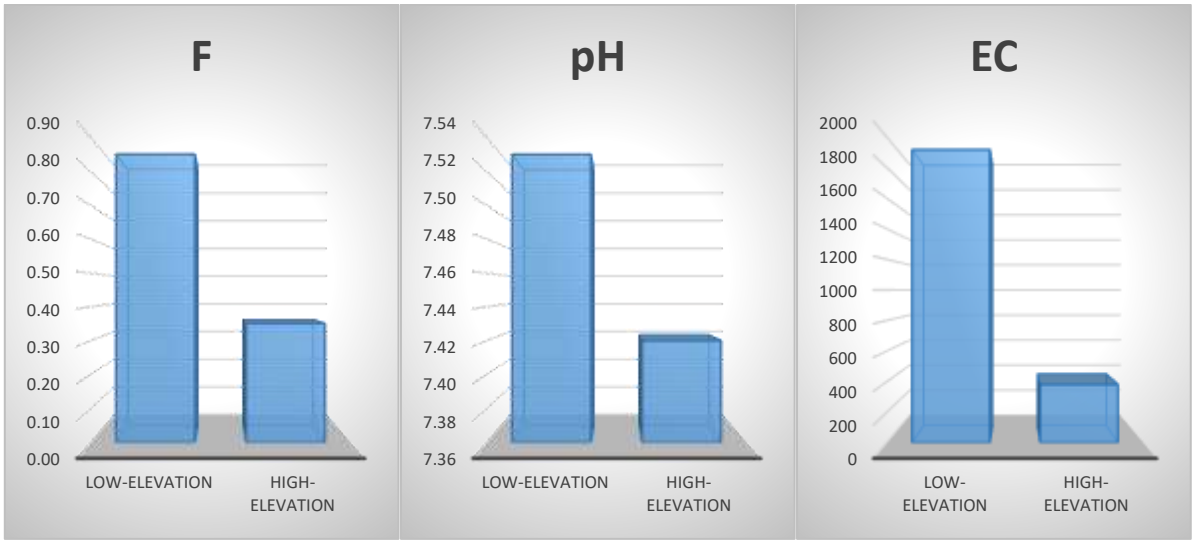

Figure 2. Fluoride (ppm), pH and EC (µS/cm) levels in the investigated wells

CONCLUSIONS

This study demonstrates that topographic elevation differences significantly influence groundwater fluoride geochemistry in the İpsala Basin, even at similar well depths. The transition from the high-elevation slope to the low-elevation plain triggers geogenic fluoride enrichment (from 0.351 to 0.851 ppm), driven by prolonged water-rock interactions and alkaline anion exchange as evidenced by elevated pH and EC levels.

From a dental health perspective, groundwater from the slope aquifer is sub-optimal and leaves the local population susceptible to dental caries. Conversely, the plain aquifer provides optimal levels for caries prophylaxis but requires clinical monitoring due to the threshold risk of mild dental fluorosis under chronic exposure. These findings underscore the critical need for integrating hydrogeochemical data with public health strategies in regional water management.

ABSTRACT

The rapid increase of economic activities including agriculture, industrial development, uncontrolled gravel abstraction and unregulated urban wastewater discharges and lack of adequate infrastructure and management, has significantly increased pressure on rivers quality in Albania, thereby contributing to enhanced pollution levels. Land use particularly nearby rivers for different industrial activities and agriculture represent one of major sources of many organic and inorganic pollutants in surface and groundwater. Meanwhile untreated municipal and industrial wastewater can significantly affect the ecological functioning of river ecosystems.

This study aims to assess the long-term variation of organic pollution in the Erzeni River during 2014–2024 using the biodegradability index (BDI), calculated as the ratio of five-day biochemical oxygen demand to chemical oxygen demand (BOD_5/COD). Monitoring data covering the study period, reported in the annual environmental status reports published by the Albanian National Environmental Agency (NEA), together with the pressure analysis presented in the official Erzen River Basin Management Plan, were analyzed for two representative official monitoring sites.

The results indicate persistent presence of organic pollution, particularly in areas affected by urban, industrial, and agricultural pressures. Individual BOD_5 concentrations range from 5 to 20 mg/L, with no clearly distinguishable seasonal pattern. BDI values showed relatively limited interannual variation and generally ranged between 0.5 and 0.6. The highest individual BDI (0.89) was observed in 2021 and the lowest (0.38) in October 2014. The predominance of BDI values above 0.5 indicates that a substantial proportion of the organic matter present in the river was readily biodegradable. However, the continued occurrence of measurable BOD_5 and COD concentrations throughout the studied period suggests persistent organic inputs.

The EU WFD promotes the integrated management of water resources to support environmentally sustainable development and reduce pressures associated with excessive water abstraction and pollution. Albania has transposed such requirements in the national legislation and continuous to improve secondary legislation to better manage pollution control, environmental permitting, and water quality monitoring. Nevertheless, effective implementation of these requirements depends on robust monitoring systems, well-equipped laboratories, and clear data-sharing mechanisms. At present, these prerequisites are only partially established and operational. An integrated management approach is therefore required to (i) reduce organic and nutrient loads originating from urban wastewater discharges and agricultural activities, (ii) identify and control of heavy metal sources (urban/industrial sources), including the role of sediments in their accumulation and potential remobilization; and (iii) improve monitoring programmes through the systematic inclusion of WFD priority

substances, thereby enabling a comprehensive and WFD-compliant water quality assessment of the Erzeni River.

Keywords: River pollution, BOD/COD ratio, freshwater quality assessment.

INTRODUCTION

EU Water Framework Directive representing the fundamental legal act in shaping the water management sector since 2000 across the European countries, foresees an analysis of anthropogenic impact, as a cyclical process, in the context of the river basin management planning (1). In Albania, this approach is embedded in the national legislation therefore chemical, and not only, pollution should be frequently measured and adequately controlled. This study aims to assess the long-term variation of organic pollution in the Erzen river using the biodegradability index (BDI), calculated as the ratio of BOD/COD, where both parameters represent routine analyses of the water quality and are significantly important in controlling the total content of pollution and the management of water environment (2).
The BDI must be smaller or equal to 1.0; the higher the value, the more serious the pollution of organic matter and the higher the level of biodegradability (3), (4); (5). Rivers are often considered a sink and source of many pollutants (6) and especially if there are discharges of industrial and/or urban wastewaters induced in the water system, they show high levels of BOD_5 and COD. High presence of organic matter in water leads to a decrease of dissolved oxygen due to consumption.

Official datasets for BOD_5 and COD concentrations during 2014–2024, as published by responsible authorities in regular reports, were analyzed in two NEA representative official monitoring sites. Albania has transposed EU WFD requirements in the main but its effective implementation however depends on robust monitoring systems, well-equipped laboratories and clear data-sharing/reporting mechanisms to ensure a better pollution control management, environmental permitting tools and adequate water quality monitoring. At present, these prerequisites are only partially established.

MATERIAL AND METHOD

Two NEA representative official monitoring sites were selected for this study (Ura Beshirit and Ura Sallmonaj) based on the analysis of pressures presented in the official river basin management plan including agriculture, various industrial activities and gravel mining upstream. Data series between 2014 – 2024, as officially reported by NEA through yearly environmental status reports (7) and the official river basin management plan for Erzen river basin (8) were analyzed and selected data have been plotted to identify BDI trend and potentially asses changes in pollution patters during these years.

Yearly individual mean data of the two selected monitoring sites were analyzed to observe any differences on BDI and be able to judge over the level of pollution. According to official reports, water samples have been taken on irregular seasonal basis over the years, between two to four times per year. All BOD > COD values were excluded to ensure credibility of the results and respective BDI ratio is not considered in the trend analysis.

RESULTS AND DISCUSSION

Individual BOD_5 values range from 5 to 20 mg/L, with no clearly distinguishable seasonal pattern. BDI values showed relatively limited interannual variation and generally ranged between 0.5 and 0.6. The highest individual BDI (0.89) was observed in 2021 and the lowest (0.38) in October 2014. The predominance of BDI values above 0.5 (Table 1) indicates that a substantial proportion of the organic matter present in the river was readily biodegradable.

Table 1 BDI Mean values for both official monitoring sites

Measurement	Year/Month	EbeM1-31 BDI	EsaM1-31 BDI

EM12	Oct-17	0.64	0.63
EM13	Feb-18	1	1
EM14	Jul-18	1	1
EM15	Nov-18	0.62	0.58
EM16	Mar-19	0.03	0.57
EM17	May-19	0.07	0.63
EM18	Oct-19		0.56
EM19	Dec-19	0.40	
EM20	Feb-20	0.54	0.61
EM21	Apr-20	0.83	1
EM22	Oct-20	0.57	0.57
EM23	Mar-21	0.36	0.46
EM24	Oct-21	0.59	0.61
EM25	Mar-22	0.67	0.6
EM26	Sept-22	0.6	1
EM27	May-23	0.71	0.6
EM28	Sept-23	0.4	0.57
EM29	May-24	0.57	0.58
EM30	Oct-24	0.6	0.44
EM31	Dec-24	0.69	0.59

The BOD and COD fluctuates at both monitoring sites through the years and also on seasonal basis. (9) argues that this might be due to organic matter which comes from anthropogenic activities active in the study area (e,g plant extracts, solid wastes dumping, sewage discharges, and agricultural run-off. When BDI values range between 0.3 – 0.6 it confirms that the pollutants in waters belong to slow degradable category and >0.6 they are biodegradable (10). Results indicate persistent presence of organic pollution, particularly in areas affected by urban, industrial, and agricultural pressures and the continued occurrence of measurable BOD_5 and

COD concentrations throughout the studied period suggests persistent organic inputs. BDI mean value, combining both monitoring sites increases through the years, particularly visible from 2014 to 2016 (Figure 1).
In a snapshot overview the trend is stable after 2022 showing lower values compared to an increased one before 2020. Nevertheless, the overall trend is near to 0.5 is mostly associated with consistent discharges of urban waters and agricultural activities in the areas nearby the river area.

Few cases were observed where the individual concentrations of BOD_5 and COD were excluded from the BDI analysis due to information inconsistency.

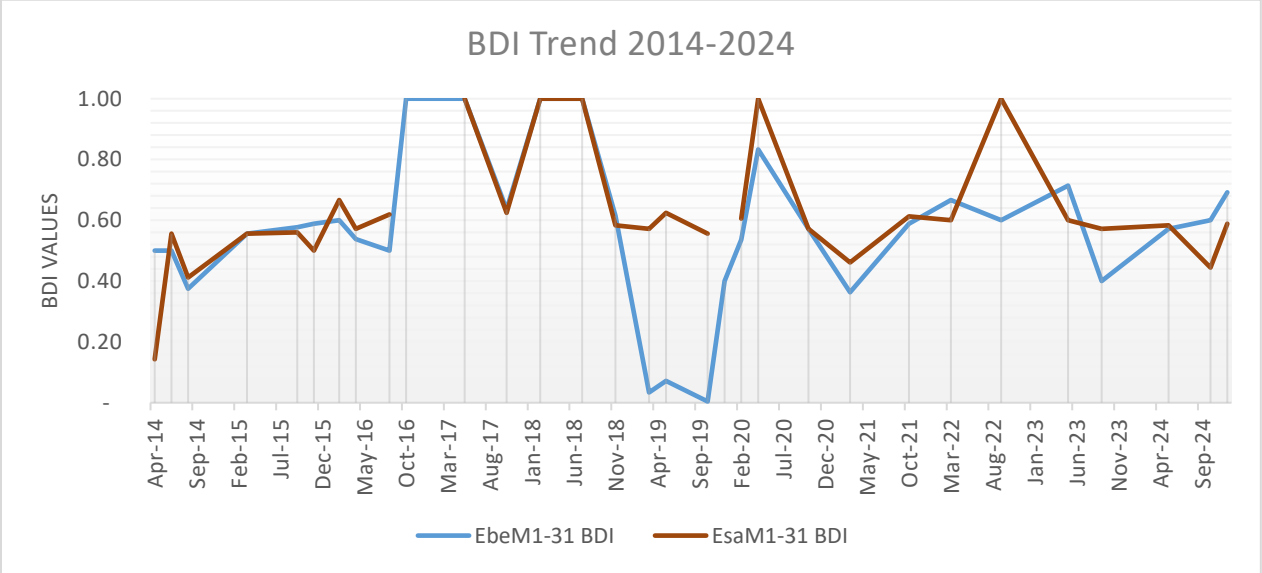

Figure 1 BDI trend concentration during 2014-2024

CONCLUSIONS

The predominance of BDI values above 0.5 indicates that a substantial proportion of the organic matter present in the river was readily biodegradable. Continued occurrence of measurable BOD_5 and COD concentrations throughout the studied period suggests persistent organic inputs. Higher BDI values in longer periods of time observed in the second monitoring site. An integrated management approach is therefore required to reduce organic and nutrient loads originating from urban wastewater discharges and agricultural activities, to identify and control of heavy metal sources (urban/industrial sources), including the role of sediments in their accumulation and potential remobilization, and to improve monitoring programmes through the systematic inclusion of WFD priority substances.

ABSTRACT
Cryopreservation of goat sperm is challenged by the vulnerability of the sperm plasma membrane to cold shock and oxidative stress-induced lipid peroxidation. Caprine spermatozoa possessing a high proportion of polyunsaturated fatty acids (PUFAs) and a low cholesterol-to-phospholipid ratio (0.30–0.35), which predisposes the membrane to cryoinjury, compound this vulnerability. Recent studies have reported on the use of cholesterol-loaded cyclodextrins (CLC) to stabilize the sperm plasma membrane and improve post-thaw semen quality. However, the role of seminal plasma (SP) during CLC-based cryopreservation remains debated. While SP supplies protective antioxidants and proteins, it also contains enzymes that degrade egg yolk-based extenders. This study evaluated the effect of pre-freeze washing (SP removal) on the functional characteristics of cryopreserved goat sperm. Overall, sperm quality was found to be comparable in washed and unwashed semen, with no significant differences in most kinematic parameters. However, unwashed sperm showed higher average path velocity (VAP), while washed sperm had significantly higher viability and straightness (STR). This suggests that, during caprine semen cryopreservation with CLC, membrane stability and kinematic performance exhibit a trade-off.

Keywords: Cryopreservation; caprine sperm; seminal plasma; sperm motility; membrane integrity

INTRODUCTION

Artificial insemination (AI) with frozen semen is a primary tool for achieving genetic progress in goat farming. In practice, however, its use is limited by inconsistent outcomes from semen freezing. These includes structural damage to sperm membrane & DNA which is catalyzed by lipid peroxidation (LPO) and by oxidative stress to which spermatozoa are exposed during freeze thaw cycle (Anand et al. 2016, Suwor et al. 2025). SP may also degrade milk extenders using enzymes and explained in detail below. The plasma membranes of goat spermatozoa has relatively high level of PUFA (polyunsaturated fatty acid) and low Cholesterol: PL (0.30-0.35)ratio, result in high membrane fluidity and hence are prone to cold shock (Anand et al. 2016, Aitken & West 1990, Darin- Bennett & White 1977, Simsek et al. 2025). These membranes aid in fertilisation normally but creates obstacles for semen during freezing process. The loss of cholesterol from the membranes during cryopreservation is another cause of cryoinjury on buck sperm (Amorim et al., 2009; Bailey et al., 2008).
The second is oxidative stress. If not neutralized by an effective antioxidant system, the oxidative stress results in lipid peroxidation (LPO), leading to loss of membrane fluidity and permeability, altering sperm metabolism (Sies, 1986; Bansal & Bilaspuri, 2011; Aitken et al., 1989; Maxwell & Watson, 1996; Peris et al., 2007). Consequently a few methods were developed in relation to improve the cholesterol load in sperm via using cholesterol loaded

cyclodextrin (CLC) method, which can be presented as addition of antioxidants and design of a new freeze medium (Konyali et al. 2013; Ashrafi et al. 2013; Kumar et al. 2025). The application of CLC was observed to reduce ROS and malondialdehyde formation, decrease of ATP depletion and preserve of the integrity of plasma membrane and acrosome in boar sperm following thawing (Zhang et al., 2024).

In spite of the membrane structure, the seminal plasma (SP) protection role in caprine semen cryopreservation is still controversial. Despite conferring protective components and enzymes to the sperm, SP enzymes can create adverse reactions with extender components. The buck seminal plasma has enzymes that can hydrolyze specific components of the classic extenders, like those found in milk or egg yolk. The main examples are EYCE (a phospholipase A2) and a BUSgp60 glycoprotein lipase, which are both capable of degrading egg yolk lipids into lyso-phospholipids and free fatty acids, both damaging for the sperm membrane and the acrosome (Pellicer-Rubio et al., 1997; Pellicer-Rubio & Combarnous, 1998; Esteve et al., 2025). Certain SP enzymes act on milk components similarly, complicating the use of milk-based extenders. For these reasons, despite evidence that SP helps maintain the viability and motility of cold-stored and frozen semen (Maxwell & Johnson, 1999; Azerêdo et al., 2001), standard practice in caprine semen cryopreservation calls for removing SP by centrifugation before freezing. However, it is not without its complications. Mechanical removal of SP by centrifugation may damage membrane integrity as well as impair sperm kinetics (Maxwell & Johnson, 1999; Azerêdo et al., 2001). Also, SP also contains protective elements like proteins and antioxidants that shield sperm cells from free radical mediated damage (Maxwell & Johnson, 1999; Azerêdo et al., 2001; Ohaneje et al., 2021) Thus, SP removal presents a dual-edged sword: it eliminates a source of enzymatic harm while also eliminating a source of protection. Given this duality, we examined how centrifugal removal of SP affects the quality of post-thaw goat semen. We hypothesized that centrifugation prior to freezing would shift the balance between two competing effects—the loss of toxic SP components and the mechanical stress/oxidative load introduced by centrifugation—and that this balance would be reflected in post-thaw sperm motility and membrane integrity.

MATERIAL AND METHOD

Animals and Semen Collection

Semen was collected from five Arbia breed bucks, selected based on semen volume, mass motility, individual motility, and sperm concentration. Two ejaculates were collected per buck, yielding a total of 10 ejaculates. The two ejaculates from each buck were pooled to obtain one sample per buck (n = 5). Each sample was divided into two aliquots and diluted to a concentration of 360×10^6 spermatozoa/mL.

Experimental Design

Table 1 summarizes the sperm processing for unwashed and washed groups. Both groups were incubated for 15 min at 22 °C in the presence of CLC.

Table 1. Sperm processing for unwashed and washed groups

Group	Treatment
Unwashed	Treated directly with 150 µL of Tris-based cryopreservation diluent containing cholesterol-loaded cyclodextrin (CLC).
Washed	Centrifuged twice at 500 × g for 15 min in 1 mL Tris-based cryoprotectant (CP) diluent, resuspended in an equal volume of Tris-based CP diluent after the second centrifugation, then treated with 150 µL of Tris-based cryopreservation diluent containing CLC.

Cryopreservation Protocol

Following CLC treatment, each sample was diluted threefold with an egg yolk-based freezing extender to obtain a final concentration of 120×10^6 spermatozoa/mL. The extended semen was loaded into 0.25 mL French straws, sealed, and equilibrated for 2 h at 4 °C. Straws were then frozen by holding them vertically 4 cm above liquid nitrogen vapor for 15 min before plunging into liquid nitrogen. For thawing, straws were immersed in a water bath at 37 °C for 40 s.

Post-Thaw Sperm Quality Assessment

Sperm Motility Analysis

Sperm motility was evaluated using a computer-assisted sperm analysis (CASA) system. Post-thaw semen suspensions were diluted 1:50 in Tris-based diluent and loaded onto a pre-warmed (37 °C) slide using a 10 µL pipette. The suspension was covered with an 18 × 18 mm coverslip and examined under a video-enhanced phase-contrast microscope (CROSS, 100× objective; Discovery Sensing, Inc., USA). Four fields per sample were captured, each containing ≥ 200 spermatozoa. Analysis settings: 25 frames/s, head area 20–90 µm², curvilinear velocity (VCL) > 10 µm/s (Tamayo-Canul et al., 2011). The following kinematic parameters were recorded (Table 2).

Table 2. Parameters studied and their description

Parameter	Description
TM	Total motility (%): percentage of spermatozoa with VCL > 10 µm/s
PM	Progressive motility (%): percentage of spermatozoa with VCL > 25 µm/s and straightness (STR) > 80%
VCL	Curvilinear velocity (µm/s)
VSL	Straight-line velocity (µm/s)
VAP	Average path velocity (µm/s)
LIN	Linearity (%)
ALH	Amplitude of lateral head displacement (µm)
BCF	Beat-cross frequency (Hz)
STR	Straightness (%)
WOB	Wobble (%)

Sperm Viability (Eosin-Nigrosin)

Sperm viability was evaluated using the eosin-nigrosin staining technique. A 10 µL semen suspension was mixed with 10 µL eosin-nigrosin solution, smeared on a slide, air-dried, and examined under a light microscope at 400× magnification. Two hundred spermatozoa were

counted per sample. Viable sperm excluded the dye (unstained), whereas non-viable sperm appeared red or pink (Björndahl et al., 2003; Vale et al., 2014).

Statistical Analysis

The calculation of means, standard error of the mean (SEM), and statistical analysis were performed using Statview 4.02 software (Abacus Concepts Inc., Berkeley, CA, USA). Values for each parameter are expressed as mean ± SEM. A two-way analysis of variance (ANOVA), followed by a Fisher post-hoc test, was used to determine the effect of washing the seminal plasma on the observed variation. Values were considered significant at $p<0.05$.

RESULTS AND DISCUSSION

Effect of Seminal Plasma Washing on Post-Thaw Sperm Parameters

The effects of seminal plasma washing on post-thaw caprine sperm quality parameters are summarized in Table 3.

Washing significantly improved viability (from 72.0% to 82.8%) and straightness (STR). Conversely, average path velocity (VAP) was significantly higher in unwashed samples (88.6 µm/s) compared to washed samples (76.3 µm/s). Total motility, progressive motility, and curvilinear velocity (VCL) were numerically higher in unwashed semen, though these differences did not reach statistical significance. VSL, LIN, ALH, BCF, and WOB were unaffected by treatment.

Table 3. Effects of seminal plasma washing on post-thaw caprine sperm parameters (mean ± SEM)

Parameter	Unwashed	Washed	P-value
Viability (%)	72.0 ± 0.9	82.8 ± 2.3	≤ 0.05
Total motility, TM (%)	92.4 ± 4.3	86.1 ± 0.2	0.20
Progressive motility, PM (%)	69.5 ± 3.1	57.2 ± 0.5	0.06
VCL (µm/s)	105.5 ± 3.2	91.5 ± 1.7	0.06
VSL (µm/s)	59.9 ± 3.0	57.0 ± 1.6	0.40
VAP (µm/s)	88.6 ± 2.2	76.3 ± 2.2	≤ 0.05
LIN (%)	56.9 ± 4.6	62.3 ± 0.6	0.30
ALH (µm)	2.2 ± 0.5	2.3 ± 0.05	0.80
BCF (Hz)	9.05 ± 1.0	9.8 ± 0.3	0.50
STR (%)	67.5 ± 5.0	74.6 ± 0.5	≤ 0.05
WOB (%)	84.1 ± 4.6	83.4 ± 0.8	0.80

Taken together, these data point to a trade-off rather than a clear advantage: washing protects membrane integrity and directional movement, whereas retaining SP preserves sperm velocity.

Discussion

Seminal plasma (SP) removal before freezing in an egg yolk–citrate extender with CLC had a complex effect on post-thaw buck sperm, consistent with the unusually lipid-rich, cryolabile structure of goat sperm membranes (Kumar et al., 2025). The post-wash rise in viability supports SP removal as conferring some membrane protection, while higher VAP and numerically greater total motility, progressive motility, and VCL in unwashed samples suggest SP also benefits motility. SP therefore plays both a protective and a damaging role: washing removes harmful enzymatic activity but also some motility-enhancing components.

This pattern sits within a genuinely mixed literature. Azerêdo et al. (2001) reported the opposite effect in frozen-thawed goat spermatozoa, where SP removal decreased motility and vigor rather than improving membrane integrity, whereas other work shows washing before 5 °C storage improves motility, acrosome integrity, and HOST response. The 10.8-point viability gain observed here thus fits an inconsistent evidence base, even though washing also removes metabolic components SP would otherwise supply (Kumar et al., 2025).

The likely mechanism is reduced SP-driven lipid damage. Pellicer-Rubio et al. (1997) and Pellicer-Rubio and Combarnous (1998) identified a bulbourethral lipase in buck SP that degrades sperm in milk-based extenders via free fatty acids and lysolecithins. An egg yolk–coagulating enzyme in goat semen (Roy, 1957) is, per Kumar et al. (2025), similarly detrimental in egg yolk media, hydrolyzing yolk lecithin into lysolecithin and priming the membrane for capacitation-like changes and acrosomal degeneration; washing likely reduces exposure to this agent. Watson (2000) similarly identified freeze-thaw as the most damaging stage of cryopreservation.

The contribution of SP to motility is different: it provides proteins, lipids, enzymes and antioxidants that buffer cold shock (Maxwell & Johnson, 1999), a stabilizing role also reported by Azerêdo et al. (2001). Here, unwashed samples reached VAP of 88.6 µm/s versus 76.3 µm/s for washed samples, with TM, PM, and VCL trending similarly — suggesting specific SP components support faster movement even as they compromise membrane integrity.

The extender system constrains these effects. CLC stabilizes membranes against cold and osmotic stress; Darin-Bennett and White (1977) showed ram and bull sperm carry a lower membrane cholesterol-to-phospholipid ratio than cold-tolerant species, and that introducing cholesterol raises resistance to chilling and osmotic shock while preserving viability and motility (Darin-Bennett & White, 1977; Salmon et al., 2016). Mocé et al. (2014) reported similar CLC benefits under fast and slow freezing, and Salmon et al. (2017) showed CLC improves resistance specifically to SP-mediated injury — explaining why VSL, LIN, ALH, BCF, and WOB were unaffected by washing, since mechanical (washing) and chemical (CLC) neutralization of SP damage may converge on the same outcome for these traits. CLC alone, however, is insufficient for optimal preservation, as confirmed by the present finding of differences in viability and STR between washed and unwashed samples. Under CLC, membranes maintained integrity and acceptable motility in both groups, but viability and STR were significantly higher in washed sperm ($p \leq 0.05$), possibly reflecting residual enzymatic damage in CLC-treated sperm, or, more likely, a selection effect in which washing removes dead and degenerate cells (Naing et al., 2011). Total motility, ALH, BCF, LIN, and WOB did not differ between groups, indicating no detrimental effect of SP once its damaging activity was partly blocked by CLC. Extensive washing can improve cryopreservation by removing deleterious enzymes and ROS-generating molecules (Naing et al., 2011), but the manipulation involved carries its own risk of physical damage to spermatozoa.

Work on Angora bucks offers a useful comparison: The benefit of centrifugation was found to be highly dependent on extender (Sarıözkan et al., 2010) where a Bioxcell extender outperformed standard Tris for post-thaw motility, membrane integrity, pregnancy rates and antioxidant activity. Washing is also laborious and carries the risk of sperm loss (Tuli & Holtz, 1994), so providing a strong extender together with cholesterol supplementation to reduce the need for washing has both operational and biological benefits.

Kozdrowski et al. (2007) provide a contrasting result: comparing plasma removal with 20% egg yolk against no removal with 1.5% egg yolk in French Alpine bucks, they found plasma removal improved VAP, VSL, STR, LIN, ALH, and motility — opposite to our VAP result. This likely reflects a confound, since egg yolk concentration (not plasma removal alone) differed between their groups, and egg yolk cholesterol is itself cold-protective; our design

held CLC and egg yolk constant, isolating SP's effect more cleanly and likely explaining our trade-off rather than a uniform improvement. Kozdrowski et al. (2007) also cite Leboeuf et al. (2000) on the bulbourethral-derived EYCE (a phospholipase A hydrolyzing egg-yolk lecithin to toxic lysolecithin) and Verstegen et al. (2002) on ALH, VAP, VSL, STR, and LIN as indices of fertilizing capacity. Still, results remain inconsistent: Tuli and Holtz (1994) found no benefit to plasma removal in Boer goats, and Ritar and Salamon (1991) attribute post-thaw variability to interacting effects of male, collection month, egg yolk concentration, and plasma removal — reinforcing that SP removal cannot be assessed independent of the extender system.

Santiago-Moreno et al. (2017) demonstrated that density gradient centrifugation was superior to washing methods in removing dead sperm with increased VSL, VAP, progression rates. This is yet another example of how it is the technique of removal not just that the dead sperm is removed that affects results. While it seemed as if dead cells and all our waste were disposed of, and that no physically trauma was done to our sample since the level of viablity did not decrease, it is obvious that some degree of functional compromise was performed, because of the increase in VAP (having successfully avoiding using to much force and too long centrifuge, following guidelines from Kumar et al. (2025).

VSL, LIN, ALH, BCF, and WOB were largely conserved across treatments, suggesting SP removal acts on survival and select velocity traits rather than the fundamental architecture of motility; within an egg yolk–citrate/CLC system, membrane stabilization preserves core motility patterns regardless of SP status. The primary effect of washing is thus a redistribution between viability and specific velocity traits, not a wholesale loss of motility.

Practically, washing is worthwhile when post-thaw survival and directional movement (STR) are the priority, as in controlled AI programs; where time and simplicity matter and CLC/egg yolk are already in the protocol, retaining SP is reasonable, since the viability cost is offset by higher velocity. The recommendation is thus conditional: washing improves viability and STR but is not strictly necessary when the extender system is already strongly cryoprotective.

To summarize, both our data and the literature support a bifunctional view of SP in goat semen cryopreservation: damaging membranes through lipase activity and enzyme–lipid interactions (Kumar et al., 2025) while also contributing to motility preservation. Washing improved viability and STR, while unwashed sperm retained higher VAP and a numerical edge in TM, PM, and VCL; under CLC-based cryopreservation, SP removal enhances membrane stability without being strictly essential for acceptable post-thaw quality.

CONCLUSIONS

Based on the study, washing seminal plasma before freezing improved post-thaw viability and straightness (STR) of goat sperm, whereas retaining seminal plasma preserved higher average path velocity (VAP) and a numerical advantage in total motility, progressive motility, and curvilinear velocity. These findings indicate a trade-off between membrane integrity and kinematic performance during CLC-based cryopreservation of caprine semen. While seminal plasma removal is not strictly essential when using cholesterol-loaded cyclodextrin and egg yolk-based extenders, it remains beneficial when the priority is post-thaw survival and directional movement for artificial insemination programs.

VALORIZATION OF AGRICULTURAL WASTE INTO ACTIVATED CARBON : CHARACTERIZATION AND PERFORMANCE FOR PHARMACEUTICAL POLLUTANT REMOVAL FROM WATER

*Belkharchouche Djanet * , Belkharchouche Drifa ***

***Laboratory of Energy Physics and Renewable Energies, University of Constantine 1, Algeria*

**Department of Process Engineering, University of Constantine 3, Algeria*

ABSTRACT

In this study, an activated carbon was prepared from **bean pods (Vicia faba)**, an abundant agricultural waste, by chemical activation. Two activating agents were compared : **phosphoric acid**, used at impregnation ratios of 100%, 150%, and 200%, and **sulfuric acid**, used at 200%. The results showed that the carbon activated with **200% phosphoric acid** exhibited the best performance, with an adsorption capacity of **107.5 mg/g**, compared to **90 mg/g** for the carbon activated with sulfuric acid, and only **2.98 mg/g** for the raw pods. The influence of several parameters on the adsorption process was also investigated, namely **pH, temperature, ionic strength, and initial pollutant concentration**.

Adsorption equilibrium was reached within only **5 minutes** for concentrations below **150 mg/L**, reflecting rapid kinetics, satisfactorily described by the **pseudo-second-order kinetic model**. Fitting of the experimental data to the **Langmuir model** revealed monolayer adsorption. The thermodynamic study also allowed determination of the main parameters associated with the process, namely **Gibbs free energy, enthalpy, and entropy**.

The properties of the resulting activated carbon, notably its **specific surface area and functional characteristics**, were investigated and confirmed by **BET, FTIR, and pHpzc** analyses.

These results show that the valorization of bean pods into activated carbon constitutes a **sustainable, economical, and effective** approach for removing pharmaceutical residues present in water. This process fully falls within a **circular economy** approach, aimed at converting agricultural waste into high-value-added materials for the preservation and treatment of water resources.

Keywords: agricultural waste; activated carbon; adsorption; metoprolol; environment; remediation; circular economy.

INTRODUCTION

Pharmaceutical residues are increasingly detected in aquatic environments and represent an environmental concern due to their persistence and their potential effects on living organisms. Among these contaminants, metoprolol, a β-blocker widely used in the treatment of cardiovascular diseases, is frequently found in surface waters and wastewater treatment plant effluents, notably owing to its low biodegradability.

Among the various treatment techniques, adsorption onto activated carbon constitutes an effective method for removing organic micropollutants. However, the cost of conventional

activated carbons encourages the development of alternative, economical, and sustainable materials, particularly from agricultural waste.
In this perspective, bean pods (Vicia faba) represent an interesting precursor for the production of activated carbons. Their valorization allows both the reduction of agricultural waste and the production of a high-value-added material. Chemical activation with H_3PO_4 (100, 150, and 200%) and H_2SO_4 (200%) was used to improve the textural and functional properties of the resulting materials.

Objective

Prepare and characterize activated carbons from bean pods, using H_3PO_4 and H_2SO_4 as activating agents, then evaluate their performance for the removal of pharmaceutical pollutants in aqueous media, using metoprolol as a model pollutant.

RESULTS

Textural characterization

Activation with H_3PO_4 strongly improves the textural properties of the bean pods. The BET specific surface area increases with the activation ratio and reaches its maximum value for BPPAC 200%.

Table 1. BET specific surface areas of the prepared activated carbons

Material	BPPAC 100%	BPPAC 150%	BPPAC 200%	BPSAC 200%
Cumulative pore volume V_{cum} (cm^3/g)	0.0731	0.0439	0.0417	0.0426
Total pore volume V_{tot} (cm^3/g)	18.835	34.435	43.248	40.331
Cumulative pore surface area S_{cum} (m^2/g)	16.674	9.791	7.545	9.791

S_{BET} (m^2/g)	**1032.114**	**1040.744**	**1100.391**	**38.251**
Average pore diameter ($4V_{tot}/S_{BET}$) (Å)	**665.484**	**1323.499**	**1572.059**	**4.217**

Material	**S(BET) (m^2/g)**
BPPAC 100%	1032.11
BPPAC 150%	1040.74
BPPAC 200%	**1100.39**
BPSAC 200%	38.25

BPPAC 200%: S(BET) = 1100.39 m^2/g

Adsorption performance

Chemical activation strongly improves the adsorption of metoprolol compared to the raw pods (2.98 mg/g). The best performance is obtained with carbons activated by H_3PO_4, particularly BPPAC 200%.

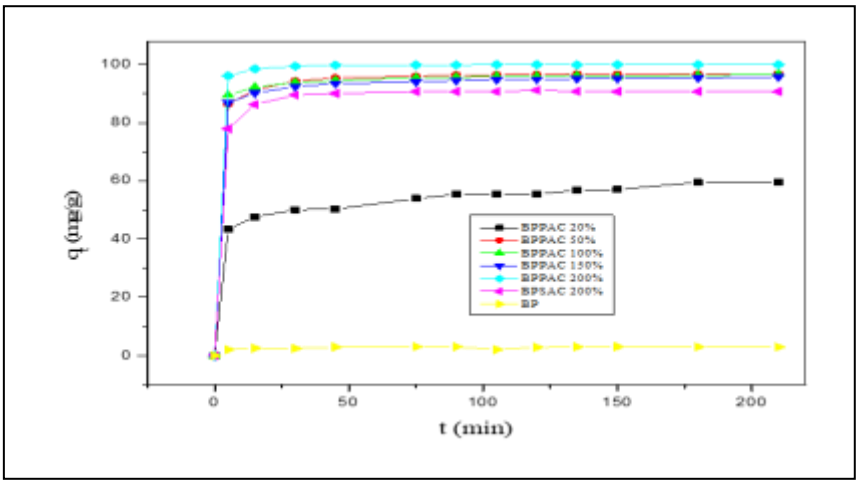

Figure 1. Effect of activation ratio on metoprolol adsorption.

Effect of pH

The adsorption capacity remains close to 78.38 mg/g in acidic media, then increases to a maximum of 94.55 mg/g at pH 10, before decreasing in more basic media.

pHpzc ≈ 4 | pKa ≈ 9.5 | q_e,max ≈ 94.55 mg/g at pH 10

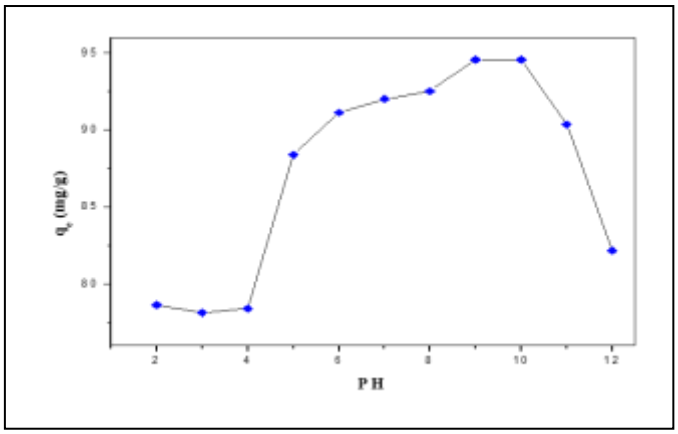

Figure 2. Effect of initial pH on metoprolol adsorption onto BPPAC.

Adsorption kinetics

Adsorption is rapid, with equilibrium reached within approximately 5 min for $C_0 < 150$ mg/L.
The pseudo-second-order (PSO) model describes the experimental data very well :
$R^2 = 0.9999–1.000$
The calculated adsorption capacities show excellent agreement with the experimental values.

Adsorption equilibrium

The equilibrium data show an excellent fit to the Langmuir 2 model.
20 °C: $R^2 = 0.998$
30 °C: $R^2 = 0.982$
50 °C: $R^2 = 0.995$
At 20 °C, the experimental capacity reaches $q_{e,exp} = 110.87$ mg/g.
These results are consistent with adsorption occurring mainly as a monolayer on the accessible sites of the activated carbon.

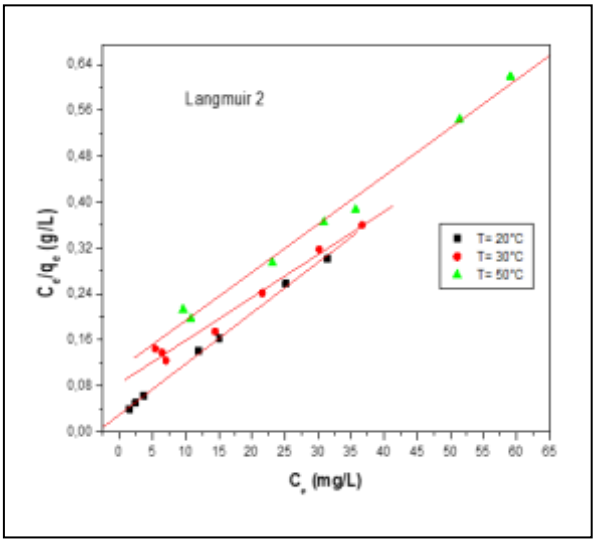

Figure 3. Linearization of the Langmuir 2 model for metoprolol adsorption onto BPPAC.

DISCUSSION

Surface properties

The high specific surface area of BPPAC 200% (1100.39 m²/g) confirms the effectiveness of activation with H_3PO_4 in developing the textural properties of the material.
The FTIR analyses reveal changes in surface chemistry after activation, particularly in the oxygenated functional groups likely to contribute to interactions between the activated carbon and metoprolol.

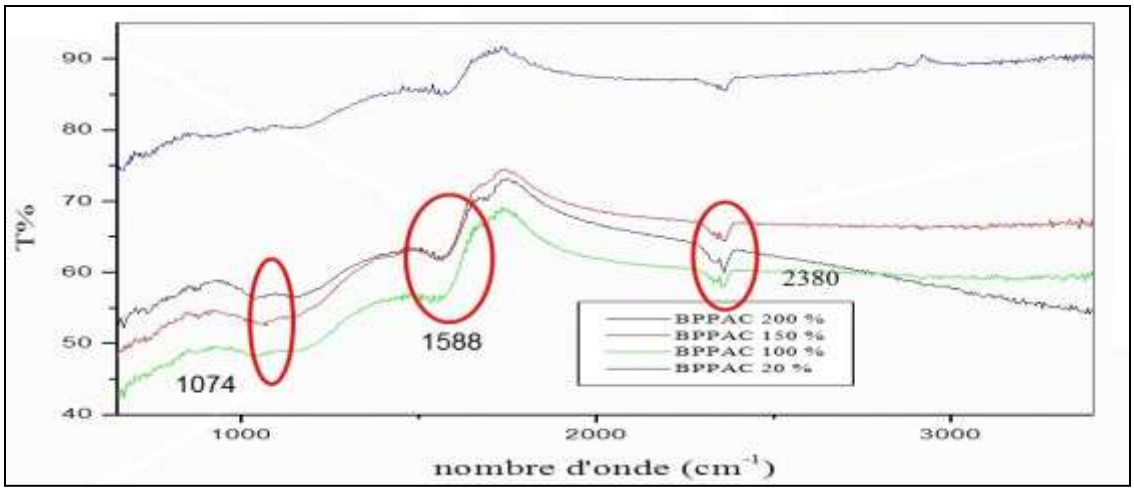

Figure 4. FTIR spectra of BPPAC carbons obtained at different H_3PO_4 activation ratios**.**

Adsorption mechanism

The relationship between the pHpzc of BPPAC ≈ 4 and the pKa of metoprolol ≈ 9.5 highlights the role of electrostatic interactions in the change of adsorption with pH.
The excellent fit to the pseudo-second-order model ($R^2 \approx 1$) describes the adsorption kinetics, while the Langmuir 2 model (R^2 up to 0.998) is consistent with adsorption occurring mainly as a monolayer.

Thermodynamics

The adsorption capacity decreases as the temperature increases :

20 °C → 110.87 mg/g
30 °C → 106.93 mg/g
50 °C → 95.44 mg/g

$\Delta G° < 0$ → thermodynamically favorable process
$\Delta H° < 0$ → exothermic process
$\Delta S° < 0$ → decreased disorder at the solid–solution interface

Overall interpretation

The performance of BPPAC results from the combined effect of its high specific surface area, its porous structure, its surface chemistry, and adsorbate–adsorbent interactions. These results confirm the value of activating bean pods with H_3PO_4 to produce an effective adsorbent for removing pharmaceutical pollutants in aqueous media.

CONCLUSION

BET specific surface area of BPPAC 200% = 1100.39 m^2/g
Maximum metoprolol removal = 98%
Fast equilibrium for $C_0 < 150$ mg/L ≈ 5 min
Pseudo-second-order model = $R^2 \approx 1$
Langmuir 2 model at 20 °C $R^2 = 0.998$
Maximum desorption = 60%

Activation of bean pods with H_3PO_4 at 200% yields the material with the best performance among the conditions studied. Metoprolol adsorption is rapid, well described by the pseudo-second-order model and consistent with adsorption occurring mainly as a monolayer according to the Langmuir model.
The process is thermodynamically favorable and exothermic ($\Delta G° < 0$; $\Delta H° < 0$). Desorption of up to 60% of the adsorbed metoprolol was achieved with a HNO_3 solution at 0.1 mol/L.
The valorization of bean pods into activated carbon constitutes a promising approach combining the removal of pharmaceutical pollutants, the valorization of agricultural waste, and the circular economy.

ABSTRACT

Global climate change poses a significant threat to agricultural production and food security, particularly by increasing the frequency and severity of abiotic stress factors such as salt and drought. These stress conditions lead to osmotic imbalance, ion toxicity (especially Na^+/K^+ imbalance), excessive reactive oxygen species (ROS) production, and disruption of cell membrane integrity in plants, resulting in growth and yield losses. Melatonin, a critical plant hormone, stands out in the fight against these negative effects due to its strong antioxidant properties and regulatory roles in stress response mechanisms. Melatonin improves essential physiological processes such as seed germination, photosynthesis, and carbon fixation, as well as enhancing stress tolerance by promoting the accumulation of osmolytes, sugars, and other endogenous hormones (auxins, gibberellic acid, and cytokinins). Furthermore, it enhances the activity of enzymatic and non-enzymatic antioxidant systems, enabling effective ROS clearance and regulating the expression of stress-responsive genes. Studies show that melatonin plays a significant role in maintaining Na^+/K^+ ion homeostasis, preserving cell membrane integrity, reducing lipid peroxidation, improving photosynthetic performance, and maintaining plant water balance under salt and drought stress. It also plays important roles in the regulation of stress-related genes and phytohormone signaling networks. These multifaceted effects of melatonin make it stand out as an environmentally friendly biostimulant in sustainable agricultural practices and a promising approach to enhancing stress tolerance against the negative impacts of climate change. A deeper understanding of melatonin's protective mechanisms on ion balance and membrane integrity will pave the way for innovative approaches to improving stress tolerance.

Keywords: melatonin, salt stress, drought stress, ion homeostasis, membrane integrity, antioxidant defense.

INTRODUCTION

Climate change is one of the most important factors threatening agricultural production and food security. Environmental stressors such as increasing temperatures, drought, floods, frost, and changing rainfall patterns directly and negatively affect the growth, development, and yield processes of plants. In particular, abiotic stress factors such as salinity, drought, extreme heat, and cold lead to significant changes in the physiological and molecular structures of plants. Recent studies allow us to understand more closely the adaptation mechanisms that plants develop against such stress conditions. Findings on how plants can survive in situations where

multiple stressors occur simultaneously have reached remarkable dimensions (Li et al., 2009; Hu et al., 2023).

The two most common abiotic stress factors limiting agricultural production on a global scale are salinity and drought. According to the FAO's Global Report on Saline Soils published in 2024, approximately 1.38 billion hectares of land worldwide are affected by salinity, and approximately one billion hectares are at risk of salinization. Climate change, dwindling water resources, and unsustainable land management indicate that these areas will expand even further in the coming years. Salt stress causes osmotic pressure and ion toxicity in plants, reducing the water uptake capacity of roots; this suppresses growth and development, leading to crop losses (Rozema and Flowers, 2008; Abobatta, 2020). Similarly, drought stress disrupts the water balance of plants by reducing the amount of water in the root zone, causing yield losses in many crops. In fact, yield losses caused by drought are higher compared to many other abiotic stress factors. Although the effect of drought varies depending on the plant species, developmental stage, and the duration and severity of the stress, it negatively affects growth and physiological activities at every stage of development (Valliyodan and Nguyen, 2006). In addition, drought disrupts the integrity of the cell membrane, negatively affecting ion transport and nutrient balance; it reduces the transpiration rate but does not limit nutrient uptake to the same extent (Farooq et al., 2012).

Plants develop numerous adaptation mechanisms at the morphological, physiological, biochemical, and molecular levels to minimize the negative effects of salinity and drought. Morphological changes such as reduced leaf area, slowed shoot growth, and increased root development, as well as physiological responses like stomatal closure, increased water use efficiency, and maintenance of cellular turgor, are just a few examples (Krasensky and Jonak, 2012). In addition, the accumulation of osmolytes such as proline, glycine betaine, and soluble sugars contributes to the maintenance of cellular osmotic balance, while the synthesis of stress-related proteins aids in the stabilization of biomolecules. However, salt and drought stress lead to disruption of cell membrane integrity, overproduction of reactive oxygen species (ROS), and particularly disruption of Na^+/K^+ ion homeostasis (Maryum et al., 2022). Loss of selective permeability of the cell membrane, disruption of ion balance, and ROS accumulation lead to decreased photosynthetic activity, slowed growth, and consequently, crop losses (Apel and Hirt, 2004; Chaves et al., 2009). Therefore, plants activate antioxidant defense systems to limit ROS accumulation and adapt to stress conditions by regulating phytohormone signaling networks (Rao et al., 2025).

Recent research highlights melatonin as a crucial signaling molecule in the regulation of these defense mechanisms. First identified as a neurohormone in animals, the discovery that melatonin is also synthesized in plants has increased interest in its role in regulating plant growth and development and abiotic stress tolerance (Arnao and Hernández-Ruiz, 2019; Ramasamy et al., 2023). In addition to its strong antioxidant properties, melatonin reduces ROS-induced oxidative damage by increasing the activity of antioxidant enzymes such as superoxide dismutase (SOD), catalase (CAT), and peroxidase (POD), promotes osmolyte accumulation, and regulates plant stress responses by interacting with phytohormones such as auxin, gibberellic acid, and cytokinin (Roychoudhury, 2023; Khan et al., 2024).

Among melatonin of protective effects against salt and drought stress, maintaining ion balance and membrane integrity is of critical importance. Studies show that melatonin applications contribute to ionic homeostasis by maintaining Na^+/K^+ ion balance, regulate membrane permeability by reducing lipid peroxidation occurring in the cell membrane, and thus protect cell integrity (Hassan et al., 2022; Zeng et al., 2022). Furthermore, melatonin has been reported to regulate the activity of various ion transporters, primarily Na^+/H^+ antiporters, strengthen the antioxidant defense system, and increase plant stress tolerance by modulating the expression of genes related to stress response (Wei et al., 2022). However, studies comprehensively

addressing the physiological, biochemical, and molecular mechanisms of melatonin in maintaining ionic homeostasis and cell membrane integrity, particularly under salt and drought stress conditions, are limited. In this study, the role of melatonin in maintaining ionic balance and cell membrane integrity under salt and drought stress was evaluated in light of current literature; These mechanisms have been shown to have potential contributions to increasing stress tolerance in plants and to sustainable agricultural practices.

MELATONIN BIOSYNTHESIS AND PHYSIOLOGICAL FUNCTIONS IN PLANTS

Melatonin, or N-acetyl-5-methoxytryptamine, is an important biomolecule with a very wide distribution in the biological world, found in almost all living organisms. First discovered in vertebrates, this molecule was considered for many years to be a neurohormone exclusive to animals (Lerner et al., 1958; Reiter, 1991). However, in 1995, two independent research groups revealed that melatonin is also found in plants, giving a completely different direction to studies in this field. These initial findings, especially on cereals, fruits, and vegetables, opened the door to research into the role of melatonin in plant physiology (Dubbels et al., 1995; Hattori et al., 1995). Today, it is known that melatonin is synthesized in very different organism groups such as bacteria, algae, higher plants, invertebrates, and vertebrates. This clearly demonstrates that melatonin is an evolutionarily well-established molecule with fundamental biological functions (Posmyk and Janas, 2009).

In all living organisms, the starting point for melatonin synthesis is tryptophan, an essential amino acid. Tryptophan is a precursor not only for melatonin but also for serotonin, found in all plants and animals, and indole-3-acetic acid (auxin), an important hormone in plants. Although melatonin can be produced from tryptophan via different biosynthetic pathways, the most widely accepted pathway is as follows: Tryptophan → Tryptamine → Serotonin → 5-methoxytryptamine → Melatonin. Numerous enzymes are involved in this conversion chain (Zhao et al., 2019). In the first step, the tryptophan decarboxylase (TDC) enzyme converts tryptophan to tryptamine. Next, the tryptamine 5-hydroxylase (T5H) enzyme comes into play and converts tryptamine into serotonin; the presence of this enzyme has been particularly proven in rice plants (Kang et al., 2007). In plants, the conversion from serotonin to 5-methoxytryptamine occurs via the acetylserotonin methyltransferase (ASMT/COMT) enzyme. This enzyme first converts serotonin to N-acetylserotonin (NAS). Finally, the 5-methoxytryptamine N-acetyltransferase/arylalkylamin N-acetyltransferase (SNAT/AANAT) enzyme completes the synthesis by converting this molecule into melatonin.

Melatonin is a signaling molecule that plays a key role in regulating daily (circadian) and seasonal rhythms in both plants and animals. In animals, melatonin synthesis increases during the dark and decreases during the light, and this cycle is considered a fundamental mechanism in the functioning of the biological clock (Reiter, 1991). A similar situation exists in plants; melatonin levels are regulated by photoperiod and circadian rhythm. However, this variation can differ depending on the plant species, developmental stage, and environmental conditions (Arnao and Hernández-Ruiz, 2015; 2020). The general trend is that melatonin synthesis peaks during the dark or just before sunrise. However, in some species, a second wave of synthesis can be observed during daylight hours due to oxidative stress triggered by high light intensity and temperature. This shows that melatonin not only regulates biological rhythms but is also active in sensing environmental signals and activating protective mechanisms against oxidative stress. With all these characteristics, melatonin is considered an important biostimulant that bridges the gap between photoperiodic responses and adaptation to environmental stress in plants.

In plants, melatonin is a versatile biomolecule that regulates growth and development. Its chemical structure and biosynthesis pathway are similar to indole-3-acetic acid (IAA) in the auxin group. Therefore, it can promote root formation, hypocotyl elongation, shoot

development, and overall plant growth, exhibiting auxin-like effects, especially at low concentrations (Kanvar et al., 2018; Arnao and Hernández-Ruiz, 2020). However, the direction and intensity of these effects vary depending on the plant species, developmental stage, and the applied melatonin dose. Indeed, high concentrations of melatonin can even exhibit growth-suppressive effects. Beyond this, melatonin supports plant development by playing a role in many physiological processes such as seed germination, photosynthesis, chlorophyll synthesis, regulation of root architecture, and delaying senescence.

One of melatonin's most notable properties is its function as a powerful antioxidant and stress regulator in plants (Yu et al., 2018). Melatonin, in addition to directly scavenging reactive oxygen species (ROS), limits oxidative damage by increasing the activity of antioxidant enzymes such as SOD, CAT, POD, and glutathione reductase (GR). This protects cell membrane integrity, reduces lipid peroxidation, and increases membrane stability. Furthermore, melatonin enhances plant tolerance to numerous abiotic stress conditions such as salinity, drought, low temperature, and heavy metal stress by promoting osmolyte accumulation, increasing photosynthetic efficiency, and regulating the expression of stress-related genes (Zhang et al., 2015; Zeng et al., 2022). With all these multiple effects, melatonin promotes plant growth. It stands out as a powerful regulatory molecule that stimulates and enhances stress tolerance.

MELATONIN-MEDIATED PROTECTION AGAINST SALT AND DROUGHT STRESS

Salinity and drought are the primary abiotic stress factors limiting growth and development in plants. These two stressors trigger a chain reaction of physiological disturbances in the plant, including osmotic pressure, ion toxicity, water imbalance, and excessive production of reactive oxygen species (ROS). In this process, the accumulation of Na^+ ions within the cell increases while K^+ uptake decreases; this imbalance leads to disruption of ion homeostasis, negatively affecting enzyme activity, metabolic processes, and photosynthesis performance. Simultaneously, excessive ROS production accelerates lipid peroxidation, impairs the selective permeability of the cell membrane, and leads to loss of membrane integrity. As a result of all these disruptions, electrolyte leakage from cells increases, water use efficiency decreases, and plant growth and yield are significantly reduced (Li et al., 2019; Yusuf et al., 2024).

Recent studies have shown that melatonin acts as a multifaceted regulator in mitigating these physiological and biochemical disruptions. Melatonin, as a powerful free radical scavenger, not only directly neutralizes ROS but also enhances plant defense capabilities by increasing the activity of antioxidant enzymes such as SOD, CAT, ascorbate peroxidase (APX), POD, and GR. It also contributes to maintaining cellular osmotic balance by promoting the accumulation of osmolytes and soluble sugars. Furthermore, it supports cell membrane stability by reducing lipid peroxidation and malondialdehyde (MDA) formation (Hassan et al., 2022; Pardo-Hernández et al., 2020).

One of melatonin's most notable effects is its regulatory role in maintaining ionic homeostasis. Studies have shown that melatonin application limits Na^+ accumulation and reduces K^+ loss by regulating the expression of Na^+/H^+ antiporters and high-affinity K^+ transporters, thus significantly contributing to the maintenance of intracellular Na^+/K^+ balance (Yan et al., 2020; 2021). Maintaining ion balance, preserving membrane integrity, and reducing oxidative damage allows for more efficient photosynthetic mechanisms. This slows down chlorophyll degradation, improves gas exchange, and increases water use efficiency. In addition, melatonin contributes to the regulation of genes related to stress responses and various phytohormone signaling networks, further strengthening the adaptation of plants to salt and drought conditions (Tahjib-Ul-Arif et al., 2025). With all these multifaceted protective effects, melatonin has great potential as an environmentally friendly and effective bio-stimulant in sustainable agricultural

practices; It is considered one of the prominent biomolecules, especially in strategies aimed at maintaining ionic homeostasis and membrane integrity.

MOLECULAR MECHANISMS UNDERLYING MELATONIN-MEDIATED STRESS TOLERANCE

Melatonin not only functions as a powerful antioxidant in plants, but also plays a crucial role as a bioregulator, regulating numerous signaling pathways and enhancing tolerance to salinity and drought. Recent research reveals that the protective effect of melatonin is based on molecular processes such as the regulation of stress-related gene expression, coordination of signaling interactions between phytohormones, calcium (Ca^{2+})-mediated signal transduction, and control of nitric oxide (NO)-related redox mechanisms. All these mechanisms work together and interactively to maintain ion balance, preserve cell membrane integrity, and enable plants to adapt more successfully to stressful conditions (Gu et al., 2022; Ahmad et al., 2023; Pan et al., 2023).

One of melatonin's most critical roles is its ability to reshape the expression of stress-responsive genes. Under challenging conditions such as salt and drought, melatonin applications regulate the activity of stress-sensitive transcription factors and genes involved in defense mechanisms, enabling plants to more accurately interpret stress signals and develop appropriate defense strategies (Byeon and Back, 2014). In addition, melatonin controls ROS accumulation by increasing the expression of genes encoding enzymes related to the antioxidant defense system, minimizes oxidative damage, and contributes to the maintenance of cellular redox balance (Sheshadri et al., 2018; Gu et al., 2022). Particularly under salt stress, melatonin regulates genes associated with ion transport and homeostasis, limiting Na^+ accumulation in the cytoplasm, maintaining K^+ levels in balance, and thus reducing ion toxicity (Tahjib-Ul-Arif et al., 2025).

Another vital mechanism where melatonin exerts its influence is the coordination of complex signaling networks among phytohormones. Melatonin is no longer seen as a molecule acting alone; Melatonin is considered a regulator that shapes plant stress responses in interaction with abscisic acid (ABA), auxin (IAA), gibberellin acid (GA), cytokinins (CK), ethylene (ET), jasmonic acid (JA), and salicylic acid (SA) (Samanta and Roychoudhury, 2023). Particularly in conditions such as drought and salinity, melatonin's adjustments to ABA levels play a crucial role in controlling stomata, increasing water use efficiency, and maintaining osmotic balance. Melatonin also promotes root development via the auxin signaling pathway, supporting water and mineral uptake; it regulates cytokinin and gibberellin metabolism, ensuring continued growth. In addition, by interacting with JA and SA signaling pathways, it further strengthens antioxidant defenses and the activation of stress-related genes (Ahmad et al., 2023; Samanta and Roychoudhury, 2023).

Calcium (Ca^{2+}) is one of the key second messenger molecules involved in the transmission of stress signals in plants. Melatonin is known to regulate Ca^{2+}-mediated signal transduction, supporting the activation of stress response genes, the antioxidant defense system, and ionic homeostasis. This makes the adaptation mechanisms that plants develop against salt and drought stress more effective (Liu et al., 2020; Huang et al., 2022).

The effects of melatonin on stress tolerance are further enhanced by its interaction with NO. NO acts as an important signaling molecule in plants and, together with melatonin, plays a role in activating the antioxidant defense system, maintaining ROS balance, and regulating redox homeostasis. This interaction significantly contributes to mitigating oxidative damage, maintaining cell membrane integrity, and increasing plant tolerance to salt and drought (Pardo-Hernández et al., 2020; Ahmad et al., 2023; Kolupaev et al., 2024).

In summary, melatonin is a key player in plant defense against salinity and drought by activating multi-layered molecular mechanisms such as the regulation of stress response genes, coordination of phytohormone interactions, and management of Ca^{2+} and NO-mediated

signaling pathways. This integrated signaling network provides a strong foundation for maintaining ionic homeostasis, preserving cell membrane integrity, and enhancing overall stress tolerance.

CONCLUSIONS

As the effects of global climate change become increasingly apparent, salinity and drought stand out as the most significant abiotic stressors threatening agricultural production and food security. These challenging conditions hinder plant growth and lead to yield losses through mechanisms such as osmotic imbalance, ion toxicity, oxidative damage, and disruption of cell membrane integrity. However, recent research reveals that melatonin acts as a versatile and powerful regulator in mitigating these negative effects. Melatonin significantly increases plant tolerance to salinity and drought by activating the antioxidant defense system, maintaining ion balance and cell membrane integrity, supporting photosynthetic activity, and regulating gene expression and phytohormone signaling networks. With all these properties, melatonin stands out as an environmentally friendly, effective, and promising bio-stimulant for sustainable agricultural practices. Further elucidation of the molecular mechanisms related to melatonin in different plant species and under varying stress conditions is of paramount importance. This will both increase the efficiency of melatonin in agricultural applications and make significant contributions to the development of new plant varieties with high stress tolerance.

ABSTRACT

Crustaceans are an important component of benthic communities and can provide valuable information on environmental conditions and ecological change in marine ecosystem. This study investigates the structure and seasonal dynamics of crustacean assemblages along the Himara coast, comparing the Porto Palermo protected area with the Qeparo coastal area. Sampling was conducted during four periods: autumn 2023, spring 2024, autumn 2024, and spring 2025. At each site and sampling period, three transects and three sampling areas were surveyed. A total of 58 crustacean taxa were recorded, and their abundance was quantified. In addition, the abundance and percentage cover of four balanid species (Cirripedia) were assessed to provide further information on the structure of the sessile crustacean community. Community composition and seasonal variation were analyzed using multivariate statistical approaches, including PERMANOVA, together with analyses of taxonomic richness and abundance. The study aims to determine whether crustacean assemblages differ significantly between Porto Palermo and Qeparo, whether community structure varies among seasons, and whether the magnitude and pattern of spatial differences change seasonally. The results will provide baseline information on the composition, abundance, and seasonal dynamics of crustacean assemblages and identify common and characteristic taxa in the two coastal areas. This information will contribute to the long-term ecological assessment of the Porto Palermo protected area and Qeparo coastal site.

Key words: benthic community, crustaceans, biodiversity, protected areas, seasonal variation, multivariate statistical analyses.

INTRODUCTION

Rocky coastal ecosystems are among the most heterogeneous marine habitats and support diverse benthic communities due to the structural complexity of the hard substrates (Gimenez et al. 2022). Crevices, cavities and associated algal communities provide suitable conditions for a wide range of organisms and contribute to the maintenance of high levels of coastal biodiversity. In the Mediterranean Sea, one of the areas with the highest marine biodiversity on a global scale, but also under constant anthropogenic pressure (Bianchi & Morri 2000; Coll et al. 2010), rocky coasts are particularly important habitats, where the composition and structure of the benthic community can vary significantly at relatively small spatial scales and across seasons (Marina et al. 2015; Sturaro et al. 2014; Sala et al. 2012).

Crustaceans constitute an important group of benthic marine communities. They include mobile taxa associated with rocky substrates and algal habitats, as well as sessile forms such as balanids (Cirripedia) (Hamdy et al. 2017).

For the crustacean community, seasonal changes can result in changes in species richness, abundance, and community composition (Scipione & Zupo 2010; Gambi et al. 1992; Rumbold et al. 2017). Recent studies have shown that the presence and dominance of crustaceans, both native and non-native, can vary significantly from month to month according to environmental context, highlighting that without repeated sampling, biodiversity changes unnoticed (Kazanavičiūtė et al. 2024).

The Ionian coast consists of extensive rocky habitats that support diverse marine benthic communities, where most studies have focused on macroinvertebrates, macroalgae and Posidonia oceanica meadows (Beqiraj et al., 2008; Beqiraj & Kashta, 2013; Beqiraj, 2014; Beqiraj & Ballesteros, 2018; Fraschetti et al., 2011; Kashta et al., 2005; Kashta et al., 2007; Kashta & Beqiraj, 2009; Kasemi et al., 2008; Kasemi et al., 2013; Pititto etal., 2009; Ruci et al., 2014; Ruci et al., 2023), but detailed studies on the spatial and seasonal dynamics of the crustacean community remain relatively limited (Vaso & Gjiknuri (1993).

A comparison of the two areas, Porto Palermo and Qeparo, across seasons may provide an opportunity to assess both spatial and temporal components of crustacean community structure (Sturaro et al. 2014; Di Franco et al. 2009).

The aim of this study is to identify the crustacean community structure and seasonal changes along the Himara coast, comparing the protected area of Porto Palermo (Beqiraj et al. 2008, Beqiraj & Kashta 2013, Beqiraj 2014), with the coastal area of Qeparo.

MATERIAL AND METHODS

Sample collection

Benthic crustaceans were collected from two sampling sites Qeparo (40°03'05"N19°48'45"E) and Porto Palermo Bay (40°03'41"N19°47'34"E) along the Himara coast, in shallow water, during four sampling periods: Autumn 2023, Spring 2024, Autumn 2024, and Spring 2025 (Fig. 1). At each site and sampling period, three transects were established, and within each transect three quadrats were randomly sampled (nine replicates per site per period), using conventional techniques for benthic samples from hard substrates, as described by Bianchi et al. (2003), Keklikoglou et al. (2018), Mikac et al. (2020), Salomidi (2003), and Zenetos et al. (2000). Each quadrat consisted of a standardized 50 × 50 cm frame, subdivided into 25 equal squares of 10 × 10 cm, to facilitate systematic counting of individuals. After collection, Samples were preserved using 4% formaldehyde solution and were taken to the laboratory for further analysis. Taxonomic identification of crustacean specimens followed standard identification guides for Mediterranean Crustacea including Ruffo (ed., 1982–1998, Parts 1–4), Riedl (1991), Argano et al. (1995), Zettler & Zettler (2017), and Trainito (2004). The nomenclature and systematic classification of all identified taxa were verified against the World Register of Marine Species (WoRMS).

Figure 1. Map of sampling sites: a) Porto Palermo; b) Qeparo

Statistical analyses

Statistical analysis assessed both univariate and multivariate characteristics of crustacean communities in Porto Palermo and Qeparo during the four sampling periods. Taxonomic richness and abundance were used to describe the main characteristics of the communities and to assess spatial and seasonal variability. Total abundance (N) was the number of individuals

recorded per replicate, summed across replicates for each zone and season. Taxonomic richness (S) was the number of crustacean taxa identified per replicate, zone, and season. We also calculated relative abundance for each taxon, following the approach used by (Kazanavičiūtė et al. 2024). This was the percentage of a taxon's abundance out of the total abundance in each zone-season combination. Relative abundance let us identify dominant and characteristic taxa, regardless of differences in sampling effort or total abundance between zones and seasons.

We assessed changes in crustacean community composition using multivariate analyses based on a Bray–Curtis similarity matrix (Bray & Curtis 1957) calculated from square-root transformed abundance data, following standard practice for community-level analyses (Clarke & Warwick 2001). We used non-metric multidimensional scaling (NMDS; Kruskal 1964; Clarke 1993) to show patterns of similarity between samples. We used PERMANOVA (Anderson 2001; McArdle & Anderson 2001) to test the effects of location and season, and their interaction, on community composition. The location × season interaction told us whether the difference between Porto Palermo and Qeparo stayed the same across seasons, or changed over time.

RESULTS AND DISCUSSION

There were 58 crustaceans identified from both localities for all periods. Out of this total number, 47 crustacean species were found in Porto Palermo while 40 crustacean species were found in Qeparo.

Richness and abundance both changed by site and season. Porto Palermo had more taxa than Qeparo in three of the four periods: 39 vs. 23 in autumn 2023, 31 vs. 25 in spring 2024, 28 vs. 25 in spring 2025. Only autumn 2024 was different Qeparo had slightly more taxa there (19 vs. 17) (Figure 2a).

Abundance told the opposite story. Qeparo had more individuals than Porto Palermo in both spring periods: 3955 vs. 1339 in 2024, 3848 vs. 1320 in 2025.

Porto Palermo remained higher only in autumn 2023 (2995 versus 1979). This shows something important: Porto Palermo has more species but fewer individuals; Qeparo has fewer species but with high peaks of abundance. Making them two areas with different dynamics (figure2b).

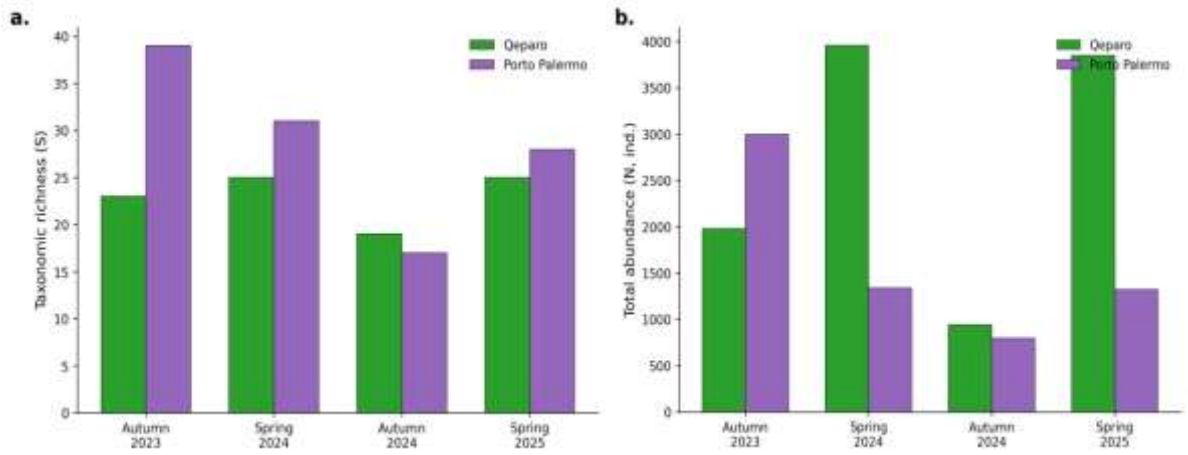

Figure 2: Taxonomic richness (a) and total abundance (b) of crustacean communities.

In Qeparo, one of the abundant taxa in all seasons was *Aphohyale crassipes*. The relative abundance of this taxon increased from autumn 2023 to autumn 2024. In addition, in spring 2024, *Heteroanais oerstedii* was one of the abundant taxa, whereas *Ptolyhyale eburnea* was valuable. In spring 2025, the most abundant taxon was *Autonoë angularis*. Moreover, *Protohyale schmidtii* had an obvious increase in this season (figure 3).

In Porto Palermo, *Aphohyale crassipes* was one of the dominating taxa in all seasons, particularly in autumn 2024. Another taxon that was abundant in autumn 2023 was *Pleonexes helleri*, whereas in spring 2024 and autumn 2024 *Elasmopus pocillimanus* had an obvious increase. Finally, in spring 2025, the abundant taxon was *Elasmopus pocillimanus* along with *Aphohyale crassipes* (figure 3).

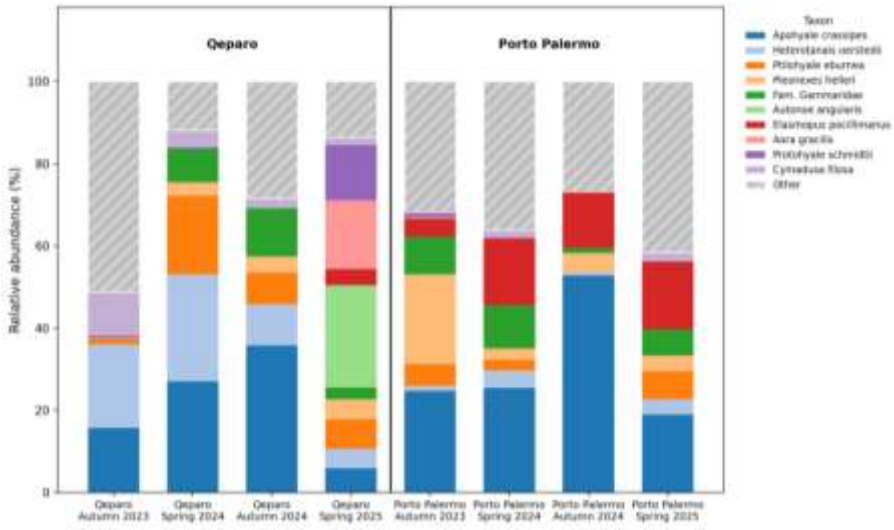

Figure 3: Seasonal abundance of dominant Crustacean taxa (Qeparo & Porto Palermo, 2023-2025)

Points corresponding to Qeparo and Porto Palermo communities (figure 4) partly intersect in the middle of the chart; therefore, the two communities share some similarities. However, the distribution of the points belonging to Qeparo is broader than the distribution of points belonging to Porto Palermo.

Consequently, dispersion is the characteristic that differs the stability of the samples of the two communities. In particular, Qeparo is characterized by a higher diversity of the samples, while the samples from Porto Palermo are similar to each other.

Season is another characteristic that influences the location of the points. For instance, the points of spring 2025 (diamonds) for Qeparo community are isolated and positioned in the upper right corner. Moreover, the points of autumn 2024 (triangles) for the two communities are positioned below the other seasons' points. Thus, seasons influence the location of the sample almost as much as areas do.

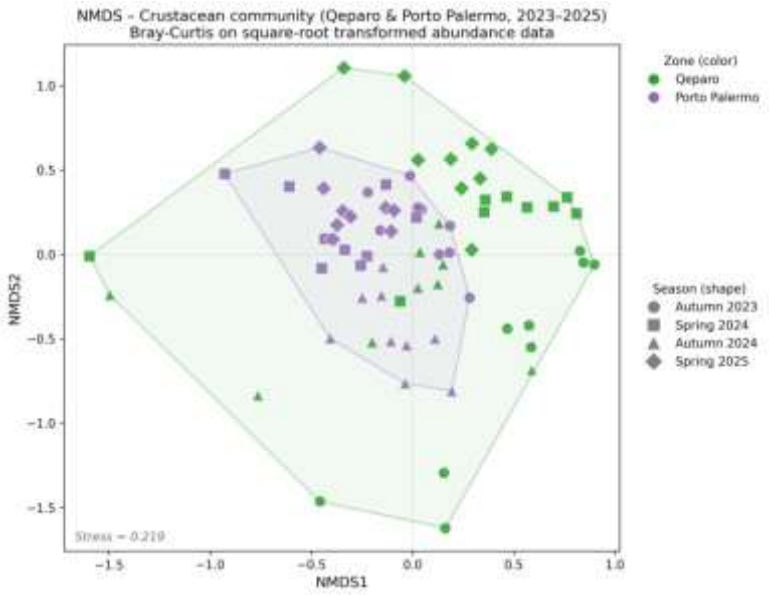

Figure 4: Comparison of the Crustacean community between the two sampling areas Qepare & Porto Palermo

The PERMANOVA analysis (Table 1) evidenced highly significant differences for both factors (zone and season) and their interaction. Assemblage structure different significantly between Qeparo and Porto Palermo (Pseudo-F = 11.11, P (perm) = 0.001), among the four sampling periods (Pseudo-F = 6.67, P(perm) = 0.001), and the zone × season interaction is also highly significant (Pseudo-F = 4.70, P(perm) = 0.001), indicating that spatial differences between the two sites are not consistent through time.

Such assemblage patterns were well represented by the nMDS plot (Figure 4), which showed partial separation between Qeparo and Porto Palermo samples, with greater dispersion of Qeparo replicates along both axes. This pattern is consistent with the higher temporal variability in taxonomic composition and abundance recorded at Qeparo across the four sampling periods, as reported in Figure 2.

The residual variance (58.6%) remained comparatively high, a pattern commonly observed in crustacean assemblage data from hard-bottom habitats, and likely reflects fine-scale variability among replicates within each zone and season, in addition to the structuring effects of zone and season themselves.

Table 1. Results of (PERMANOVA) testing the effects of zone, season, and their interaction on crustacean assemblage structure, based on a Bray–Curtis resemblance matrix calculated from square-root transformed abundance data (999 permutations).

Source	Df	MS	Pseudo-F	P(perm)
Zone	1	1.7091	11.11	0.001
Season	3	1.0261	6.67	0.001
Zone × Season	3	0.7223	4.7	0.001
Res	64	0.1538		
Total	71			

CONCLUSIONS

A distinction was found between Porto Palermo and Qeparo. We documented 58 taxa of crustaceans in total. Porto Palermo had more taxa (47) than Qeparo (40) and shared 29 taxa.

The richness and abundance were inversely correlated. While Porto Palermo showed a higher number of species, Qeparo had more individuals. Qeparo had also higher peaks in abundance, which indicates different functioning of the sites instead of the latter being "richer".

The effect of the season was also observed. Zone × season interaction was significant, and thus the difference between Porto Palermo and Qeparo differed from season to season.

The dominant taxa are also telling their stories. *Apohyale crassipes* remained dominant in Porto Palermo throughout all four seasons. In Qeparo, the dominant taxon changed every season, first *Heterotanais oerstedii*, then *Ptilohyale eburnea*, then *Autonoe angularis* and *Protohyale schmidtii*. Thus, the Qeparo community shows a lower stability than the Porto Palermo community.

In general, we can say this study gives an initial baseline on the crustacean community of this area of the Himara coast. This information will be useful for future monitoring of the protected Porto Palermo area in comparison to Qeparo as a reference area.

ABSTRACT

Refractory gold ores pose significant challenges to gold extraction and require effective pretreatment strategies to improve recovery. Their refractory behaviour mainly stems from complex mineralogical composition; gold particles may occur as fine disseminations or be associated with sulfide and gangue minerals, limiting their accessibility during conventional extraction processes such as direct cyanidation.

As high-grade, readily treatable gold deposits become increasingly depleted, industrial interest has shifted toward refractory gold ores, which generally respond poorly to conventional extraction methods. Under standard cyanidation conditions, gold recovery from these ores is often limited, frequently remaining below 80%. This refractory behaviour may result from several factors, including cyanide-consuming elements. Copper, in particular, can strongly interfere with cyanidation at elevated concentrations because it forms stable cyanide complexes, increasing cyanide consumption and reducing cyanide available for gold dissolution.

In this context, the present study aimed to evaluate the leaching behaviour of the investigated ore and determine suitable pretreatment and leaching conditions to improve gold extraction. For this purpose, cyanide leaching tests were conducted in conjunction with physicochemical and mineralogical characterisation of the ore. The results showed that cyanide consumption increased with increasing initial cyanide concentration, suggesting the presence of cyanide-reactive species, particularly copper- and iron-bearing minerals. These findings confirm the ore's refractory behaviour and emphasise the need for an optimised pretreatment strategy to reduce reagent consumption and enhance gold recovery. The NH_3–$Pb(NO_3)_2$ pretreatment increased gold recovery from 58% to 85% under 0.3 g/L NaCN conditions.

INTRODUCTION

Refractory gold ores represent an increasing challenge for the extractive metallurgy industry because their complex mineralogical composition often limits the effectiveness of conventional cyanidation. Gold may occur as fine inclusions or may be physically encapsulated within sulfide and other gangue minerals, restricting contact between gold and the cyanide solution (La Brooy et al., 1994; Fernández et al., 2000). In addition, refractory ores may contain several mineralogical constituents and elements, including Fe, Cu, Zn, As, Sb, Pb, Hg, Se, Te, carbonaceous matter, and silicate phases, which can adversely affect cyanidation through cyanide consumption, oxygen consumption, passivation, preg-robbing, or other mechanisms (Larrabure & Rodríguez-Reyes, 2021). **Copper is particularly problematic** because readily cyanide-soluble copper minerals form stable copper–cyanide complexes, increasing cyanide consumption and potentially reducing gold extraction efficiency (Jiang et al., 2001; Bas et al., 2015).

During cyanide leaching, cyanide-soluble copper minerals may dissolve and form stable copper–cyanide complexes (Breuer et al., 2005; Medina & Anderson, 2020). These reactions consume free cyanide, decrease its availability for gold dissolution, and increase reagent consumption and operating costs (Oraby & Eksteen, 2014; Medina & Anderson, 2020). Dissolved copper–cyanide species may also complicate downstream gold recovery, cyanide recycling, and effluent detoxification (Adams et al., 2008). Consequently, the mineralogical form and concentration of cyanide-soluble copper are important parameters controlling the metallurgical performance of copper-bearing gold ores.

Several pretreatment strategies have therefore been investigated to minimise copper interference before gold cyanidation, including acid pre-leaching, oxidative treatment, roasting, bio-oxidation, and ammonia-based pretreatment (La Brooy et al., 1994; Bas et al., 2015). Alternative processing routes involving selective copper leaching and non-cyanide lixiviants such as glycine, thiosulfate, thiocyanate and chloride systems have also been proposed (Muir, 2011; Maganga et al., 2023). The effectiveness of these approaches depends strongly on copper mineralogy, gold association, and mineral liberation, making detailed mineralogical and chemical characterisation essential for selecting an appropriate treatment route (Maganga et al., 2023; Deschênes et al., 1997).

This issue is particularly relevant to gold resource development in southern Algeria, where several gold occurrences are distributed across the Hoggar region, including deposits in Tamanrasset, Ain Guezzam, and surrounding areas. Although these deposits represent important metallurgical potential, the mineralogical composition and processing behaviour of many occurrences remain insufficiently characterised, particularly their response to conventional cyanidation. The refractory behaviour of the Amesmessa ore is not primarily attributed to gold encapsulation, but to cyanide-consuming copper-bearing sulfide minerals, which reduce free cyanide availability and may promote gold surface passivation during cyanidation. A better understanding of these mineralogical constraints and their influence on reagent consumption and gold dissolution is therefore essential to evaluate the metallurgical potential of these resources and develop suitable processing strategies.

Although ammonia-assisted cyanidation has been previously investigated for copper–gold ores, most reported studies have focused on generic copper-rich ores or oxidised copper–gold

systems. The novelty of this work lies in evaluating and optimising a combined ammonia–lead nitrate pretreatment strategy for the Algerian Amesmessa gold ore from the SARL Tinmerkadin Ech 82 deposit, located about 465 km southwest of Tamanrasset in southern Algeria. This study investigates the mineralogical and chemical characteristics of this refractory copper-bearing ore and examines how copper-bearing phases affect gold extraction, cyanide consumption, and subsequent gold adsorption onto activated carbon. Unlike previous studies, this work evaluates the ore's response at cyanide concentrations close to current plant operating conditions (300 ppm NaCN), establishing relationships between ore mineralogy, copper content, reagent consumption, and gold recovery. The results show that targeted chemical conditioning with ammonia–lead nitrate can overcome mineralogical constraints, particularly those associated with copper-bearing sulfides and cyanide-consuming species, providing a more efficient processing strategy for refractory copper–gold ores.

MATERIAL AND METHOD

A representative ore sample was collected from the SARL Tinmerkadin (Ech 82) gold ore deposit in the Amesmessa gold district, southern Algeria, approximately 465 km southwest of Tamanrasset. The sample was crushed to −4 mm using a jaw crusher, followed by a roll crusher, and then ground to obtain a particle size distribution of 80% passing 75 µm (d_{80} = 75 µm). The ground material was riffled into 300 g portions for the leaching experiments. Depending on the experimental series, 300 g of ore was contacted with 500 mL to 2 L of leaching solution in 1-L beakers or sealed rolling bottles and agitated at a constant speed for 24 h. The leaching solutions were prepared with deionised water and contained NaCN at concentrations ranging from 0.3 to 3 g/L, NH_3 from 0 to 1 M, and/or Pb $(NO_3)_2$ from 0 to 1000 g/t. The pH was maintained under alkaline conditions by periodically adding 1 M NaOH, with a range of 10.5–11.0 for direct cyanidation and 9.3–10.5 for pretreatment tests. Following leaching, the residues were filtered, dried, and digested with aqua regia under controlled heating conditions. Gold, silver, and copper concentrations were determined by atomic absorption spectrometry (AAS), while the mineralogical composition of the ore was characterised by X-ray diffraction (XRD), with phase identification performed using HighScore Plus software and the PAN-ICSD database. Gold recovery was calculated as the percentage of gold extracted relative to the ore's initial gold content:

$$Au\ recovery\ \% = \frac{Au\ extracted}{Initial\ Au\ content}\ x\ 100$$

3 RESULTS

Analytical characterisation (XRD+XRF)

X-ray diffraction (XRD) determined the sample's mineralogical composition. Phase analysis used HighScore Plus software and the PAN-ICSD database. The results (Figure 1) identified quartz as the dominant phase, consistent with the Amesmessa veins being composed almost entirely of quartz. Chalcopyrite, pyrite, sphalerite, and albite were also identified as secondary phases, confirming the presence of copper-bearing sulfide minerals in the ore. Chemical analysis of the ore sample (Table 1) using XRF for whole rock and AAS for minerals shows that the sample contains gold and copper in the leach solution, with a content of 14 g/t Au and 1% Cu. The ore sample consists predominantly of quartz (75% SiO_2) and, to a small extent, sulphide minerals (2.12% S in total).

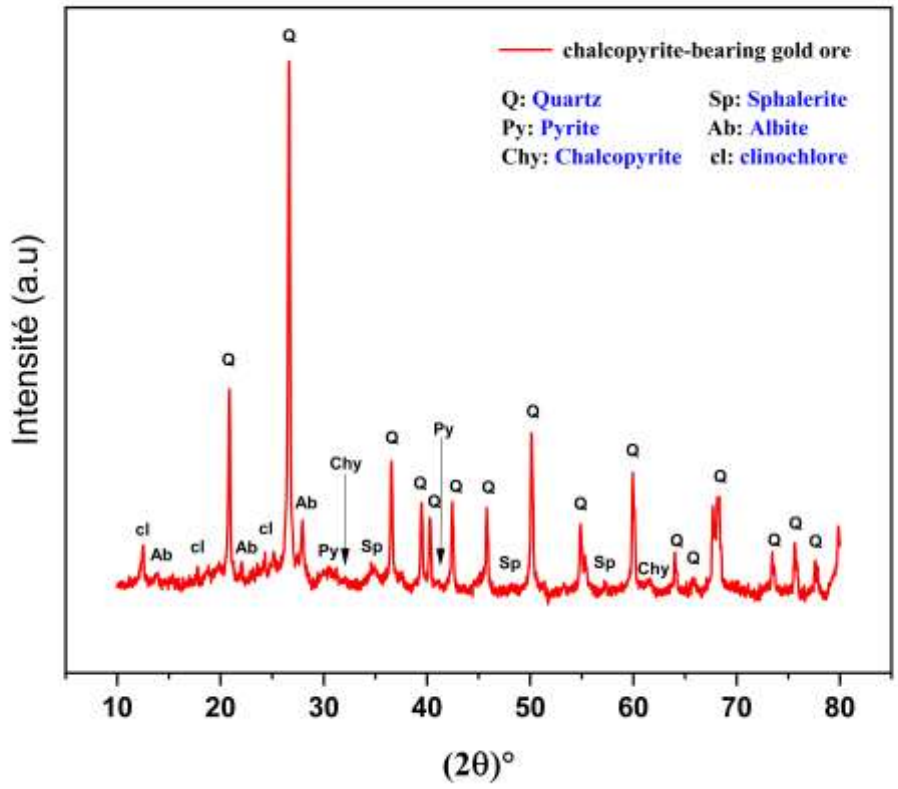

Figure 1. XRD pattern of the Amesmessa ore sample, showing quartz as the dominant phase with chalcopyrite, pyrite, and albite as secondary phases.

Table 1. Chemical and mineralogical compositions of ore and bulk concentrate samples.

w (SiO_2)/%	w(Fe_2O_3)/%	w(Al_2O_3)/%	w(CaO)/%	w(Ba)/%	w(S_{total})/%

14	0.5	1	0.10	0.11	0.04

The presence of soluble minerals, particularly those containing Fe, S, and Cu, represents a major challenge in gold processing, as these species can significantly influence cyanide consumption, gold leaching kinetics, and the overall performance of downstream recovery operations (Sceresini, 2005; Muir, 2011; Dai et al., 2012). Among these impurities, copper is particularly detrimental because its high affinity for cyanide drives excessive reagent consumption by forming stable copper–cyanide complexes. Consequently, free cyanide available for gold dissolution decreases, reducing gold extraction efficiency when cyanide concentrations are insufficient (Bas et al., 2012). Muir (2011) reported that each 1% reactive copper in the ore may consume about 30 kg/t of NaCN, significantly increasing operating costs and negatively affecting the economic viability of cyanidation. For this reason**,** pretreatment is necessary to improve gold recovery in Amessmessa ores.

Effect of NaCN concentration on direct cyanidation of gold

Cyanide leaching (bottle-roll) tests were initially conducted to establish baseline conditions and determine optimal parameters for assessing gold recovery, following the industrial standard procedure commonly used to evaluate the cyanidation potential of gold ores. In each test, we agitated a prepared ore sample (300 g) in cyanide leaching solutions with NaCN concentrations ranging from 0.3 to 3 g/L. We continuously controlled the pH between 9.3 and 10.5 to ensure suitable cyanidation conditions. We estimated the composite sample's initial gold grade at 14 g/t. We performed six leaching tests under the experimental conditions summarised in Table 2, and present the results in Figure 2.

Table 2. Leaching experimental conditions

Test N°	1	2	3	4	5	6
NaCN (g/L)	0.3	0.5	1.0	1.5	3.0	0.5
NaOH (g/L)	0.5	0.7	0.9	1.2	1.8	0.7
Water volume (L)	1	1	1	1	1	2

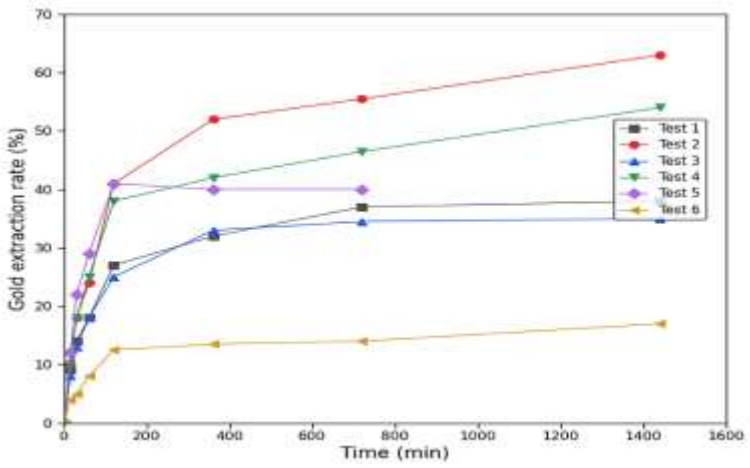

Figure 2. Effect of NaCN concentration on extraction of gold from ore

The results show a clear dependence of gold extraction kinetics on the operating conditions, particularly at prolonged agitation times. The generally low extraction rates across the six tests indicate cyanide-consuming species that limit gold dissolution. In this ore, XRD identified chalcopyrite as the main contributor to cyanide consumption and may explain the limited extraction efficiency. As shown in Figure 2, gold recovery was not proportional to NaCN concentration; the highest extraction rate was obtained at 0.5 g/L NaCN (Test 2), consistent with previous studies (Baghdadi et al., 2025). Increasing the cyanide concentration beyond this value did not improve gold recovery, indicating that additional cyanide was preferentially consumed by non-gold species rather than enhancing gold dissolution.

Ores pretreatment

To improve gold recovery, we investigated a pretreatment step to optimise the cyanidation process by reducing the impact of cyanide-consuming species. Preliminary characterisation of the ore revealed copper-bearing minerals, which can negatively affect gold leaching through excessive cyanide consumption and the formation of sulfide species that may promote gold surface passivation (Msumange et al., 2020). Therefore, two reagents were selected for conditioning prior to cyanidation: lead nitrate (50 g/t), which promotes the precipitation of free sulfide as insoluble lead sulfide (PbS) and limits gold surface passivation, and ammonia (0.5 and 1 mol/L), which reduces the detrimental effect of copper through selective complexation, thereby decreasing cyanide consumption. The underlying mechanisms involve complexation of copper ions and oxidation or removal of sulfide species to minimise passivating layers and enhance gold dissolution.

Pretreatment experiments used the same rolling-bottle setup as the direct cyanidation tests, with two conditioning times (1 h and 4 h) followed by cyanide leaching under alkaline conditions. The NaCN concentrations were maintained at 0.3 and 1 g/L, and the pH was continuously controlled at 9.3-10.5 to prevent the precipitation of copper at pH>10.5.

Effect of lead nitrate on the gold extraction rate

Lead nitrate aims to eliminate all species adsorbed on the gold surface, mainly S^{2-} sulfides.
The curve in Figure 3 illustrates the effect of adding lead nitrate on gold extraction kinetics.

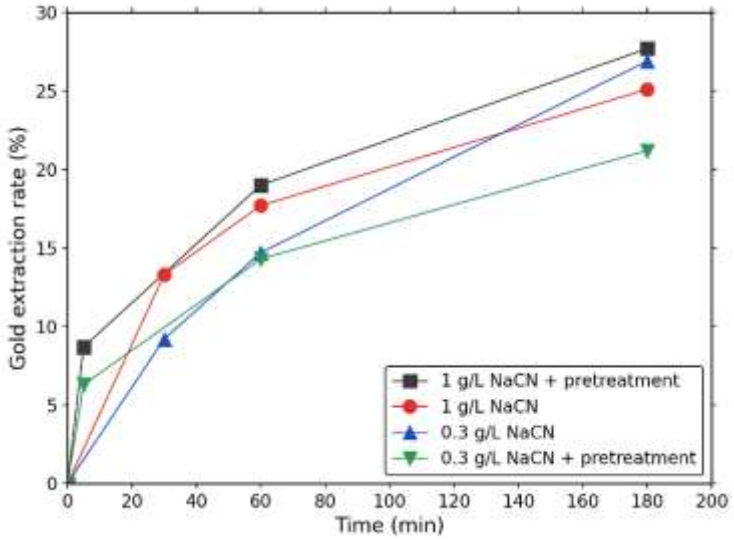

Figure 3**.** Effect of lead nitrate addition (50 g/t) on gold leaching kinetics

The curve shows the effect of adding lead nitrate (50 g/t) on extraction kinetics. Kinetics improved significantly at both cyanide concentrations (0.3 and 1 g/L). This result confirms the cyanide-consuming nature of the gold ore studied, where cyanide-consuming compounds adsorb onto the gold surface. The extraction rate is clearly proportional to cyanide concentration when using lead nitrate.
Extraction kinetics improved significantly at both cyanide concentrations tested (0.3 and 1 g/L) following lead nitrate pretreatment. This result is consistent with the ore's cyanide-overconsuming nature, in which compounds released during leaching adsorb onto the gold

surface, and confirms that the extraction rate is proportional to cyanide concentration when lead nitrate is used.

Ammonia effect

Compared with traditional cyanide leaching, the ammonia–cyanide system offers a more selective approach to gold recovery from copper–gold ores, with substantially lower cyanide consumption. (Muir et al., 1989). Figure 4 illustrates the time-dependent leaching profile for gold under increasing concentrations of NaCN and 0.5 mol/L NH_3.

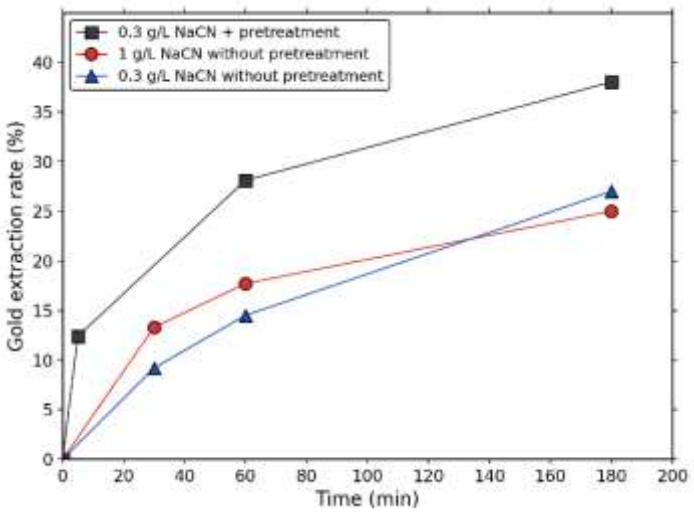

Figure 4. Effect of ammonia pretreatment (0.5 mol/L NH_3) on gold extraction kinetics,

The extraction kinetics demonstrate the significant impact of pretreatment on gold leaching performance. The pretreated sample using 0.3 g/L cyanide showed a rapid increase in gold recovery, reaching about 12% within the first few minutes, whereas both non-pretreated conditions showed nearly negligible extraction over the same period. This behaviour indicates that pretreatment effectively removes an initial kinetic barrier to gold dissolution, likely associated with surface passivation or cyanide-consuming species. The beneficial effect of pretreatment was maintained throughout leaching, with the pretreated sample achieving a final recovery of 38% after 180 minutes, compared with only 25–27% for the non-pretreated samples, an improvement of 10–13 percentage points despite the lower cyanide concentration. In contrast, the leaching profiles at 1 g/L and 0.3 g/L cyanide without pretreatment were nearly identical, with only a slight crossover at the end of the test, suggesting that increasing cyanide dosage alone does not significantly improve gold recovery. This limited improvement likely stems from preferential cyanide consumption by interfering minerals, such as copper-bearing phases and sulfides, rather than by gold dissolution. Overall, these results confirm that pretreatment plays a key role in overcoming mineralogical limitations, accelerating gold dissolution kinetics, and improving final recovery, while also enabling reduced cyanide consumption. Therefore, the pretreatment strategy is a promising approach for treating refractory copper–gold ores by improving leaching efficiency while reducing reagent requirements.

Effect of ammonia–lead nitrate mixture pretreatment on the extraction rate

To improve recovery rates, we ran a series of pretreatment tests, combining the two reagents (lead nitrate, NH_3) to investigate the mineral's behaviour and observe how the extraction rate evolves. For this, we ran five tests (without pretreatment; with 0.3 g/L NaCN; 0.5 mol/L NH_3; and 50 g/t Pb (NO_3) to evaluate the effect of pretreatment. Figure 5 illustrates the results.

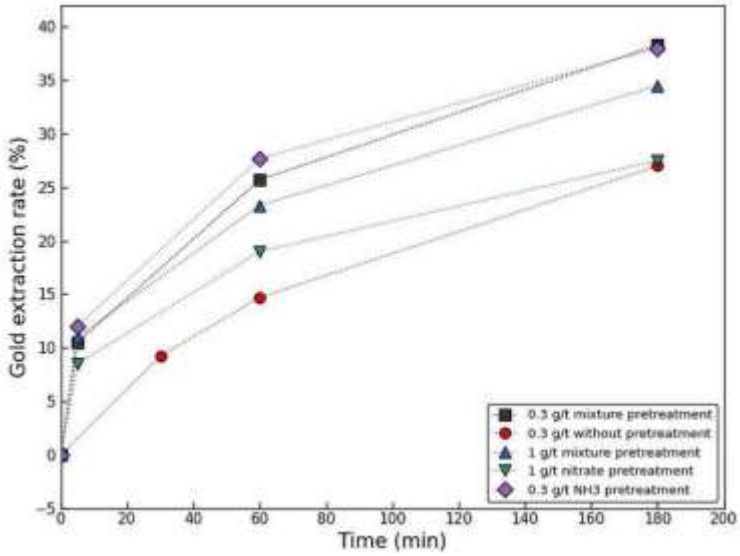

Figure 5. Effect of NH_3-Pb (NO_3) mixture on the gold extraction rate

Cyanidation with the NH_3–Pb $(NO_3)_2$ mixture yielded remarkable results at both 0.3 g/L (and 1 g/L cyanide. We recorded a clear improvement in kinetics and in recovery rate (10–12%). These results are more favourable than those obtained with lead nitrate alone. This result demonstrates the dual effect of the cyanogenic elements in our ore: one on the gold surface and the other in competition with cyanide complexation.

Both cases show high consumption, with ammonia alone (0.5 mol/L) and with the mixture, leading us to conclude that cyanide complexation is more favourable than passivation of the gold surface. In other words, the effect of cyanide consumption by copper has a greater impact than the passivation of the gold surface by sulfides.

To further optimise the mixture's effect, we repeated pretreatment using higher reagent doses and a longer conditioning time (4 h). Because the study aims to model the ore-treatment process on Amesmessa's current processing line, where the applied cyanide concentration is 0.3 g/L, 100 g/t $Pb(NO_3)_2$ and 1 mol/L NH_3.

Figure 6 demonstrates that ammonia pretreatment consistently provided higher gold extraction rates than lead nitrate alone, regardless of the reagent concentration applied. However, the combined ammonia–lead nitrate conditioning strategy exhibited the highest efficiency, confirming the synergistic effect of both reagents during the treatment of the copper-rich Amesmessa ore. Based on the calculated extraction yields, the optimised mixture pretreatment increased gold recovery from 58% without pretreatment to 85.9% under industrial processing conditions (0.3 g/L NaCN). Test 3, corresponding to the combined NH_3–$Pb(NO_3)_2$ pretreatment, achieved the highest recovery, showing that ammonia's simultaneous reduction of copper-related cyanide consumption and lead nitrate's mitigation of gold surface passivation

significantly improve cyanidation performance. These results confirm the effectiveness of the proposed pretreatment strategy in enhancing gold recovery from copper-bearing refractory ores under low-cyanide conditions.

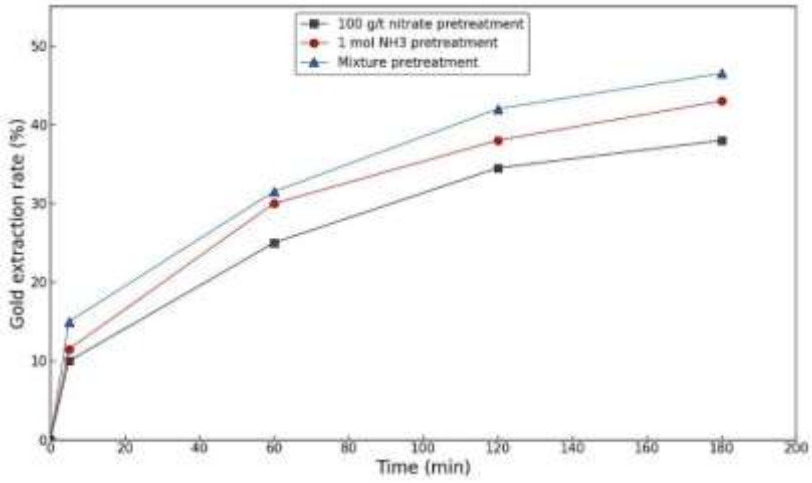

Figure 6. Effect of NH_3-Pb (NO_3) mixture on the gold extraction rate

CONCLUSION

Gold extraction from the Amesmessa ore is primarily based on cyanidation, a process whose efficiency depends on several critical factors, including ore mineralogical characteristics, cyanide concentration, and pH control under alkaline conditions. Experimental investigations were conducted at the Amesmessa mine laboratory using a representative sample collected from SARL Tinmerkadine (sample 820). These tests aimed to identify the optimal leaching parameters and pretreatment conditions required to enhance gold recovery. Based on the obtained results, the following conclusions can be drawn:
The X-ray diffraction spectrum of the ore reveals the presence of a predominant phase, quartz, in addition to other phases: chalcopyrite, pyrite, and albite.

Leaching kinetics improved after pretreatment with lead nitrate, confirming the cyanide-consumptive nature of the gold ore studied, in which cyanide-consuming compounds adsorb onto the gold surface.

Cyanidation using the NH_3–$Pb(NO_3)_2$ mixture yielded remarkable results in terms of increasing the extraction rate. This result demonstrates the dual effect of the cyanide-consumptive elements in our ore: one acting on the gold surface and the other competing with cyanide through complexation.

Industrial-scale optimisation remains necessary to further enhance gold recovery and ensure the practical applicability of the proposed leaching conditions. However, the results are promising. Pretreating with ammonia and lead nitrate (high doses, 4 hours) lifted recovery from 58% to 85%. This occurred under standard plant conditions (300 ppm NaCN). For copper-rich ore like this, it works.
The proposed pretreatment may reduce NaCN consumption, lower operating costs through improved gold recovery, and facilitate industrial application because the treatment conditions

are close to those used at the Amesmessa processing plant. Further pilot-scale studies are required to confirm its economic and industrial feasibility.

ABSTRACT

Roses are considered one of the most sought-after plants worldwide. They have a high vitamin C content and are widely used for juices, jams, and syrups. In addition, they are also used as ornamental plants for decorating natural environments and indoor spaces such as homesand offices. Roses have also found favorable conditions for growth and cultivation in Albania. The city of Albania that carries the scent of roses is Permeti. Roses are susceptible to various pests and diseases that may affect their health and aesthetic appearance. Among the pests that attack roses especially at the beginning of spring, the most hazardous are aphids. The rose aphid, *Macrosiphum rosae*, is one of the most important pests of roses worldwide and causes economic damage. The aim of this study was to identify this pest in our country. The study was conducted during 2025, from early March to late October, in the Botanical Garden of the Agricultural University of Tirana. For aphid identification, field observations were carried out; specimens were prepared as fixed slide-mounted preparations and compared with taxonomic keys and standard descriptions. The species collected in the Botanical Garden corresponded to the description of *Macrosiphum rosae.* This study, confirmed the presence of this aphid in our country and it is role in causing significant damage to rose shrubs.

Keywords: Roses, *Macrosiphum rosae*, aphids ,identification, taxonomic key, microscope, pest.

INTRODUCTION

Rose is one of the most beautiful ornamental flowers in the world, and as suchit can be found in many houses and gardens in cities due to its especialcharacteristics such as stability, long period of floral initiation, different varieties,and, of course, its beauty. (Larson, R.A.,1992). Roses is an ornamental shrub up to two meters hight, with long thorns,with large, leafy, beautifull, clustered flowers, with a pleasant smel and in white, red, yellow,ect. It is also used for various perfumes and for decorations. (https://sq.wikipedia.org/wiki/Trandafili). Rose hasbeen most important crop in the floriculture industry. The genus Rosa includes 200 species and 18,000 cultivars. (Weiss,1997; Gudin,S, 2000). Those rose bushes can suffer from several problems such as diseases and pests. Roses are can to various types of pests and diseases that can affect their health and aesthetic appearance. (https://sq.jardineriaon.com.2025). Aphids or plant lice are serious pests of various crops including rose. (K.Zamir Rasib, et.al.,2021). Aphids feed on buds, shoots and leaves, colonies may persist throughout the year but are most numerous and troublesome in late spring and early summer. (Buczacki.S.T,et.al.,1998). Strong infestation by the aphid results in the deformation of stems, leaves and flowers. (Jaskiewiez, B.,1997). Roses can support several species of aphid in the spring and summer, the most common is usually Macrosiphum rosae (https://gd.eppo.int/taxon). Macrosiphum rosae, the

rose aphid, is a species of sap-sucking aphids in the subfamily Aphidinae. (Cichocka E., 2003), (Gudin, S., 2000). The rose aphid, Macrosiphum rosae, is one of the most important pests on roses in the world and it causes economic damage. (Mehrparvar M.,et.al.2016). This insect stops growth of leaf bud, flower buds and twigs by eating them and also prohibits flowering and causes weakness of flower buds. In severe infection, it causes deformated and mottledpetals which this reduces flowers beauty.(Mehrparvar et al. 2009). Aphids are observed in two colourful races: green and rosy-brown ones . It is a holocyclic, host alternating and olyphagous species (Cichocka E., 2003). In order to reduce the economic losses inflicted by roses aphids ,it is necessary to study different biological parameters of this pest species so that an effective management plan can be formulated (Yousuf I,et.al.,2020). Management is done with the development of thorough insect and disease scouting, record keeping, development of soundcultural and sanitation practices (David, J.S., 2001). Early detection is key. The sooner the presence of aphids is identified, the easier it will be to eradicate them and the less likely there will be serious damage to the plant.http://www.fjalori.shkenca.org/

MATERIALS AND METHODS

Time and place of study

The study was conducted during 2025 from the beginning of March to the end of October. The location for the study was chosen to be an area of the Tirana district within the Campus of the Agricultural University of Tirana. Many rose bushes of the genus Rosa spp are concentrated there. The purpose of this study was to identify *Macrosiphum rosae* in these rose bushes.
Tirana, being 30 km from the coast, has a hot subtropical-mediterranean climate with an average of 260-290 sunny days per year. Summer is hot and dry due to the dominance of subtropical high-pressure systems, while winter has moderate temperatures. Even in spring, temperatures have increased, favoring many diseases and pests.

Figure 1. Study area

Figure 2. Study area from (google earth)

Study method.

In this study, to identify the presence of *Macrosiphum rosa* (Linnaeus, 1758) in rose bushes in our country, the following was used:
• field observation
• slide-mounted specimens

• comparison with taxonomic keys and standard descriptions

To identify the pest in the laboratory, a weekly sampling method was used from March to the end of October. Each week, 5 rose bushes were selected and a branch of each rose bush was randomly cut as a sampling unit. Since most rose aphid colonies are located along a 10 - 15 cm length of the main part of the branches, these 15 cm of branches were selected and cut. These branches were placed in plastic bags where the sampling dates were marked on each sample, which were taken to the laboratory for examination with a magnifying glass and microscope.

Figure 3. Field observation for the identification of *M.rosa*

In addition to weekly sampling, the rose plants were carefully inspected, especially inside the branches and at the upper levels of the roots, collecting all aphids that were found with a small brush in a bottle of 70 % ethanol and then identified in the laboratory. Even during the hot summer months, June, July, August and September, checks were made three times a month to see if this aphid remained hidden in the rose plants or migrated to secondary plants. These samples, in addition to being analyzed with a magnifying glass and microscope, were also analyzed by preparing fixed preparations, which consists of a more in-depth analysis of the different parts of the fixed insect.

We based ourselves on the classical method according to (Hille Ris Lambers.1950 - 1970), for the preparation of fixed aphid preparations, the sequence of work used is as follows:

Preservation in 70-80 % alcohol

Maceration which serves to dissolve the soft fatty parts, as well as to bleach the sclerotized parts, where the insects become transparent and the individual parts are easily distinguished with a microscope. They were boiled in 10 % KOH for 30 min or they can be left for 24 hours in the environment until they become transparent.

Rinsing with distilled water.

They are placed in 50 ml of 70% alcohol and three drops of HCl, where they are left for 5 min for neutralization.

Fuchsin staining is performed (0.5 grams of fuchsin + 25 ml of 10 % HCl + 300ml of distilled water). The staining lasts 30 min.

The lice are placed in the center of the slide and 70 % alcohol is poured over them, leaving for 3 - 5 minutes.
Add one drop of Wintergreen 0.1% and leave for three minutes, remove the oil, dry the preparation and then add 3 drops of Canadian balsam, place the lamella and in this state the preparation is not moved for 6 days.

After the preparation of the fixed preparations, the specimens were analyzed with a steriomicroscope, and on the basis of the special characteristics of *Macrosiphum rosa*, its identification was possible. Identification of the pest was done by studying their morphological characters under microscope and comparing them with literature available on their morphology.

Figure 4. Stereomicroscope observation for the identification of *M.rosa*

RESULTS AND DISCUSSION.

The study was carried out on a 200 m^2 area planted with roses (*Rosa spp*.) within the Agricultural University of Tirana in the Botanical Garden. The identification of aphids was based on a combination of host plant, pest symptoms, morphological characters and comparison with taxonomic keys based on standard entomological literature of various authors. The host plant was rose bushes which is also the main host for these pests. From phytosanitary monitoring in the field with a magnifying hand lens, practical identification was achieved mainly through field observations and bioecological characteristics of the pest. Aphids were observed on young shoots in buds and on young leaves, dense colonies were observed, typical of rose aphids. The populations were mainly located in the young parts of the plant on young shoots and on the underside of the rose leaves where they fed on plant juices. The increase in the populations of these individuals during the spring in this area of Tirana was favored by moderate temperatures and high relative humidity. The damages were typical for the rose aphid (*Macrosiphum rosae*) such as: deformation of young shoots, wrinkling of leaves, slowing of development and secretion of honeydew which favors the development of black mold. Individuals of this species had an elongated body, which helps distinguish it from other types of plant aphids, green, pink or reddish in color, long antennae and thin legs. Another identifying feature was the relatively long black and cylindrical cornicles, as well as the elongated and light-colored tail typical of the rose aphid.

Figure 5. Monitoring symptoms on rose bushes

After field monitoring, the species were taken to the laboratory and their identification began, through the use of taxonomic keys and microscopic analysis of diagnostic parts.
The species collected in the botanical garden after examination, matched the description of *Macrosiphum rosae* through these features:

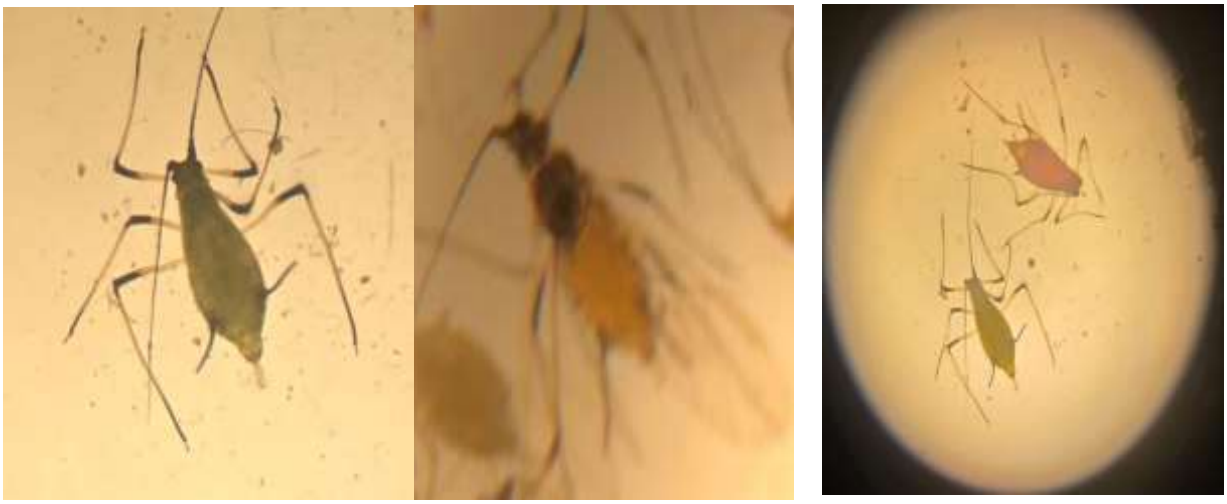

Figure 6. Identification of *Macrosiphum rosae* with a stereomicroscope

.

Wingless form (aptere)

Host plant is rose.
Body relatively large (2.2 - 3.6) elongated and thin, not short and oval.
Body color light green, pink or reddish brown.
Surface often shiny.
Antennae very long, 3.6 mm dark in color and with many rhinaria (sensory organs).
Siphonculi (cornicles) are long, straight, black, with a prominent reticulum at the tip.
The caudas i long, slender and light in color.

Legs long and thin and joints of legs dark in color

Even the winged form(alate) matched the description of the characters of *Macrosiphum rosae*:

Size 2.5 - 3.6 mm
Body shape more slender and elongated.
Thorax black, body color green
Head dark and sclerotized
Antennae long and with many sensors
Two pairs of transparent wings
Cornicles long, cylindrical black
The cuda is long and slender.
Long legs, thin tibia with black color.

DISCUSSION

The results of field observations and laboratory analyses confirmed the presence of the rose aphid *Macrosiphum rosae* (Linnaeus, 1758) in rose bushes cultivated in the territory of the Campus of the Agricultural University of Tirana. This species is considered one of the most widespread aphids of the family Aphididae that affects plants of the *Rosaceae* family and is widely reported in temperate and Mediterranean climate regions Blackman & Eastop (2000). During field monitoring, it was observed that these individuals formed dense colonies mainly on the vegetative tops and flower buds of the host plants. The infestation was accompanied by the presence of molasses on the leaf surface, as well as deformation and twisting of young plant tissues. Similar symptoms have been reported by David et al. (1975) and Heie. (1986-1995), who emphasize that the physiological damage caused by this species negatively affects the vegetative and aesthetic development of the rose.

The morphological characteristics of the observed individuals were consistent with the descriptions reported in the international literature. Body color ranged from light green to pink or reddish, while the alate and apterous forms presented obvious differences in the development of body structures, especially in pigmentation and wing development. According to Tomiuk & Wohmann (1990), this morphological variability is related to environmental factors and the biological stages of aphid development.

Morphological identification of *Macrosiphum rosae* was carried out through the analysis of external body characters observed with a stereomicroscope. The identification process was based on the use of taxonomic keys and on the comparison of the morphological structures of the alate and apterous forms. Morphometric characters were compared with the data presented by David et al. (1975), while diagnostic descriptions were based on the standard references of Blackman & Eastop (2000).

According to these authors, *M. rosae* is characterized by an elongated, spindle-shaped body, with a length ranging from 1.7 - 3.6 mm. The antennae and legs are relatively long, while the sphinuculi (cornicles) are cylindrical, black and well developed. The cauda appears elongated and with paler pigmentation compared to the rest of the body. These diagnostic characteristics were also found in the individuals analyzed during this study.

The agreement of the results obtained with the data of the international literature shows that the methodology used for the monitoring and identification of *M. rosae* was appropriate for the agroclimatic conditions of the Tirana area. Also, the results suggest that the climatic conditions of this area favor the development and reproduction of this species, especially during periods

of moderate temperatures and high relative humidity, factors which are considered important for the dynamics of aphid populations (Blackman & Eastop, 2000).

CONCLUSIONS

The presence of the rose aphid Macrosiphum rosae was confirmed in the agro-ecological conditions of our country.
Macrosiphum rosae represents an important pest for rose bushes and a potential vector of plant viruses.
Species identification was successsfully accomplished based on monitoring typical symptoms in the field of host plants.
The analysis of diagnostic morphological characters was carried out using taxonomic keys available in standard foreigen literature.
Wingless and winged forms were identified, indicating high adaptability and spread.
In addition to *M.rosae* ,other species of aphids were also identified on rose bushes, but the identification of other species was not the focus of our study.
It is essential to inspect rose bushes regularly, paying special attention to the transition periods between seasons.
Green aphids tend to hide on the underside of leaves, young shoots and flower buds.
It is advisable to inspect both sides of the leaves and not to forget the areas with softer growth, as they are often the first to settle there.
In the agroecological conditions of Albania the development of pest populations is favored by moderate spring temperatures and adequate relative humidity.
Continuous monitoring and implementation of integrated management strategies is recommended.

"**POPULATION DYNAMICS OF THE POTATO TUBER MOTH (*PHTHORIMAEA OPERCULELLA*) IN THE DIVJAKË REGION, ALBANIA"**

Florie REXHAJ [1]Dhurata SHEHU [2],Ajten BERXOLLI[3]

Agricultural University of Tirana, Faculty of Agriculture and Environment, Plant Protection Department

Corresponding author e-mail:frexhaj@ubt.edu.al

ABSTRACT

Potato (*Solanum tuberosum* L.) is one of the most economically important agricultural crops in Albania. Among its major insect pests, the potato tuber moth, *Phthorimaea operculella* (Zeller, 1873), causes significant yield losses both in the field and during storage. The aim of this study was to evaluate the seasonal population dynamics of this pest under the agroecological conditions of the Divjakë region, one of the main potato-producing areas in Albania. The study was conducted from March to October 2025 in a 1-ha potato field planted with the Arizona cultivar. Population dynamics were monitored using two Delta Econex pheromone traps, and moth captures were recorded periodically throughout the growing season.The results showed that adult activity began in April, with low capture levels below the economic threshold. During the first potato production cycle (March – June), the pest population remained at low levels. The first generation was completed at the end of June in the epigeal part of the host plant. This infestation had no impact on the yield. A marked increase in moth captures was observed during July, August, and September, coinciding with temperatures ranging from 33 to 38°C and the development of successive generations. High temperatures and low humidity favored rapid reproduction, resulting in a significant increase in population density. A gradual decline in captures was recorded from late September through October, corresponding to decreasing temperatures and the end of the cropping cycle. The findings indicate that early potato production is exposed to a relatively low risk of infestation by *P. operculella*, whereas the second production cycle is considerably more vulnerable due to the accumulation of successive generations and favorable climatic conditions. Continuous monitoring using pheromone traps is an effective tool for predicting population fluctuations and supports.

Key words: Potato, (*Phthorimaea operculella),* monitoring, population, management.

INTRODUCTION

Potato (*S.tuberosum* L.) is the fourth major food crop around the world after rice (*Oryza sativa* L.), wheat (*Triticum* spp.L.), and maize (*Zea mays* L.).
(Xu,J.et.al.,2019))&(Gao,Y.L.et.al.,2021). In Albania, potato production represents an important agricultural sector, with an annual output estimated at approximately 245,000–255,000 tons. (https://www.abaonline.al). However, potato production is challenged by many factors including pests and diseases, particularly *P. operculella.* (Graft, J.E.,1917). Phthorimaea operculella (Zeller, 1873), commonly known as the potato tuber moth, is a lepidopteran species belonging to the family Gelechiidae. (https://en.wikipedia.org/). The

potato tuber moth, *Phthorimaea operculella* (Lepidoptera: Gelechiidae), is an oligophagous pest that has been foundfeeding on more than 60 plants in different parts of the worldwith the majority of the hosts belonging to the Solanaceae family (Das,G.P et,al., 1994). It causes significant economic losses in potato production in subtropical and tropical areas.(Das,G.P,et.al.,1992). *P.operculella* is a pest of both field and storage conditions (Gilboa S.et.al.,1995). The damaging stage of the pest is the larva .(Lal, L, 1993).The larva attacks all vegetative parts of the potato, and most economic damage occurs to potato tubers both before harvest in the field and during storage. (R. S. Chandel et.al.,2019). Foliar damage by *P. operculella* to the potato plants does not usually cause significant yield losses. (Graft, J.E., 1917). Currently, pest management practices are effective in controlling *P.operculella.* https://www.sciencedirect.com **.**The use of synthetic pheromones that interfere with insect mating for pest control has been widely demonstrated in numerous Lepidoptera and other insect species. (Claudia Vasquez.,2009)**.** *Phthorimaea operculella* male moths are attracted to pheromones, which are concentrated chemicals of the female "scent" impregnated in a rubber septum in the center of a sticky liner insert within delta traps (Rondon, 2020). For its management, use of healthy seed, field sanitation, deep planting, and proper ridging contribute significantly. (R.S .Chandel ,et.al.,2019). Pesticide application is most widely used management strategy to control *P. operculella*. (Trivedi,T.P,et.al.,1992). As most of the economic damage occurs when *P. operculella* infests the tubers, so researchers should focus on management of this insect pest during tuber period. (Amone.S,et.al.,1998) & (Gao,Y.L.,2018).

MATERIAL AND METHODS

Time and place of study

The study was conducted from March to the end of October 2025 in the Divjaka region, one of the main potato-growing areas in Albania. The objective of the study was to analyze the seasonal population dynamics of the potato tuber moth (*Phthorimaea operculella*), identify periods of high infestation risk, and provide recommendations for the integrated management of this pest. The potato cultivar used in the study was Arizona.

Divjaka is located in the Western Lowland of Albania and is characterized by a typical Mediterranean climate, with mild, rainy winters and hot, dry summers. Average temperatures range from approximately 5–12°C in January to 30–35°C in July, providing favorable conditions for the development and population growth of *P. operculella* throughout the potato growing season.The soils in the Divjaka region are predominantly sandy and alluvial, providing highly favorable conditions for potato cultivation. In addition, the region's climatic conditions, characterized by high summer temperatures, adequate humidity, and the continuous cultivation of potato crops, create an optimal environment for the development and establishment of the potato tuber moth (*Phthorimaea operculella*). These environmental conditions favor the pest's survival, reproduction, and population growth throughout the entire growing season.

Figure 1. Stadi area in Divjaka

Study method

To monitor the population dynamics of the potato tuber moth (*Phthorimaea operculella*) in the Divjaka region, a pheromone-based monitoring system was employed. The experimental field covered an area of 1 ha, with a row spacing of 75 cm and a plant spacing of 30 cm.

Monitoring was carried out using triangular Econex Delta traps equipped with sticky inserts and species-specific sex pheromone lures. The traps were installed approximately 20 cm above the crop canopy, as adult moths typically fly close to the plants. Two traps per hectare were used: one placed in the center of the field and the other at the field margin, avoiding the direction of the prevailing wind to minimize interference with pheromone dispersion.

Under normal conditions, traps were inspected every seven days, whereas during periods of increased pest activity they were checked every 3–4 days. After each inspection, captured moths were counted, removed using forceps, and the data were recorded, leaving the sticky surface clean for the next assessment.

The pheromone lures were replaced every 4–6 weeks due to the high summer temperatures, which accelerated pheromone volatilization. Sticky inserts were replaced every 7–14 days, depending on the number of captured insects and the accumulation of dust. Frequent strong winds in the study area caused considerable dust deposition, reducing the adhesive efficiency of the trap surfaces.

To monitor the population dynamics of *Phthorimaea operculella*, regular weekly observations were conducted through visual inspections using a hand lens. Systematic monitoring enabled the assessment of the pest's population dynamics by first determining and recording its location within the crop, followed by continuous observations of population development throughout the growing season.

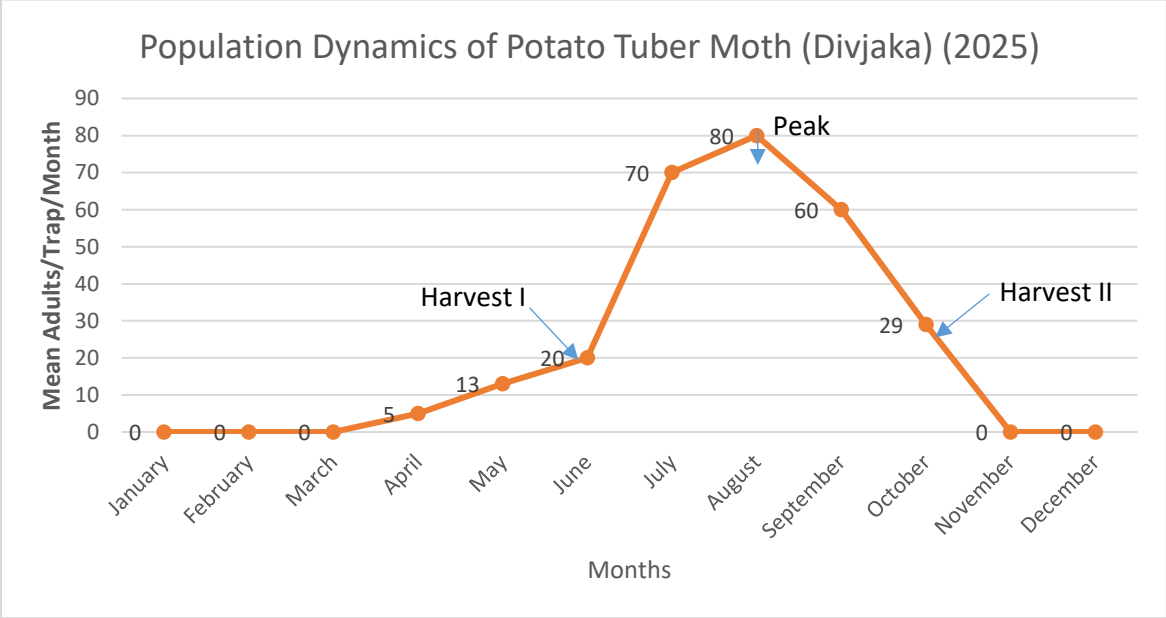
Figure 2. Monitoring plot

Figure 3 .Leaf damage

RESULTS AND DISCUSSION

Trap inspections began immediately after their installation in March. Initially, the traps were checked every morning until the first adult moths were captured. Thereafter, monitoring was carried out weekly through regular and systematic inspections. Captured moths were removed using forceps, and the number of individuals captured was recorded in a dedicated field notebook.

Table 1. Average weekly number of *Ph.operculella* adults captured for trap during the monitoring period.



Months	Average catch/trap/week
March	0
April	5
May	13
June	20
July	70
August	80 (peak)
September	60
October	29

As shown in table 1, the first adult flights of *Phthorimaea operculella* were recorded in April, with low trap catches during the first week. As temperatures increased, moth activity gradually intensified, reaching a monthly average of approximately 5 adults per trap per week. In May, moth activity remained below the economic threshold, with an average of 13 adults per trap per week.

During June, the average number of captured adults increased to 20 moths per trap per week. However, this population level did not pose a significant threat to potato production, as feeding damage was mainly confined to the above-ground (epigeal) parts of the plants, while the first potato crop had already completed its vegetative cycle.

In the following months, the number of captured adults increased markedly, corresponding to the rise in air temperature and the development of successive generations of the pest. Overlapping generations resulted in a continuous increase in the population, and the nature of the damage shifted predominantly to the potato tubers, where infestation levels became relatively high.

Graphic 1. Population Dynamics of *Phthorimaea operculella* in Divjakë (2025)

The data presented in graphic 1 also illustrate the seasonal population dynamics of *Phthorimaea operculella*. Adult moth activity began in April, with a monthly average of 5 adults per trap per week. During May, a gradual increase in moth activity was observed, reaching a monthly average of 13 adults per trap per week. This increase was favored by temperatures ranging from 24 to 28°**C** and the active vegetative growth of the potato crop.

The peak of the first generation was recorded in June, with a monthly average of 20 adults per trap per week. This generation completed its development primarily on the vegetative (epigeal) parts of the plant. Infestation of the above-ground plant tissues remained low and did not affect the yield of the first potato crop in the Divjaka region.

Figure 4. Harvest of the first potato crop in the Divjaka region, Albania (2025).

Successive generations of *Phthorimaea operculella* initially developed on potato tubers remaining in the field after harvest and on wild solanaceous host plants, particularly *Datura stramonium* L., before subsequently colonizing the second potato crop. The highest pest activity was recorded during July, August, and September, with average trap catches of 70, 80, and 60 adults per trap per week, respectively. The population peak occurred in August.

These population peaks coincided with high summer temperatures (33–38°C), which favored rapid population growth and the continuous development of successive generations. Under these climatic conditions, each generation was completed within approximately 22–24 days, resulting in a rapid increase in pest density.

In October, moth activity declined to an average of 29 adults per trap per week, mainly due to decreasing temperatures and the completion of the potato crop's growing season.

During the 2025 growing season, the second potato crop in the Divjaka region was severely affected by *P. operculella*. Prolonged high temperatures accelerated the development of successive generations, leading to intense tuber infestation and substantial yield losses.

The results obtained from monitoring with Econex Delta traps baited with species-specific sex pheromone lures demonstrated that this technique is an effective and reliable method for monitoring the seasonal population dynamics of *Phthorimaea operculella*. The information obtained can be used to identify periods of highest pest risk and to optimize the timing of integrated pest management (IPM) measures.

DISCUSSION

The results of this study demonstrated that the population dynamics of *Phthorimaea operculella* in the Divjaka region were primarily influenced by temperature and local agroecological conditions. The gradual increase in the number of male moths captured in Delta traps baited with sex pheromones from April to August is consistent with the findings of Rondon (2020) and Kroschel and Sporleder (2006), who reported that high temperatures accelerate pest development, shorten the life cycle, and promote the occurrence of multiple generations during the growing season.

Sex pheromone traps are widely recognized as a reliable tool for the early detection of adult moth activity and for determining the optimal timing of control measures within Integrated Pest Management (IPM) programs (Rondon, 2020; Sporleder et al., 2004). Similarly, Yan et al. (2023) reported that trap efficiency is influenced by trap height, trap type, and pheromone

dosage, with traps positioned at the crop canopy level capturing the highest numbers of male moths.

Our findings are also consistent with those of Aryal et al. (2020), who reported that *P. operculella* populations exhibit several seasonal peaks and that their development is strongly influenced by temperature and local agroecological conditions.

The completion of the first generation by the end of June indicates that the early potato crop in the Divjaka region is exposed to relatively low pest pressure. Harvesting of the first crop was completed in early June, before the potato tuber moth population reached the economic threshold. This observation is in agreement with the findings of Cota (2003), who concluded that the first potato crop is generally protected from economically significant damage by *P. operculella*, as infestations during this period are largely confined to the above-ground (epigeal) plant tissues and do not significantly affect tuber yield.

Overall, the results confirm that continuous monitoring using Delta traps baited with sex pheromones provides an effective method for tracking the seasonal population dynamics of *P. operculella*. Knowledge of these population trends is essential for identifying periods of greatest pest risk, optimizing the timing of control measures, and improving the effectiveness of Integrated Pest Management (IPM) strategies in potato production.

CONCLUSIONS

Monitoring *Phthorimaea operculella* populations using sex pheromone traps is essential for:

Early detection of the pest.

Determining the optimal timing for control measures.

Environmentally safe pest monitoring, as pheromone traps are highly species-specific and do not harm beneficial insects.

Evaluating the effectiveness of implemented pest management strategies.

Reducing unnecessary pesticide applications, thereby supporting sustainable Integrated Pest Management (IPM) programs.

The potato tuber moth (*Phthorimaea operculella*) completed several generations between June and the end of October under the climatic conditions of the Divjaka region. Early potato cultivars were exposed to relatively low pest pressure and were generally protected from economically significant damage.

In contrast, the second potato crop was highly vulnerable to infestation by *P. operculella*. Therefore, more intensive monitoring using sex pheromone traps is strongly recommended to ensure early detection and timely implementation of control measures.

The ability of *P. operculella* to produce multiple overlapping generations within a single growing season makes this pest particularly problematic in warm Mediterranean environments such as Divjaka.

Effective management of this key potato pest requires timely intervention before economic damage occurs through the implementation of an Integrated Pest Management (IPM) strategy that combines:

Agronomic (cultural) measures, including deeper planting of seed tubers, adequate soil covering (hilling), regular irrigation, removal of exposed tubers, and destruction of crop residues.
Physical and mechanical control methods.
Biological control measures.
Chemical control, applied only when pest populations exceed the economic threshold and in accordance with IPM principles.

ABSTRACT

Elaeagnus angustifolia L. (Elaeagnaceae), commonly known as Russian olive, is rich in bioactive compounds with potential health benefits. This study aimed to comprehensively evaluate the total phenolic content (TPC), antioxidant capacities, and antimicrobial activities of various extracts and decoctions obtained from the fruits and aerial parts of *E. angustifolia* collected from Eskişehir and Bursa provinces (Türkiye). TPC was determined via the Folin-Ciocalteu method and expressed as mg gallic acid equivalents per gram of extract (mg GAE/g). Antioxidant performance was evaluated using the DPPH radical scavenging assay (IC_{50}, mg/mL). Antimicrobial evaluation was conducted against *Escherichia coli* ATCC 8739, *Staphylococcus aureus* ATCC 6538, *Pseudomonas aeruginosa* ATCC 9027, *Candida parapsilosis* ATCC 22019, and *Candida albicans* ATCC 90028 using the broth microdilution method to determine Minimum Inhibitory Concentrations (MIC, µg/mL). Tetracycline and Amphotericin B were utilized as standard reference drugs.TPC values ranged widely from 16.8±0.02 to 67.8±0.06 mg GAE/g. The highest phenolic concentration was recorded in sample 5A (Eskişehir, aerial parts, 70% ethanol; 67.8 ±0.06 mg GAE/g), which concurrently exhibited the strongest DPPH radical scavenging activity with the lowest IC_{50} value (0.275±0.02 mg/mL). Conversely, sample 1E (Bursa, fruits, ethyl acetate) displayed the lowest TPC (16.8±0.02 mg GAE/g) and the weakest antioxidant capacity (IC_{50}: 2.101±0.05 mg/mL). The antimicrobial screening revealed variable efficacy across formulations. The highest antibacterial potency was observed in sample 1A against both *E. coli* and *S. aureus*, with a MIC value of 500 µg/mL. For antifungal action, sample 5B demonstrated the highest efficacy against *C. parapsilosis* with a MIC of 500 µg/mL. In contrast, *P. aeruginosa* exhibited strong resistance to almost all extracts (MIC >4000 µg/mL). The results demonstrate that *E. angustifolia* aerial parts and fruit formulations possess significant antioxidant and selective antimicrobial properties, which strongly correlate with their total phenolic levels. In particular, 70% ethanol extracts of aerial parts present promising profiles. These findings suggest that *E. angustifolia* could serve as a valuable natural source of bioactives for pharmaceutical and nutraceutical applications.

Keywords: *Elaeagnus angustifolia*, Antibacterial, Antifungal, DPPH, Total Phenolic Content

INTRODUCTION

Elaeagnus angustifolia L. can be identified by its distinctive small, elliptical pomes that are reddish-brown in color and measure about 1.5 to 2 cm long. Its leaves are long and elliptical, featuring sharp tips and short stalks [Hamidpour et al., 2016; Saboonchian et al., 2014]. Because it shares a close visual resemblance with the common olive tree, people frequently call it wild olive, Russian olive, or oleaster, which is its most common English name. This deciduous species belongs to the Elaeagnaceae family and generally grows into a large shrub or a small tree between 2 and 7 meters tall, easily recognized by its silvery-green branches [Hamidpour et al., 2016; Hassanzadeh et al., 2018]. There are more than 90 species within the *Elaeagnus* genus, showing a broad geographical distribution across the semi-tropical regions of Asia, Europe, and North America. In several European countries, it is primarily favored as an urban ornamental plant; however, in Central and Eastern Anatolia, it is extensively cultivated for its edible fruits [Cansev et al., 2011]. Almost every part of the plant, including its roots, bark, blossoms, leaves, and fruits, exhibits notable medicinal qualities, paving the way for its versatile use in the food, pharmaceutical, and fragrance industries [Hassanzadeh et al., 2018]. In Russia, E. angustifolia has a long-standing reputation as a highly therapeutic plant and has been widely adopted in the folk medicine of various Asian and Trans-Caucasian regions due to its medicinal benefits [Abizov et al., 2008].

Herbal decoctions and infusions prepared from the leaves, flowers, bark, and fruits of local populations have been utilized for generations to manage a variety of health problems and physical conditions. For instance, drinking infusions made from its flowers or eating raw or cooked fruits is believed to help relieve coughs, colds, fevers, nausea, vomiting, jaundice, asthma, and diarrhea, while also being considered beneficial during tetanus management [Ahmadiani et al., 2000]. Ethnobotanical data from Iran indicate that traditional practitioners regularly recommend the fruits to ease pain in individuals suffering from joint inflammation, whereas they use the blossoms to treat tetanus. In the traditional medicine of Türkiye, a hot tea prepared from the flowering twigs of the plant is documented as a traditional remedy for treating diabetes in the Gönen district of Balıkesir province [Sarikaya et al., 2010]. Similarly, folk practices support using the fruit for its diuretic, tonic, antipyretic, and antidiarrheal actions, as well as for managing kidney complaints [Ayaz and Bertoft, 2001; Gurbuz et al., 2003]. Phytochemical analyses indicate that the *E. angustifolia* contains a rich diversity of secondary metabolites, such as flavonoids, polysaccharides, sitosterols, carotenoids, cardiac glycosides, terpenoids, coumarins, phenolcarboxylic acids, amino acids, saponins, vitamins, and tannins. In fact, these specific flavonoid components have drawn significant interest from food and medical scientists owing to their robust in vitro and in vivo antioxidant properties, along with their capacity to scavenge free radicals, interrupt radical chain pathways, and chelate metal ions (Liu and Yao, 2007). In addition to their role as antioxidants, the structural phenolics and terpenes found within these extracts are believed to be directly associated with the plant's antimicrobial modes of action, potentially breaking down microbial cell walls and interrupting internal pathways. The fruits are particularly high in proteins, sugars, vitamins (such as tocopherol, vitamin C, carotene), and major minerals including calcium, magnesium, potassium, sodium, and phosphorus, along with iron and manganese. They are also rich in substantial lipid and fatty acid fractions, including palmitic, palmitoleic, and linoleic acids, phospholipids, glycolipids [Hamidpour et al., 2016; Goncharova et al., 1995; Okmen and Turkcan, 2014; Sahan et al., 2015]. An earlier piece of research focused directly on analyzing the essential elements, polyphenolic levels, and total antioxidant potential of the fruits [Cansev et al., 2011]. Meanwhile, another study proposed that dried fruit flour could serve as a valuable functional ingredient in food formulations due to its dense nutritional properties [Sahan et al., 2013]. This high bioactive content in the different tissues of *E. angustifolia* explains its strong

biological activities [Incilay, 2014]. Because of these qualities, current studies have explored incorporating the fruit into various food products to enhance their functional value [Sahan et al., 2013; Cakmakci et al., 2015].

The flowers and leaves are reported to concentrate large quantities of phenolic and flavonoid compounds [Saboonchian et al., 2014], while the fruits and seeds display strong antioxidant activity [Wang et al., 2012].

Modern pharmacological screenings continue to highlight the anti-inflammatory, antioxidant, antimicrobial, and anticancer potential of *E. angustifolia* [Hamidpour et al., 2016]. Furthermore, previous evaluations of *E. angustifolia* leaf extracts have highlighted their selective antibacterial efficacy against food pathogens, particularly demonstrating a maximum inhibition zone against *Yersinia enterocolitica*, while concurrently exhibiting prominent antioxidant activity through stable DPPH free-radical scavenging profiles [Okmen and Turkcan, 2014].

Therefore, the present study aimed to evaluate and compare the total phenolic contents, DPPH radical scavenging capacities, and antimicrobial profiles of 70% ethanol extracts, ethyl acetate extracts, and decoctions obtained from the fruits and aerial parts of *E. angustifolia*. To observe potential variations induced by geographic factors, plant materials were collected from Eskişehir and Bursa provinces (Türkiye). The antimicrobial potency was determined via Minimum Inhibitory Concentration (MIC) against a panel of pathogens, including *Escherichia coli*, *Staphylococcus aureus*, *Pseudomonas aeruginosa*, *Candida parapsilosis*, and *Candida albicans*. Ultimately, this research aims to contribute to the scientific understanding of the traditional uses of *E. angustifolia* and evaluate its potential as a natural source for future pharmaceutical and nutraceutical applications.

MATERIAL AND METHOD

Plant Material

In 2025, wild specimens of *Elaeagnus angustifolia* were gathered from the provinces of Bursa and Eskişehir. The botanical identification of the collected plants was performed using the diagnostic keys in Flora of Turkey and the East Aegean Islands (Davis, 1982) and supported by field photographs. The corresponding voucher specimens were authenticated and deposited at the Anadolu University Herbarium in Eskişehir, Türkiye under the voucher codes: ESSE 16286 and 16287).

To preserve the chemical integrity of thermolabile secondary metabolites, the freshly harvested aerial parts (comprising leaves and flowers) and fruits were first washed thoroughly under running tap water to remove physical debris, rinsed with distilled water, and subsequently left to dry at ambient room temperature in a well-ventilated, shaded area. Once completely dried, the plant materials were finely pulverized using a laboratory grinder before the extraction process. Solvent extraction was carried out using 70% ethanol and ethyl acetate, maintaining a material-to-solvent ratio of 10 g per 100 mL. This maceration process was repeated for three consecutive cycles, with each round lasting 8 hours. At the end of each cycle, the solution was filtered, and the remaining plant residue was remacerated with fresh solvent to optimize total yield. The collected filtrates were pooled and concentrated to dryness on a rotary evaporator at 37°C. Following the evaporation of the organic solvent, the remaining aqueous fraction of the ethanol extract was thoroughly dried using a freeze-dryer (lyophilizer). The crude dry extracts were maintained at +4°C for subsequent experimental steps. Additionally, aqueous decoctions of the fruit samples were prepared according to traditional methods. All crude dry extracts were tightly sealed and stored at +4 °C in dark glass vials until subsequent *in vitro* bioassays.

Figure 1. General view of *Elaeagnus angustifolia* during different vegetation periods: (a) flowering stage, (b) fruiting stage

Determination of Total Phenolic Content (TPC)

The total phenolic content (TPC) of the *E. angustifolia* extracts was evaluated colorimetrically utilizing the Folin-Ciocalteu reagent (FCR) protocol, with the final values expressed as milligrams of gallic acid equivalents per gram of dry weight (mg GAE/g DW) (Singleton et al., 1999). Briefly, a 0.20 mL aliquot of each extract was blended with 1560 µL of distilled water and 0.10 mL of the Folin-Ciocalteu reagent. Following a brief reaction interval spanning 1 to 8 minutes, the mixture was treated with 0.300 mL of a 20% sodium carbonate (Na_2CO_3) solution. The resulting reaction tubes were incubated at a controlled temperature of 25 °C for 2 hours. After incubation, the optical density (absorbance) was monitored at 760 nm employing a BioTek microplate spectrophotometer. Quantitative calculations were derived from a standard calibration curve constructed using a series of gallic acid concentrations ranging from 0.03 to 1 mg/mL. To guarantee experimental precision, a blank control was processed simultaneously, and all analyses were performed in triplicate; the results are presented as mean values ± standard deviation (SD).

DPPH Radical Scavenging Activity

The antioxidant potential of both the fruit and aerial part extracts of *E. angustifolia* was determined via the DPPH (2,2-diphenyl-1-picrylhydrazyl) radical scavenging method, adapting the methodology outlined by Agiel et al. (Agiel et al., 2024). A stock solution of DPPH was prepared at a concentration of 80 µg/mL. For the assay, 200 µL of each plant extract (dissolved in MeOH at an initial concentration of 5 mg/mL) was introduced into the first row of a 96-well microplate. The remaining wells were pre-filled with 100 µL of methanol (MeOH).

A series of two-fold serial dilutions was executed across the plate to achieve a final concentration gradient spanning from 5 mg/mL down to 0.039 mg/mL. The scavenging reaction was triggered by introducing 100 µL of the DPPH stock solution into each well, after which the plate was incubated in darkness for 30 minutes. In this experimental setup, gallic acid was

employed as the reference standard (positive control), a mixture of DPPH and MeOH functioned as the negative control, and pure MeOH was used as the blank.
Following incubation, the absorbance of the reaction mixtures was recorded at 517 nm at room temperature using a BioTek microplate spectrophotometer. The percentage of DPPH radical inhibition was calculated according to the standard formula reported in Reference 21. Half-maximal inhibitory concentration (IC_{50}) values were computed through non-linear regression analysis using SigmaPlot 13.0 software (SPSS Inc., Chicago, IL). All calculations are expressed as the mean values obtained from three independent experimental replicates.
DPPH Scavenged (%) = [(Abscontrol – Abssample)/Abscontrol] × 100

Antimicrobial Activities

The Gram-positive *Staphylococcus aureus* ATCC 6538 and Gram-negative *Escherichia coli* ATCC 8739, *Pseudomonas aeruginosa* ATCC 9027, and yeast *C. parapsilosis* ATCC 22019, and *C. albicans* ATCC 90028strains were used. The following antimicrobial agents used Tetracycline and Amphotericine B. Mueller-Hinton Agar (MHA), and Tryptic Soy Agar (TSA) were used to ensure the viability of the strains used in the study. The Mueller-Hinton Broth (MHB) and RPMI 1640 medium were used for the antimicrobial activity test. The initial concentration of the extracts was set at 8000 µg/mL. For the standards, the initial concentration was 128 µg/mL.

Antibacterial Activity (MIC, µg/ mL)

The microdilution technique (M-100-S16) for aerobic microorganisms published by the Clinical and Laboratory Standards Institute (CLSI) was used, with some modifications to the protocol (CLSI, 2006; Göger et al., 2018; Göger et al., 2023). To revive the standard culture strains to be used in antimicrobial susceptibility testing, they were inoculated into petri dishes containing Mueller Hinton Agar (MHA) and Tryptic Soy Agar (TSA) and incubated at 37°C for 24 hours. At the end of incubation, single colonies that had grown on the culture medium were transferred to tubes containing Mueller-Hinton Broth (MHB) and incubated at 37°C for 24 hours. After 18–24 hours of incubation, the cultures grown in the liquid medium were adjusted to a concentration of McFarland No. 0.5 (approximately 10^8 CFU/mL for bacteria) using a densitometer. For the experiment, microplate dishes with 96 “U”-type wells were used. After these steps, the microplate wells were sealed and incubated at 35–37°C for 16–20 hours. At the end of the incubation period, 15 µL of resazurin reagent was added to each well to determine the presence of growth. The plates were then incubated for an additional 1–2 hours at 37°C to allow for color development. At the end of incubation, the uncolored areas were identified as concentrations where no growth occurred, and the minimum inhibitory concentration (MIC) values were determined.

Anticandidal Activity (MIC, µg/ mL)

This procedure was performed using the microdilution technique (M27-A2) protocol for fungi published by the Clinical and Laboratory Standards Institute (CLSI, 2002). The standard *Candida* strains used in antifungal activity tests. To revive, the cultures were inoculated into petri dishes containing Sabouraud’s Dextrose Agar (SDA) and incubated at 37°C for 24 hours. At the end of incubation, single colonies that have grown on the medium were transferred to tubes containing 0.85% sodium chloride, vortexed thoroughly, and then adjusted to a turbidity of McFarland No. 0.5 (10^6 CFU/mL for yeast culture) using a turbidimeter. The culture was then diluted in RPMI medium to a concentration of 10^3 CFU/mL and used for the test. Serial two-fold dilutions were performed on the extracts, the plates are inoculated the microorganism and incubated at 35–37°C for 16–20 hours. At the end of the incubation period, a small amount of resazurin reagent was added to the plates to determine the presence of growth in the wells. At the end of incubation, areas that do not change color are identified as concentrations where no growth occurred.

RESULTS AND DISCUSSION

Total Phenolic Content (TPC) and Antioxidant Activity

The quantitative results for the total phenolic content (TPC) and DPPH radical scavenging capacities (IC_{50}) of the various E. angustifolia extracts (70% ethanol, ethyl acetate, and traditional decoctions) from Eskişehir and Bursa provinces are presented in Table 1. The evaluated samples demonstrated a wide variation in TPC, ranging from 16.8 ± 0.02 to 67.8 ± 0.06 mg GAE/g extract. The highest total phenolic concentration was observed in sample 5A (Eskişehir, aerial parts, 70% ethanol extract) with 67.8 ± 0.06 mg GAE/g extract, which concurrently exhibited the most potent DPPH radical scavenging activity with the lowest IC_{50} value of 0.275 ±0.02 mg/mL. This performance was followed by sample 1A (Bursa, aerial parts, 70% ethanol extract), which possessed a TPC of 50.8 ± 0.05 mg GAE/g extract and an IC_{50} of 0.361 ± 0.01 mg/mL. Sample 1B (Bursa, aerial parts, ethyl acetate extract) also showed a significant phenolic level (40.2 ± 0.05 mg GAE/g extract) and antioxidant capacity (IC_{50}: 0.430 ± 0.07 mg/mL). Conversely, lower phenolic contents and weaker antioxidant capacities were consistently found in the fruit extracts. The lowest phenolic concentration was recorded in sample 1E (Bursa, fruits, ethyl acetate extract) with 16.8 ± 0.02 mg GAE/g extract, exhibiting a high IC_{50} of 2.101 ± 0.05 mg/mL. This was followed by sample 5F (Eskişehir, fruits, ethyl acetate extract) with a TPC of 19.1 ± 0.03 mg GAE/g extract and an IC_{50} of 1.983 ±0.03 mg/mL. Generally, the aerial parts of *E. angustifolia* demonstrated a higher concentration of phenolic compounds and antioxidant performance compared to their corresponding fruit parts, regardless of the geographical origin.

Table 1. Data on TPC and DPPH$^{\bullet}$ Assay of *Elaeagnus angustifolia* extracts

Extracts	**Origin/Plant part**	**Solvent**	**TPC (mg GAE/g ext.)**	**DPPH (IC_{50} mg/mL)**
1A	Bursa, aerial parts	70% EtOH	50.8±0.05	0.361±0.01
1B	Bursa, aerial parts	Ethyl Acetate	40.2±0.05	0.430±0.07
1D	Bursa, fruits	70% EtOH	35.3±0.07	0.481±0.05
1E	Bursa, fruits	Ethyl Acetate	16.8±0.02	2.101±0.05
1F	Bursa, fruits	Decoction	26.9±0.04	1.562±0.06
5A	Eskişehir aerial parts	70% EtOH	67.8±0.06	0.275±0.02
5B	Eskişehir aerial parts	Ethyl Acetate	34.1±0.02	0.501±0.01
5D	Eskişehir, fruits	70% EtOH	32.9±0.02	0.513±0.05
5F	Eskişehir, fruits	Ethyl Acetate	19.1±0.03	1.983±0.03
5E	Eskişehir, fruits	Decoction	33.7±0.01	0.708±0.06
GA				0.002±0.0003

Values are expressed as mean ± SD (n = 3). TPC: Total Phenolic Content
mg GAE/g ext.: Total phenols expressed as gallic acid equal milligrams of gallic acid per gram (dry weight) of extract, GA: gallic acid

These results are consistent with prior findings in the literature. Saboonchian et al. (2014) observed that the flowers and leaves of *E. angustifolia* contain elevated levels of phenolic and flavonoid compounds compared to other parts. While Berktaş and Çam (2020) suggested that the bioactive content of the fruits might surpass that of the leaves in certain specific cultivars, our empirical data clearly demonstrate that the aerial parts of both the Bursa and Eskişehir populations possess a far superior phenolic and antioxidant profile.

Furthermore, our findings validate that the DPPH radical scavenging activity of *E. angustifolia* is correlated with its phenolic profile, which is in agreement with Faramarz et al. (2015). Comparing the extraction solvents, polar 70% ethanol proved to be the most efficient system for recovering potent radical-scavenging phenolics. This observation is supported by Si et al. (2011), who documented that polar fractions of *E. angustifolia* exhibit significant DPPH scavenging capacities, and Amini et al. (2019), who verified that polar leaf extracts possess excellent radical scavenging attributes due to their concentrated polar phenolic fractions.

Antimicrobial Activity

The minimum inhibitory concentrations (MIC, µg/mL) of the *E. angustifolia* extracts against five pathogenic strains are compiled in Table 2. The extracts demonstrated that the antimicrobial efficacy profile depends on the plant part and extraction solvent.

Table 2. *In Vitro* Antimicrobial Efficacy (MIC, µg/mL) of *E. angustifolia* Extracts

Extracts	*Escherichia coli*	*S. aureus*	*P. aeruginosa*	*C. parapsilosis*	*C. albicans*
1A	500	500	>4000	2000	4000
1B	1000	>4000	>4000	1000	4000
1D	>4000	>4000	>4000	4000	8000
1E	>4000	>4000	>4000	2000	8000
1F	>4000	>4000	>4000	8000	8000
5A	4000	>4000	>4000	2000	4000
5B	1000	>4000	4000	500	2000
5D	>4000	>4000	>4000	4000	8000
5F	4000	>4000	>4000	1000	2000
5E	>4000	>4000	>4000	1000	8000
TET	0.125	0.125	4	-	-
AMP	-	-	-	4>	128

TET: Tetracycline, AMP: Amphotericin B. Values are represented as MIC (µg/mL).

Among the tested extracts, the polar 70% ethanol extract of Bursa aerial parts (1A) displayed the most prominent antibacterial potency, inhibiting the growth of both the Gram-negative *E. coli* and the Gram-positive *S. aureus* at a low MIC of 500 µg/mL. Moderate antibacterial activities against *E. coli* were also observed for the ethyl acetate extracts of aerial parts from both Bursa (1B) and Eskişehir (5B), with a MIC of 1000 µg/mL. Conversely, the opportunistic pathogen *P. aeruginosa* displayed resistance against almost all tested formulations, with MIC values exceeding 4000µg/mL (with the sole exception of sample 5B, which yielded a MIC of 4000µg/mL). The fruit extracts, regardless of the solvent used, showed low antibacterial potential, with MIC values typically exceeding 4000µg/mL against all tested bacterial strains.

These findings strongly align with İncilay (2014), who observed that polar leaf and flower extracts of Turkish *E. angustifolia* possess strong antimicrobial action against Gram-positive bacteria, particularly *S. aureus*, whereas fruit extracts remain virtually inactive. Our results confirm that the fruit formulations (1D, 1E, 1F, 5D, 5F, 5E) are substantially less effective against bacterial pathogens, exhibiting MIC values ≥4000µg/mL. The general resistance of *P. aeruginosa* to our extracts is a widely recognized phenomenon among Gram-negative bacteria,

primarily arising from their highly selective outer membrane barrier. This resistance profile is supported by Okmen and Türkcan (2014), who reported that certain Gram-negative bacteria and yeast species display marked insensitivity to leaf extracts of *E. angustifolia*.

In the antifungal evaluation, the pathogenic yeast *C. parapsilosis* was found to be significantly more susceptible to the *E. angustifolia* extracts than *C. albicans*. The most notable anticandidal activity was achieved by sample 5B (Eskişehir, aerial parts, ethyl acetate extract) against *C. parapsilosis* with a MIC of 500µg/mL. This was followed by the ethyl acetate extracts of Bursa aerial parts (1B) and Eskişehir fruits (5F), which both inhibited *C. parapsilosis* at a MIC of 1000µg/mL. Interestingly, the aqueous decoction (INF) of Eskişehir fruits (5E) also exhibited promising antifungal activity against *C. parapsilosis* with a MIC of 1000µg/mL, which was superior to its organic solvent counterparts. The marked susceptibility of *Candida* species towards ethyl acetate formulations (such as 5B and 1B) suggests that relatively less polar solvents are efficient at extracting specific lipophilic constituents, such as terpenoids, lipophilic flavonoids, or fatty acids, which may possess targeted cell-membrane disrupting antifungal properties. This hypothesis regarding selective solvent extraction is supported by Khan et al. (2016), who demonstrated that less polar extracts (such as ethyl acetate and n-hexane) of *E. angustifolia* anatomical parts display specialized and powerful antifungal profiles compared to their highly polar counterparts.

It is well-established that the chemical composition and biological activities of medicinal plants vary significantly due to geographic, climatic, and edaphic conditions. In the present study, minor yet noteworthy variations were observed between the samples collected from Eskişehir and Bursa provinces. Specifically, while the Eskişehir population yielded the highest TPC and strongest antioxidant capacity (5A), the Bursa population demonstrated the most potent antibacterial profile against *E. coli* and *S. aureus* (1A). These differences emphasize the distinct role of regional microclimates, altitude, and soil chemistry in modulating the biosynthetically active pathways of *E. angustifolia*.

From an ethnobotanical perspective, these empirical results strongly validate the historical and traditional uses of this species. In the traditional folk medicine of Türkiye, Iran, and Pakistan, preparations (such as decoctions and infusions) of *E. angustifolia* are widely utilized to alleviate throat infections, fever, joint pain, and inflammatory conditions (Ali & Qaiser, 2009; Sarıkaya et al., 2010). The prominent antioxidant capacities and selective antimicrobial properties demonstrated by the aerial parts and fruit formulations in this study provide a robust, evidence-based scientific foundation for their traditional therapeutic claims.

CONCLUSIONS

In conclusion, this study provides a detailed and comparative pharmacological evaluation of wild *E. angustifolia* populations harvested from Eskişehir and Bursa provinces. The integrated findings confirm that the aerial parts, particularly when extracted with 70% ethanol, represent a valuable natural reservoir of phenolic antioxidants and selective antimicrobial agents. Additionally, the selective anticandidal potency of the ethyl acetate and traditional decoction formulations highlights the therapeutic promise of these extracts. These findings contribute valuable scientific data to the botanical and pharmaceutical literature, strongly supporting the potential application of *E. angustifolia* as a natural bioactive source for future pharmaceutical and nutraceutical developments.

ABSTRACT

Background: *Epilobium parviflorum* is a perennial plant that grows in wetlands in Europe, Asia, and North Africa; traditionally used for urinary and prostate disorders, but its side effects and safety in patients receiving anticoagulant therapy remains poorly documented.
Case presentation: We report the case of a 69-year-old man treated with acenocoumarol for dilated cardiomyopathy who presented with an excessive international normalized ratio (INR) of 5.6 after daily consumption of *Epilobium parviflorum* herbal tea. The patient also had also elevated creatinine levels.
The patient's anticoagulant therapy was modified, and pharmacological and therapeutic monitoring was initiated, his kidney function was closely checked until it stabilized.
Methods: A follow-up of clinical and biological parameters was performed, and in silico analyses were carried out on the major phytoconstituents of *E. parviflorum* to explore possible mechanisms of interaction.
Results: Serum creatinine showed a gradual decrease after withdrawal of the infusion. In silico predictions suggested potential inhibition of CYP2C9 and CYP3A4 by myricetin and quercetin, which may explain the observed increase in anticoagulant effect.
Conclusion: This case highlights the risk of clinically significant herb-drug interactions and emphasizes the importance of systematically asking patients about herbal medicine use during anticoagulant treatment.

INTRODUCTION

Epilobium parviflorum, commonly known as small-flowered willowherb, is a medicinal plant traditionally used to manage conditions such as fever, rheumatic pain, headaches, and mucosal or skin infections. Recently, its popularity has grown significantly for treating benign prostatic hyperplasia (BPH) and other urinary disorders, despite limited scientific evidence regarding its efficacy and safety profile [1-3].

Fig. 1: Epilobium parviflorum

The aerial parts of *Epilobium* species are particularly rich in secondary metabolites (Fig. 2) [1]. These bioactive constituents are believed to drive the plant's anti-inflammatory, and antioxidant properties [4,5].

Fig. 2: Main secondary metabolites of the small-flowered willowherb

However, this complex chemical makeup also raises concerns about potential, yet poorly investigated, drug-plant interactions [6].

As the self-medication use of *E. parviflorum* for BPH rises, patients frequently combine it with conventional pharmacotherapy without realizing the associated risks. In particular, its high flavonoid and tannin content can alter the enzymatic and metabolic activity of various drugs, potentially modulating their therapeutic efficacy or inducing toxicity [6-8].

In this context, *E. parviflorum* is of particular interest in North Africa; notably, we successfully collected specimens in eastern Algeria (Constantine). Here, we report the long-term monitoring of a patient under acenocoumarol therapy who developed severe, excessive anticoagulation following the regular consumption of *E. parviflorum* herbal tea. To elucidate the underlying biological mechanisms, *in silico* ADMET and toxicity predictions were conducted on its major phytoconstituents.

MATERIAL AND METHODS

Data collection

this study reports the long-term monitoring of a patient receiving acenocoumarol who experienced excessive anticoagulation after consuming *Epilobium parviflorum* herbal tea. Clinical information was collected during routine medical care, including INR measurements, therapeutic modifications and serum creatinine values obtained during and after discontinuation of herbal tea consumption.

1.2. In silico analysis

Three major phytochemicals reported in *E. parviflorum* (myricetin, quercetin and oenothein B) were selected based on phytochemical studies. Their chemical structures obtained from PubChem and inserted in SMILES format. The pharmacokinetic and toxicity profiles were evaluated using ADMETlab 3.0, a platform that predicts how a molecule is Absorbed,

Distributed, Metabolized, Excreted, and how Toxic it might be, and ProTox 3.0, a tool specifically designed to predict organ toxicity.

Case description

The aerial parts of Epilobium spp are rich in secondary metabolites, mainly polyphenols such as flavonoids, phenolic acids and tannins, as well as lipophilic compounds such as steroids [1]. the small-flowered species are rich in flavonoids, mainly myricetin and quercetin, and in tannins, mainly oenothein B, giving them anti-inflammatory, analgesic, antioxidant, antibacterial and antiproliferative properties [4,6,7,8].

The complex constituents of Epilobium *spp* makes it dangerous in combination with medication.

The growing interest in certain species of fireweed for its potential efficacy in treating benign prostatic hyperplasia has led to an increase in its consumption, often without consideration of its potential risks [8].

To illustrate this risk, let's take the example of our patient, a 69-year-old man who presented for the first time to the hospital Didouche Mourad, Constantine, Algeria, for a haemostasis test. The result showed a low PT and an INR of 5.6.

The patient's history revealed that he was diabetic, in addition to having dilated cardiomyopathy for which he had been treated with acenocoumarol 4 mg, a vitamin K antagonist (VKA) for over a year at a dose of 3/4 tablet (Cp) - 1/2 Cp in alternation.

The last INR value recorded one month previously was within the therapeutic range **[2-3].**

As the patient's treatment remained unchanged, the questioning focused on his diet, which showed that he had no notion of the need for a diet adapted to his anticoagulant treatment. In addition, he had been taking a cup of fireweed-tea every evening for more than a week.

The high tannin and flavonoid content of E. parviflorum may explain the increase in INR and the risk of haemorrhage. In fact, tannins' ability to complex proteins gives them an inhibitory

effect on multiple enzyme systems [9]. Flavonoids, such as myricetin and quercetin, also have an antiplatelet aggregation effect [10] in addition to an inhibitory effect on cytochrome P450 (CYP450) isoenzymes 2C9 and 3A4, which significantly increases the activity of anticoagulants [11-15].

A therapeutic education session was then required, and led to the following recommendations:

- Skip the day's anticoagulant intake and check the INR the next day,
- Explanation of the effects of acenocoumarol, the need for regular monitoring and the many interactions with drugs, food and plants,
- And finally, the need to stop taking herbal tea, which increased the effect of the VKA.

The patient was cooperative and receptive to the information, but he wanted to continue taking the herbal tea because since he started taking it, his prostate problems had disappeared, specifically his polyuria, incontinence, urinary retention and pelvic pain, which gave him a better quality of sleep.

We then advised limiting the daily amounts consumed and instituting withdrawal periods with close monitoring of INRs in order to manage the interaction and find the appropriate dosage.

The patient resumed his treatment at 1/2 Cp the following day, as he was unable to perform an INR.

Subsequent INR tests were carried out on D5 and D9 after resumption, and the results were between 2 and 3.

Our patient finally stopped taking herbal tea after a month and a half, which led us to increase the dosage (3/4 tablet).

During the period of continuous Epilobium consumption, serum creatinine remained moderately elevated (17 and 18.21 mg/L). After stopping of the herbal tea, creatinine level progressively decreased to 16.17 mg/L one month later and subsequently to 15.56 and 14.24 mg/L during follow-up (Table.1).

Table 1: Evolution of the patient's creatinine levels

Time	**Creatinine (mg/L)**	**Creatinine (µmol/L)**
During herbal tea	17	150.3
During herbal tea	18.21	161
1 month after discontinuation	16.17	143
Follow-up	15.56	137.5
Follow-up	14.24	125.88

The pharmacokinetic and toxicity profiles of the major bioactive compounds isolated from *Epilobium parviflorum* were evaluated using two complementary *in silico* platforms: ADMETlab 3.0 and ProTox 3.0 [16 - 17].

ADMETlab 3.0 was used to predict the absorption, distribution, metabolism, excretion, and toxicity (ADMET) properties of the selected phytoconstituents. A particular focus was placed on the potential of inhibition of CYP450 enzymes, with a particular emphasis on its capacity to inhibit CYP2C9 and CYP3A4. These isoforms play a critical role in the hepatic metabolism of a wide range of drugs, including oral anticoagulants such as acenocoumarol. The analysis revealed that myricetin and quercetin exhibited severe predicted inhibition against both CYP2C9 and CYP3A4, whereas oenothein B showed no predicted inhibition of CYP2C9 and only weak interaction with CYP3A4.

ProTox 3.0 was subsequently employed to evaluate organ-specific toxicity endpoints, with a particular emphasis on nephrotoxicity. The ProTox 3.0 predictions indicated a low ADMET risk for both myricetin and oenothein B, while quercetin triggered a ProTox Alert, suggesting a higher potential for adverse renal effects.

The results of the in-silico network pharmacology predictions are summarized in Table 2.

Table 2: ADMET prediction [16 - 17].

Compound	**CYP2C9/ Score**	**CYP3A4/ Score**	**Nephrotoxicity**
Myricetin	Inhibitor (0.995)	Inhibitor (0.999)	low ADMET risk
Quercetin	Inhibitor	inhibitor	ProTox alert
Oenothein B	no inhibition predicted	weak	low ADMET risk

Discussion:

This case highlights the significant, yet often overlooked, risks associated with the concurrent use of herbal remedies and conventional medications. Specifically, it demonstrates the potential for *Epilobium parviflorum* to interact negatively with acenocoumarol.

The high tannin and flavonoid content, of *E. parviflorum* appears to be the primary culprit in the observed increase in the patient's INR. They can inhibit enzyme systems, which are crucial for the metabolism of acenocoumarol. This leads to an enhanced anticoagulant effect, significantly increasing the risk of hemorrhage.

Interestingly, a gradual decrease in serum creatinine was observed after discontinuation of the herbal tea. Although this temporal association does not establish causality, it raises the hypothesis that prolonged exposure to Epilobium, direct or indirect (for example through dehydration, drug interaction, or underlying disease modulation), deserves further investigation.

The case emphasizes the importance of thorough patient history taking, particularly regarding the use of herbal remedies. Therapeutic education played a crucial role in this case, especially as the patients often fail to report the use of herbal remedies, which can lead to undetected drug interactions and adverse effects. This highlights the need for clinicians to proactively inquire about the use of herbal products.

CONCLUSION:

This case study demonstrates that the concomitant use of Epilobium parviflorum and acenocoumarol may expose patients to clinically significant drug-herb interactions. Long-term monitoring also revealed changes in renal function that coincided with the consumption of herbal tea, although a causal relationship cannot be confirmed.

In silico findings suggest that myricetin and quercetin from *E. parviflorum* may interfere with the specific cytochrome P450 pathways required for acenocoumarol metabolism, raising a significant concern for pharmacokinetic herb–drug interactions. In contrast, oenothein B appeared to present a more favorable safety profile with minimal CYP450 inhibition and low predicted nephrotoxicity.

It is the responsibility of physicians and pharmacists to regularly monitor their patients. They should systematically investigate the use of herbal medicines in patients undergoing anticoagulation therapy and report any adverse effects to the relevant pharmacovigilance center.

ABSTRACT

Ammonium (NH_4^+) adsorption is an important soil process that regulates nitrogen retention, fertilizer use efficiency and NH_4^+ availability for plant uptake. By retaining NH_4^+ within the soil matrix, this process reduces nitrogen losses through leaching and nitrification, thereby enhancing nutrient conservation. However, excessive NH_4^+ adsorbed may temporarily reduce ammonium availability to plants, potentially limiting short-term nitrogen uptake. Therefore, quantifying the NH_4^+ adsorption capacity of soils is essential for optimizing nitrogen management in agricultural systems. In this study, NH_4^+ adsorption capacity of selected soils from the Ishëm River Basin was evaluated using batch adsorption experiments with 0.01 M $CaCl_2$ as the background electrolyte. Air-dried soil samples were equilibrated with NH_4Cl solutions containing 0, 5, 10, 20, 50 and 100 mg NH_4^+ L^{-1} at a soil-to-solution ratio of 1:10 for 24 h. The equilibrium NH_4^+ concentration was determined spectrophotometrically using the indophenol blue method and NH_4^+ adsorbed was calculated as the difference between the initial and equilibrium NH_4^+ concentrations. Results showed that NH_4^+ adsorption increased progressively with increasing initial ammonium concentration in all soils. Compared with the sandy soil (5.2% clay), soils with higher clay contents exhibited substantially greater NH_4^+ adsorption. The soil containing 62.5% clay reached a maximum adsorption of 394.86 mg kg^{-1}, corresponding to 39–76% of the applied NH_4^+, whereas the sandy soil reached only 150 mg kg^{-1} (9–30% of applied NH_4^+). The highest NH_4^+ adsorption was observed in the soil with an intermediate clay content (31.6%), reaching 506 mg kg^{-1} (47.47–65.1% of applied NH_4^+), likely due to the combined effects of clay minerals and its relatively high organic matter content (4.66%), which enhanced ammonium retention. Overall, the results highlight the important role of clay content in regulating NH_4^+ adsorption, with organic matter likely acting as a complementary factor that enhances ammonium retention.

Keywords: Ammonium adsorption; Batch adsorption experiments; Clay content; Organic matter; Ishëm River Basin

INTRODUCTION

To maximize crop yields, agricultural soils are extensively supplemented with nitrogen (N), which serves as a critical macronutrient for plant development and vegetative growth (Diaz & Rosenberg, 2008). Crop growth relies heavily on the uptake of nitrogen in its two primary inorganic states: nitrate (NO_3^-) and ammonium (NH_4^+) (Marschner, 1995). However, despite the fact that modern agricultural practices depend predominantly on mineral fertilizers to supply these forms, the actual utilization efficiency of these inputs remains very low (Yadav, 2024). Approximately half of the nitrogen applied to agricultural systems escapes plant uptake and may be lost into the environment via leaching, surface runoff, denitrification and volatilization (Anas et al., 2020).

The soil behavior of ammonium (NH_4^+) is notably unique compared to other inorganic nitrogen species. This ion is subject to multiple competing pathways: it can be fixed within clay mineral interlayers, adsorbed onto soil cation exchange sites, incorporated into microbial biomass or oxidized through the nitrification process (Havlin et al., 2014). Due to its positive charge, ammonium exhibits a robust affinity for soil particles, distinguishing its behavior from that of the highly mobile nitrate ion. Beyond its adsorption onto cation exchange complexes, NH_4^+ can undergo fixation within the structural interlayer lattices of particular clay minerals, where it remains temporarily inaccessible for plant uptake (Nieder et al., 2011). Primarily occurring in 2:1 type clay minerals such as illite and vermiculite, ammonium fixation is driven by specific interlayer zones that selectively bind NH_4^+ (Mortland, 1966).

The ammonium fixation capacity of a soil fluctuates in response to a complex pattern of physicochemical attributes. Factors such as wetting and drying dynamics, cation exchange capacity (CEC), temperature, pH, organic matter content, ammonium concentration and particle size distribution collectively modulate the magnitude of this fixation (Nommik & Vahtras, 1982; Clemente & Bernal, 2006).
Ammonium fixation has a dual effect on nitrogen dynamics in soil. It can protect NH_4^+ from rapid nitrification, thereby mitigating subsequent losses from denitrification and leaching (Scherer, 1993; Steffens & Sparks, 1999; Juang et al., 2001). On the other hand, can reduce the availability of fertilizer-derived NH_4^+ for crop uptake (Scherer et al., 2014).
The objective of this study was to evaluate the ammonium adsorption capacity of selected soil samples through laboratory adsorption experiments using calcium chloride ($CaCl_2$) as the background electrolyte and different initial ammonium concentrations. The study further aimed to assess the relationship between ammonium adsorption and selected soil physicochemical properties, providing insights into the mechanisms controlling nitrogen retention in soil.

MATERIALS AND METHODS

Soil sampling and analysis

The soil samples used in this study were collected from the Ishëm River Basin, located in central-western Albania. Sampling was carried out at a depth of 0–30 cm across the basin. The collected soil samples were transported to the laboratory and pretreated according to ISO 11464:2006. The samples were air-dried at room temperature, disaggregated and sieved through a 2 mm mesh to remove coarse fragments and visible roots.

The prepared soil samples were analyzed for selected physicochemical properties, including soil pH, measured in a 1:5 soil-to-water suspension according to ISO 10390:2021; electrical conductivity (EC), measured in a 1:5 soil-to-water extract according to ISO 11265:2025; soil organic matter, determined by the potassium dichromate oxidation method; total nitrogen (TN), determined using the Kjeldahl method according to ISO 11261:1995; total phosphorus (P-tot), determined using the molybdenum blue method according to ISO 6878:2004 and soil texture, determined by the hydrometer method according to ISO 11277:2020.

Determination of ammonium adsorption capacity

The ammonium adsorption capacity of the soil samples was determined using a batch equilibrium adsorption procedure adapted from previously published procedures for ammonium adsorption in soils (Ranjbar & Jalali, 2013; Sieczka & Koda, 2016).

For each treatment, 2.00 g of air-dried soil (<2mm) were weighed and transferred into 50 mL polypropylene centrifuge tubes. A 0.01 M calcium chloride ($CaCl_2$) solution was used as the background electrolyte to maintain constant ionic strength throughout the experiment. Ammonium solutions containing 0, 5, 10, 20, 50 and 100 mg NH_4-N L^{-1} were prepared from a 1000 mg NH_4-N L^{-1} stock solution using analytical-grade ammonium chloride (NH_4Cl) dissolved in 0.01 M $CaCl_2$. 20 mL of each working solution were added to the soil samples, resulting in a soil-solution ratio of 1:10 (w/v). Each treatment was prepared in duplicate.

To inhibit microbial nitrification during the equilibration period, three drops of chloroform ($CHCl_3$) were added to each centrifuge tube. The tubes were sealed and placed on an orbital shaker at 150 rpm for 24 h at room temperature (25 ± 1 °C) to allow adsorption equilibrium to be reached. Following equilibration, the suspensions were centrifuged at 3500 rpm for 15 min and the supernatants were filtered through 0.45 μm syringe membrane filters. The equilibrium ammonium concentration (C_e) was determined colorimetrically using the indophenol blue method at 655 nm with a UV–Vis spectrophotometer.

The amount of ammonium adsorbed by the soil (q, mg kg^{-1}) was calculated by mass balance as:

$$q = (C_0 - C_e) \times V/m$$

Where C_0 is the initial ammonium concentration (mg L^{-1}), C_e is the equilibrium ammonium concentration (mg L^{-1}), V is the volume of the solution (L), and m is the dry mass of the soil (kg).

The obtained adsorption data were used to evaluate the ammonium adsorption capacity of the investigated soils and to examine its relationship with the measured soil physicochemical properties.

RESULTS AND DISCUSSION

Physical Chemical properties of the selected soils

The physicochemical characteristics of the three soil samples are presented in Table 1. The soils showed considerable differences in clay, organic matter and total nitrogen content, while pH values ranged from 6.81 to 7.70, indicating slightly acidic to neutral conditions. Electrical conductivity (EC) was low in all samples (26.20–110.95 μS cm^{-1}), indicating the absence of salinity problems.

Table 1: Physical chemical properties of selected soils

Code	pH	EC	LO	W	P –Tot	TN	Clay	Silt	Sand
		µS cm^{-1}	%	%	mg kg^{-1}			%	
N1	7.59	110.95	4.66	5.41	247.10	2953.05	31.62	23.72	44.66
N2	7.70	83.20	1.90	8.66	182.81	2010.04	62.48	27.16	10.36
N3	6.81	26.20	0.94	3.19	246.41	1020.33	5.16	20.64	74.20

The greatest differences were observed in soil texture. Sample N2 had the highest clay content (62.48%), N1 presented an intermediate content (31.62%), while N3 was dominated by the sandy fraction (74.20%) and had only 5.16% clay. Since clay particles provide negatively charged exchange surfaces capable of retaining ammonium ions, the observed differences in soil texture are expected to influence ammonium adsorption capacity. In contrast, the high sand content in N3 suggests a lower potential for ammonium retention due to its lower specific surface area and limited number of exchange sites (Nieder et al., 2011).

Organic matter content was highest in N1 (4.66%) and lowest in N3 (0.94%), while total nitrogen followed the same trend. This pattern reflects the well-known relationship between soil organic matter and nitrogen reserves, as organic matter constitutes the main nitrogen reservoir in most soils (Ladha et al., 2011; Ren et al., 2014).

These differences in texture, organic matter and nitrogen content indicate that the three soils present different physicochemical conditions, which are expected to affect their ability to adsorb NH_4^+.

Ammonium Adsorption Capacity

The experimental results showed that the amount of NH_4^+ adsorbed by the soils increased with increasing ammonium application rates (Table 2). However, the adsorption response of the three soils varied depending on their physicochemical characteristics. At all application levels, soils N1 and N2 exhibited considerably higher adsorption capacities compared to soil N3. At the highest NH_4^+ application rate (1000 mg kg^{-1}), soil N1 presented the highest amount of adsorbed NH_4^+ (506.33 mg kg^{-1}), followed by N2 (394.86 mg kg^{-1}), while N3 exhibited the lowest value (88.95 mg kg^{-1}).

The low adsorption capacity of soil N3 can be related to its predominantly sandy texture and very low clay content (5.16%), which limit the number of active exchange sites for NH_4^+ retention. In contrast, the higher clay content in N1 and N2 provided more favorable conditions for ammonium adsorption.

These findings are consistent with those reported by Nieder et al. (2011) who highlighted the important role of soil texture in ammonium fixation. Their study showed that coarse-textured soils generally retain much lower amounts of adsorbed NH_4^+ (10–90 mg kg^{-1}) than fine-textured soils (90–460 mg kg^{-1}). This difference is mainly attributed to the lower clay content and the smaller number of adsorption sites available in coarse soils, which limits their capacity to retain ammonium.

Table 2: Ammonium adsorption capacity and adsorption efficiency of the studied soils at different NH_4^+ application rates

Applied NH_4^+ (mg kg^{-1})	N1		N2		N3	
	Adsorbed NH_4^+ (mg kg^{-1})	Adsorption (%)	Adsorbed NH_4^+ (mg kg^{-1})	Adsorption (%)	Adsorbed NH_4^+ (mg kg^{-1})	Adsorption (%)
50	32.55	65.09	38.01	76.01	12.66	25.32
100	53.92	53.92	58.16	58.16	28.19	28.19
200	112.08	56.04	107.00	53.50	58.04	29.02
500	237.34	47.47	236.93	47.39	150.77	30.15
1000	506.33	50.63	394.86	39.49	88.95	8.89

When the results were expressed as percentage of NH_4^+ adsorbed, a slightly different behavior was observed between the soils. Soil N2 showed the highest adsorption efficiency at the lower application rates (76.01% at 50 mg kg^{-1} and 58.16% at 100 mg kg^{-1}), reflecting the influence of its high clay content (62.48%). However, with increasing NH_4^+ application rate, the relative adsorption efficiency decreased, while soil N1 maintained a higher adsorption percentage at the highest applied concentration (50.63% at 1000 mg kg^{-1}).

Although soil N2 had the highest clay content, the highest absolute adsorption capacity at the highest application rate was recorded in soil N1. This result suggests that in addition to the clay fraction, the higher organic matter content in N1 (4.66%) may have contributed to the increased capacity of the soil to retain NH_4^+, especially under conditions of high ammonium loading.

Overall, the results indicate that NH_4^+ adsorption is controlled by the interaction between soil texture and organic matter content. As documented by Nommik & Vahtras (1982), clay content appears to be one of the main factors determining adsorption capacity, while organic matter plays a complementary role in maintaining this capacity as ammonium concentrations increase.

Relationship between applied NH_4^+ and adsorbed NH_4^+

To better describe the relationship between the amount of NH_4^+ applied and adsorbed, the experimental data were fitted with a power regression model (Figure 1, Table 3). The model showed a very good relationship for soils N1 (R^2 = 0.9966) and N2 (R^2 = 0.9971), while a lower R^2 value (0.8241) was recorded for soil N3, indicating a greater variability in the adsorption process.

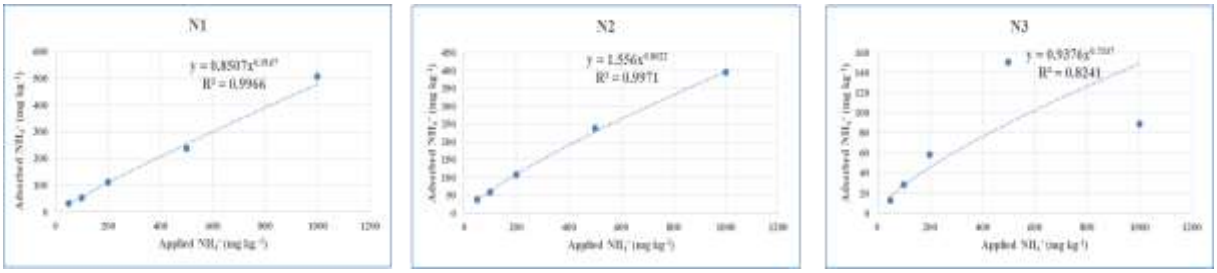

Figure 1: Relationship between applied NH_4^+ and adsorbed NH_4^+ described by a power regression model.

The value of the regression exponent (b) gradually decreased from N1 (0.9167) to N2 (0.8022) and N3 (0.7337), which indicates that with increasing NH_4^+ application rate, the increase in the adsorbed amount becomes less proportional.

Table 3: Power regression equations describing the relationship between applied and adsorbed NH_4^+ in the studied soils

Soil	Power regression equation	R^2 Value
N1	$y = 0.8507x^{0.9167}$	0.9966

N2	$y = 1.5560x^{0.8022}$	0.9971
N3	$y = 0.9376x^{0.7337}$	0.8241

The exponent of soil N1, which is closer to the value of 1, indicates that adsorption increased almost proportionally over the entire range of tested concentrations. In contrast, the lower value of the exponent for soil N3 indicates that the adsorption efficiency decreased more rapidly with increasing NH_4^+ application rate. These results are consistent with the differences in soil texture and organic matter content, discussed above.

CONCLUSIONS

The preliminary results obtained so far suggest that the adsorption capacity of NH_4^+ varied among the studied soils and was influenced by their physicochemical properties, particularly soil texture and organic matter content. In all soils, the amount of adsorbed NH_4^+ increased with increasing application rates, although clear differences in adsorption capacity were observed.

Soil N1 exhibited the highest adsorption capacity, while soil N3 showed the lowest. The lower adsorption capacity of N3 may be related to its low clay content and dominance of the sandy fraction. Although soil N2 had the highest clay content, the higher adsorption capacity observed in N1 suggests that, in addition to clay content, its higher organic matter content may have contributed to its greater ability to retain NH_4^+, especially at higher application rates.

The power regression model provided a good description of the relationship between applied and adsorbed NH_4^+, especially for soils N1 and N2, suggesting that this approach may be useful for describing NH_4^+ adsorption behavior in these soils. Overall, the findings indicate that NH_4^+ retention in soils is likely controlled by the combined influence of several physicochemical properties, with clay content and organic matter appearing to play important roles.

These findings represent the results obtained to date from the three soils investigated in this study. Further analyses are ongoing and the assessment will be extended to additional soil samples collected from different areas of the Ishëm River Basin to provide a more comprehensive understanding of NH_4^+ adsorption capacity and its relationship with soil physicochemical properties across the basin.

ABSTRACT

The search for sustainable protein alternatives has intensified due to increasing global population and environmental concerns associated with conventional protein sources. This study evaluated the standardized ileal digestibility (SID) of amino acids and protein quality of black soldier fly larvae (BSFL) (*Hermetia illucens*) meal compared to soybean meal in broiler chickens. A total of 70 male Ross 308 broiler chickens at 34 days of age were used in a completely randomized design with 7 treatments and 5 replicates. Experimental diets included purified diets containing BSFL meal or soybean meal as the sole protein source, a basal corn-soybean meal diet, mixture diets (50:50), and a nitrogen-free diet for measuring endogenous losses. All diets contained 0.5% chromic oxide. Birds were fed experimental diets from 34 to 38 days, and ileal digesta was collected at day 38. Chemical composition analysis showed BSFL meal contained 36.21% crude protein, significantly lower than soybean meal (43.45%). However, the SID of protein in BSFL meal (89.86%) was significantly higher than soybean meal (81.75%). Methionine digestibility in BSFL meal (91.93%) was substantially higher than soybean meal (75.17%), while lysine digestibility was 92.25% versus 88.52%, respectively. However, valine digestibility in BSFL meal (75.85%) was significantly lower than soybean meal (94.79%), and cystine digestibility (82.86%) was also lower than soybean meal (101.53%). The DIAAS value for BSFL meal (72.6%) was significantly higher than soybean meal (59.6%). Methionine + cystine was identified as the first-limiting amino acid for both sources. In conclusion, despite its lower protein concentration, BSFL meal exhibits high protein quality and digestibility, particularly for lysine and methionine, making it a viable alternative protein source. However, the lower digestibility of valine and cystine requires attention in diet formulation, and a synergistic combination with soybean meal is recommended for optimal results.

Keywords: Black soldier fly larvae, *Hermetia illucens*, Amino acid digestibility, Protein quality, DIAAS, Broiler chickens

INTRODUCTION

The global demand for animal protein is projected to increase by 70% by 2050, placing unprecedented pressure on feed protein sources (FAO, 2012). Soybean meal, the predominant plant protein source, faces sustainability challenges including deforestation, high water consumption, and reliance on genetically modified crops. Fish meal production is constrained by declining wild fish stocks (Tacon & Metian, 2008). Therefore, identifying sustainable, cost-effective alternatives has become essential for global food security.

Edible insects have emerged as promising alternatives due to their efficient feed conversion, ability to be reared on organic wastes, and favorable nutritional profiles (Van Huis et al., 2013; Makkar et al., 2014). Among various species, black soldier fly (*Hermetia illucens*) has gained

significant attention as a candidate for mass production. BSFL meal contains 35-45% protein and 15-35% fat, with a relatively balanced amino acid profile (Elwert et al., 2010; Schiavone et al., 2017). The insect is capable of converting a wide range of organic wastes into high-quality biomass, making it an environmentally sustainable protein source (Surendra et al., 2016; Abd El-Hack et al., 2020).

The presence of chitin in insect exoskeletons presents unique challenges for digestibility assessment. Chitin, a nitrogen-containing polysaccharide, may affect protein and amino acid digestibility, making accurate measurement essential for proper feed formulation (Finke, 2013; Jonas-Levi & Martinez, 2017). Modern poultry nutrition relies on standardized ileal digestibility (SID) values rather than total amino acid concentrations to formulate balanced diets (Ravindran & Bryden, 1999). This approach enables more precise matching of bird requirements and reduces nitrogen excretion (Wayne et al., 2010).

Recent studies have evaluated the amino acid digestibility of BSFL meal with varying results. Mahmoud and Ravindran (2025) reported SID coefficients of 0.83 for lysine, 0.89 for methionine, and 0.82 for threonine in black soldier fly prepupae meal. Alafif et al. (2025) reported SID ranges of 86.77-89.17% for BSFL amino acids, depending on rearing substrate. Bovera et al. (2015) demonstrated that BSFL meal could effectively replace soybean meal in broiler diets without negative effects on growth performance. Dabbou et al. (2018) and Lee et al. (2018) confirmed positive effects of BSFL meal on intestinal morphology and immune responses.

However, comprehensive studies comparing BSFL meal with soybean meal using the DIAAS methodology in the local context are limited. Therefore, this study was conducted to determine the standardized ileal amino acid digestibility and protein quality of BSFL meal compared to soybean meal in broiler chickens using the DIAAS methodology.

MATERIAL AND METHOD

Birds and Management

A total of 70 male Ross 308 broiler chickens at 34 days of age were obtained from a commercial flock and randomly assigned to 7 experimental treatments with 5 replicates (2 birds per replicate). Birds were housed in metabolic cages (30 × 40 cm) equipped with separate feeders and waterers in an environmentally controlled room with temperature maintained at 24±1°C and a lighting program of 23 hours light and 1 hour dark. All birds received commercial diets based on Ross 308 recommendations until 33 days of age and were fed experimental diets from 34 to 38 days.

Experimental Diets and Treatments

The experiment was conducted as a completely randomized design (CRD) with 7 treatments and 5 replicates. Experimental diets were formulated as semi-purified diets based on corn starch and glucose (as carbohydrate sources) and soybean oil (as fat source), with vitamins and minerals added according to Ross 308 requirements for the finisher period. All diets contained 0.5% chromic oxide (Cr_2O_3) as an indigestible marker and were formulated without free amino acids.

The experimental treatments included:

Basal diet (BD): Corn-soybean meal based diet

Nitrogen-free diet (NFD): For measuring basal endogenous amino acid losses

Purified BSFL diet: NFD + BSFL meal as the sole protein source

Purified soybean meal diet: NFD + soybean meal as the sole protein source

Mixture diet (50:50): BD + BSFL diet (1:1 ratio)

All feed ingredients were analyzed for chemical composition before diet formulation.

Sample Collection and Chemical Analysis

Birds were fed experimental diets from day 34 to 38 (4 days). At the end of day 38, all birds were slaughtered by cervical dislocation. The terminal ileum (from Meckel's diverticulum to 4 cm anterior to the ileo-cecal junction) was immediately dissected, and ileal digesta were gently flushed with distilled water, pooled per replicate, and stored at -20°C until analysis.

Proximate analysis: Dry matter, ash, crude protein, crude fat, and crude fiber were determined according to AOAC (2005) standard methods. Crude protein was determined by the Kjeldahl method (N × 6.25).

Chromic oxide measurement: Chromium concentration in diets and ileal digesta was measured by spectrophotometry according to Fenton and Fenton (1979).

Amino acid analysis: Amino acid concentrations were determined using ion-exchange chromatography (amino acid analyzer) following acid hydrolysis with 6N HCl at 110°C for 24 hours. For sulfur-containing amino acids (methionine and cystine), performic acid oxidation was performed prior to hydrolysis.

Calculations

Amino acid digestibility, digestible amino acid content, and DIAAS were calculated using standard formulas as described in Paper 1.

Statistical Analysis

Data were analyzed using the GLM procedure of SAS (version 9.4) in a completely randomized design. Treatment means were compared using Duncan's multiple range test at $P < 0.05$ significance level.

RESULTS AND DISCUSSION

Chemical Composition

The chemical composition of BSFL meal and soybean meal is presented in Table 1. BSFL meal contained 36.21% crude protein, significantly lower than soybean meal (43.45%). The total amino acid content in BSFL meal (34.42%) was slightly lower than soybean meal (36.18%).

Table 1. Chemical composition of black soldier fly larvae meal and soybean meal (% dry matter)

Parameter	BSFL Meal	Soybean Meal	SEM
Crude Protein	36.21c	43.45b	0.35
Crude Fat	31.50a	1.40b	0.44
Crude Fiber	14.90a	6.20b	0.33
Ash	11.40a	7.20b	0.29
Essential Amino Acids			
Lysine	2.28c	2.83b	0.04
Methionine	0.76b	0.68c	0.01
Arginine	1.61c	2.58b	0.03
Threonine	1.14c	1.77b	0.02
Valine	3.61b	1.76c	0.05
Leucine	2.26c	2.78b	0.05
Isoleucine	1.76b	1.62c	0.02
Phenylalanine	1.50c	1.82b	0.02
Histidine	1.03b	0.96c	0.01
Non-Essential Amino Acids			
Glutamic acid	3.96c	6.39b	0.10
Glycine	2.65b	1.62c	0.05
Alanine	2.16b	1.61c	0.04
Serine	2.14b	1.87c	0.03

a,b,c Values within rows with different superscripts differ significantly ($P < 0.05$)

The crude protein content of BSFL meal (36.21%) is within the range reported by other researchers (Elwert et al., 2010; Nyangena et al., 2020). The relatively lower protein concentration compared to soybean meal is primarily due to higher fat (31.50%) and ash (11.40%) content in BSFL meal. However, it is noteworthy that the total amino acid content (34.42%) is very close to crude protein (36.21%), indicating that the majority of nitrogen in BSFL meal is in the form of amino acids, with minimal non-protein nitrogen contribution from chitin. This finding is consistent with Finke (2013) who reported high protein recovery in BSFL meal.

When normalized per unit of protein (Table 2), BSFL meal had comparable lysine (6.32%) to soybean meal (6.57%) but significantly higher valine (10.03%), methionine (2.10%), and isoleucine (4.90%). The high valine proportion in BSFL protein is remarkable and indicates that BSFL meal is exceptionally rich in branched-chain amino acids, which are important for muscle protein synthesis.

Table 2. Amino acid composition of BSFL meal and soybean meal (% of protein)

Amino Acid	BSFL Meal	Soybean Meal	SEM
Lysine	6.32a	6.57a	0.10
Methionine	2.10a	1.59b	0.03
Arginine	4.48c	6.01a	0.09
Threonine	3.16c	4.12a	0.05
Valine	10.03a	4.08c	0.08
Leucine	6.29b	6.47b	0.10
Isoleucine	4.90a	3.77c	0.04
Phenylalanine	4.16a	4.22a	0.06
Histidine	2.86a	2.24c	0.02
Total Amino Acids	95.63a	84.16b	0.74

a,b,c Values within rows with different superscripts differ significantly (P < 0.05)

Apparent and Standardized Ileal Digestibility

Table 3 presents the apparent (AID) and standardized (SID) ileal digestibility values for BSFL meal and soybean meal. BSFL meal exhibited significantly higher SID for protein (89.86%) compared to soybean meal (81.75%). This superiority was also observed for most essential amino acids, with notable exceptions for valine and cystine.

Table 3. Apparent and standardized ileal digestibility of protein and amino acids in BSFL meal and soybean meal (%)

Parameter	AID		SID	
	BSFL	Soybean	BSFL	Soybean
Protein	88.55b	80.56c	89.86a	81.75b
Essential Amino Acids				
Lysine	90.29a	87.45b	92.25a	88.52b
Methionine	90.75b	73.88c	91.93b	75.17c
Arginine	94.42b	91.69c	95.97b	92.26c
Threonine	86.77c	90.45b	88.04c	91.30b
Valine	73.72c	90.82b	75.85c	94.79a
Leucine	87.72b	83.96c	89.18b	85.68c
Isoleucine	87.23b	88.57b	88.17b	89.59b
Phenylalanine	88.50a	83.57b	91.74a	87.26b
Histidine	94.18b	91.82c	95.51b	92.03c
Non-Essential Amino Acids				
Cystine	70.42c	92.94b	82.86b	101.53a
Glycine	90.30b	81.29c	91.24b	82.80c
Alanine	89.31b	90.76b	90.82b	92.91b

a,b,c Values within rows (AID or SID) with different superscripts differ significantly ($P < 0.05$)

The high digestibility of BSFL meal protein (89.86% SID) confirms its excellent amino acid availability despite the presence of chitin. This finding is consistent with Schiavone et al. (2017) who reported high nutrient digestibility for partially defatted BSFL meal, and with Alafif et al. (2025) who reported SID ranges of 86.77-89.17% for BSFL amino acids.

The most remarkable finding was the substantially higher methionine digestibility in BSFL meal (91.93% SID) compared to soybean meal (75.17% SID). This represents a significant competitive advantage, as methionine is the first limiting amino acid in poultry diets (Lemme

et al., 2004). The high lysine digestibility in BSFL meal (92.25% SID) also exceeds soybean meal (88.52% SID), indicating excellent lysine availability. Mahmoud and Ravindran (2025) reported SID coefficients of 0.89 for methionine and 0.83 for lysine in BSFL prepupae meal, which are slightly lower than our values (0.92 and 0.92, respectively). This difference may be due to differences in insect strain, rearing substrate, processing method, or life stage (larvae vs. prepupae).

However, two important limitations were identified. First, valine digestibility in BSFL meal (75.85% SID) was significantly lower than soybean meal (94.79% SID). This finding is consistent with Matin et al. (2021) who reported variable and sometimes low valine digestibility in insect meals (as low as 60%). The low valine digestibility may be partly due to binding of this amino acid to the chitin matrix or specific resistant protein structures. Rumpold and Schlüter (2013) suggested that chitin can bind to proteins and render them indigestible. Second, cystine digestibility in BSFL meal (82.86% SID) was lower than soybean meal (101.53% SID), likely due to stable disulfide bonds in insect proteins that are resistant to proteolytic enzymes.

Digestible Amino Acid Content

Table 4 presents the digestible amino acid content of BSFL meal and soybean meal. The standardized digestible protein content in BSFL meal (32.53 g/100g) was slightly lower than soybean meal (35.51 g/100g) due to the lower total protein concentration.

Table 4. Standardized digestible amino acid content of BSFL meal and soybean meal (g/100g)

Amino Acid	BSFL Meal	Soybean Meal
Digestible Protein	32.53c	35.51b
Lysine	2.10c	2.50b
Methionine	0.70b	0.51c
Arginine	1.55c	2.38b
Threonine	1.00c	1.62b
Valine	2.74b	1.66c
Leucine	2.02c	2.38b
Isoleucine	1.56b	1.45c
Phenylalanine	1.37c	1.58b
Histidine	0.99b	0.89c
Total Digestible Amino Acids	31.02c	32.90b

a,b,c Values within rows with different superscripts differ significantly ($P < 0.05$)

Despite the lower total digestible amino acid content, BSFL meal provides significant amounts of methionine (0.70 g/100g), which is 37% higher than soybean meal (0.51 g/100g). This is a valuable characteristic for poultry diets where methionine is often supplemented synthetically. However, the lower protein concentration of BSFL meal means that higher inclusion levels may be needed to achieve target protein levels.

Protein Quality Assessment (DIAAS)

Table 5 presents the DIAAS values for BSFL meal and soybean meal calculated based on Ross 308 starter requirements. BSFL meal had a significantly higher DIAAS value (72.6%) compared to soybean meal (59.6%). Methionine + cystine was identified as the first-limiting amino acid for both sources.

Table 5. DIAAS values for BSFL meal and soybean meal based on Ross 308 starter requirements

Amino Acid	Requirement (mg/g protein)	BSFL Meal	Soybean Meal
Methionine	24.09	89.3%	59.6%
Methionine + Cystine	43.64	72.6%	72.9%
Lysine	57.27	112.7%	122.9%
Threonine	38.18	80.5%	119.4%
Valine	43.64	193.0%	107.1%
Leucine	63.18	141.6%	106.1%
Isoleucine	38.18	125.6%	106.9%
Arginine	59.55	79.5%	112.5%
DIAAS Score		**72.6%**	**59.6%**

The DIAAS score of 72.6% for BSFL meal indicates that it is a "moderate" quality protein source (<75%), but still superior to soybean meal (59.6%). The limiting amino acid is the sulfur amino acid group (methionine + cystine), consistent with findings for other insect meals (Matin et al., 2021). However, the severity of this limitation is less pronounced than in soybean meal, where methionine alone is the limiting factor with a score of only 59.6%.

The high valine and leucine scores in BSFL meal (193.0% and 141.6%, respectively) are noteworthy, indicating that BSFL meal is exceptionally rich in branched-chain amino acids. This is consistent with the high valine concentration (10.03% of protein) observed in BSFL meal. These amino acids play key roles in muscle protein synthesis and energy metabolism (Wu et al., 2013).

Comparison of Methodologies

A comparison of the two methodology approaches (purified diet vs. complete diet) revealed interesting patterns. The complete diet method yielded significantly higher SID estimates for

some amino acids like valine (increased from 79.35% to 91.85%) and isoleucine (increased from 90.54% to 98.91%), indicating synergistic effects within the complete diet matrix. This suggests that in practical diets, the digestibility of certain amino acids in BSFL meal may be higher than estimated from purified diets alone.

CONCLUSIONS

Based on the comprehensive evaluation of black soldier fly larvae meal in this study, the following conclusions can be drawn:

Moderate protein concentration: BSFL meal contains 36.21% crude protein, lower than soybean meal (43.45%), but with most nitrogen (95.63%) in the form of amino acids.

Excellent digestibility: Despite the presence of chitin, BSFL meal shows high standardized ileal digestibility of protein (89.86%) and most amino acids, significantly higher than soybean meal (81.75%).

Superior methionine digestibility: Methionine digestibility in BSFL meal (91.93%) is substantially higher than soybean meal (75.17%), providing 37% more digestible methionine per unit weight.

Important limitations: Valine digestibility (75.85%) and cystine digestibility (82.86%) are significantly lower than soybean meal (94.79% and 101.53%, respectively), requiring attention in diet formulation.

Good protein quality: The DIAAS value of BSFL meal (72.6%) is significantly higher than soybean meal (59.6%), indicating superior inherent protein quality. The first-limiting amino acid is methionine + cystine for both sources.

Practical implications: BSFL meal can serve as a viable alternative protein source in poultry diets. However, its lower protein concentration means higher inclusion levels may be required to meet target protein levels. The optimal strategy involves synergistic combination with soybean meal, where BSFL meal provides high-quality methionine and soybean meal compensates for lysine and arginine.

Research needs: Future research should focus on optimizing rearing substrates and processing methods to improve valine and cystine digestibility, exploring the potential of enzymatic hydrolysis to enhance overall protein quality, and conducting long-term feeding trials to confirm the practical benefits of BSFL meal in commercial poultry production.

ABSTRACT

Rapid population growth, uncontrolled industrial expansion, and changing consumption patterns have led to a significant increase in food industry waste, making it one of the most critical challenges threatening environmental and economic sustainability globally. This ecological crisis has necessitated minimizing food processing waste and reintegrating it into the economy through value-added applications, thereby highlighting the concepts of the circular bioeconomy, biorefineries, and green technology approaches. Solid and liquid by-products generated during the industrial production of fermented products, particularly wine, beer, dairy, soy, vinegar, and kombucha, exhibit remarkable functional and therapeutic potential owing to their high-value biological constituents, including proteins, free amino acids, polyphenolic antioxidants, and prebiotic oligosaccharides. To recover these bioactive compounds from cellular matrices while preserving their natural structural integrity, next-generation green technologies, such as ultrasound-assisted extraction, microwave-assisted extraction, supercritical fluid systems, and solid-state fermentation, have been widely employed. These recovered, or microbially resynthesized functional compounds can be utilized in a wide range of applications within the food, materials, biomedical, and healthcare sectors as antimicrobial preservatives capable of suppressing pathogenic microorganisms and cellular signaling mechanisms, nanotechnologically encapsulated nutraceuticals, active and intelligent packaging films, and biodegradable polymers (PLA/PHA) serving as sustainable alternatives to petrochemical-based materials. Fermented food by-products have also been successfully incorporated into functional foods, with brewer's spent grain being used in bread, pasta, and snack formulations and cheese whey being utilized in functional and sports beverages. These innovative valorization strategies not only drastically reduce the organic load associated with Chemical Oxygen Demand (COD) and Biological Oxygen Demand (BOD), thereby mitigating environmental impacts, but also provide promising solutions for producing functional products that support human health at the molecular level. Accordingly, this article reviews the most recent advances in the utilization of fermented food by-products as a source of bioactive compounds, the green technologies employed for their recovery, and their potential applications in functional product development.

Keywords: Fermented food by-product, Functional products, Fermentation, Sustainability, Valorization.

INTRODUCTION

Rapid population growth, uncontrolled industrial expansion, and changing consumption patterns have led to a significant increase in solid waste and by-products within the food

industry, making sustainable waste management a critical global issue. The inadequacy of current waste management policies results in a large portion of this organic biomass being released into nature as an environmental burden or incurring high disposal costs (Chetrariu and Dabija, 2020; Verma et al., 2021). However, modern biorefinery systems and circular bioeconomy approaches enable food processing wastes to be evaluated beyond the traditional concept of waste, transforming these resources into valuable raw materials that can be utilized in the production of high-value-added functional components, bioactive molecules, and sustainable biomaterials (Camargo et al., 2022; Faria et al., 2023). In this context, preventing biomass waste and converting wastes into functional products both serve sustainable development goals and offer innovative solutions to the food and pharmaceutical industries (Naibaho et al., 2025; Topi et al., 2025).

With a deep-rooted history and wide application in the food industry, the fermentation sector generates high amounts of organic by-products in direct proportion to the magnitude of its production volume (Swetha et al., 2023; Woraprayote et al., 2023). Pomace, peels, sediments, and wastewaters generated during the production of products such as wine, beer, fermented milk, fermented fruits and vegetables, vinegar, and kombucha constitute a significant source of valuable components such as secondary metabolites, proteins, dietary fiber, and fermentable sugars (Lac et al., 2024; Aradwad et al., 2025). Traditionally considered to have low added value and used primarily as animal feed or fertilizer, these byproducts are now emerging as valuable sources to produce nutraceuticals and bioactive peptides, which promote human health and reduce the risk of various diseases (Lopes et al., 2025).

Within the fermented food industry, the valorization of by-products originating specifically from wine and beer production into high-added-value components has become one of the research fields receiving intense interest in recent years. Grape pomace, peels, seeds, and sediments generated during industrial wine production contain high proportions of phenolic compounds with antioxidant and cardioprotective properties, such as anthocyanins, catechins, and proanthocyanidins (Suescun-Ospina et al., 2023; Constantin et al., 2024; Cánovas et al., 2025). Similarly, spent yeasts and malt rootlets generated during beer production are by-products rich in bioactive peptides, beta-glucans, and flavor-enhancing nucleotides that hold potential for use in functional food formulations (Halahlah et al., 2025; Couto et al., 2026; Soto-Maldonado et al., 2026). On the other hand, cheese whey, a major by-product of cheese manufacturing, not only serves as a valuable source for the recovery of bioactive proteins but can also be utilized as a carbon source in the microbial production of biodegradable bioplastics such as polyhydroxyalkanoates (Mota et al., 2026).

With rising consumer demands in recent years, studies focusing on the conversion of by-products generated during the production of fermented products, such as kombucha and vinegar, into high-added-value components have also gained importance (Maske et al., 2026). Cellulosic biofilm and acidic liquid by-products derived from kombucha production are utilized in the development of innovative functional products across a wide range of areas, from food packaging applications to the production of biomedical products (Vianna et al., 2025; Hartono et al., 2026). Similarly, by-products such as okara formed as a result of soy fermentation hold significant potential in the development of value-added food products thanks to their compositions rich in various bioactive phytochemicals and prebiotic dietary fibers (Zhou et al., 2019).

Ensuring the efficient recovery of bioactive compounds found in fermented food by-products while preserving their properties largely depends on the efficiency of the applied extraction and purification technologies. In this context, recent studies show that environmentally friendly and high-efficiency processes such as green synthesis approaches, ultrasound- and microwave-assisted extraction, supercritical fluid technologies, and solid-state fermentation are coming to the forefront as alternatives to conventional chemical methods that require high temperatures

or the use of toxic solvents (Eche et al., 2025; Mia et al., 2025; Garzón et al., 2026). Furthermore, utilizing nanotechnological carrier systems to enhance the bioavailability and stability of the recovered compounds stands out among current approaches in this field (Zhu et al., 2024; Mirzakulova et al., 2025). Among other applications, as a key component of holistic biorefinery approaches, the conversion of fermented food by-products into functional food ingredients, bioenergy sources and innovative agricultural products, such as feed additives aimed at reducing methane emissions, is also receiving notable attention (Selmi et al., 2025; Mato et al., 2026).

In this review, current recovery strategies, technological advancements, and application areas aimed at converting fermented food by-products into high-added-value products are discussed. Furthermore, the potential of these by-products for use in the development of functional products has been evaluated in terms of sustainable waste management and the circular bioeconomy, and future perspectives have been evaluated.

FERMENTED FOOD BY-PRODUCTS

Within the fermentation sector, one of the largest-volume subsectors of the global food industry ecosystem, millions of tons of organic waste and by-products are generated annually depending on the scale of production capacity. In sustainable waste management and circular economy approaches, these residues are evaluated differently than unprocessed traditional agricultural waste. The primary reason for this is that these by-products undergo controlled microbial bioprocesses, during which they are biochemically modified by the metabolic activities of microorganisms, acquiring a more stable and complex matrix structure (Chetrariu and Dabija, 2020; Eche et al., 2025). Based on the operational outputs of production processes, fermented food by-products are classified into two main groups: solid fractions, such as pomace, spent grain, sediments, and microbial biomass, and liquid phases, such as cheese whey, acidic waters, and post-fermentation liquids. These by-products are rich in high-quality proteins, free amino acids, soluble and insoluble dietary fibers, and microbial secondary metabolites making them an important raw material source for the recovery of high-added-value components in advanced biorefinery processes (Zhou et al., 2019; Mia et al., 2025).

When the distribution of fermented food by-products is examined according to industrial sources, the alcoholic and non-alcoholic fermented beverage sectors stand out in terms of volume. Brewer's spent grain and brewer's yeast, which are the primary by-products of brewing processes, rank among important biomass sources for the recovery of high-added-value components due to their compositions rich in lignocellulosic fibers and highly digestible microbial proteins (Naibaho et al., 2025; Couto et al., 2026; Soto-Maldonado et al., 2026). In the wine industry, grape pomace (including skins, seeds, and stalk residues) generated during the maceration and primary fermentation stages, alongside wine lees settled at the tank bottoms, are extensively discussed in the literature as fermented by-products rich in plant secondary metabolites, particularly phenolic compounds (Suescun-Ospina et al., 2023; Lopes et al., 2025; Topi et al., 2025). Regarding animal-derived fermented food by-products, the dairy industry constitutes a significant source. Particularly, cheese whey and acidic process waters generated from cheese and strained yogurt production possess significant potential for bioconversion and recovery processes thanks to their high-quality serum proteins (alpha-lactalbumin, beta-lactoglobulin) and lactose contents (Mirzakulova et al., 2025; Selmi et al., 2025; Mota et al., 2026). In plant-based fermentation processes, okara, a by-product of soybean processing; vinegar production by-products; and microbial biofilms formed during kombucha production stand out for their prebiotic oligosaccharide content, organic acid profiles, and high bacterial cellulose content, respectively. These unique compositional characteristics enable the utilization of these by-products as valuable raw material sources in functional product design (Zhou et al., 2019; Maske et al., 2024; Vianna et al., 2025; Hartono et al., 2026).

RECOVERY STRATEGIES FOR FERMENTED FOOD BY-PRODUCTS

The utilization of bioactive and functional components present in the composition of fermented food by-products in the formulations of value-added products depends on the effective separation of these components from complex cellular and polymeric structures without disrupting their integrity. In

conventional extraction methods, the prolonged use of high temperatures and toxic organic solvents causes the denaturation of temperature-sensitive phenolic compounds, the cleavage of peptide bonds, and a decrease in overall process efficiency. To overcome these disadvantages caused by conventional methods, focus has shifted toward innovative green technologies such as ultrasound- and microwave-assisted extraction systems and supercritical fluid technologies that aim to increase process efficiency while reducing environmental impacts. These advanced approaches shorten the processing time by facilitating the release of target bioactive components from the matrix into the solvent, while simultaneously minimizing energy consumption and waste generation derived from toxic chemical solvents (Swetha et al., 2023; Naibaho et al., 2025).

When the mechanisms of action of the innovative green extraction technologies are examined, it is stated that ultrasound-assisted extraction accelerates the mass transfer of bioactive compounds by mechanically disrupting cellular structures through cavitation waves generated in the liquid medium. In the literature, it is reported that this method has been successfully applied in the high-yield recovery of polyphenolic compounds with antioxidant properties from winemaking by-products (Constantin et al., 2024). Microwave-assisted extraction, based on the principle of electromagnetic heating, rapidly heats the water molecules within the target matrix, increasing intracellular pressure and causing the cell wall to rupture from the inside out. It is noted that this specific method significantly shortens the extraction time in obtaining functional compounds from lignocellulosic fermented by-products with complex structures, such as brewer's spent grain (Aradwad et al., 2025). On the other hand, supercritical fluid extraction offers a highly selective process without leaving toxic solvent residues or causing thermal degradation, primarily using carbon dioxide in a state above its critical temperature and pressure values. It is anticipated that this advanced technology is also considered one of the most promising green strategies for isolating high-purity and value-added nutraceutical components from fermented food industry by-products (Naibaho et al., 2025).

In addition to physical and chemical extraction methods, the direct application of biotechnological processes to fermented by-products is considered to play a significant role in recovery procedures. In this context, solid-state fermentation stands out as one of the primary approaches employed in the re-fermentation of solid fermented by-products with low water activity using specific mold or bacterial strains. During the solid-state fermentation process, it is reported that microorganisms secrete extracellular enzymes that hydrolyze cellulose, hemicellulose, and lignin complexes within the by-product matrix; thereby converting conjugated phenolic compounds bound to the plant cell wall into their free forms, significantly increasing the biological activity and antioxidant capacity of the material (Verma et al., 2021; Garzón et al., 2026). Since these functional hydrolysates and liquid extracts obtained through microbial or enzymatic processes exhibit structures sensitive to environmental factors, they are stabilized using micro/nanoencapsulation and nanotechnological carrier matrices to prevent potential oxidative or thermal degradation that may occur during the storage and end-use stages. It is stated that thanks to these applied protective systems, bioactive compounds can be successfully converted into final raw material forms suitable for industrial use (Mirzakulova et al., 2025; Mota et al., 2026).

APPLICATION OF FERMENTED FOOD BY-PRODUCTS

Today, complex organic by-products generated by high-volume production processes in the fermented food industry are being utilized in various industrial application within the framework of the circular bioeconomy, owing to their rich bioactive components (Chetrariu and Dabija, 2020; Eche et al., 2025). Broadly, these by-products have a wide utilization potential in areas such as the development of biodegradable packaging films, production of functional foods with enhanced nutritional value, renewable energy-focused biofuel production, active packaging technologies, recovery of antimicrobial components against foodborne pathogens and spoilage microorganisms, and biofilm control. Among these application areas, functional product development approaches hold a significant place; by utilizing the by-products in pasta, muffins, snacks, anthocyanin-rich kombucha-like beverages, and cheese whey-based sports drinks, the protein, dietary fiber, antioxidant, and mineral contents of the products can be enriched (Cánovas et al., 2025; Couto et al., 2026; Eche et al., 2025; Mirzakulova et al., 2025). On the other hand, by-products such as brewer's spent grain, which

is rich in lignocellulosic fiber, and brewer's spent yeast, which is a microbial protein source, are evaluated as valuable industrial raw materials not only in food formulations but also in biofuel production in line with sustainable clean energy goals (Couto et al., 2026). The utilization of fermented food by-products in materials technology also constitutes an important research area. High-added-value components obtained from these by-products through recovery and bioconversion strategies are also considered significant raw material sources in the development of bio-based and biodegradable packaging materials as alternatives to petroleum-based synthetic plastics. In this context, polylactic acid and polyhydroxyalkanoate-based biopolymers, which are obtained through the bioconversion of carbon sources recovered from by-products, can be used as matrices in the production of packaging materials with lower environmental impacts (Swetha et al., 2023; Selmi et al., 2025). In active packaging applications, antimicrobial peptides and polyphenol-rich antioxidant fractions recovered from fermented food by-products can be integrated into different packaging matrices to impart functional properties. By ensuring the controlled release of bioactive compounds onto the food contact surface, these systems contribute to the limitation of microbial growth and lipid oxidation, thereby offering significant potential for preserving food quality and extending shelf life (Vianna et al., 2025; Mota et al., 2026).

In addition to packaging applications, antimicrobial components recovered from fermented food by-products can also be utilized directly in foods as natural preservatives. In particular, the recovery of antimicrobial metabolites such as bacteriocins, organic acids, and hydrogen peroxide produced by lactic acid bacteria during fermentation from liquid by-products offers significant potential in terms of natural preservation strategies aimed at controlling the growth of foodborne pathogens (Woraprayote et al., 2023). The antimicrobial effects of these metabolites can emerge not only through direct mechanisms, such as the disruption of cell membrane integrity, but also through the suppression of the quorum sensing system, which regulates intercellular communication among bacteria, by certain components. The suppression of the quorum sensing mechanism can affect the expression of genes associated with virulence and biofilm formation, thereby limiting the ability of pathogens to adhere to surfaces and form protective biofilms (Zhu et al., 2024). Consequently, it is considered that contamination risks that may arise in food matrices can be successfully brought under control by means of these biological components without the need for chemical and synthetic preservatives.

FERMENTED FOOD BY-PRODUCTS IN FUNCTIONAL PRODUCT DEVELOPMENT

Fermented food by-products constitute a significant source for functional product development due to their content of nutritional and bioactive components such as proteins, dietary fiber, phenolic compounds, vitamins, and minerals (Aradwad et al., 2025; Mia et al., 2025). The incorporation of industrial by-products such as brewer's spent grain, grape pomace, and cheese whey into various food formulations improves the nutritional value of the products and imparts or enhances functional attributes such as antioxidant properties (Cánovas et al., 2025; Eche et al., 2025; Mirzakulova et al., 2025; Couto et al., 2026). While this approach allows for the development of novel products with enhanced nutritional and functional properties, it also contributes to the conversion of by-products generated in the food industry into value-added components (Mia et al., 2025). Table 1 presents recent studies on the utilization of these by-products in different product categories, including baked goods, snacks, and fermented beverages.

Table 1. Recent studies evaluating the utilization of fermented food by-products in functional product development

Functional Food Product	**Fermented Food By-product**	**Application Purpose**	**Results**	**References**
Anthocyanin-rich, kombucha-like fermented functional beverage	Wine lees and grape pomace	To evaluate the applicability of winemaking by-products (grape pomace and wine lees) as raw materials in the development of kombucha-like functional beverages.	The addition of wine lees contributed to increasing the antioxidant capacity by elevating the anthocyanin content of the functional beverage. Furthermore, it ensured the preservation of the microbial and physicochemical stability of the product during a 21-day storage period.	Cánovas et al. (2025)
Functional baked goods (muffins)	Brewer's spent grain (BSG)	To investigate the effects of different drying methods on the chemical composition, physicochemical properties, and bioactive compounds of BSG, and to evaluate the quality and consumer acceptance of BSG-fortified muffins.	The incorporation of 15% BSG flour yielded a 22.59% increase in total dietary fiber and a 13% increase in protein without affecting consumer acceptance.	Shih et al. (2020)
Functional baked goods (pasta)	Brewer's spent grain (BSG)	To evaluate the properties of bioprocessed BSG as an ingredient for pasta formulation and to verify its nutritional and antioxidant properties.	The 15% utilization of bioprocessed BSG increased protein digestibility (from approximately 76.22% to 88.52%) and lowered the predicted glycemic index.	Schettino et al. (2021)

Functional baked goods (bread)	Brewer's spent grain	To evaluate the effects of partially replacing wheat flour with brewers' spent grain on dough properties, bread quality, and nutritional value.	It has been reported that adding spent brewer's grain to bread formulations at a 10% rate contributes to improving nutritional properties by reducing the product's energy value from 225 kcal to 204–216 kcal, while increasing the dietary fiber content per 100 g of product from approximately 5 g to 10 g and the protein content from 13.4 g to 15 g.	Czubaszek et al. (2022)
Functional and prebiotic beverages	Whey	To develop a functional beverage using whey protein isolate, inulin, and fruit juice concentrates, and to evaluate the bioactive properties of the obtained product.	Within the scope of evaluating whey, a liquid fermented food by-product, in the production of functional beverages, formulations containing 5% whey protein isolate, 4% inulin, and 10% fruit juice concentrate (apple, raspberry, or cranberry) were developed. It was reported that following digestion, the ACE (angiotensin-converting enzyme) inhibitory activity of these formulations reached 78.63%, and the DPPH radical scavenging activity reached 74.83%. Furthermore, they demonstrated antimicrobial	Kotsaki et al. (2025)

			activity by forming inhibition zones of up to 29.46 mm against pathogenic microorganisms.	

As evident from the table, each waste material has a unique application area and imparts distinct value to the product. While cheese whey provides an ideal base for sports beverages owing to its liquid form and composition, brewer's spent grain is a highly effective source of fiber in solid form baked goods such as bread and pasta (Eche et al., 2025; Mirzakulova et al., 2025). Beverages derived from grape pomace, on the other hand, are developed for consumers who prefer antioxidant-rich products (Cánovas et al., 2025). At this point, the major challenge facing manufacturers is preserving the sensory quality of foods, as the conventional taste, texture, and aroma of the foods to which by-products are added may undergo changes (Eche et al., 2025; Couto et al., 2026). Determining the correct inclusion ratios and developing appropriate formulations are critical steps in consumer acceptance of these novel products (Eche et al., 2025).

SUSTAINABILITY AND FUTURE PERSPECTIVES OF FERMENTED FOOD BY-PRODUCT MANAGEMENT

The valorization of fermented food by-products in integrated biorefinery systems is of great importance in terms of the efficient utilization of industrial resources and the mitigation of the environmental impacts of food production. In particular, the discharge of cheese whey, acidic process waters, and other liquid by-products which possess a high organic load alongside high chemical and biochemical oxygen demand into receiving environments without adequate treatment can lead to significant environmental problems in aquatic ecosystems, such as eutrophication, a reduction in dissolved oxygen levels, and the disruption of ecological balance (Selmi et al., 2025; Topi et al., 2025). In contrast, the recovery of these by-products via advanced biotechnological processes and their conversion into functional components, biopolymers, or biofuels not only alleviates the environmental and economic burden stemming from waste management but also contributes to the generation of value-added products and the attainment of circular economy objectives. Furthermore, studies based on life cycle assessments demonstrate that converting fermented food by-products into value-added products can, under appropriate process conditions, contribute to reducing greenhouse gas emissions and the overall environmental impacts of food production systems (Chetrariu and Dabija, 2020; Eche et al., 2025).

In the future, more effective utilization of metabolic engineering and artificial intelligence-supported bioprocess technologies is anticipated in the valorization of fermented food by-products. Microorganisms developed through genetic modification and targeted adaptation techniques could enable the high-yield conversion of complex carbon sources found in by-products into targeted functional components. Accordingly, the development of next-generation industrial strains aimed at the valorization of different by-products stands out as a prominent research area (Mia et al., 2025; Selmi et al., 2025). Furthermore, the development of smart encapsulation systems for the protection and controlled release of bioactive components is among the approaches that may gain significance in the future. Moreover, the utilization of biomaterials such as kombucha bacterial cellulose produced during the fermentation process carries substantial potential for the development of innovative products in the packaging and biomedical fields (Vianna et al., 2025; Hartono et al., 2026). Nevertheless, to transfer these approaches from laboratory and pilot scales to industrial production, provided that technical limitations related to scaling up are overcome, the economic viability of the processes is

demonstrated, and standards concerning biosafety and regulatory frameworks are established, it can be stated that the biotechnological recovery of fermented food wastes will significantly contribute to global sustainability goals.

CONCLUSIONS

Fermented food by-products are not merely environmental concerns that requires disposal; they are considered high-potential raw material sources for the food industry due to their rich bioactive compounds. Approaches such as advanced green extraction techniques, solid-state fermentation, and enzymatic hydrolysis enable the recovery and bioconversion of valuable components from complex fermented matrices, allowing these by-products to be utilized as value-added resources in food, packaging, biofuel, and biotechnological applications. While contributing to the reintegration of fermented food by-products into the production cycle and the more efficient use of resources, this multifaceted valorization approach supports waste reduction, and the establishment of a sustainable value chain based on a zero-waste approach within the food supply chain. Consequently, it is anticipated that industrial upscaling efforts supported by process optimization, current legal regulations, and academia-industry collaborations will promote the widespread conversion of fermented food by-products into value-added products, thereby making significant contributions to the achievement of circular bioeconomy goals.

ABSTRACT

Greenhouse climate control is characterized by coordinated control of environmental conditions, resource usage, and crop production under continuous changes in all parameters. The traditional methods of rule-based control and PID controller show poor adaptability; at the same time, reinforcement learning (RL) as a standalone solution may need extensive real-world training. In this paper, it presents the digital twin-supported RL approach to optimization of greenhouse climate control and crop growing performance. The suggested approach uses IoT sensors, a digital twin based on physics-informed and data-driven modeling of greenhouse climate and crop-growing process, and RL agents in the closed-loop control cycle. The digital twin serves as the simulation tool providing safe environment for offline policy training prior to deployment into the real world. It conducts experiments comparing this approach to PID/rule-based control and RL separately. Digital twin and RL approach leads to reduced seasonal energy usage to 108.7 kWh/m²/season along with increased crop production of 21.4 kg/m² and improved temperature tracking, measured by the RMSE metric of 0.86 °C. It outperforms the PID approach in terms of energy usage by 23.7%. Additional adaptation to real sensors reduces twin prediction RMSE to 0.41 °C and achieves 97.2% policy convergence.

Keywords: Digital twin, reinforcement learning, greenhouse climate control, precision agriculture, crop growth optimization.

I. INTRODUCTION

There has been increasing pressure placed on the urban built environment with respect to both resources and ecology since the turn of the millenium, as urbanization started to grow globally. Global Urbanization Outlook, United Nations: More than 68% of the world's population will be living in urban areas by 2050, according to the 2018 revision [1]. The agricultural land around cities has been encroached on by urban sprawl at a pace much higher than population growth rates [11]. Meanwhile, urban low-carbon transitions need to account for the considerable role of the food system in the generation of greenhouse gas emissions in production, processing, transport, and consumption [3]. Parks and other green areas in cities face health risks for their residents and threaten to compromise the provision of ecosystem services that are already in precarious supply. Goal 2 of the United Nations' Sustainable Development Goals (SDGs): Zero hunger and goal 11 of the SDGs: Sustainable cities and communities - these goals create policy background for the development of green infrastructure and urban agriculture in response to the challenges [4]. More government involvement in the promotion of urban green production and ecological consumption is also required by UN-Habitat's World Cities Report 2022.

The need to address the variability of fields, as opposed to considering them homogeneous areas, led to the emergence of precision agriculture. Although the use of technologies such as machine guidance, canopy sensors, soil sensors, and UAV imagery has become more

widespread over the past decade, many farmers find that various systems don't work in synchronization. Research related to UAV assessment of crops and monitoring of soil and microbial activity operates with different data streams, and there have been very few attempts to merge these data into one decision-making framework, which creates fragmentation in the literature [2][5]. Thus, even though there is an extensive development of precision agriculture technologies, most of them provide fragmented information about plant or soil activity [10]. DTs can fill in this knowledge gap and provide the framework for merging these data streams into one synchronized and predictive model of the whole farm environment.
Applications of DTs are limited and mainly experimental in nature at the current stage of development of precision agriculture. This work's overarching goal is to survey the state of the art in digital twin technology as it pertains to agricultural applications [13]. To map the landscape, scoping evaluations are useful for new domains, such the integration of DTs in agriculture [6]. Consequently, this study aims to employ PRISMA-ScR methodology to compile a literature review on DTs in precision agriculture, highlighting existing work, trends, concepts, and gaps in the field. A scoping review is necessary to map the broader landscape, synthesize all heterogeneous approaches, and identify research gaps and future directions. This is because, although there are systematic literature reviews on the subject [7], they focus on specific agricultural aspects such as forestry, soil and nutrients, water stress and irrigation, machinery, crop monitoring, livestock, etc. The disjointed evolution of DTs in farming is what inspired us to conduct this study so that this may provide more conceptual clarity and methodological guidance.

1.1 Organization of the Study

The rest of the paper consists of four major sections. In Section 2, the literature review is presented. It includes digital twins' definition, differences between digital twins and digital shadows, application of digital twins in agriculture, wearables-glove-based
teleoperation, greenhouse and hydroponics systems controlled via IoT. The research methodology is described in Section 3. It covers IoT-based state acquisition and encoding, digital twins design, reinforcement learning agent development, policy transfer and closed loop implementation, and evaluation. Specifically, the proposed framework makes use of observations about greenhouse climate and crop growth to define the state space. The greenhouse digital twin is designed as the simulation environment for reinforcement learning training and later real-life application. The results are shown in Section 4. It covers general control performance, sim-to-real transfer and adaptation, climate control accuracy, and interpretation of obtained results. Finally, Section 5 concludes the paper by highlighting the efficiency of applying digital twins and reinforcement learning for energy-efficient climate control of greenhouses.

1.2 Contribution of the Study

The main contribution of the proposed study is the creation of the digital twin assisted reinforcement learning framework that combines predictive simulation and adaptive greenhouse control. Contrary to traditional rule-based/PID control and reinforcement learning, the proposed framework creates a closed loop interaction between physical greenhouse, digital twin, reinforcement learning agent and actuators so that real sensor observations can be used to update digital twin representation and make the decisions accordingly reinform. Another contribution is the use of hybrid physics-guided, and data enabled digital twin to model greenhouse microclimate and crop growth dynamics and provide the means for safer and more efficient offline reinforcement learning policy training before actual application. A further

contribution is made in form of sim-to-real transfer and continuous online adaptation where real sensor feedback is used to improve twin prediction accuracy and reinforce learning policy convergence. Finally, the framework is evaluated based on energy consumption, crop yield, temperature regulation accuracy, water use efficiency, reward convergence, and digital twin prediction accuracy, and improvements in comparison with PID/rule-based and reinforcement learning approaches are shown.

II. LITERATURE REVIEW

One promising technology that could potentially address these constraints would be digital twins. Through remote monitoring and control abilities enabled by a high-fidelity virtual copy of a physical system with continuous data synchronization through bidirectional connections, digital twins can be utilized [8]. However, there is an essential distinction between digital twins and digital shadows based on the way how data is connected. According to definition, a digital shadow is created by one-directional flow of data from a real object to its digital representation, and, therefore, allows for tracking in real time, while changes applied to a digital copy will not influence a real one. Meanwhile, digital twin enables the two-directional data flow via synchronization of a digital model with the physical system to govern or operate on a physical counterpart [9]. Digital twins are known to have been used in optimization of design, simplification of operations and reduction of costs in such fields as manufacturing, aircraft and urban infrastructures. At the same time, the use of this technology remains limited only to agrivoltaic and agriculture spheres [14][15]. Data visualization and one-way monitoring remain the extent of efforts put now, and many digital twins remain just digital shadows with no simulation capabilities and input from the system. Such situation presents a challenge as well as an opportunity for further agrivoltaic research and practices.

Since the proposed DT framework depends on WG-based teleoperation systems as an essential part of an interaction interface, let us consider the literature review on the issue. According to the research, a vision-tracking system and WG-based teleoperation control frameworks were applied. Compared to the vision method, the glove-based approach was proven to be more accurate and effective. However, it is less comfortable and more complicated for a user. To operate a robotic hand-arm system remotely, a special data glove was designed and used by the researchers of. The National Aeronautics and Space Administration (NASA) has put the wearable-based teleoperation control framework into action by using two CyberGloves to command robots to perform manual manipulations like threading nuts into bolts and knotting. Virtual interaction scenarios can now take advantage of a new approach that makes use of WGs. This opens the door to new possibilities, like task training and 3D modeling. This environmental sensing technique is informed by solutions for greenhouse and hydroponic systems that are based on the internet of things (IoT), which this will now investigate in light of this work's agricultural context. Internet of Things (IoT) uses in hydroponic farming have been the subject of prior study [12]. While discusses methods for automating pH level adjustments, electrical conductivity maintenance, and environmental monitoring in greenhouses, [15] lays out a system for monitoring and analyzing data in real-time in small to medium-sized greenhouses.

III. RESEARCH METHODOLOGY

Figure 1 above presents the closed-loop design of the proposed architecture — in the form of a rectangular loop, not a linear stack used previously, because this system is inherently cyclic — where the sensor readings are passed clockwise, from the physical greenhouse to the digital

twin, then through the RL agent to the actuators and back to the greenhouse in the next observation. Coloring convention: blue = sensing/data; purple = simulation; amber = decision-making; teal = physical actuation.

3.1 Data Collection and State Encoding

IoT sensors constantly record greenhouse climate factors (air temperature, relative humidity, CO_2 concentration, photosynthetically active radiation, soil moisture content) and crop development factors (leaf area index, canopy height, biomass estimation from imaging). They constitute the observed state vector fed into the digital twin and the RL agent.

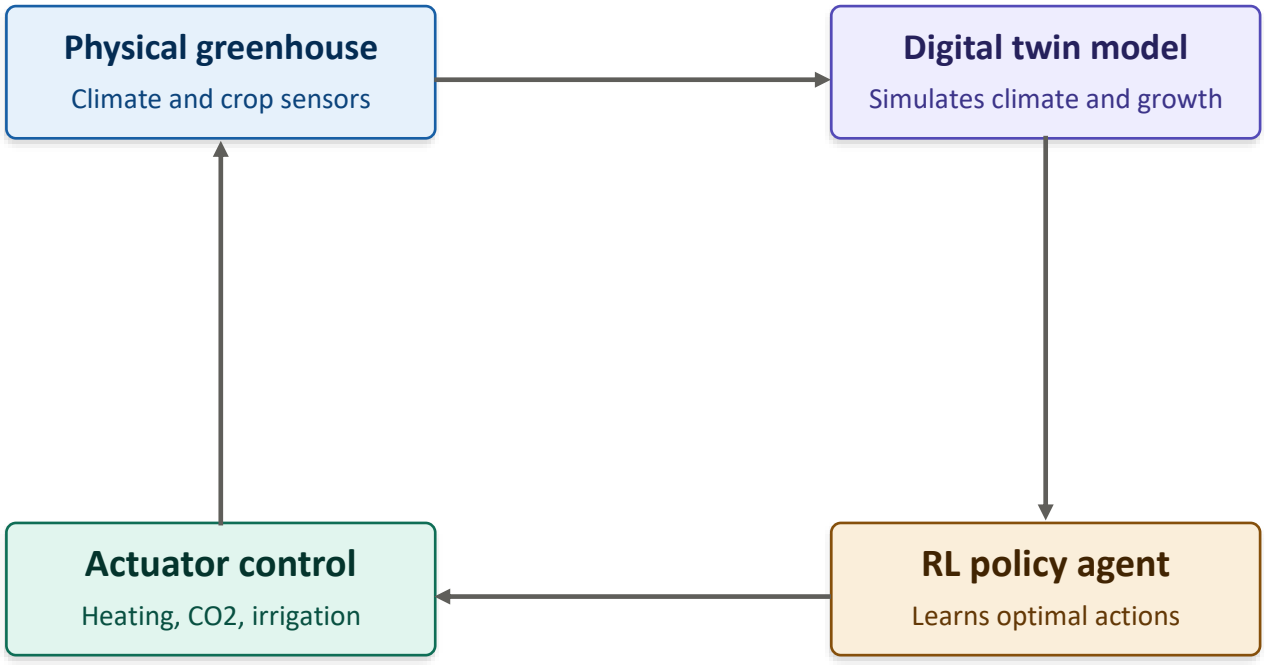

Figure 1. Closed-loop methodology of the digital twin-assisted reinforcement learning framework for greenhouse climate control.

3.2 Digital Twin Creation

A hybrid physics-guided, data-enabled digital twin is created to simulate the greenhouse microclimate dynamics and the crop growth reaction, enabling safe offline policy training before its actual implementation in the field. The state transition of the twin is represented in Equation (1) as:

$$x_{(t+1)} = f(x_t, a_t) + w_t \quad (1)$$

where x_t denotes the greenhouse state vector at time t (temperature, humidity, CO_2, light, crop growth stage), a_t represents the control action performed (setpoints for heater/vent/CO_2 injection/irrigation), $f(\cdot)$ denotes the learned or physics-based transition model of the digital twin, and w_t is process noise that captures the effects of any unmodelled disturbances such as the weather.

3.3 Reinforcement Learning Agent

An RL agent (Deep Deterministic Policy Gradient or Proximal Policy Optimization agents) learns to perform actions in the digital twin, a training environment for it, and learn a policy $\pi(a_t|x_t)$ to maximize the total cumulative reward during an episode (growing season or some defined horizon) which is given by equation (2):

$$R_t = \alpha.G_t - \beta.E_t - \gamma.T_t - T_{target} \quad (2)$$

where G_t is the increment of the crop growth, E_t is the energy/resource consumption (heating, CO2 supply, watering), T_t is the actual greenhouse temperature, Ttarget is the desired greenhouse temperature for the crop, and α, β, γ are the corresponding weights for growth, efficiency, and climate tracking accuracy, respectively.

3.4 Policy Transfer and Deployment of the Closed Loop

A control policy developed using the simulation model is then transferred to a real-world system where the measurements from the physical sensors feed back into the digital twin (closing the loop shown in Fig. 1). The continuous updating allows the digital twin to track the real-world plant and climate state and adjust the RL policy on-line.

3.5 Evaluation Procedure

The comparison of RL-optimized policy performance with respect to a conventional controller implemented by the rule-based/PID control scheme is made in terms of: (i) crop growth performance, (ii) energy consumption, and (iii) climate setpoint tracking error.

IV. RESULTS AND DISCUSSION

4.1 Overall Control Performance

A comparison between the proposed RL controller integrated with the digital twin and a traditional PID/rule-based controller along with an RL agent trained in isolation is presented in Table 1. The proposed approach was able to reduce energy usage in seasons by 23.7% and 15.3% as compared to the PID controller and the standalone RL approach respectively.

Table 1. Overall performance comparison of control strategies

Strategy	Energy consumption (kWh/m²/season)	Yield (kg/m²)	Temp. RMSE (°C)	Water use efficiency (kg/m³)
PID / rule-based	142.5	18.2	1.85	22.4
Standalone RL (no twin)	128.3	19.6	1.42	24.8
Digital twin-assisted RL (proposed)	108.7	21.4	0.86	27.9

The figure 2 compares the smoothed reward trajectories for the RL agent and the digital twin-assisted RL agent during 2,000 training episodes. The agent trained with the assistance of the

digital twin converged faster and attained a much higher asymptotic reward level. This implies that the predictive state transitions (Equation 1) generated by the digital twin were much more informative and efficient in terms of the samples utilized for training.

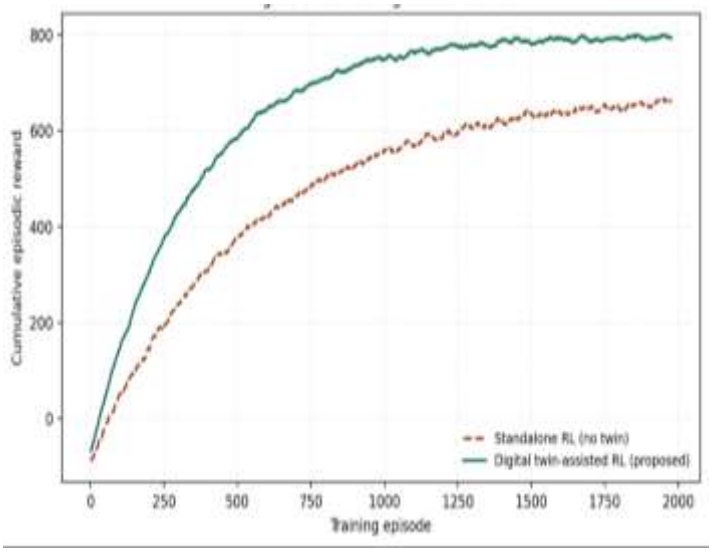

Figure 2. Training reward convergence of standalone reinforcement learning and digital twin-assisted reinforcement learning agents.

Figure 3 shows the seasonal energy consumption (in panel a) and the crop yields (in panel b) under each of the three approaches, in correspondence to the results provided in Table 1. Monotonic improvements in this case demonstrate the progressive benefits of (i) learning-based control in comparison with fixed control schemes and (ii) learning in a simulation-accurate digital twin in comparison with the real environment.

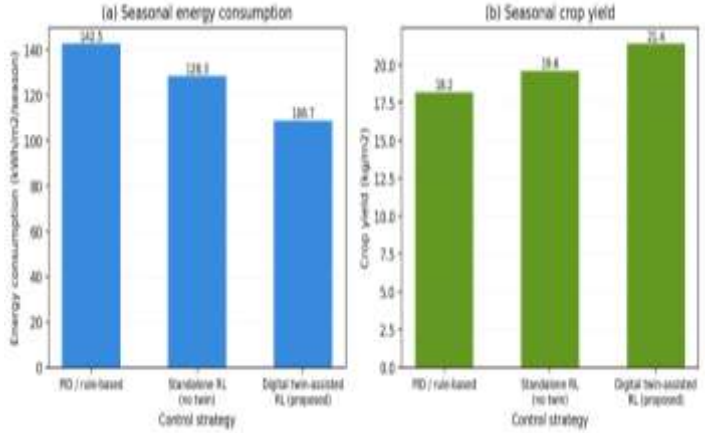

Figure 3. Comparison of seasonal energy consumption and crop yield across different greenhouse control strategies.

4.2 Sim-to-Real Transfer and Adaptation

In Table 2, it presents the results obtained during the three phases of deployment described in Section 3.4: simulation-only training, tuning on real sensor data, and continual online adaptation. It will see that the RMSE of twin predictions decreased from 1.10°C to 0.41°C due

to closing the loop using real sensor feedback, as described in Fig. 1, and the policy convergence reached 97.2%.

Table 2. Performance across sim-to-real transfer phases

Phase	Episodes	Avg. reward	Twin prediction RMSE (°C)	Policy convergence (%)
Pure simulation training	2,000	612.4	1.10	78.3
+ Real-sensor fine-tuning	500	754.8	0.62	91.7
+ Continuous online adaptation	Ongoing	812.6	0.41	97.2

4.3 Climate Tracking Accuracy

The Figure 4 demonstrates the performance of the PID controller by comparing actual greenhouse temperature against the setpoint on a typical day. The PID controller demonstrates significant and quite frequent fluctuations about the setpoint, especially at the midday peak of solar heat gain where fast adjustments for ventilation are needed. The RL controller assisted by the digital twin shows much better alignment with the setpoint during all hours of the day; indeed, it is well justified by the small RMSE values observed in Table 1 since the digital twin makes the agent capable of predicting thermal loads before the actual deviation occurs.

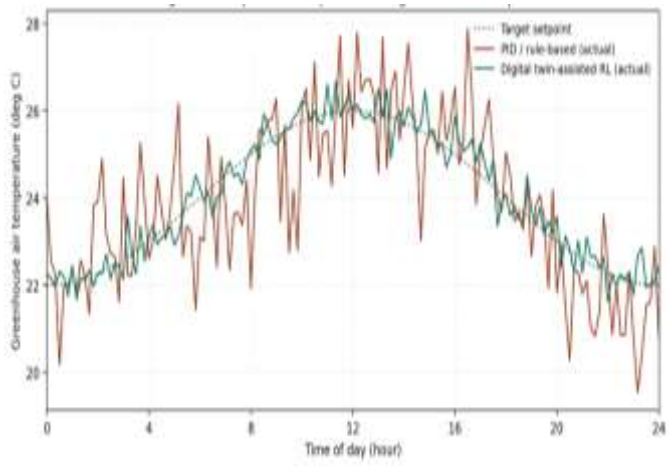

Figure 4. Comparison of greenhouse temperature tracking performance between PID control and digital twin-assisted reinforcement learning control.

4.4 Discussion

The presented results demonstrate validity of the core assumption that combining RL agent with an ever-updated digital twin surpasses both approaches using fixed rules and RL without a twin. It is due to the twin helps train the RL policy extensively offline (using Equation 1 transition model) and fine-tune it using the objective function based on Equation 2 which considers energy consumption and the setpoint value in addition to the yield value optimization. The residual tracking error in the proposed approach which is relatively small but still present

may be explained by the residual sim-to-real mismatch and other disturbance factor (w_t in Equation 1).

V. CONCLUSION

In conclusion, this research outlined an innovative framework for intelligent control of greenhouse conditions and optimization of crop growing through a combination of continuous IoT sensor data collection, digital twin technology that includes the development of physics-guided and data-driven models, and reinforcement learning and physical closed-loop actuation for the creation of an adaptive and predictive greenhouse system. According to the findings, the proposed framework showed obvious superiority over the classic PID/rule-based method and traditional reinforcement learning in terms of energy savings and crop production. Seasonal energy consumption decreased to 108.7 kWh/m²/season, in contrast to 142.5 kWh/m²/season consumed by the PID/rule-based system, and crop yield rose to 21.4 kg/m². Temperature tracking was much more effective with a reduced RMSE equal to 0.86 °C. In addition, digital twins allowed for fast learning and reward convergence due to state transition prediction during the offline training stage. At the sim-to-real transfer stage, fine tuning of the digital twin prediction based on real-sensor data and online continuous adjustment led to a decrease in the prediction error to 0.41 °C and an increase in the reward convergence rate to 97.2%. These findings proved that synchronization of the physical greenhouse system and digital twins is important to ensure control accuracy and resources effectiveness.

COMBINED TOXICITY OF MICROPLASTICS AND CHEMICAL POLLUTANTS IN AQUATIC ORGANİSMS

Duygu Özhan TURHAN
Department of Biology, Faculty of Arts and Science, Inonu University, Malatya 44280, Turkey

duygu.turhan@inonu.edu.tr

ABSTRACT

Microplastics are widespread contaminants in aquatic ecosystems and have received increasing attention in recent years due to their potential environmental impacts. In aquatic environments, microplastics do not occur in isolation but coexist with heavy metals, pesticides, pharmaceuticals, and various organic contaminants. Their large surface area and physicochemical properties facilitate the adsorption of different chemicals onto their surfaces, raising concerns about their potential role in modifying the transport, bioavailability, and toxicity of coexisting pollutants.

This review aims to evaluate the toxicological effects of combined exposure to microplastics and chemical pollutants in aquatic organisms. Available evidence indicates that interactions between microplastics and heavy metals, pesticides, pharmaceuticals, and other organic contaminants may vary depending on polymer type, particle size, surface characteristics, aging processes, and the physicochemical conditions of the surrounding environment. Combined exposures have been associated with oxidative stress, alterations in antioxidant defense systems, neurotoxic and genotoxic responses, as well as adverse effects on growth, development, reproduction, and behavior. However, the influence of microplastics on the toxicity of coexisting chemicals is not uniform. Depending on the properties of the contaminant, microplastic characteristics, exposure duration, and concentration, combined exposure may result in synergistic, antagonistic, or additive effects.

Overall, interactions between microplastics and chemical pollutants represent an important factor that may modify the biological effects of contaminants in aquatic ecosystems. Considering combined effects alongside the toxicity of individual pollutants in environmental risk assessment may provide a more realistic understanding of exposure scenarios occurring in natural aquatic environments.
Keywords: microplastics, combined toxicity, aquatic organisms, environmental pollutants, ecotoxicology

INTRODUCTION

1. Definition and Environmental Formation of Microplastics

Plastic products are widely used in applications ranging from daily life to industry due to advantageous properties such as light weight, durability, versatility, and low production cost. However, the rapid increase in plastic use and the long-term persistence of the resulting plastic waste in the environment have made plastic pollution an important global environmental problem. Plastic materials entering the environment can fragment over time into smaller plastic particles under the influence of physical, chemical, and biological processes. Microplastics (MPs) are generally defined as synthetic polymer particles with an upper size limit of 5 mm, although there is no definitive consensus regarding the lower size limit. Furthermore, the

continued fragmentation of microplastics under environmental conditions may lead to the formation of nanoscale plastic particles (Li et al., 2018).

2. Environmental Transport and Distribution of Microplastics

Certain characteristics of microplastics, such as their light weight, diverse morphologies, and extremely long lifespans, contribute substantially to their transport between environmental compartments. These properties also make microplastics one of the most widespread pollutants worldwide. Nearly all plastics and plastic-derived materials are produced on land and enter different environments through various pathways. In most scenarios, land acts as the initial receiving compartment for microplastics, which subsequently enter the environment through direct littering, improper waste management, accidental losses during disposal, and industrial spills (Horton & Dixon, 2018).

3. Physicochemical Properties of Microplastics and Their Role as Chemical Carriers

An important chemical characteristic common to microplastics is their capacity to adsorb and accumulate environmental pollutants, including heavy metals and organic contaminants. Moreover, microplastics contain various chemical additives, such as plasticizers and flame retardants, suggesting that they may act as both a “carrier” and a “source” of other chemicals. Microplastics are generally resistant to chemical reactions; however, exposure to UV radiation can induce photochemical degradation and lead to higher fragmentation rates. In addition, the hydrophobic properties of microplastics can determine their interactions within aquatic habitats and organisms. Consequently, microplastics exhibit distinctive environmental pollutant characteristics that influence their distribution, uptake, and toxicity in aquatic species (Hasan et al., 2024).

4. Biological Effects of Microplastics on Aquatic Organisms

The adverse effects of microplastics on fish reproduction have also become a growing concern. For example, microplastics may have serious consequences for the endocrine systems of fish. Plasticizers and various bisphenol analogues and phthalates, which are important endocrine disruptors, may leach from microplastics into the environment. These chemicals may mimic or induce hormonal imbalances, potentially leading to reduced fertility rates, alterations in offspring growth, or even changes in sex ratios (Hasan et al., 2024).

Huang et al. (2024) exposed juvenile *Carassius auratus* to different concentrations of polystyrene microplastics (PS-MPs; 200, 800, and 3200 µg/L) for 32 days and evaluated their effects on growth, tissue damage, and gene expression. PS-MPs were reported to accumulate particularly in the gastrointestinal tract and gills, and exposure resulted in varying degrees of histopathological damage in the intestine, gills, brain, and liver. In addition, the severity of tissue damage increased with increasing PS-MP concentration, and changes were detected in the expression of the genes examined in the liver, intestine, and gills (Huang et al., 2024).

5. Interactions of Microplastics with Organic Pollutants and Heavy Metals

According to previous studies, microplastics can act as carriers capable of adsorbing and enriching heavy metals as well as organic pollutants such as polycyclic aromatic hydrocarbons (PAHs), polychlorinated biphenyls (PCBs), pharmaceuticals, and personal care products (PPCPs) from water or soil. Microplastics are highly mobile. After adsorbing organic pollutants, they may transport these contaminants to new environments and cause adverse effects (Zhang et al., 2023).

Microplastics can adsorb and accumulate various organic pollutants, including persistent organic pollutants such as polycyclic aromatic hydrocarbons (PAHs) and polychlorinated biphenyls (PCBs), as well as different heavy metals. The adsorption of heavy metals onto microplastic surfaces is influenced by several factors, including the physicochemical properties of the particles, surface modifications, aging, and environmental conditions (Ateia et al., 2022).

6. Interactions of Microplastics with Antimicrobials and Microorganisms

Various studies have investigated the adsorption and desorption behavior of antibiotics, particularly macrolides and quinolones, on different types of MPs, mainly polystyrene, polyethylene, and polylactic acid. To date, most studies have focused on the adsorption properties of pristine MPs, whereas desorption behavior has been investigated to a more limited extent. However, a large proportion of MPs present in the environment are aged. Once antibiotics are adsorbed by MPs, they can be transported along with the movement of MPs. Therefore, determining whether adsorbed antibiotics can desorb from microplastic surfaces is important for assessing the risks that these pollutants may pose in new environments (Zhang et al., 2023).

The co-occurrence of MPs and antimicrobials in the environment raises concerns regarding their combined ecological effects. Antimicrobials, which have substantially improved human and animal health and agricultural productivity, now frequently contaminate the environment through sources such as agricultural runoff and industrial discharges. For example, hydrophobic polymers such as polyethylene or polystyrene readily adsorb nonpolar antimicrobials, whereas charged or functionalized surfaces can bind ionizable antibiotics such as sulfonamides or tetracyclines. Their environmental presence not only poses ecological risks but also contributes to the proliferation of resistance genes (Tang, 2025).

7. Combined Toxicity of Pollutant Mixtures

Interactions between microplastics and coexisting pollutants may result in synergistic, antagonistic, or additive effects. When MPs carry other pollutants such as DBP, their large surface area may enable them to accumulate greater amounts of contaminants through an adsorptive carrier effect, thereby increasing toxicity. Conversely, MPs may reduce the bioavailability of pollutants through adsorption and enrichment, thereby decreasing their bioaccumulation. In addition, whether the interaction is synergistic or antagonistic may depend on MP concentration. Aggregation, disaggregation, and the corresponding exposure levels vary among different MP concentrations, which can result in inconsistent toxicity responses (Liang et al., 2025).

Turhan et al. (2026) evaluated the individual and combined effects of polyethylene microplastics (PE-MPs) and deltamethrin (DEL) during the early life stages of *Xenopus laevis*.

PE-MPs alone did not cause marked mortality or malformations in embryos but induced changes in biochemical responses. Under combined exposure to DEL and PE-MPs, additive, antagonistic, and synergistic interactions were reported depending on the biomarker and developmental stage. In embryos, additive effects were observed for GST and CaE, antagonistic effects for AChE, while the CAT response showed antagonistic or synergistic characteristics depending on the DEL concentration (Turhan et al., 2026).

The toxic effects of mixtures of MPs and hazardous chemicals may differ from the inherent toxicity of the individual substances depending on factors such as mixture concentration and ratio and interactions among the components. During the embryonic development of the amphibian *Rhinella arenarum*, non-toxic concentrations of copper and nonylphenol produced toxic effects depending on the mixture ratio (Aronzon et al., 2020). In *Daphnia magna* exposed to a mixture of silver ions and two different metal oxide nanoparticles, a synergistic effect greater than the toxic effects of the individual substances was confirmed (Park et al., 2019).

Liang et al. (2025) evaluated the combined toxicity of polypropylene microplastic fibers (MPFs) and dibutyl phthalate (DBP) in *Chlorella vulgaris*. Combined exposure was reported to cause more pronounced effects on photosynthesis, oxidative stress, and metabolism than individual exposures. In addition, the direction of combined toxicity changed depending on MPF concentration, with synergistic interactions at high MPF concentrations and antagonistic interactions at low MPF concentrations.

Wang et al. (2022) investigated the individual and combined toxic effects of polyvinyl chloride microplastics (PVC-MPs) and di(2-ethylhexyl) phthalate (DEHP) on *Danio rerio* embryos and larvae. The study used 0.1 ppm PVC-MPs and 71 µg/L DEHP, representing an environmentally relevant concentration. Individual exposure to PVC-MPs and DEHP inhibited embryo hatching, whereas this effect was reduced under combined exposure. Individual exposures also caused toxic effects on oxidative stress and cardiac development, while these effects were alleviated during combined exposure. The researchers reported an antagonistic interaction between PVC-MPs and DEHP and suggested that adsorption of DEHP by PVC-MPs, thereby reducing its bioavailability and bioaccumulation, may contribute to this antagonistic effect.

Zhang et al. (2022) showed that aged microplastics increased the accumulation of roxithromycin in *Carassius auratus* tissues in a microplastic size-dependent manner. Both aged microplastics and roxithromycin significantly increased superoxide dismutase (SOD) and catalase (CAT) activities in the liver and intestine while suppressing acetylcholinesterase (AChE) activity in the brain. In addition, smaller aged microplastics intensified roxithromycin-induced damage in the liver, gills, and brain, whereas larger microplastics caused more severe intestinal damage.

Similarly, in a 28-day study evaluating the combined effects of oxytetracycline and polystyrene microplastics on juvenile yellow catfish (*Pelteobagrus fulvidraco*), neither oxytetracycline nor 100 µg/L microplastics alone significantly affected growth, antioxidant and digestive enzyme activities, or intestinal microbial diversity. In contrast, combined exposure to oxytetracycline and 100 µg/L polystyrene microplastics increased SOD and CAT activities, caused mild intestinal damage, and increased the abundance of Proteobacteria (Tang, 2025).

CONCLUSION

The available evidence indicates that interactions between microplastics and chemical pollutants may significantly modify their toxic effects in aquatic organisms. Depending on microplastic characteristics, pollutant properties, concentration, and exposure conditions, combined exposure may result in synergistic, additive, or antagonistic effects. These interactions can influence oxidative stress, neurotoxicity, growth, development, and other biological responses. Therefore, evaluating microplastics and chemical pollutants separately may not adequately reflect exposure scenarios in natural aquatic environments. Further studies using environmentally relevant concentrations and different microplastic–pollutant combinations are needed to better understand these complex interactions and to improve ecological risk assessment.

ABSTRACT

Carbohydrates play a fundamental role in plant growth and development by serving as the primary source of metabolic energy and by contributing to physiological adaptation under changing environmental conditions. The present study aimed to determine the variation in total soluble carbohydrate content of *Ginkgo biloba* L. seedlings with respect to seedling age and sampling time during the growing season. Two-, three-, and four-year-old seedlings were used as plant material. Leaf samples were collected from 20 seedlings in each age class (60 seedlings in total) at the beginning and at the end of the growing season. Total soluble carbohydrate content was determined using the phenol–sulfuric acid method described by Dubois et al. (1956), and the results were expressed as mg g^{-1} dry weight. Within each sampling period, differences among seedling ages were evaluated by one-way analysis of variance (ANOVA), followed by Duncan's multiple range test to identify homogeneous groups. In addition, changes in carbohydrate content between the beginning and the end of the growing season were compared for each seedling age using the independent samples *t*-test.

At the beginning of the growing season, total soluble carbohydrate content increased with seedling age, with mean values of 90.77, 93.94, and 98.24 mg g^{-1} in two-, three-, and four-year-old seedlings, respectively. The differences among age classes were statistically significant ($p < 0.05$), and Duncan's test identified the four-year-old seedlings as the group with the highest carbohydrate content. In contrast, this pattern was reversed at the end of the growing season, when the highest carbohydrate content was recorded in two-year-old seedlings (133.77 mg g^{-1}), whereas the lowest value was observed in four-year-old seedlings (116.35 mg g^{-1}). Differences among age classes at the end of the growing season were highly significant ($p < 0.01$). Furthermore, Wilcoxon signed-rank test revealed significant differences in total soluble carbohydrate content between the beginning and the end of the growing season for each seedling age.

The findings demonstrate that total soluble carbohydrate content in *Ginkgo biloba* seedlings is influenced not only by seedling age but also by the stage of the growing season. The reversal in carbohydrate distribution among age classes from the beginning to the end of the growing season suggests age-dependent differences in carbohydrate accumulation, utilization, and reserve allocation during seasonal growth. These results provide new insights into the physiological dynamics of carbohydrate metabolism in *Ginkgo biloba* seedlings and contribute to a better understanding of age-related physiological processes that may support future nursery management and silvicultural practices.

INTRODUCTION

Climate change is associated with numerous environmental challenges, including rising temperatures, alterations in precipitation regimes, drought, declining water resources, floods, and increases in the frequency and intensity of heat waves (Turan, 2018). Among these impacts, drought is one of the major environmental factors directly affecting plant growth and development. Due to its geographical location and climatic characteristics, Türkiye is among the countries facing considerable risks of drought and desertification (Tüfekçioğlu and Tüfekçioğlu, 2018). Indeed, according to the desertification risk map developed for Türkiye, 12.7% of the country's land area is classified as being at low risk, 53.2% at moderate risk, and 25.5% at high risk of desertification (TÜBİTAK, 2015).

Throughout their growth and development, plants exhibit a range of physiological, biochemical, and molecular responses to changing environmental conditions. The magnitude and nature of these responses may vary depending on genotype and species, the intensity and duration of environmental stress, plant age, and developmental stage (Bray, 1997). Therefore, when evaluating the physiological characteristics of plants, it is important to consider not only environmental conditions but also plant age and developmental stage.

Carbohydrates are fundamental organic compounds produced through photosynthesis and play essential roles in providing energy for plant growth and development, storing carbon, and facilitating its transport among different plant organs. In addition, soluble carbohydrates are important physiological components involved in plant adaptation to changing environmental conditions. Changes in environmental conditions can substantially affect the synthesis, utilization, and allocation of carbohydrates, particularly starch and sucrose (Wang and Stutte, 1992; Keller and Ludlow, 1993; Dien et al., 2019). Under stress conditions such as water limitation, changes in the balance between photosynthetic carbon gain and carbon consumption may increase plant dependence on non-structural carbohydrate reserves (Guehl et al., 1993).

Soluble sugars are considered not only important sources of metabolic energy but also key compounds involved in plant adaptation to environmental conditions. An accumulation of soluble carbohydrates under stress conditions has been reported in several plant species (Munns and Weir, 1981; Thomas, 1990; Guehl et al., 1993). Such increases may be associated with reduced sugar consumption resulting from decreased growth, starch hydrolysis, and changes in carbohydrate translocation among plant organs. Therefore, determining soluble carbohydrate concentrations in different plant organs and their variation throughout plant development is important for evaluating plant physiological status and responses to changing environmental conditions (Gill et al., 2001).

Ginkgo biloba L. is a unique gymnosperm and the only extant species of the family Ginkgoaceae (Shareena and Kumar, 2022). With an evolutionary history extending approximately 270 million years to the Permian period, *G. biloba* is commonly referred to as a "living fossil," as its fundamental morphological characteristics have remained relatively unchanged over a remarkably long geological period (Zhou and Zheng, 2003). Native to China, *G. biloba* is now widely cultivated throughout temperate regions and is particularly valued in urban forestry and landscape applications (Del Tredici, 1991).

Ginkgo biloba is a deciduous tree that can reach 20–35 m in height and has high ornamental value owing to its characteristic fan-shaped leaves, which turn bright yellow in autumn. Its tolerance to urban pollution, resistance to pests and diseases, adaptability to a wide range of environmental conditions, and remarkable longevity further enhance its value for use in urban environments (Stanković, 2016). The species is also of considerable pharmacological importance because of the various biologically active compounds present in its leaves and seeds

and has consequently been the subject of extensive research on its ecological, physiological, and pharmacological properties (van Beek, 2002; Mahadevan and Park, 2008).

Because carbohydrate metabolism is closely associated with plant growth, development, and adaptation to environmental conditions, carbohydrate concentrations may vary depending on plant age and phenological stage. Particularly in perennial woody plants, seasonal changes in the balance among carbohydrate production, utilization, translocation, and storage may be reflected in leaf soluble carbohydrate concentrations. Therefore, determining changes in carbohydrate content among seedlings of different ages during the same growing season is important for elucidating age-related physiological differences.

The present study aimed to determine the variation in total soluble carbohydrate content of *Ginkgo biloba* seedlings in relation to seedling age and growing season. For this purpose, total soluble carbohydrate contents in the leaves of two-, three-, and four-year-old seedlings were determined at the beginning and end of the growing season, allowing comparisons both among seedling age classes and between sampling periods within each age class. The findings are expected to contribute to a better understanding of age- and season-related physiological changes in *G. biloba* seedlings and to provide useful information for future nursery management and landscape applications.

MATERIAL AND METHOD

The study was conducted using two-, three-, and four-year-old *Ginkgo biloba* L. seedlings grown under open-field conditions at the Research and Application Greenhouse of the Faculty of Forestry, Karadeniz Technical University (Figure 1). A total of 60 seedlings were included in the study, with 20 seedlings representing each age group. To evaluate age- and season-related changes in leaf total soluble carbohydrate content, leaf samples were collected at two different stages of the growing season: at the beginning of the growing season (May 2025) and at the end of the growing season (October 2025). Leaf samples obtained from the respective age groups during both sampling periods were subsequently used for the determination of total soluble carbohydrate content. According to the long-term climatic records for Trabzon Province covering the period from 1927 to 2023, where the Research and Application Greenhouse of the Faculty of Forestry is located, the mean annual temperature is 14.8 °C and the mean annual total precipitation is 828.9 mm.

Total soluble carbohydrate (TSC) content was quantified using the phenol–sulfuric acid assay based on the method of Dubois et al. (1956). Following collection, leaf samples were placed in paper bags and oven-dried at 65 °C for 48 h. The dried samples were subsequently ground to a fine powder, and 0.1 g of each sample was accurately weighed for analysis. Soluble carbohydrates were extracted from the powdered leaf material with 80% ethanol for 24 h. After extraction, the samples were centrifuged at 5000 rpm for 10 min, and the resulting supernatant was used for carbohydrate determination. For colorimetric analysis, a 50 µL aliquot of the supernatant was transferred into a glass tube and mixed with 1 mL of 5% phenol solution using a vortex mixer. Subsequently, 5 mL of sulfuric acid was added, and the mixture was thoroughly vortexed again. The reaction mixtures were allowed to stand at room temperature for 1 h to complete color development and cooling. Absorbance was then measured at 490 nm using 3-mL cuvettes. Total soluble carbohydrate concentrations were calculated from a standard calibration curve and expressed on a dry-weight basis as mg/g DW.

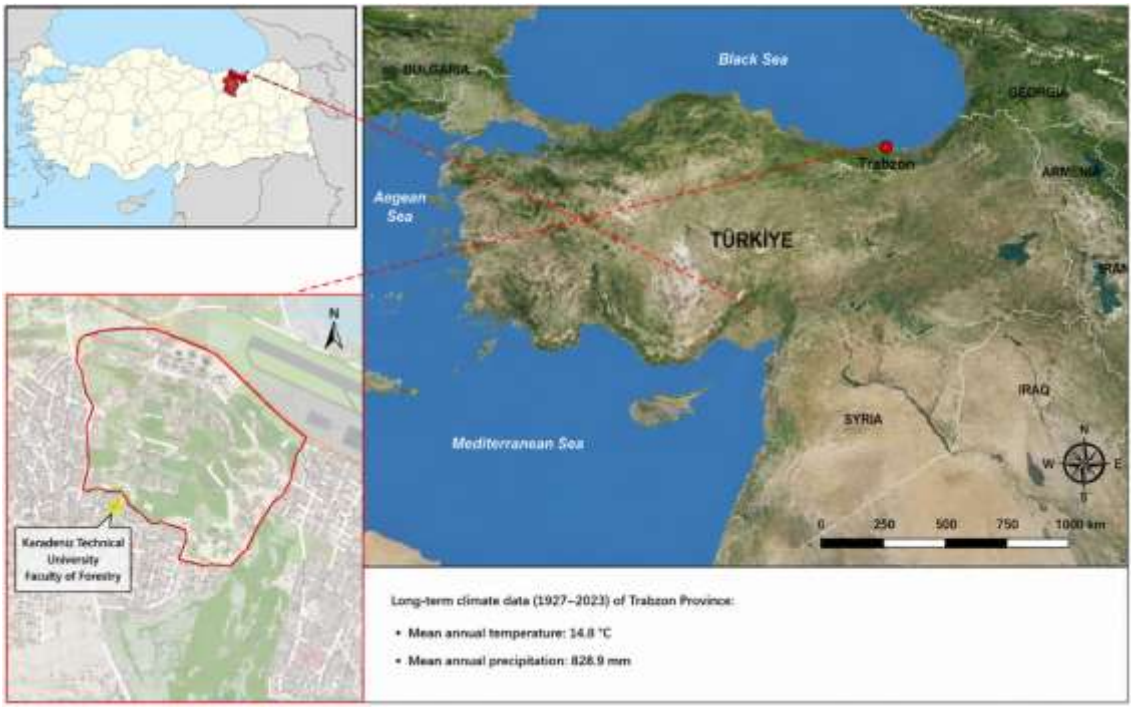

Figure 1. Geographical location of the study area

Statistical analyses were performed using IBM SPSS Statistics 23.0. Differences in total soluble carbohydrate content among two-, three-, and four-year-old *Ginkgo biloba* seedlings were analyzed separately for each sampling period using one-way analysis of variance (ANOVA). When significant differences were detected, Duncan's multiple range test was applied to identify homogeneous groups among seedling ages. In addition, total soluble carbohydrate contents measured at the beginning and at the end of the growing season were compared separately for each seedling age using the Wilcoxon signed-rank test. Statistical significance was evaluated at the $p < 0.05$ level.

RESULTS

Descriptive statistics for total soluble carbohydrate (TSC) content of two-, three-, and four-year-old *Ginkgo biloba* seedlings, together with the results of the Wilcoxon signed-rank test comparing May and October measurements, are presented in Table 1.

Table 1. TSC values of *Ginkgo biloba* seedlings of different ages

Seedling Age	Min. (mg/g)		Max. (mg/g)		Mean ± SE (mg/g)		Wilcoxon test Sig.
	May	Oct	May	Oct	May	Oct	
2-year-old	81.18	127.65	102.06	143.24	90.77 ± 2.45	133.77 ± 2.02	0.005
3-year-old	86.47	114.12	105.59	129.12	93.94 ± 2.13	120.53 ± 1.69	0.005
4-year-old	95.00	105.88	100.59	129.41	98.24 ± 0.65	116.35 ± 3.03	0.005

$p<0.01$: There is a statistically significant difference at the 99% confidence level

Total soluble carbohydrate content varied considerably according to seedling age and sampling period (Table 1). In May, the mean TSC content was highest in four-year-old seedlings (98.24 ± 0.65 mg/g), followed by three-year-old (93.94 ± 2.13 mg/g) and two-year-old seedlings (90.77 ± 2.45 mg/g). In October, however, this pattern was reversed, with the highest mean TSC content recorded in two-year-old seedlings (133.77 ± 2.02 mg/g), followed by three-year-old (120.53 ± 1.69 mg/g) and four-year-old seedlings (116.35 ± 3.03 mg/g). The TSC values ranged from 81.18 to 102.06 mg/g in two-year-old, 86.47 to 105.59 mg/g in three-year-old, and 95.00 to 100.59 mg/g in four-year-old seedlings in May. In October, the corresponding ranges increased to 127.65–143.24, 114.12–129.12, and 105.88–129.41 mg/g, respectively. Wilcoxon signed-rank test results showed that TSC content increased significantly from May to October in all three seedling age groups ($p<0.01$).
The results of one-way ANOVA examining differences in total soluble carbohydrate (TSC) content among seedling age groups in May and October are presented in Table 2.

Table 2. Results of variance analysis regarding TSC content of seedlings of different ages

		Sum of Squares	df	Mean Square	F	P
May	Between Groups	281.088	2	140.544	3.840	0.034
	Within Groups	988.133	27	36.598		
	Total	1269.221	29			
Oct	Between Groups	1653.391	2	826.696	15.410	0.000
	Within Groups	1448.445	27	53.646		
	Total	3101.836	29			

$p<0.01$: There is a statistically significant difference at the 99% confidence level
$p<0.05$: There is a statistically significant difference at the 95% confidence level

One-way ANOVA revealed significant differences in TSC content among the three seedling age groups in both sampling periods (Table 2). In May, the effect of seedling age on TSC content was statistically significant ($F = 3.840$, $p < 0.05$). A considerably stronger age-related difference was observed in October, when the ANOVA indicated a highly significant effect of seedling age on TSC content ($F = 15.410$, $p < 0.01$). These results demonstrate that TSC content differed among two-, three-, and four-year-old seedlings during both sampling periods, with the differences among age groups becoming more pronounced at the end of the growing season.

The results of Duncan's multiple range test showing differences in total soluble carbohydrate (TSC) content among seedling age groups in May and October are presented in Figure 2. In May, four-year-old seedlings had the highest mean TSC content (98.24 ± 0.65 mg/g) and were classified in group a, whereas two-year-old seedlings had the lowest mean value (90.77 ± 2.45 mg/g) and were classified in group b, indicating a significant difference between these two age groups. Three-year-old seedlings (93.94 ± 2.13 mg/g) were placed in the intermediate ab group and therefore did not differ significantly from either two- or four-year-old seedlings. In October, the trend changed markedly. Two-year-old seedlings exhibited the highest TSC content (133.77 ± 2.02 mg/g) and formed group a, while three-year-old (120.53 ± 1.69 mg/g) and four-year-old seedlings (116.35 ± 3.03 mg/g) were both classified in group b. Thus, in October, two-year-old seedlings had significantly higher TSC content than the other two age groups, whereas no significant difference was detected between three- and four-year-old seedlings.

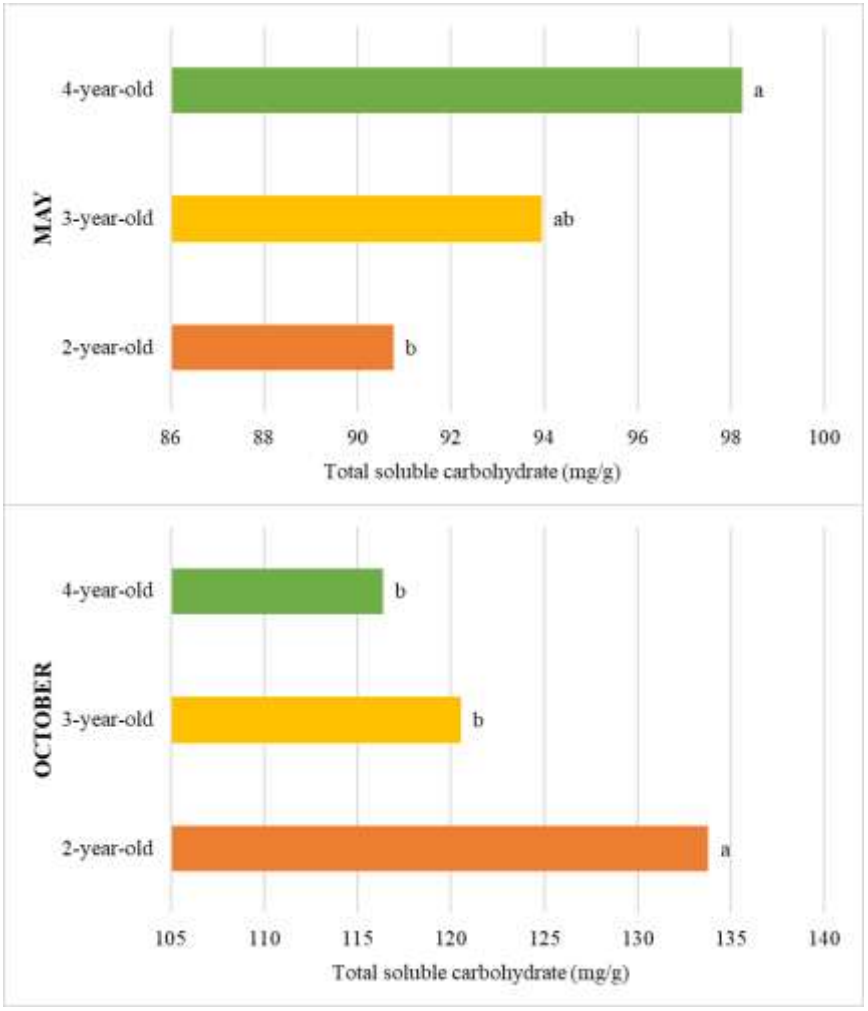

Figure 2. Duncan test results for May and October measurements of seedlings of different ages based on TSC content

DISCUSSION AND CONCLUSION

The present study demonstrated that total soluble carbohydrate (TSC) content in *Ginkgo biloba* leaves was influenced by both seedling age and sampling period. TSC content increased significantly from May to October in all three age groups; however, the magnitude of this increase differed among seedling ages. Moreover, the ranking of age groups changed considerably during the growing season. While four-year-old seedlings exhibited the highest TSC content in May, two-year-old seedlings had the highest value in October. These findings indicate that seasonal changes in carbohydrate metabolism in *G. biloba* seedlings are closely associated with developmental stage and that seedlings of different ages may differ in the balance between carbohydrate production, utilization, and allocation.

Seasonal variation in carbohydrate concentration is a characteristic feature of perennial woody plants because non-structural carbohydrates represent a dynamic balance between carbon acquisition through photosynthesis and carbon demand for growth, respiration, storage, and other metabolic processes. Soluble sugars also perform functions beyond carbon storage, including transport, energy metabolism and osmoregulation (Hartmann and Trumbore, 2016). A broad synthesis of seasonal NSC dynamics showed that soluble sugars, starch, and total NSC vary substantially during the year and that carbohydrate concentrations may increase as plants

approach the dormant period, particularly in temperate environments (Martínez-Vilalta et al., 2016). Therefore, the higher TSC concentrations observed in October in the present study may reflect changes in the source–sink balance toward the end of the growing season, when demand for active vegetative growth declines and a greater proportion of assimilated carbon may remain in soluble or reserve forms.

Evidence from *G. biloba* also supports pronounced seasonal regulation of carbohydrate metabolism. Guo et al. (2024), investigating seasonal development of current- and second-year xylem in *G. biloba*, reported marked seasonal changes in non-structural carbohydrate concentrations together with substantial changes in genes and metabolites involved in carbohydrate metabolism. They also found a positive association between ABA concentration and non-structural carbohydrate content, indicating that seasonal carbohydrate dynamics in *Ginkgo* are closely integrated with developmental and hormonal regulation. Similarly, Li et al. (2020) demonstrated pronounced physiological and transcriptomic changes in *G. biloba* leaves during the transition from green leaves to autumn senescence, including reductions in photosynthetic activity and substantial alterations in ABA- and jasmonic-acid-related pathways. These findings support the view that the increase in TSC observed from May to October in the present study occurred within a broader seasonal reorganization of carbon metabolism rather than simply representing continuous carbohydrate accumulation throughout the growing period.

Nevertheless, seasonal changes in individual soluble sugars do not necessarily follow the same direction as changes in total soluble carbohydrate content. Horbowicz et al. (2022) identified sucrose, glucose, and fructose as major soluble sugars in *G. biloba* leaves and reported substantial changes in their concentrations during natural leaf senescence. In particular, glucose and fructose declined as leaves progressed toward natural senescence, while sucrose metabolism also changed markedly. This apparent difference from the present results should be interpreted cautiously because the two studies evaluated different carbohydrate fractions and different phenological intervals. Horbowicz et al. (2022) quantified individual sugars during the relatively narrow transition from September to natural senescence in October, whereas the present study compared total soluble carbohydrates between May and October using the phenol–sulfuric acid assay. Thus, differences in sampling stage, analytical approach, and the carbohydrate fractions measured may explain the contrasting responses. Importantly, the October samples in the present study represent the end of the growing season and should not necessarily be considered equivalent to fully senescent leaves.

Another important finding was the reversal of the age-related differences between the two sampling periods. In May, TSC content increased with seedling age, and four-year-old seedlings had significantly higher TSC content than two-year-old seedlings. In October, however, two-year-old seedlings accumulated significantly more TSC than both three- and four-year-old seedlings. The seasonal increase was therefore proportionally strongest in the youngest seedlings and progressively smaller with increasing seedling age. Such differences may be associated with ontogenetic changes in source–sink relationships and carbohydrate allocation. Seedling age can influence photosynthetic carbon acquisition, growth demand, storage capacity, and the distribution of NSC among leaves, stems, and roots. For example, Han et al. (2025) demonstrated clear age-dependent differences in organ-specific NSC allocation and carbon coordination between one- and three-year-old *Pinus yunnanensis* seedlings, showing that developmental stage can substantially modify carbohydrate allocation strategies. Although that study involved another tree species and shade treatments, it provides physiological support for the age-dependent differences observed here.

Recent evidence obtained directly from *G. biloba* seedlings further emphasizes the importance of carbohydrate partitioning among plant organs. Tang et al. (2026) reported that defoliation of two-year-old *G. biloba* seedlings increased soluble sugar and starch concentrations in the

remaining leaves while decreasing carbohydrate reserves in stems and roots. Their results demonstrate that changes in leaf carbohydrate concentration can occur simultaneously with an opposite response in other organs and therefore reflect active redistribution of carbon within the plant. Accordingly, the higher October TSC concentration of two-year-old seedlings in the present study should not necessarily be interpreted as a greater whole-plant carbohydrate reserve. It may instead reflect age-specific differences in the retention, utilization, or translocation of carbohydrates in leaves. Measurements of soluble sugars and starch in stems and roots, together with leaf measurements, would be required to determine whether the age-related differences observed here represent differences in whole-plant carbon storage or primarily in organ-specific allocation.

Overall, the results indicate that both seedling age and seasonal development are important determinants of leaf TSC content in *G. biloba*. The significant increase from May to October in all age classes demonstrates a strong seasonal component, whereas the reversal in the ranking of age groups indicates that this seasonal response is age dependent. The relatively high TSC concentration of four-year-old seedlings at the beginning of the growing season and the pronounced late-season increase in two-year-old seedlings suggest differences in carbohydrate utilization and allocation among developmental stages. However, because the present study quantified total soluble carbohydrates only in leaves at two sampling dates, the underlying mechanisms cannot be attributed specifically to changes in photosynthesis, carbohydrate translocation, starch–sugar conversion, or environmental acclimation. Future studies incorporating repeated sampling throughout the growing season and simultaneous measurements of individual soluble sugars, starch, photosynthetic traits, and carbohydrate concentrations in leaves, stems, and roots would provide a more comprehensive understanding of age-dependent carbon dynamics in *G. biloba*. Nevertheless, the present findings demonstrate that seedling age should be considered when evaluating the physiological status and seasonal carbohydrate dynamics of *G. biloba* seedlings and provide a useful basis for future nursery and ecophysiological studies.

ABSTRACT

On commercial cattle farms in Romania, it is essential to comply with the specific requirements regarding animal welfare and protection in accordance with the applicable European legislative framework. In particular, this article focuses on higher welfare standards for young cattle in fattening operations.

The study focuses on cattle farms authorized by the sanitary-veterinary authorities that house young female and male cattle up to 32 months of age, with a minimum live weight of 450 kg per head, and addresses three specific requirements that support the welfare of these animals, namely: an increase of at least 15% in the space allocated to each animal, ensuring enhanced comfort in the resting area, and providing optimized feed rations to enhance animal welfare and reduce greenhouse gas emissions.

It can be concluded that the results observed as a result of the improved animal welfare following the implementation of these requirements will be appropriately highlighted for the farms analyzed.

Key words*:* young cattle, animal welfare, greenhouse gas emissions

INTRODUCTION

As a scientific field, animal welfare emerged as a distinct discipline around 1990, following decades of ethical debate and numerous scientific contributions from fields such as ethology, nutrition, anatomy, and veterinary medicine. Scientific interest was not the sole factor contributing to its development. Public concern regarding the way animals were treated and raised also played a significant role in shaping animal welfare science. (Angela Krueger et al., 2020)

However, global standardisation remains limited. In principle, welfare assessment programmes have been developed to establish benchmark levels for cattle welfare and to provide consumers with assurance that farmers comply with higher welfare requirements. In

order to highlight similarities and differences among existing approaches, an analysis was conducted of several cattle welfare assessment programmes commonly used at European level and implemented at farm level. In addition, observations are provided regarding the types of indicators included in the assessment of animal welfare on farms raising young cattle for fattening. (Angela Krueger et al., 2020)

Prior to 2006, the various Member States of the European Union had their own national standards, coordinated by their respective national veterinary authorities. Subsequently, the Community Action Plan on the Protection and Welfare of Animals was established. Its main objectives included setting the strategic direction for animal welfare and protection, as well as promoting welfare principles and research in this field. In 2009, the first animal welfare assessment protocols were published within the European Union. This Action Plan paved the way for European research projects developed by scientists with extensive expertise in this field and a strong interest in improving the welfare of farm animals throughout the European Union. (Angela Krueger et al., 2020)

The present scientific analysis focuses on a series of studies addressing the legislative framework applicable within the European Union, with the aim of identifying higher welfare conditions. Otherwise, the analysis may also be interpreted from the perspective that improvements in welfare standards for young cattle could contribute to the development of advanced European standards for the livestock sector under consideration.

Animal welfare is a complex concept, and assessing an animal's welfare status requires effective monitoring tools. A recent analysis of animal welfare assessment systems has demonstrated that current protocols are comprehensive, covering various aspects related to housing, feeding, health, and behaviour. (Daniel M. Weary, Marina A.G von Keyserlingk., 2023)

We reviewed a range of scientific studies on cattle welfare that aimed to describe higher welfare standards and associated them with specific benefits and risks. Most of the articles examined adopted a predominantly positive perspective and, in some cases, made general statements that had not been subjected to sufficiently thorough evaluation. We therefore conclude that approaches to animal welfare are often biased, placing greater emphasis on benefits to humans rather than on the welfare of the animals themselves. (Daniel M. Weary, Marina A.G von Keyserlingk., 2023)

In the future, greater attention is expected to be given to welfare standards in general and to cattle welfare in particular, together with the increasingly widespread use of different monitoring methods to continuously assess the welfare status of farm animals. The primary objective of this study is to upgrade welfare parameters based on farm records. The final assessment of welfare performance will depend on how these parameters and assessment tools are used by the end beneficiaries. (Daniel M. Weary, Marina A.G von Keyserlingk., 2023)

MATERIALS AND METHODS

At European Union level, welfare conditions for young cattle raised for fattening can be improved through three main approaches: increasing the available space allocated to each animal by at least 15%; providing enhanced comfort conditions in resting areas; and providing optimised diets designed to improve animal welfare while reducing greenhouse gas emissions. (Regulation (EU) 2016/429, Regulation (EU) 2017/625, Regulation (EU) 2021/2115)

I.Increasing the available space allocated to each animal by at least 15%

A.Housing systems consisting of individual pens or group pens

Where the housing facility is divided into pens, the usable floor area available in each pen or compartment is determined through measurements as follows:

the length and width of the pen, compartment, or rearing area are measured;
the area occupied by feeding and watering equipment within the pen, compartment, or rearing area is determined by measurement;
the number and category of animals present in the respective pen, compartment, or rearing area are recorded.

Where pens of different dimensions are present, measurements are carried out separately for each pen.

B.Housing systems without separate pens

Where the housing facility is not divided into pens and consists of a common rearing area, the length and width of the rearing area are measured.

In addition:

the area occupied by feeding and watering equipment, structural columns, and passageways within the rearing area is determined;
the number and category of animals present in the rearing area are recorded.

The above data are entered into a calculation formula to determine the available floor space, as follows:

Available floor space per animal = (length × width − area occupied by feeding and watering equipment) / number of cattle

The resulting value is then compared with the minimum floor-space requirements established under the higher welfare conditions.

Welfare indicators for young cattle raised for fattening

Increase in the available space allocated to each animal by at least 15%

Body weight of young cattle*	**Minimum usable floor-space standard**	**Specific requirement**
Up to 150 kg	1.50 m²	1.725 m²
150–220 kg	1.70 m²	1.955 m²
221–300 kg	1.80 m²	2.070 m²
Above 300 kg	2.50 m²	2.875 m²

* Animal body weight may be determined using one of the following methods:

Using a weighing scale, which must have a valid and up-to-date metrological verification.

If the farm does not have a weighing scale or if the scale has not undergone valid metrological verification, animal body weight may be estimated using body measurements. The thoracic circumference (P) and the oblique body length (L) are measured, and body weight is subsequently calculated in kilograms according to the following formula:

$G\ (kg) = P^2\ (cm) \times L\ (cm) / 10{,}000$

II.Provision of enhanced comfort conditions in resting areas

The second approach concerns the assessment of absorbent bedding materials used in the areas selected for determining stocking density.

For compliance with the minimum requirements, it is verified whether the farmer uses absorbent materials at a rate of **2 kg/animal/day**. For compliance with higher welfare requirements, it is verified whether absorbent bedding materials are provided at a rate of **3 kg/animal/day**.

For rearing areas in which the requirement of 3 kg/animal/day is not met, the quantity of absorbent material used per young bovine per day is calculated by relating the quantity recorded in the farm's material-use register to the number of animals present in the respective rearing area on the date of the inspection.

Farms using mattresses and hygroscopic materials

For farms using mattresses and hygroscopic materials, it is verified whether mattresses are provided and whether hygroscopic material consisting of chopped or shredded plant fibres—such as wood shavings, sawdust, or chopped straw—is applied over the insulating layer, as documented in the farm's hygroscopic-material register.

For compliance with the minimum requirements, the use of mattresses is verified. For compliance with the higher welfare requirements, the use of hygroscopic materials consisting of chopped or shredded plant fibres (wood shavings, sawdust, or chopped straw) over the insulating layer is verified, at a rate of **300 g/animal/day**.

The quantity of hygroscopic material applied per young bovine per day is determined by relating the quantity of material used on the respective day, according to the farm records, to the number of animals present.

III.Provision of optimised diets to improve welfare and reduce greenhouse gas emissions

The third approach involves the verification of monthly feed analysis reports issued by a specialised laboratory.

The availability of the relevant analytical documents is verified, together with evidence that each animal receives an optimised and nutritionally balanced diet. In particular, the **crude protein content of the feed should range between 10% and 20% of dry matter, while the dry matter content should range between 40% and 90%**.

RESULTS AND DISCUSSION

The complexity of animal welfare assessment, particularly in the case of young cattle, has led to the development of several assessment systems, each presenting specific strengths and limitations. The analysis of three relevant animal welfare programmes—namely, increasing the available space allocated to each animal by at least 15%, providing enhanced comfort conditions in resting areas, and providing optimised diets aimed at improving welfare and reducing greenhouse gas emissions—demonstrated the importance of considering several complementary aspects. (Regulation (EU) 2016/429, Regulation (EU) 2017/625, Regulation (EU) 2021/2115)

These include the environmental conditions in which animals are kept, direct measurements performed on the animals, and management decisions adopted at farm level. Animal welfare programmes should incorporate assessments covering animals of all ages. They should also contribute to the identification of methods for detecting pain and suffering, as well as to the evaluation of farmers' ability to provide a safe, hygienic, and appropriate environment for the animals. (Regulation (EU) 2016/429, Regulation (EU) 2017/625, Regulation (EU) 2021/2115)

Assessment systems for the welfare of young cattle raised for fattening are also beneficial to farmers, given that animal welfare is directly associated with production performance. Appropriate housing conditions, adequate resting areas, and nutritionally balanced diets can contribute not only to improved welfare outcomes but also to the sustainable performance of cattle production systems. (Regulation (EU) 2016/429, Regulation (EU) 2017/625, Regulation (EU) 2021/2115)

CONCLUSIONS

The primary objective of this study is to contribute to the improvement of animal welfare performance in farmed animals. The final assessment of higher welfare conditions will depend on the purpose for which the assessment system is implemented and used by farmers.

If the implementation of these measures across all livestock holdings provides a reliable support tool capable of effectively contributing to the improvement of animal welfare conditions, the resulting impact can be considered positive. Achieving this objective currently represents an important concern for the Member States of the European Union.

The systematic application of welfare indicators based on measurable parameters and farm records may provide a practical framework for monitoring welfare conditions and supporting evidence-based decision-making at farm level. Such an approach may also contribute to the progressive harmonisation and improvement of welfare standards for young cattle within the European Union.

ABSTRACT

Recent studies have demonstrated that ESBL-producing *E. coli* are globally common in aquatic environments such as lakes and rivers, detecting viable ESBL producers in a high proportion of water samples. The main objective of this study was to investigate the occurrence, diversity, and phenotypic and molecular characteristics of ESBL-producing *E. coli* in the aquatic environment, in the Shkumbini River Ecosystem. Antimicrobial susceptibility analysis of the ESBL producing E. coli revealed that 100 % of isolates were resistant to at least one antimicrobial agent in three or more antimicrobial categories thus characterized as multidrug resistant (MDR). Molecular characterization of ESBL producing isolates revealed the prevalence and diversity of the β-lactamase resistance genes among them. The most prevalent ESBL Genotype was blaCTX-M-1 (33.33%, 5/15). Overall, the findings of our study are worrisome, emphasizing the importance of rivers as potential reservoirs of antibiotic resistance genes (ARGs), imposing serious threats to public health as well as the necessity of a more detailed analysis of genomic features of ESBL *E. coli* isolates to better understand the pathogenic potential and the epidemic characteristics of them in the aquatic ecosystem. Considering the continuous interaction between aquatic ecosystems, human activities, and animal production systems, the detection of ESBL-producing E. coli in the Shkumbini River emphasizes the urgent need for coordinated One Health-based surveillance programs to identify transmission pathways and develop effective strategies for controlling the environmental dissemination of antimicrobial resistance.

Key words: ESBL-producing *E.Coli*, surface water, antibiotic resistance genes

INTRODUCTION

Our study encompassed a range of sampling locations, including areas impacted by human sewage and wastewater contaminated with animal waste from wet markets or slaughterhouses. We collected 8 samples from both upstream and downstream sites. The downstream samples provided valuable information on the presence and concentrations of ESBL-*E. coli*, primarily due to inputs from the surrounding community, including sewage discharges and waste. Furthermore, we conducted comprehensive analysis on the total E. coli present in the collected samples. Using these total *E. coli* counts, we calculated the proportion of colonies that were ESBL producers among the overall *E. coli* population (WHO). Furthermore, we undertook extensive analyses to thoroughly explore their antibiotic resistance profiles, while concurrently investigating the presence of ESBL genes.

MATERIALS AND METHODS

The proposed methodology introduces a realistic approach to the selection of sampling locations based on field survey and the use of geospatial techniques to account for the impact of human activities (Vikas, 2015). The water from the Shkumbin river has been and is used for different purposes like bathing, washing of clothes, and also for agriculture.

During the study we implemented a standardizes sampling protocol in which the minimum depth of 30 cm below the water surface was consistently maintained, with no samples exceeding 50 cm. Sampling was conducted at predetermined locations, predominantly on bridges. Each sample, consisting of 1 liter, was promptly transferred to a thermos and stored for up to 8 hours for preservation. To ensure proper preservation, we decided to store the samples in refrigerator as immediate analysis was not conducted at that time (Claiborne), (ISO, 2006-08). The concentration of ESBL-*E.Coli* in water exhibit considerable variation doe to the variability of fecal contamination levels different type of waste and the availability of no-contaminated water source as rainfall and upland spring. Because of this we have in front of us a major challenge in accurately prediction water contamination levels in other sampling periods. Therefore, to ensure the presence of countable numbers of colonies, multiple 10-fold dilutions of each sample were analyzed. Another approach was utilized simultaneously due to its advantage of allowing us to isolate pure strains of a single species or segregate strains from a mixed population, selectively reducing or removing unknown organisms. This reduction is achieved thought a repeated process of suspending an initial solution into fixed volumes of liquid diluent (ISO 6.-1. , 2017). After confirming the presence of gas in the tubes, we proceed with indole test as means to differentiate between E. Coli and Enterobacter aerogenes (ISENBERG, 1958) (MacWilliams, 2009). Simultaneously in order to obtain accurate result, a volume of 100 ml from the sample was filtered through a membrane with pore size of 0.45 mm (ISO 8. , 2018). To determine the presence of ESBL activity, the membrane was incubated on TBX (Tryptone Bile X-glucuronide) agar plate supplemented with 4µg/ml CTX (Cefotaxime). By adhering to established protocol and employing rigorous purification techniques, we successfully isolated a total of 16 colonies of ESBL *E. coli* (ISO 7. , 2023) (WHO).

After isolating the Esbl colonies, we continued with phenotypic confirmation methods to confirm their presence. These methods are based on the principle that clavulanic acid can inhibit ESBL enzymes, resulting in a synergistic effect when combined with CTX and Ceftazidime. We conducted the tests using antibiotic disks: Cefoxitin (FOX), Cefotaxime (CTX), Ceftazidime (CAZ), Aztreonam (ATM) and Amoxycillin/Clavulanic Acid (AMC). The incubation was performed at a temperature of 37°C for a period of 16-18 hours (EUCAST, July 2017) (WHO).

To extract genomic DNA from individual bacterial colonia simple method was applied. Carefully selecting 1 to 5 individual colonies (depending from their size) from the agar plate, to ensure an ample quantity of DNA. Those colonies have been collected by using a sterile

inoculating loop and then resuspended in 100 µl sterile deionized H2O. This suspension was placed at 97 ◦C and "cooked" for 5–10 minutes using a water bath, after that solution was shake for 5 minutes at a rate of approximately 2000-6000 oscillations per minute. To separate the supernatant containing DNA we centrifuge the cell lysate at 15,000 × g, 5–15 minutes. Usually, a small volume ranging from 1-5 µl is added to a PCR reagent mix (Edward R. B. Moore, January 2004) (Omar B. Ahmed, 2017).

For every DNA extracted a various PCR multiplex were employed for molecular characterization including: Mcr-1, Mcr-2, Mcr-3, Mcr-4, Mcr-5 (Rebelo Ana Rita, Euro Surveill. 2018); ShV, OXA 1, TEM; OXA, NMD, KPC (Bogaerts P, 2013) (Dallenne C, 2010); CTX-M 8/ 25; IMP, VIM; CTX-M 1, CTX-M 2, CTX-M 9 (M.C. El bouamri, 2015,) (Bogaerts P, 2013).

RESULTS

The table, displays the findings of six samples that tested positive for ESBL in E. coli. These E. coli organisms were found in 100 ml water samples that were collected. Out of the six samples that showed growth, 15 distinct colonies were selected based on suspicion of ESBL. After conducting synergy tests, we were able to isolate 15 distinct E. coli colonies that tested positive for ESBL.

Antibiograms were performed for each of the isolated strains to determine their antibiotic resistance profiles. The obtained results have shown higher resistance of strains towards Streptomycin was 93.33%, Ampicillin 93.33%, 73.33% Gentamycin, 40% Tetracycline and Trimethoprim, 33.33% Ciprofloxacin,26.67% Chloramphenico,13.33% Meropenem and no resistance at all from Imipenem.

Molecular characterization of ESBL producing isolates revealed the prevalence and diversity of the β-lactamase resistance genes among them. The most prevalent ESBL Genotype was blaCTX-M-1 (33.33%, 5/15).

DISCUSSION

Based on the performed analyses, it is evident that ESBL genes are in circulation in Elbasan region. In relation to antibiotics, the antibiogram indicates the development of resistance against commonly utilized antibiotics in Albania. Following his trend is anticipated to yield more significant repercussions in the future, imposing serious threats to public health as well as the necessity of a more detailed analysis of genomic features of ESBL *E. coli* isolates to better understand the pathogenic potential and the epidemic characteristics of them.

ABSTRACT

The rapid changes in science and technology, the evolving needs of individuals and society, and the innovations and advancements in learning and teaching theories and approaches have directly impacted the roles expected of individuals. This transformation defines an individual who produces knowledge, uses it functionally in life, solves problems, thinks critically, is entrepreneurial, determined, possesses communication skills, can empathize, and contributes to society and culture, etc. For these reasons, the Climate, Environment, and Innovative Solutions Curriculum aims to contribute to students becoming individuals who can find solutions to the problems in our environment. The curriculum, within the framework of virtue, values, and actions, aims to guide students from actions to values, from values to virtuous individuals, and from virtuous individuals to the ultimate goal of becoming peaceful individuals in a livable environment. The Climate, Environment, and Innovative Solutions course curriculum addresses climate change, the interaction of environmental systems with humans, and environmental problems. The program also includes topics such as environmental problems, the fundamentals of innovative solutions, and efforts to develop innovative solutions. Given that the environment and environmental problems occupy a significant place in our lives today, and because children need to be educated and develop attitudes on these issues from a young age, this research aims to evaluate the Climate, Environment, and Innovative Solutions Course Curriculum and Annual Plan implemented in Turkey, as perceived by university students. For this purpose, a qualitative research method was used in the study. As a data collection method, 22 final-year science education students who went to schools for internships were asked to evaluate the curriculum on A4 paper, and then the data were interpreted. When students' statements are evaluated, it is seen that the program is effective in some areas and unsuccessful in others.

Keywords: Climate, Environment and Innovative Solutions, Curriculum, Annual plan, Science education students

INTRODUCTION

Human activities in the human environment cause air, water, soil, noise, and light pollution on the one hand, and on the other hand, they play a significant role in global climate change by increasing global warming. Furthermore, the issue of sharing water and energy resources has transformed from an environmental challenge into an international economic and political problem. Reversing this worsening trend as soon as possible has become one of humanity's most important tasks. At this point, it is not enough to simply protect the natural environment; solutions to the problems must also be found, and a safe, clean, and sustainable

understanding of the natural environment must be developed. Action plans at local, national, and global levels that mitigate the impact of environmental challenges and protect and improve the environment need to be implemented worldwide. To leave a more livable world for future generations, the current lifestyle, which is based on "more production" and "more consumption," must first transform into a sustainable lifestyle free from waste. An important point to emphasize is that the use and management of natural resources should be approached in a way that ensures their sustainability and passes them on to future generations, rather than in a destructive and damaging manner (Ministry of National Education, 2026).

Climate change is predicted to increasingly threaten the future security and well-being of humanity (Türkeş, 2022). This threat is making its effects felt more and more each day, without any distinction between underdeveloped and developing countries. Despite the Intergovernmental Panel on Climate Change (IPCC) reports demonstrating that climate change is caused by human activities, it is still not considered a serious problem by countries (Aydın and Demirbaş, 2020). Climate change has affected human life throughout history. However, after the industrial revolution in the 19th century, humans also began to influence the climate through their activities, and the impact of humans on climate change began to increase (Şen, 2022; Karaaslan and Çetin, 2025).

With the increase in environmental problems, people's perspectives on nature have changed. The previously dominant romantic viewpoint has gradually given way to an attitude that investigates and questions environmental problems (Kılıç, 2013; Dere and Çinikaya; 2023). When examining the development of environmental education in the 20th century, it is necessary to mention some important steps. Firstly, the books "The Silent Spring" and "Our Synthetic Environment," published in 1962, created significant awareness of the global impact of chemical products (Ünder, 1996). In 1971, an international study entitled "Study of Man's Impact on Climate" was published with the support of the Swedish Academy of Sciences (Hulme, 2016; Dere and Çinikaya; 2023).

Six years after Turkey signed the Paris Agreement in 2015, it was ratified by the Grand National Assembly of Turkey (TBMM) on October 6, 2021, and published in the Official Gazette (Official Gazette, October 7, 2021). Following the ratification of the agreement, the name of the Ministry of Environment and Urbanization was changed to "Ministry of Environment, Urbanization and Climate Change" in order to draw attention to the issue of climate change (Official Gazette, October 29, 2021). Article 12 of the Paris Agreement emphasizes that signatory countries should provide climate change education and cooperate to raise public awareness of climate change (Official Gazette, October 7, 2021).

As is known, with environmental problems reaching a global dimension, environmental education has been on the agenda of many international meetings since the 1970s. In Turkey, environmental responsibility is addressed within the framework of cooperation between the state and citizens, as stipulated in Article 56 of the 1982 Constitution. In 1999, a protocol was signed between the Ministry of Environment and Forestry and the Ministry of National Education aiming to include environmental issues in various levels of education (preschool, primary, secondary, and apprenticeship training) and to organize in-service training courses on environmental education for students and teachers nationwide. Essentially, in Turkey, until the Paris Agreement was signed in 2015, environmental issues were covered in subjects such as life skills, science, social studies, geography, and biology. The Climate, Environment and Innovative Solutions course is a brand new course introduced as an elective in high schools as part of the Ministry of National Education's (MEB) curriculum update. This course is not a direct replacement for a specific old course; rather, it is a new, focused curriculum added to the elective course pool by expanding its scope.

One of the tools that prepares individuals to both combat climate change and adapt to its effects is education (Açıkalın, Sarı and Erçetin, 2024). Education has a positive impact on our

thoughts, behaviors, and communication with present and future generations in the fight against climate change (Mochizuki and Bryan, 2015; Karaaslan and Çetin, 2025). One of the most important aspects of combating and adapting to climate change is effective environmental education. Effective environmental education will make individuals and society better prepared for the consequences of climate change. Climate change education, which is particularly linked to environmental education, stands out in this preparation (Karaaslan and Çetin, 2025).

Understanding the causes and consequences of climate change and discussing appropriate responses aims to increase individuals' attitudes and motivation to make informed decisions and take responsible actions (Anderson, 2010). Climate change education should aim to prepare children for a rapidly changing, uncertain, and risky future (Stevenson et al., 2017).

With the 21st century, environmental education, with its multidisciplinary structure, occupies a unique position within both formal (preschool, primary, secondary, high school, and undergraduate) and non-formal education. Within this scope, the Climate, Environment and Innovative Solutions Curriculum aims to enable students to recognize, develop interest and curiosity about nature and their immediate environment, to have a positive attitude, to understand the relationship between humans and the environment, to view a livable environment as a legacy for future generations within the framework of sustainability, to have knowledge about the causes and consequences of climate change in the world and in Turkey and to take responsibility in this context, to have knowledge about environmentally friendly technologies, to become familiar with environmentally related professions, and to adopt the principles of environmental ethics. In this context, the Climate, Environment and Innovative Solutions course plays an important role in raising individuals who can generate knowledge, solve problems, evaluate events with a critical perspective, possess advanced communication skills, have high empathy, and contribute to social and cultural development (Ministry of National Education, 2022; Gülersoy and Gülersoy, 2023).

The Climate, Environment, and Innovative Solutions course will enable students to perceive the variable and dynamic environment from a holistic perspective. While the concept of "environment" considers the natural and human environment as a whole, the concept of "environmental" refers to events and phenomena related to the environment. This course focuses primarily on the various environmental problems arising from the interaction of natural and human systems, and how to address these problems. For students to understand and evaluate these focused problems and ways to cope with them, and to develop their own solutions, they first need to have a holistic perspective. Students can gain a holistic perspective when they see examples of human impacts on an environmental system, the resulting environmental problems, and proposed solutions to ensure the sustainability of environmental systems, all presented together.

The aim of this research is to compare the 2026 Environment, Climate and Innovative Solutions Curriculum and its topics, published by the Ministry of National Education (MEB), from various perspectives as viewed through the lens of student approaches.

MATERIAL AND METHOD

The study was structured according to a qualitative research approach. In this context, the data used in the research were obtained from materials in which students' opinions were collected in writing. The study was conducted using data collected from 22 final-year students taking the Environmental Education course in the Science Education Department of the Faculty of Education at Trakya University during the Fall semester of the 2025-2026 academic year. The students consisted of 2 male and 20 female individuals. They were asked to express their impressions and experiences from their internships and program reviews on A4 paper. These

data were then coded sequentially from 1 to 22. Below, some students' statements are presented and evaluated in the findings section.

RESULTS AND DISCUSSION

The Climate, Environment, and Innovative Solutions course consists of 6 units. The number of learning outcomes and durations for each unit are presented in Table 1. Based on this content, some of the data obtained from 22 students in this section are presented below.
The student in the S1 group expressed their thoughts about the course as follows: “This course aims to create environmental awareness and a sense of sustainable living among students. The inclusion of fundamental topics such as the concept of the environment, ecosystems, the use of natural resources, environmental problems, and climate change in the annual plan demonstrates that environmental education is addressed from a holistic perspective. Presenting the topics sequentially also helps children establish cause-and-effect relationships. Addressing the issue of climate change by linking it to human activities and environmental problems enables students to connect this process to their daily lives. Addressing environmental issues from both local and global perspectives helps children develop a sense of responsibility towards the environment.”

Table 1. Units, number of learning outcomes, and class hours for the Climate, Environment, and Innovative Solutions course (Ministry of National Education. 2026).

UNIT	Number of Learning Outcomes	Lesson Hours	Percentage%
1 CLIMATE CHANGE	1	8	11
2. ENVIRONMENT AND HUMANITY	4	10	14
3. ENVIRONMENTAL PROBLEMS	5	22	30
4. FUNDAMENTALS OF INNOVATIVE SOLUTIONS TO ENVIRONMENTAL PROBLEMS	4	10	14
5. DEVELOPING INNOVATIVE SOLUTIONS TO ENVIRONMENTAL PROBLEMS	4	18	25
SCHOOL-BASED PLANNING *	-	4	6
TOTAL	18	72	100

Student code S3 provides positive feedback regarding the course's contribution to developing students' environmental awareness. “The fact that the annual plan does not limit itself to addressing environmental issues solely at the institutional knowledge level, but focuses on current environmental crises such as climate change and sustainability, is considered a positive approach. Connecting the topics to the disciplines of biology, chemistry, and geography helps students perceive the ecosystem as a holistic structure rather than in separate parts. Addressing concepts such as carbon footprint, in particular, allows students to question their own environmental impact and develop a green career mindset. It is believed that this content-rich plan will significantly improve ecological literacy levels if theoretical knowledge is supported by students analyzing the problems they encounter in their living environment.”

The student code S4 indicates that the course is student-centered. "It has a holistic structure that addresses environmental and climate issues from a local to a global perspective. The content begins with the human-nature relationship and continues with topics such as cyclical nature, environmental problems, global climate change, the effects of climate change

in Turkey, and sustainable development. The content aims to develop environmental awareness, a sense of responsibility, and an understanding of sustainable living among students. In addition to theoretical knowledge, the program prioritizes connecting it to daily life, project-based work, and raising awareness. Overall, the annual plan has a current, functional, and student-centered content aimed at raising individuals who are sensitive, conscious, and active in addressing the environmental and climate issues of our time."

The student in course S6 finds the course insufficient in terms of content depth, application, and critical thinking, and expresses their thoughts as follows. "The annual curriculum in secondary education provides an important framework for developing environmental awareness and understanding of climate change.

The plan covers current issues such as climate change, the environment and people, environmental problems, and the foundations of innovative solutions to environmental problems. However, I believe the content is largely superficial, and fundamental scientific concepts such as greenhouse gases, the matter cycle, and the climate crisis are not explored in depth.

The limited number of weekly lesson hours leads to a large number of learning outcomes being achieved in a short period of time, and especially to project-based and application-based studies not being carried out effectively. Although projects and awareness-raising activities have been mentioned, the explanations for their implementation and evaluation are not clear enough. I also think that the repetition of teaching methods and techniques in a similar way for weeks on end causes the plan to remain monotonous in practice. I observe that the course content focuses primarily on developing individual awareness, and that the economic, social, and political dimensions of environmental problems are not sufficiently explored.

In conclusion, while the plan is functional in terms of raising basic awareness, I can say that it has areas that need improvement in terms of content depth, practicality, clarity of measurement and evaluation, and critical thinking skills."

Student S7 states that the subjects are covered superficially due to the low number of weekly class hours. "The annual plan for the climate, environment, and innovative solutions course implemented in secondary education provides an important framework for raising environmental awareness and understanding of climate change.

The plan covers current issues such as human-nature relations, environmental problems, global climate change, and sustainable development. However, it appears that the content is largely superficial, and fundamental scientific concepts such as greenhouse gases, the matter cycle, and the climate crisis are not explored in depth.

The limited number of weekly lesson hours leads to a large number of learning outcomes being delivered in a short period of time, and especially to project-based and application-based studies not being carried out effectively. Although projects and awareness-raising activities have been mentioned, the explanations regarding the implementation and evaluation of these activities are not sufficiently clear. Furthermore, the repetition of teaching methods and techniques in a similar manner throughout the weeks leads to the plan remaining monotonous in practice.

The course content appears to focus primarily on developing individual awareness, while the economic, social, and political dimensions of environmental problems are not adequately explored. In conclusion, while the plan is functional in terms of raising basic awareness, it has areas that need improvement in terms of content depth, practicality, clarity of measurement and evaluation, and critical thinking skills."

The student with code S8 expresses the positive and negative aspects of the course. "The annual plan for the Environmental Education and Climate Change course generally demonstrates a holistic, systematic, and student-centered approach.

The plan follows a flow that begins with "Climate Change" and ends with "School-based planning. This enables students to understand environmental and climate issues from simple to complex, and from local to global. Including current concepts such as ecological footprint, climate crisis, zero waste, recycling, and upcycling makes it easier for students to connect them to their daily lives.

In addition to direct instruction, active student participation is encouraged through methods and techniques such as field trips, observation, drama, project design, station activities, and brainstorming. The use of tools and resources such as textbooks, whiteboards, interactive whiteboards, slides, the internet, photographs, videos, and documentaries is planned. While the use of the internet and video is mentioned, the use of technological tools such as climate modeling, CO_2 monitoring applications, and digital mapping could be further encouraged. The plan could diversify methods such as more experimental and field studies, and digital simulations.

The emphasis placed on values such as justice, responsibility, respect, and patriotism in each learning outcome demonstrates that the course aims not only at imparting knowledge but also at developing attitudes and behaviors.

The plan incorporates Türkiye's specific impacts of climate change, mitigation efforts, and projects such as zero waste, enabling students to engage with the realities of the country. The inclusion of green professions and future employment fields demonstrates the course's aim to contribute to students' future plans. Different literacy areas are covered, such as environmental, water, agricultural, food, and financial literacy.

Students' awareness of global citizenship could also be strengthened by placing more emphasis on issues such as climate justice, global cooperation, and sustainable living practices. Overall, this plan stands out as a balanced and feasible plan aimed at developing environmental literacy in students. The suitability of the topics and learning outcomes for the age group, and their integration with values education, are the plan's strongest points."

The student code S10 indicates that the course helps students develop into environmentally conscious, responsible, and aware individuals. "Upon reviewing its content, I see that it is a contemporary course that aims not only to impart environmental knowledge to students, but also to cultivate students as environmentally conscious, responsible, and aware individuals. Activities such as project design, poster and brochure creation, and informing the local community encourage active student participation and ensure that learned information is applied to daily life. It's also very good that the achievements encompass local, national, and global dimensions. However, the program also has some limitations. The high number of learning objectives and the dense content in some units can lead to superficial learning, especially in classroom applications. Trying to fit such broad topics as global climate change, disasters, environmental pollution, and sustainability into a limited number of class hours can make time management difficult for teachers. Another issue is the potential for environmental problems and the climate crisis to instill intense anxiety and feelings of hopelessness in students. Furthermore, making field studies and observation activities focused on local environmental issues mandatory will enhance the retention of learning. The program can be strengthened with solution-oriented activities and more hands-on fieldwork."

Students coded S11 express current issues and solution-oriented thinking skills more effectively. "The spiral, holistic structure aimed at transforming environmental awareness from knowledge to behavior is reflected in the subject matter. The plan begins with climate change and progresses through topics such as the environment and people, environmental problems, the foundations of innovative solutions to environmental problems, developing innovative solutions to environmental problems, and school-based planning. The content is related to students' daily lives and includes concepts such as ecological footprint and greenhouse gases.

The aim is to develop students' problem-solving skills, responsibility, and social awareness through sustainable development.

In general, the plan aims to cultivate individuals who are sensitive to environmental issues, by not only providing knowledge but also developing attitudes, values, and behaviors. In this respect, the course content contributes to students' ability to evaluate local and global environmental problems in terms of cause and effect relationships and to acquire solution-oriented thinking skills."

The student with code S12 focused on the contribution of the course to responsibility and awareness. "When the 'Climate, Environment and Innovative Solutions' course curriculum is examined, it can be seen that the content is designed in a holistic structure that not only identifies environmental problems but also aims to equip students with multifaceted and vital competencies such as environmental, water, agricultural, and food literacy. In particular, integrating current and strategic issues such as the "zero waste" project and recycling into the curriculum encourages students to acquire practical skills in waste management, such as designing projects and developing products, rather than simply possessing theoretical knowledge. Furthermore, linking the causes and consequences of global climate change to its effects specific to Turkey, and exemplifying sustainable living models such as ecological villages in tranquil cities, demonstrates that the course aims to instill in students a global vision as well as a sense of local responsibility."

The student in question, code S14, argues that the course aims to make students responsible and environmentally conscious. "The purpose of the annual plan is to ensure lasting environmental awareness. It is holistic and continuousIt is student-centered. Looking at the first unit, climate change, it discusses greenhouse gases and global warming. I can say that this gives the topic a global dimension for the students. The second unit is Environment and Human. This unit discusses human-environment interaction and the harmony of the natural balance. The environmental problems unit aims to enable students to interpret human activities that cause environmental problems; to analyze the environmental impacts of air pollution, water scarcity and pollution, and soil degradation; and to interpret the environmental impacts of biodiversity loss. The importance of the student's sense of responsibility is emphasized. Production and consumption habits are discussed. Examples from daily life are given to enable the student to integrate the topic into their daily life. The unit "Fundamentals of Innovative Solutions to Environmental Problems" aims to enable students to analyze the importance of environmental rights and participation in solving environmental problems, to reason about environmental problems within the context of struggle strategies, to critique economic and social projects within the scope of the responsibilities imposed by international environmental agreements, and to interpret innovative projects in terms of their causes and consequences for environmental sustainability. The aim of the "Innovative Solutions to Environmental Problems" unit is for students to be able to empathize with stakeholders affected by the environmental problems they observe, to evaluate the research problem they have defined regarding developing innovative solutions to environmental problems, to develop innovative ideas for solving the defined problem, and to design a model for the innovative idea they have developed. Finally, this annual plan aims to foster a sense of responsibility and environmental awareness in students. The annual plan aims to help us develop a holistic perspective."

Student S16 expressed very positive opinions regarding the course. "Upon examining the annual plan for the 'Climate, Environment, and Innovative Solutions' course taught in secondary education, it is evident that the topics are addressed in a meaningful and pedagogically coherent manner. The plan's approach, starting with climate change and concluding with the concept of school-based planning, allows students to grasp environmental and climate issues from simple to complex, and from local to global levels. This structure contributes to understanding environmental problems in terms of cause-and-effect relationships.

Including current and frequently encountered concepts such as ecological footprint, climate crisis, zero waste, recycling, and upcycling in the annual plan makes it easier for students to relate the course content to their daily lives. In addition, addressing topics such as sustainable energy use, transportation, production and consumption habits, natural resource management, population growth, and migration helps students understand the multifaceted nature of environmental problems. Furthermore, including different literacy areas such as environmental, water, agricultural, food, and financial literacy in the plan is an important element in supporting students' development as informed individuals.

The course delivery avoids relying solely on lectures; instead, it incorporates methods and techniques such as field trips, drama, role-playing, project development, station work, discussions, and case studies, encouraging active student participation and learning through doing. The use of tools such as textbooks, interactive whiteboards, visual and auditory materials, the internet, videos, and documentaries also aims to increase the retention of learning.

One of the striking aspects of the plan is that each learning outcome is linked to values such as justice, responsibility, respect, patriotism, and accountability. This demonstrates that the course aims not only to impart knowledge but also to develop environmentally conscious attitudes and behaviors.

In conclusion, the annual plan for the "Climate, Environment and Innovative Solutions Course" offers comprehensive and holistic content that addresses knowledge, skills, and values dimensions together, aiming to develop an awareness of sustainable living among students.”

Student S20 states that the course is not only about transferring information but also about aiming for behavioral change. "Upon reviewing the annual plan, it is evident that the course has a holistic approach that addresses cognitive, affective, and behavioral goals together. The course content aims not only to teach students environmental concepts, but also to develop awareness and a sense of responsibility towards environmental problems.

The inclusion of current and globally significant topics such as climate change, global warming, greenhouse gases, carbon footprint, and sustainability in the introductory unit of the plan directly links the course to contemporary environmental issues. In this context, students become aware of the economic, social, and political consequences of climate change.

Furthermore, the inclusion of fundamental environmental concepts such as environment, ecosystem, biodiversity, and human-nature relations provides students with the necessary foundation to understand the global environmental problems discussed in later units.

The inclusion of individual and societal responsibilities towards environmental problems, environmental awareness, and environmental ethics in the annual plan demonstrates that the course is structured not only to impart knowledge but also to aim for behavioral change.”

The student with code S21 argues that, with the necessary adjustments and enrichments, the course will be effective in raising environmentally conscious and responsible individuals. "The course generally has current and functional content aimed at instilling environmental awareness and climate change consciousness. The units' progression towards the relationship between the environment and people, and towards developing innovative solutions to environmental problems, shows that the topics are arranged from simple to complex. Including topics related to daily life such as ecological footprint consumption habits, water and energy conservation, helps students understand environmental problems in a concrete way. Furthermore, the program's strengths include supporting student active participation through project presentations and awareness-raising activities. The "Climate Change and Turkey" unit also allows students to become aware of its effects on our country. However, the high subject density in some units may create practical difficulties in terms of class hours.

The limited depth of the discussion of scientific concepts and the insufficient inclusion of concrete examples for measurement and evaluation are areas where the program needs improvement. While the impacts of disasters and climate change are significant, practical

studies could be increased. Consequently, with necessary adjustments and enhancements, this course has the potential to play an effective role in fostering environmentally conscious and responsible individuals. or example, I used the book used in this course as a resource for preparing a lecture presentation. The topic was global climate change. The information is very vague, and it creates difficulties because the information given to the student is not fully related to science. Topics related to science, such as the greenhouse effect and the carbon cycle, can be elaborated on in more detail."

The S22 program emphasized student development on a unit basis. "According to the annual plan I reviewed, the course comprises 6 units, 18 learning outcomes, and 72 lesson hours. The topics start with fundamental concepts and progress to more complex and global issues. This approach is good. It puts the student at the center. The topics raise the student's awareness. This is an important point. The first unit, "Climate Form," has quite detailed content. The topic addresses a current issue, including its causes and effects. However, it could have been supported with more examples from daily life. Students could have been asked to prepare materials such as drawings and posters. The second unit is "Environment and Human." This unit emphasizes establishing interaction between the student and their environment and fostering awareness of their surroundings. Out-of-school learning is included here, which is good but insufficient. More flexibility is needed in this area, adapting to city and school conditions. Depending on the school's circumstances, some lessons could be taught in the schoolyard, allowing for flexibility. In the second unit of "Circular Nature," the students were encouraged to become aware of the natural events happening around them. In the unit covering water and matter cycles, technological materials can be used to support the topics, contributing to more understandable and lasting learning. The environmental problems unit (Unit 3) specifically addresses environmental pollution. He/she presented this both locally and globally. That's good. However, he asked for an explanation and calculation of a concept like ecological footprint with examples. It would have been better if he/she had first specified what it is. The students may not have seen or heard of this concept before. It ensures greater sustainability. The unit on the foundations of innovative solutions to environmental problems addresses the importance of environmental rights and participation in solving environmental problems, reasoning about environmental issues, the ability to critique economic and social projects within the framework of responsibilities imposed by international environmental agreements, and the interpretation of innovative projects in terms of their causes and consequences for environmental sustainability. This unit aims to develop analytical, reasoning, and critical thinking skills. Connections are made to real life situations. In these respects, the topics are good. It aims to raise students as more conscious and sensitive citizens. I believe that this course should include more extracurricular learning activities (trips to national parks, etc.) to foster greater sensitivity and awareness by being in close contact with the environment."

DISCUSSION AND CONCLUSIONS

"The curriculum of the 'Climate, Environment and Innovative Solutions' course aims to contribute to the goal of enabling students to become individuals who can develop solutions to environmental problems." The curriculum aims for students to progress from actions to values, from values to virtuous individuals, and from virtuous individuals to the ultimate goal of being a "Peaceful Individual in a Livable Environment" within the framework of the Virtue-Value-Action Framework (Ministry of National Education, 2026).

The Climate, Environment, and Innovative Solutions Curriculum addresses climate change, the interaction of environmental systems with humans, and environmental problems. The curriculum also includes topics such as environmental problems, the fundamentals of

innovative solutions, and the development of innovative solutions (Ministry of National Education, 2026).

The effectiveness of curriculum programs depends on the learning outcomes being at least at the understanding level of the cognitive process steps (Anderson and Krathwohl, 2001). This statement should not be interpreted as meaning that the learning outcomes included in the curriculum are more at the understanding level than at the cognitive process level. As the analysis results show, the Climate, Environment, and Innovative Solutions Curriculum focuses more on learning outcomes at the comprehension level, while the number of learning outcomes at the higher-level cognitive process stages—analysis and creation, as well as application and evaluation—is insufficient. Compared to other curricula (Gökler, 2012; Büyükalan and Baysal, 2019; İlhan and Gülersoy, 2019a; İlhan and Gülersoy, 2019b; İlhan and Gülersoy, 2019c; Özdemir, 2020; Öztürk et al., 2020; Akhan, 2021; Alkın Şahin et al., 2022; Koca, 2022), the positive aspect is the existence of learning outcomes at the level of creation. Indeed, Mayer (2002) states that effective teaching is achieved through gains related to the application, analysis, evaluation, and creation steps of the cognitive process dimension (Gülersoy and Gülersoy, 2023).

The inadequacy of learning outcomes at the application and evaluation levels highlights a negative aspect of the program. In summary, it suggests that the course will not be sufficiently effective in achieving meaningful learning in terms of knowledge accumulation and cognitive process dimensions (Gülersoy and Gülersoy, 2023).

Education on disasters caused by climate change will become even more important in the future. In this regard, it has been observed that the learning outcomes and concepts related to disasters are included. Educating children about disasters is crucial for increasing societal resilience (Mızrak, 2018). Within the framework of this program, activities where students learn by doing and experiencing are needed to increase resilience against disasters. Education given only theoretically remains in underlined sentences in books, erased blackboards, and notebooks where notes are taken (Dere and Çinikaya; 2023).

Finally, it is deemed appropriate that the program is insufficient in terms of out-of-school learning environments and that the achievements related to out-of-school learning environments should be increased. However, research conducted in various fields within the literature highlights the cognitive, affective, and psychomotor contributions of out-of-school learning environments (Uludağ, 2017; Kuo et al., 2019; Altınbay and Gümüş, 2020; Bolu, 2021; Dere and Çifçi, 2022; Yıldız, 2022). Utilizing these pedagogical contributions can more effectively support the aims of environmental education (Dere and Çinikaya; 2023).

ABSTRACT

Head diameter is a key yield component in sunflower, yet most genomic studies of the trait stop at association mapping and rarely move toward predictive modeling. This gap matters because breeders care less about which SNP sits where and more about whether a genotype's future performance can be forecast before it ever reaches the field. Here we compared genomic prediction accuracy for head diameter across three feature representations, a compact GWAS-derived SNP set, a principal component set summarizing genome-wide variation, and a correlation-based LD-pruned set, using data from 274 sunflower accessions genotyped at 226,779 SNPs. Five models spanning linear and nonlinear families, Ridge, Lasso, Random Forest, XGBoost, and a multilayer perceptron, were evaluated under five-fold cross-validation. The best combination paired XGBoost with the GWAS-SNP feature set, reaching a mean R^2 of 0.632, consistently outperforming both larger genome-wide feature sets. A marker count analysis further showed that predictive accuracy plateaus once the number of markers approaches the size of the significant GWAS pool, around 112 SNPs; beyond that point, additional markers add little. These results indicate that a compact, association-informed marker panel can rival or exceed genome-wide predictors, offering a genotyping strategy that is both cheaper and more interpretable for sunflower breeding programs.

Keywords: Sunflower, Genomic prediction, GWAS, Machine learning, Head diameter, Marker economy

1. INTRODUCTION

Sunflower occupies a peculiar position among the world's oilseed crops: it supplies a substantial share of global vegetable oil while tolerating drought and marginal soils better than many of its competitors, standing out as a crop capable of stable yield across a wide range of environmental conditions (Badouin et al., 2017). That resilience is tied to a genome that took unusually long to characterize: the species carries roughly 3.6 gigabases of highly repetitive sequence, a technical obstacle that delayed the arrival of a usable reference genome for years (Badouin et al., 2017). When the assembly was finally resolved, it revealed clues about oil metabolism, flowering time, and the broader evolution of the Asterid lineage, opening the door to genome-scale association studies in a crop that had previously relied on far coarser tools (Badouin et al., 2017).

Among the traits breeders track in sunflower, head diameter holds a curious dual status: it is not merely one of several component traits determining seed yield, but also one of the easiest to measure in the field. Because it is comparatively easy to measure under field conditions, it

has become a favorite target across breeding programs regardless of season or location (Delen et al., 2022). Prior GWAS-based work on this trait reported substantial heritable variation: a panel of 342 accessions evaluated across the 2019, 2020, and 2022 growing seasons was combined into a single multi-year BLUP, yielding a broad-sense heritability estimate of 0.88 (Delen et al., 2022). That association study, conducted across 226,779 SNPs using both the mixed linear model and farmCPU, identified 106 and 8 significant markers respectively, of which 53 and 21 were located near annotated genes (Delen et al., 2022). A later version of the same work, extended to disc diameter, appeared in Plant Direct (Delen et al., 2024).

Genome-wide association studies (GWAS) test large numbers of single-nucleotide polymorphisms (SNPs)—individual DNA sequence variants—for statistical association with a trait of interest, and the statistical machinery behind such studies has become fairly standardized. Mixed linear models are widely used to control spurious associations driven by population structure (Yu et al., 2006), while farmCPU, introduced a decade later, offers a computationally leaner alternative that iterates between fixed and random effect components (Liu et al., 2016). Principal components are commonly used as covariates to correct for population stratification (Price et al., 2006), and PLINK remains a standard tool for filtering, pruning, and formatting genotype data for association analysis (Purcell et al., 2007).

What this literature does not yet do for sunflower is push past association mapping into prediction — and that next step matters. Significant SNPs become genuinely useful to a breeder once they can forecast the performance of untested individuals, and that forecasting task is where machine learning enters the picture; breeding programs benefit more from markers that improve prediction than from markers that are significant only in a statistical sense. Whether such methods actually improve on classical genomic prediction, and whether a compact GWAS-informed marker set can substitute for a full genome-wide panel, are questions that recent work in several other crops has begun to answer. The next section reviews that evidence before turning to the specific hypotheses tested here.

2. RELATED WORK

Whether machine learning genuinely outperforms classical genomic best linear unbiased prediction (GBLUP) remains an open question across crop species, with the answer depending on the trait, the population, and dataset size. In maize, GBLUP outperformed deep learning methods in eight of nine tested scenarios once a genotype-by-environment interaction term was included, yet the ranking reversed almost entirely once that term was dropped (Barreto et al., 2024). Sugarcane presents a starker case: because the crop is a highly non-additive, clonally propagated polyploid, an extended GBLUP model outpaced most machine learning approaches, with only a carefully tuned random forest coming close (Chen et al., 2023). In wheat, by contrast, deep learning methods surpassed GBLUP for two of five traits while performing comparably on the remaining three (Montesinos-López, A. et al., 2024). No single method wins consistently, which is precisely why feature engineering, rather than model choice alone, deserves closer scrutiny.

A more directly relevant question is whether a small set of markers, chosen for statistical significance in a prior GWAS, can match or beat predictions built from an entire genome-wide marker panel; evidence from several crops suggests it can. In oats, a study of 195 cultivars found that GWAS-derived marker subsets predicted plant height more accurately than the full genome-wide panel, with the best accuracy for that trait reached using only 100 GWAS-derived markers (Peng et al., 2025). A related pattern was reported in Russian sturgeon aquaculture, where GWAS-based SNP prioritization outperformed alternative selection strategies at densities of 10,000 markers and above, improving prediction accuracy by as much as 3.4 percent relative to whole-genome sequencing (Song, H. et al., 2025). In wheat, a framework

called GRE, combining GWAS with random forest feature selection, produced marker subsets that significantly outpredicted randomly chosen SNPs of the same size (Song, M. et al., 2025). Three unrelated crops, three converging conclusions: GWAS-informed feature selection can improve prediction without requiring the full marker panel.

Machine learning has also been folded directly into the GWAS pipeline itself, rather than applied only downstream of it. In soybean, support vector machines and random forests compared against classical MLM and farmCPU surfaced a richer set of marker-trait relationships tied to yield components than the classical methods alone (Yoosefzadeh-Najafabadi et al., 2021). The same research group later predicted multi-year yield component traits using an ensemble of a multilayer perceptron, a radial basis function network, and random forest, partially overcoming the limitations any single model showed on its own (Yoosefzadeh-Najafabadi et al., 2022). Wheat has recently seen a similarly direct comparison. Traditional GWAS tools were pitted against several machine learning approaches, including XGBoost and random forest, and the machine learning side proved particularly valuable for traits where epistatic effects appear to dominate (Milek et al., 2026).

Sample size remains an important limitation in these comparisons, particularly for deep learning methods: a recent review of multimodal deep learning approaches for genomic prediction noted that instability under small datasets is an expected outcome rather than an anomaly, since generalization capacity suffers when architectural complexity is not balanced against sample size (Montesinos-López, O. A. et al., 2024). This limitation is directly relevant here, as the present study works with a few hundred accessions rather than several thousand.

Taken together, this body of work supports two working expectations. Nonlinear ensemble methods often, though not always, edge out linear baselines, and compact GWAS-informed marker sets often rival or beat much larger genome-wide feature representations. Neither expectation has been tested in sunflower for head diameter, which is the gap this study addresses. We test three hypotheses. First, a small GWAS-selected SNP set should yield prediction accuracy comparable to, or better than, features derived from the entire genome. Second, nonlinear machine learning models, particularly Random Forest and XGBoost, should outperform the linear Ridge and Lasso baselines. Third, prediction accuracy should plateau once the number of markers used exceeds the informative core of the GWAS signal, a pattern with direct implications for how many markers a breeding program actually needs to genotype.

Table 1 situates the present study alongside these related comparisons of GWAS-informed and genome-wide prediction strategies across crop species.

Table 1. Summary of related GWAS-informed genomic prediction studies compared with the present study.

Study	Crop / system	Feature sets compared	Key finding
Barreto et al., 2024	Maize	GBLUP vs. deep learning (multi-environment, with/without G×E)	GBLUP outperformed deep learning in 8 of 9 scenarios when G×E was modeled; ranking reversed once the G×E term was dropped
Chen et al., 2023	Sugarcane	Extended GBLUP vs. machine learning	GBLUP outperformed most ML methods; only a carefully tuned random forest came close
Montesinos-López, A. et al., 2024	Wheat	Deep learning vs. GBLUP (5 traits)	Deep learning surpassed GBLUP for 2 of 5 traits and performed comparably on the remaining 3
Peng et al., 2025	Oats	100 GWAS-derived SNPs vs. full genome-wide panel (195 cultivars)	GWAS-derived subset predicted plant height more accurately than the full panel
Song, H. et al., 2025	Russian sturgeon	GWAS-prioritized SNPs (≥10,000 markers) vs. alternative selection strategies	Improved prediction accuracy by up to 3.4% relative to whole-genome sequencing
Song, M. et al., 2025	Wheat	GWAS + random forest (GRE)-selected subset vs. random SNPs of equal size	Selected subset significantly outperformed random SNPs of the same size
This study	**Sunflower**	**112 GWAS-SNP set vs. 100-component PCA vs. LD-pruned set (274 accessions, 226,779 SNPs)**	**GWAS-SNP set outperformed both genome-wide sets across all five models; XGBoost reached R^2 = 0.632, and accuracy plateaued near 112 markers**

3. MATERIALS AND METHODS

3.1 Plant materials, phenotyping, and genotyping data

Phenotypic data were drawn from a panel of 342 sunflower accessions evaluated for head diameter across the 2019, 2020, and 2022 growing seasons, following the design established by Delen and colleagues (Delen et al., 2022). Best linear unbiased predictions (BLUPs) combining the three seasons served as the trait values used throughout this study. After filtering for complete genotype and phenotype records, 274 accessions remained available for modeling.

Genotyping by sequencing yielded 226,779 SNPs across the panel, consistent with the marker density reported in the source study (Delen et al., 2022). Markers with a minor allele frequency at or below 0.05 were excluded prior to downstream analysis.

3.2 GWAS SNP selection and feature set construction

The GWAS-informed feature set was built from the union of significant SNPs identified by the two association mapping approaches applied in the source study, the mixed linear model (Yu

et al., 2006) and farmCPU (Liu et al., 2016). Combining the significant hits from both methods yielded a pool of 112 SNPs, which formed the basis of the GWAS-SNP feature set used in every subsequent model.

Three feature representations were built and compared side by side.

The GWAS-SNP feature set used the 112 markers described above directly as model inputs. This set was intentionally compact and biologically anchored, since every marker had already cleared a significance threshold in prior association testing.

The PCA feature set summarized genome-wide variation using principal components derived from the full genome-wide marker panel. Components were retained up to the point where they cumulatively explained 65 percent of total genetic variance (Price et al., 2006), resulting in 100 components used as predictors. This set captures broad genome-wide structure but is less directly interpretable than individual markers, since a single component blends thousands of markers at once.

The LD-pruned feature set removed redundant, highly correlated markers from the genome-wide panel using a correlation-based pruning procedure, loosely following the spirit of standard LD-pruning workflows (Purcell et al., 2007). This step used pairwise correlation thresholding rather than PLINK's canonical linkage disequilibrium algorithm, a simplification that speeds computation without fully replicating the population-genetic rigor of a PLINK-based pipeline.

3.3 Models

Five models were trained on each of the three feature sets, spanning both linear and nonlinear families. Ridge (Hoerl and Kennard, 1970) and Lasso (Tibshirani, 1996) were implemented as standard regularized linear regressions. Random Forest (Breiman, 2001) and XGBoost (Chen and Guestrin, 2016) were configured as ensemble tree methods with typical hyperparameter ranges for tabular genomic data. A multilayer perceptron was included to represent a deep learning baseline, given its established but variable track record in genomic prediction settings with modest sample sizes (Montesinos-López, O. A. et al., 2024).

3.4 Evaluation, robustness checks, and software

Model performance was assessed under five-fold cross-validation, with R^2, root mean squared error, mean absolute error, and Pearson correlation reported for each model and feature set combination (Table 2 and Table 3).

To probe how prediction accuracy scales with marker density, subsets of K = 10, 25, 50, 100, 150, and 250 markers were tested for Random Forest, Ridge, and XGBoost, tracing an accuracy curve intended to reveal whether, and where, performance saturates (Table 4).

Because the phenotype data combines BLUP values across 2019, 2020, and 2022 without separate year-level records, a genuine leave-one-year-out external test was not possible. Two complementary robustness checks were used instead. The first repeated five-fold cross-validation across ten independent fold splits. The second ran thirty repetitions of a random train-test holdout at a 20 percent test proportion (Table 5).

Analyses were implemented in Python using scikit-learn for the linear and Random Forest models, XGBoost for the boosted tree model, and PyTorch for the multilayer perceptron.

4. RESULTS

4.1 Phenotypic distribution

Head diameter values across the 342 phenotyped accessions followed a broadly unimodal distribution with a mean of 14.73 cm, a median of 15.07 cm, a standard deviation of 3.05 cm, and a mild negative skew (-0.38), consistent with a polygenic quantitative trait shaped by many loci of small effect. Figure 1 marks the mean with a dashed line and the median with a dotted line, and shows values ranging from a minimum of 6.79 cm to a maximum of 22.76 cm. The 274 accessions used for model training and evaluation are the subset of this panel with complete paired genotype and phenotype records.

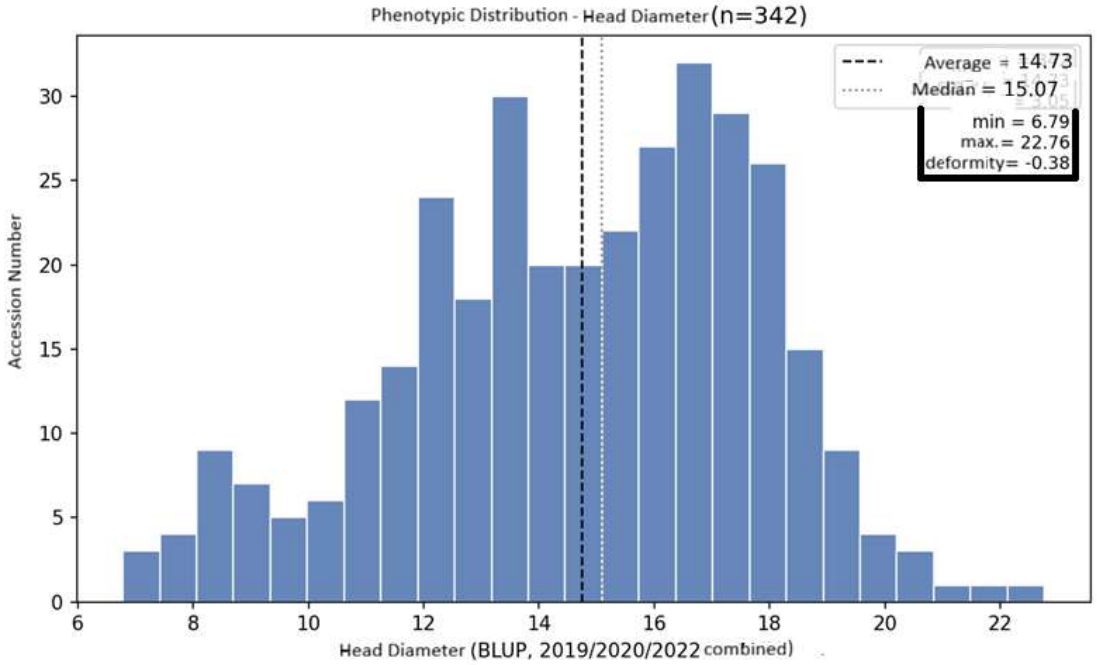

Figure 1. Distribution of head diameter BLUP values (2019/2020/2022 combined) across 342 sunflower accessions. Dashed line: mean (14.73 cm); dotted line: median (15.07 cm).

4.2 Model by feature set performance

Table 2 summarizes mean R^2 across five-fold cross-validation for every model and feature set combination.

Table 2. Mean R^2 by model and feature set (five-fold cross-validation).

Feature set	Lasso	MLP	Random Forest	Ridge	XGBoost
GWAS-SNP	0.611	0.302	0.593	0.500	0.632
LD-pruned	0.452	-1.104	0.519	0.504	0.566
PCA	0.163	-0.282	0.414	0.066	0.434

The best combination overall paired XGBoost with the GWAS-SNP feature set, reaching a mean R^2 of 0.632. Every model, without exception, performed best on the GWAS-SNP set and worst on the PCA set, a pattern that held regardless of whether the underlying algorithm was linear or tree based. Lasso on the GWAS-SNP set came remarkably close to XGBoost, at 0.611, suggesting that once the feature set itself is well chosen, even a comparatively simple linear

model can perform competitively. The multilayer perceptron struggled across the board and turned sharply negative on the LD-pruned set, at -1.104, a clear sign of overfitting given the small sample size relative to the dimensionality of that feature set.

Table 3 breaks the GWAS-SNP result down further, reporting root mean squared error, mean absolute error, and Pearson correlation alongside R^2 for every model. XGBoost led on every metric simultaneously, not just R^2, with the lowest RMSE (1.880 cm) and MAE (1.518 cm) and the highest Pearson correlation (0.806) of any model on any feature set.

Table 3. Cross-validated performance metrics (mean ± SD), GWAS-SNP feature set.

Model	R^2	RMSE (cm)	MAE (cm)	Pearson r
Lasso	0.611 ± 0.061	1.944 ± 0.127	1.561 ± 0.154	0.794 ± 0.040
MLP	0.302 ± 0.300	2.565 ± 0.499	1.783 ± 0.210	0.652 ± 0.133
Random Forest	0.593 ± 0.095	1.986 ± 0.251	1.554 ± 0.162	0.782 ± 0.053
Ridge	0.500 ± 0.131	2.191 ± 0.255	1.683 ± 0.192	0.733 ± 0.073
XGBoost	0.632 ± 0.105	1.880 ± 0.265	1.518 ± 0.188	0.806 ± 0.058

Figure 2 places these same feature-set comparisons side by side as a bar chart, making it easier to see at a glance which model and feature-set combination is best suited to predicting head diameter. Error bars show one standard deviation of R^2 across the five folds, giving a visual sense of how consistent each combination was across different data partitions.

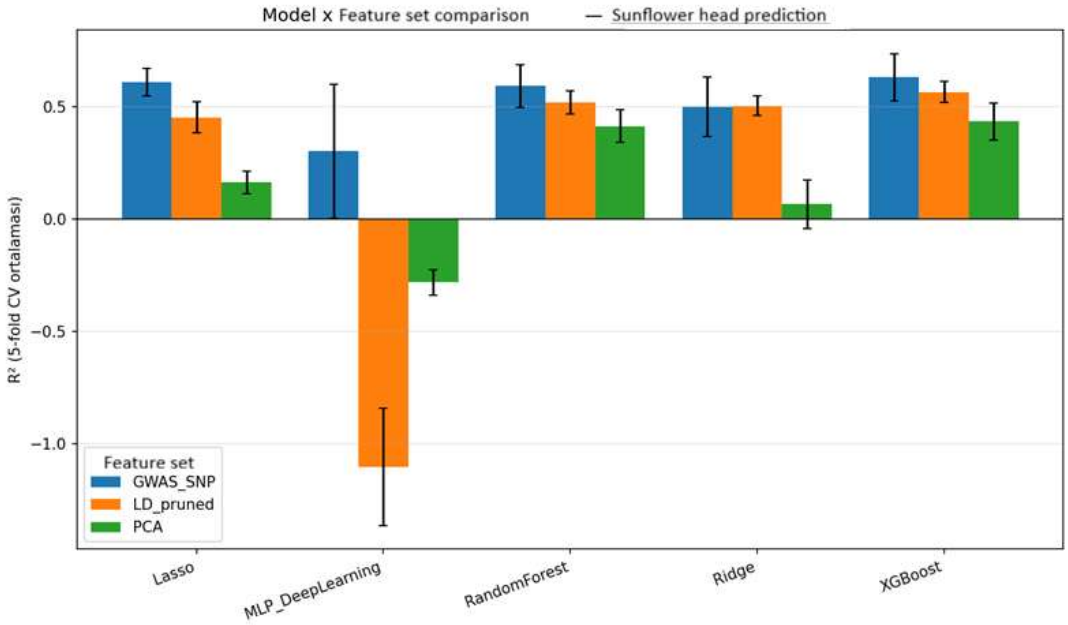

Figure 2. Mean cross-validated R^2 for each of the five models, grouped by feature set (GWAS-SNP, LD-pruned, PCA). Error bars show one standard deviation across folds.

4.3 Marker count and prediction accuracy

The marker count curve reinforced the pattern already visible in Table 2. Table 4 reports the full marker-density sweep, K = 10 to 250, for Random Forest, Ridge, and XGBoost.

Table 4. Mean R^2 as a function of marker count (K), five-fold cross-validation.

K	Random Forest	Ridge	XGBoost
10	0.502	0.452	0.522
25	0.510	0.442	0.524
50	0.513	0.441	0.543
100	0.509	0.458	0.556
150	0.595	0.500	0.659
250	0.595	0.500	0.659

Because the GWAS-SNP pool contains only about 112 markers in total, values of K beyond that point, namely K = 150 and K = 250, necessarily reuse the entire pool once it is exhausted, and the accuracy curve flattens as a result, identically for every model in Table 4. This flattening is not an artifact of the experimental design; it is itself evidence for marker economy, showing that no additional significant GWAS-SNPs remained available beyond the initial 112 to meaningfully push accuracy any higher. XGBoost benefited most from additional markers up to the plateau, climbing from 0.522 at K = 10 to 0.659 at K = 150, while Ridge gained comparatively little (0.452 to 0.500) over the same range.

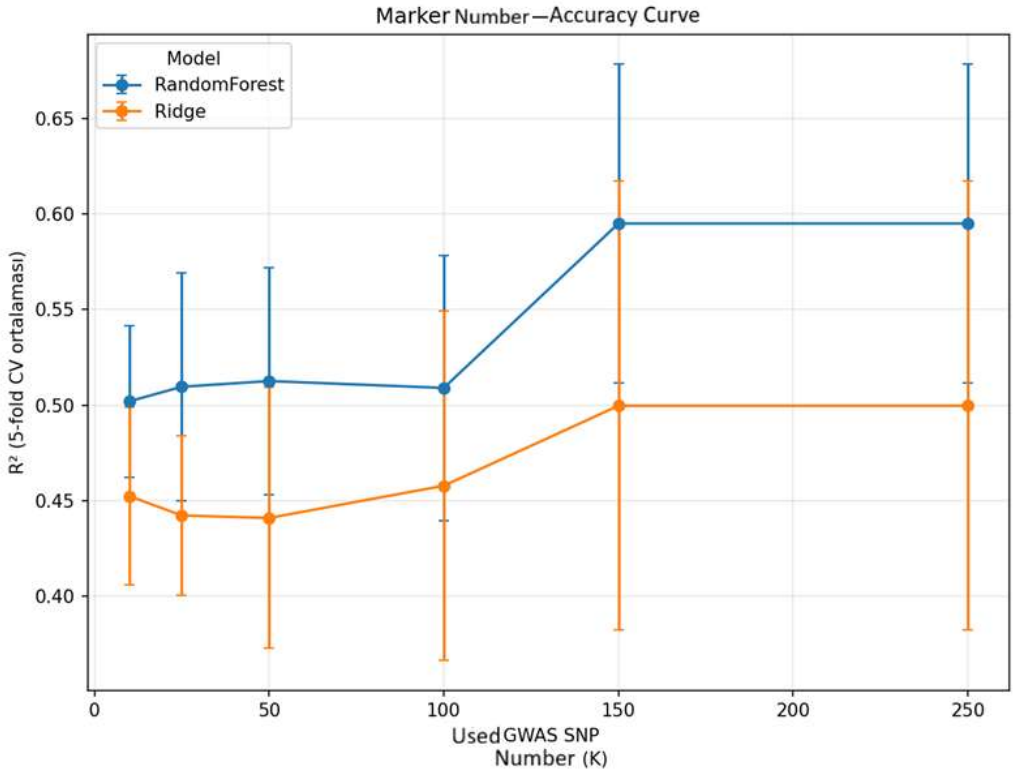

Figure 3. Marker count versus prediction accuracy, K = 10 to 250, for Random Forest and Ridge. The curve plateaus beyond the size of the significant GWAS-SNP pool (~112 markers).

4.4 Feature importance, SHAP analysis, and robustness checks

For the best performing combination, XGBoost trained on the GWAS-SNP set, gain-based feature importance identified which SNPs the model relied on most heavily (Table 6, Figure 4), while SHAP values described the direction and magnitude of each SNP's contribution to predicted head diameter (Table 7, Figure 5). Together, these two views offer a biological explanation for why the GWAS-SNP set outperformed the larger feature sets. A small number of large-effect loci appear to dominate the signal, a pattern consistent with the concentrated genetic architecture reported by the original GWAS study for this trait (Delen et al., 2022).

Table 6. Top 15 SNPs by XGBoost gain-based feature importance, GWAS-SNP set.

Rank	SNP	Gain importance
1	NC_035442.2-15637958	0.506
2	NC_035442.2-14716876	0.169
3	NC_035442.2-12398885	0.073
4	NC_035442.2-14792234	0.042

Figure 4 renders the Table 6 ranking as a bar chart, making the relative size of each SNP's contribution easier to compare visually. Because gain-based importance only reflects how often and how effectively a marker is used to split the tree, it identifies which loci the model relies on most heavily without indicating whether higher genotype dosage raises or lowers predicted head diameter, a direction that is recovered separately below.

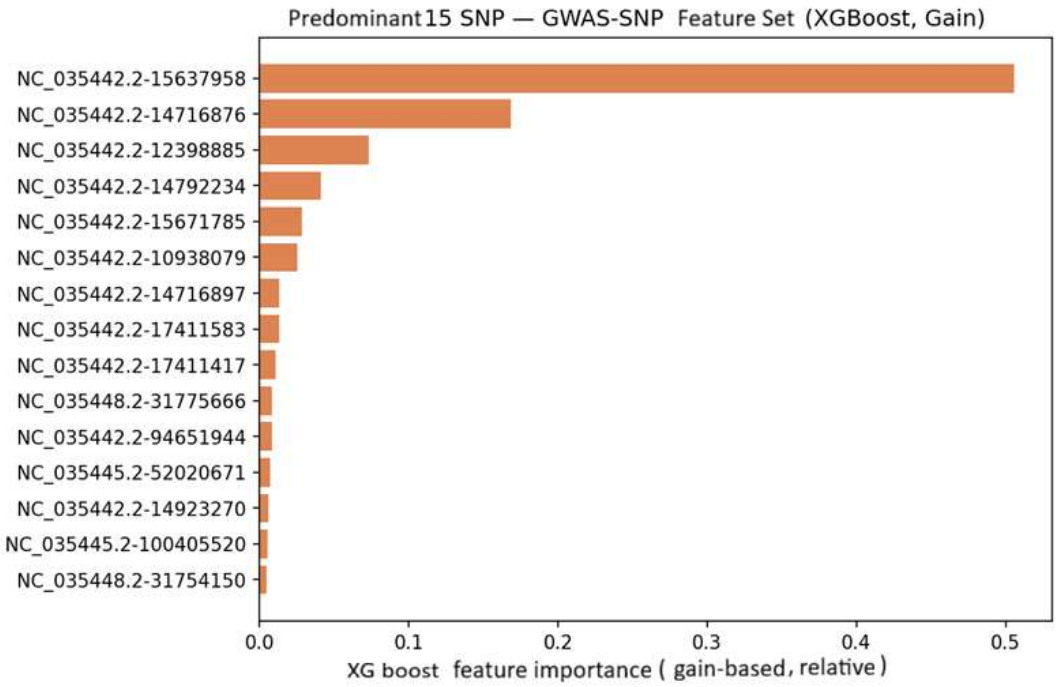

Figure 4. XGBoost gain-based feature importance, top 15 SNPs (GWAS-SNP set).

To recover that missing directional information, Table 7 reports SHAP (SHapley Additive exPlanations) values for the same set of top-ranked GWAS-SNP markers. Alongside the mean absolute SHAP value, which measures the overall magnitude of each SNP's contribution, the table also lists the mean signed SHAP value, indicating whether a marker's typical effect on predicted head diameter is positive or negative.

Table 7. Top 15 SNPs by mean absolute SHAP value, GWAS-SNP set (XGBoost).

Rank	SNP	Mean |SHAP|	Mean signed SHAP
1	NC_035445.2-100405520	0.658	0.001
2	NC_035435.2-160345299	0.600	-0.021
3	NC_035445.2-52020671	0.484	-0.002
4	NC_035437.2-67450339	0.405	0.001
5	NC_035436.2-20355884	0.349	0.000
6	NC_035442.2-14794596	0.327	0.011
7	NC_035442.2-10938079	0.300	-0.035
8	NC_035442.2-15637958	0.210	-0.008
9	NC_035448.2-31775666	0.202	-0.025

11	NC_035448.2-31753915	0.171	0.028
12	NC_035442.2-94651944	0.140	0.014
13	NC_035442.2-17411417	0.131	-0.011
14	NC_035442.2-14716876	0.097	-0.008
15	NC_035442.2-15271146	0.084	0.009

Figure 5 visualizes these results as a SHAP beeswarm plot, with each point representing one accession. Point color encodes genotype dosage from low to high, and horizontal position encodes the SHAP value, capturing both the direction and magnitude of that SNP's contribution to the predicted trait. Unlike the gain-based ranking in Table 6 and Figure 4, this view makes it possible to see whether increasing dosage at a given SNP tends to raise or lower predicted head diameter, offering a more concrete basis for biological interpretation.

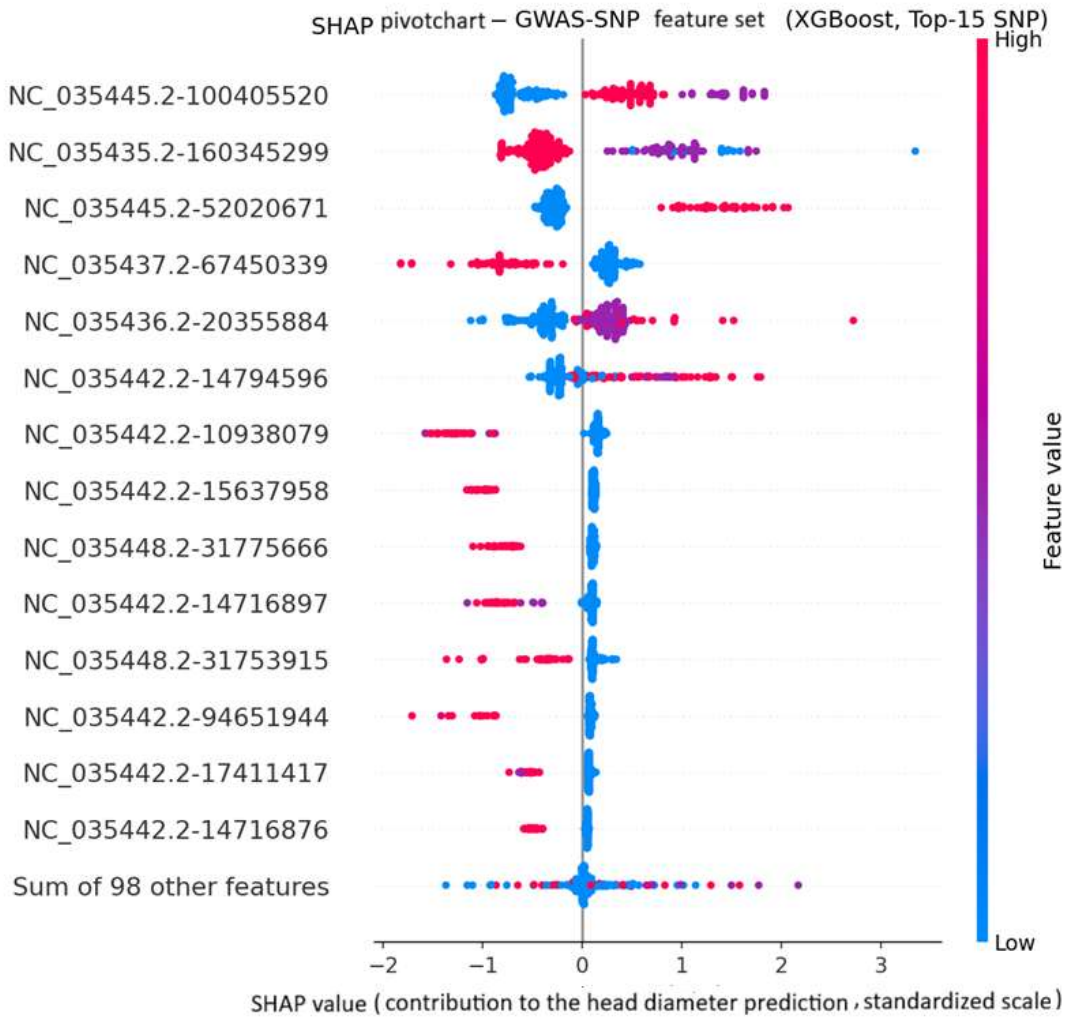

Figure 5. SHAP summary plot for the top 15 SNPs, GWAS-SNP feature set (XGBoost).

Two complementary robustness checks were run for the GWAS-SNP feature set: ten independent repeats of five-fold cross-validation, and thirty repetitions of a random train/test holdout at a 20 percent test proportion. Table 5 summarizes the resulting mean R^2 for each model alongside the original single-split figures from Table 2.

Table 5. Mean R^2 under three validation schemes, GWAS-SNP feature set.

Model	**Single 5-fold CV**	**Repeated CV (10×5-fold)**	**External holdout (30×)**
Lasso	0.611	0.595	0.571
Random Forest	0.593	0.591	0.588
Ridge	0.500	0.482	0.493
XGBoost	0.632	0.631	0.619

Figure 6 shows the full distribution of R^2 values behind the repeated-CV column in Table 5, rather than just its mean. Because ten independent reshuffles of the five-fold split were run for each model, fifty R^2 values are plotted per model, giving a fuller picture of how much the estimated accuracy depends on the specific way the data happen to be partitioned.

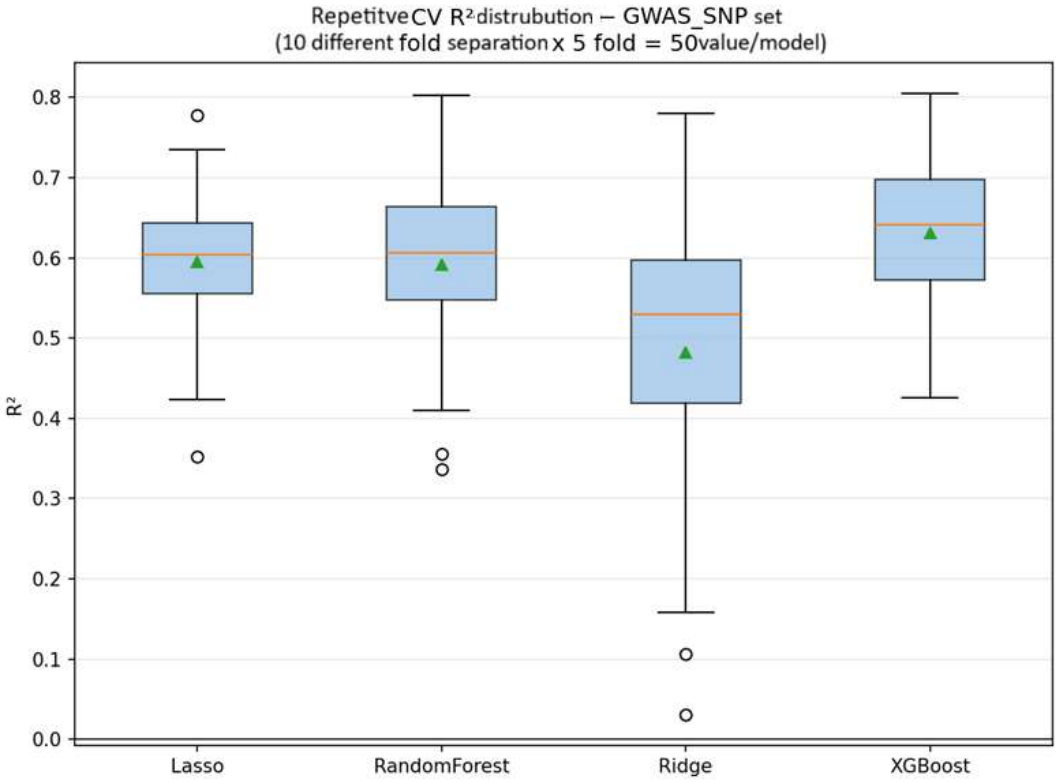

Figure 6. Distribution of R^2 across repeated 5-fold CV runs, GWAS-SNP feature set.

Within each boxplot in Figure 6, the green triangle marks the mean and the orange line marks the median R^2 across the fifty repeats. Figure 7 then steps back and compares all three validation schemes from Table 5 directly. A genuine leave-one-year-out external test could not be performed here, because the phenotype data combine BLUP values from the 2019, 2020, and 2022 seasons into a single record per accession rather than keeping separate year-level measurements; the repeated cross-validation and random holdout schemes shown below therefore serve as complementary robustness checks, confirming that the single-split results reported earlier in Table 2 are not simply an artifact of one particular, arbitrary partition of the data.

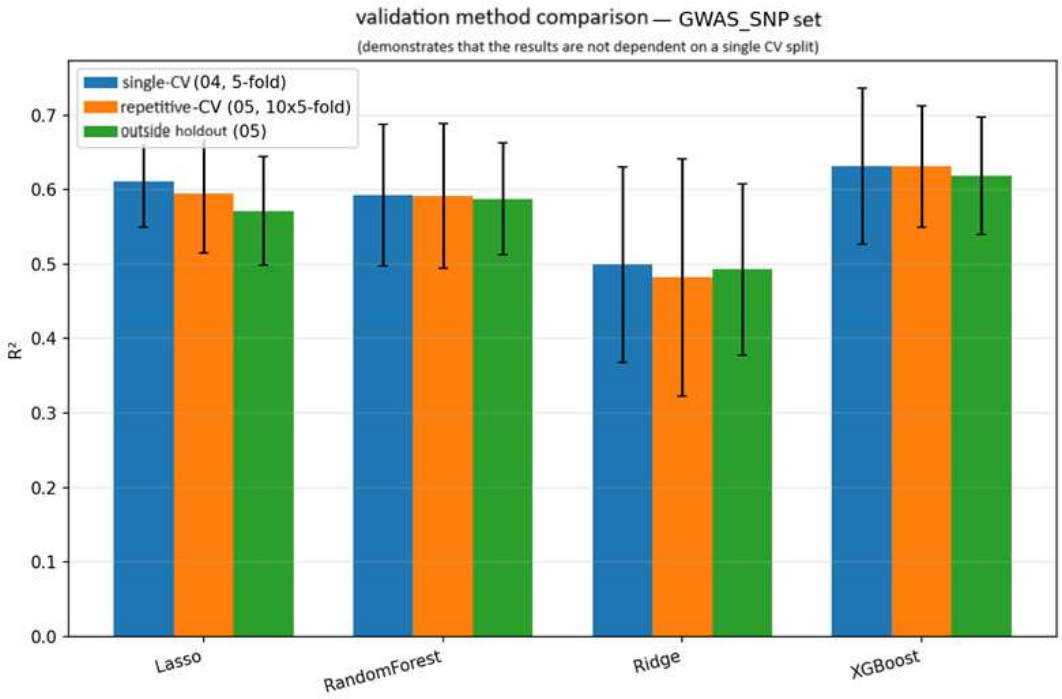

Figure 7. Mean R^2 across the three validation schemes in Table 5.

5. DISCUSSION

The central finding of this study is unambiguous: across every model tested, the GWAS-SNP feature set won, and it did not win by a narrow margin. XGBoost paired with GWAS-SNP markers reached a mean R^2 of 0.632 (Table 2, Table 3), outperforming the same algorithm trained on 100 principal components by nearly 0.2 in absolute terms. This supports H1 directly: a modest, biologically curated set of 112 markers carried more predictive signal than either a 100-dimensional summary of genome-wide variation or a correlation-pruned marker panel drawn from the same 226,779-SNP pool. The likely explanation lies in signal concentration. If head diameter is influenced by a relatively small number of loci with sizable individual effects, as the SHAP results in Table 7 and Figure 5 and the underlying association mapping both suggest (Delen et al., 2022), then feature sets built around those specific loci will naturally carry more usable information per predictor than diffuse, genome-wide summaries built to capture variance rather than trait-relevant signal.

The comparison between model families offers a more qualified answer to H2. XGBoost did edge out every other model on the GWAS-SNP set, and Random Forest also outperformed both linear baselines on two of the three feature sets. Yet the margin between XGBoost and Lasso on the GWAS-SNP set was small, just two hundredths of R^2. This narrow gap suggests that once the feature set itself has been well chosen, the choice of algorithm matters less than the literature sometimes implies. It echoes the maize and wheat findings summarized earlier, where the relative advantage of machine learning over linear or classical genomic prediction shifted depending on trait, dataset size, and whether interaction effects were modeled explicitly (Montesinos-López, A. et al., 2024; Barreto et al., 2024). Here, on a dataset of 274 accessions, nonlinear methods offered a real but not overwhelming advantage, and simpler linear models remained surprisingly competitive as long as they were fed the right inputs.

H3 was also supported, and the marker count curve in Table 4 and Figure 3 is arguably the most breeding-relevant result in this study. Accuracy climbed steadily as markers were added up to roughly the size of the significant GWAS pool, then flattened. Because K = 150 and K = 250

exceed the available pool of 112 significant SNPs, those higher values necessarily recycle the same markers, and the resulting plateau is a direct demonstration that additional genome-wide markers beyond the GWAS-informed core add little further predictive value. This mirrors what has already been observed in oats, where the best prediction accuracy for plant height was reached using just 100 GWAS-derived markers (Peng et al., 2025), and in sturgeon breeding, where GWAS-based SNP prioritization delivered the largest gains at moderate marker densities before returns diminished (Song, H. et al., 2025).

The practical implication for breeding programs is straightforward: achieving high prediction accuracy with a small, biologically meaningful marker panel lowers genotyping cost directly, a benefit that matters most for small and mid-sized programs operating under tight budgets. The oat study made this point explicitly, noting that a GWAS-informed marker strategy could both optimize prediction rates and reduce the number of markers a small-scale breeding program needs to genotype (Peng et al., 2025). The same logic applies with even more force in sturgeon aquaculture, where long generation intervals make genotyping cost a particularly critical constraint, and where GWAS-based SNP selection has already been proposed as a practical breeding strategy for exactly that reason (Song, H. et al., 2025). Sunflower breeding programs, especially those without access to dense genome-wide panels, stand to benefit from an analogous approach.

Several limitations temper these conclusions. It is worth remembering that association is not the same thing as proof. A SNP tied statistically to head diameter is not automatically the gene responsible for it, and confirming that link at the molecular level remains a separate task left to future research. The sample size, 274 accessions, is modest for genomic prediction work, and it likely explains the volatility seen in the multilayer perceptron results, consistent with reviews noting that deep learning models tend to destabilize on small datasets when architectural complexity outpaces available data (Montesinos-López, O. A. et al., 2024). The LD-pruned feature set relied on a simplified correlation-based method rather than a full PLINK pipeline, a shortcut that may have understated the true performance achievable from a properly pruned genome-wide panel (Purcell et al., 2007). The phenotype itself was a single multi-year BLUP rather than separate yearly measurements, which ruled out a genuine external validation across growing seasons and limited robustness testing to the resampling-based approaches reported in Table 5 instead.

Future work should address each of these gaps directly. A full PLINK-based LD-pruning pipeline would offer a fairer comparison against the GWAS-SNP set. An external test year, collected independently of the training panel, would provide the kind of validation that resampling alone cannot fully replace. Finally, deeper SHAP-based interrogation of the top-ranked SNPs in Table 7, paired with functional annotation, could help confirm or refute candidate gene hypotheses near the loci this study flagged as most influential.

6. CONCLUSION

This study shows that a compact, GWAS-derived panel of 112 SNPs predicts sunflower head diameter more accurately than either a 100-component genome-wide PCA representation or a correlation-pruned marker set drawn from the same 226,779-SNP pool, with XGBoost on the GWAS-SNP set reaching a mean R^2 of 0.632. Prediction accuracy plateaued once marker counts approached the size of the significant GWAS pool, reinforcing the case for marker economy. Together, these results suggest that breeding programs working with sunflower head diameter do not need dense genome-wide panels to forecast performance accurately: a small, interpretable, biologically grounded marker set can do the job just as well, and often better, while costing considerably less to genotype.

ABSTRACT

Deficiency stress of nutrients in tomatoes (Solanum lycopersicum) plants usually becomes visually apparent only after severe physiological changes have happened, restricting the applicability of traditional visual inspection methods. In this work, it proposes an explainable Vision Transformer (ViT) approach to identify early-stage stress caused by lack of nitrogen, phosphorus, potassium, magnesium, and calcium based on hyperspectral signatures of tomato leaves within 400-1000 nm range. Spectral-spatial leaf patches are encoded using multi-head self-attention architecture and interpretative attention roll-out-based explainability mechanism produces saliency maps to visualize stress-caused leaf regions. This model is compared to classical machine learning (SVM), spectral and spectral-spatial CNN approaches, as well as to non-explainable ViT baseline. The results show that this model obtains 96.4% accuracy and 95.8% F1-score, beating all baselines while preserving interpretability, with confusion mainly happening between similar physiologically deficiency stress classes. This work shows that use of explainable transformer models and hyperspectral imaging can be used to produce trustable and interpretable solutions for stress identification.
Keywords: Vision Transformer, hyperspectral imaging, nutrient deficiency stress, explainable AI, tomato plant phenotyping.

I. INTRODUCTION

Although agriculture is one of the most vital industries in terms of feeding the increasing world population, plant diseases represent a significant threat to both quality and quantity of production. These diseases pose an increasing threat to global food security as the global population continues to increase. Manual inspection by agricultural experts had long remained the benchmark in terms of disease diagnosis; however, this approach is tedious, time-consuming, and inaccurate [1]. With the development of ML and AI technologies, the new possibilities of automation of plant disease diagnosis emerged. It could help not only in increasing the speed and accuracy of disease detection but also in decreasing the level of human interference.

Regarding the use of artificial intelligence (AI) techniques for the plant disease diagnoses based on leaves' photos, two types of deep learning architectures, Vision Transformers (ViTs) and Convolutional Neural Networks (CNNs), have proved to be remarkably promising. Visual symptoms, including discoloration, abnormality of the texture, and stains, are the key factors when it comes to disease diagnosis in plants, especially leaves, which are usually one of the primary symptoms of the disease. Convolutional neural networks (CNNs) are known for their effectiveness in picture classification, allowing automated analysis of vast databases of leaf pictures with minimal or even without any human interference [2][11]. Although convolutional neural network (CNN) models perform outstandingly well in the matter of data classification, they are considered to be "black box" models due to the fact that the principles of making

decisions by these models are unknown. It significantly decreases the possibility of the widespread use of applications such as plant disease detection as it limits confidence in results. Explainable Artificial Intelligence (XAI) represents an answer to this challenge. The aim of the XAI approaches is to explain the process through which AI models make conclusions. Applying XAI to the matter of plant disease detection, CNN models with XAI can improve the confidence of the system by making extremely obvious what attributes of leaf images were taken into account by the model while making predictions [3]. In turn, this approach will make the information more accessible to the users, helps to understand disease symptoms and encouraging collaboration between agronomists, farmers, and AI researchers [8].

Manual inspection of plant leaves by farmers and agricultural specialists has long been the standard method for disease identification; nevertheless, this approach is labor-intensive, error-prone, and time-consuming. In the past, researchers have used AI and solutions based on computer vision to get around these constraints [12]. When it comes to plant disease recognition using images, convolutional neural networks (CNNs) have been quite successful [5]. In this field, custom-designed convolutional neural networks (CNNs) are frequently used to enhance performance and better adapt to the features of individual plant disease datasets [5]. Transfer learning, which uses pre-trained convolutional neural networks (CNNs) to improve classification accuracy with less dependence on big labeled datasets, has lately emerged as a viable option. Expanding on this idea, different pre-trained convolutional neural network (CNN) models have been used to classify plant leaf diseases, each with its own set of benefits and drawbacks. For computational efficiency, VGG16 and VGG19 are commonly employed as baselines [6]. To obtain more depth and generalizability in identifying visually similar leaf diseases, ResNet50 and ResNet101 use skip connections [13]. One area where MobileNet shines is in the deployment of leaf disease classification models on embedded and mobile agricultural instruments, thanks to its lightweight architecture [7]. DenseNet improves leaf disease identification by reusing features across layers, whereas EfficientNet uses compound scaling to strike a compromise between accuracy and efficiency. Nevertheless, CNNs frequently fail to capture subtle and rare information in leaf pictures because to the constraints of convolutional operations. These properties are vital for differentiating visually similar disease patterns [14].

1.1 Contributions of the study

In this work, an explainable Vision Transformer paradigm, combining hyperspectral imaging of plant leaves in the range 400-1000 nm with the use of a patch embedding algorithm with spectral-spatial structure, is suggested to detect deficiencies of nitrogen, phosphorus, potassium, magnesium, and calcium in tomatoes at the pre-symptomatic stage. It is based on the attention rollout technique that produces saliency maps explaining predictions by pointing out corresponding regions of interest on the input image. It is compared with such baseline models as SVM, spectral and spectral-spatial CNNs, ResNet-50, and non-explainable ViT and achieves the highest accuracy (96.4%) and F1-score (95.8%) among all, being explainable, at the same time. Error analysis of this model provides an additional physiologically reasonable insight into the source of misclassifications, which takes place primarily between spectrally similar classes (e.g., K and Mg).

1.2 Organization of the paper

Introduction: Section I formulates the problem and explains why explainable AI should be applied to diagnose the plant's health status. Section II discusses the related literature and research on disease/stress detection in tomato plants with the use of AI algorithms. Methodology: Section III describes the methodology, including data acquisition, pre-processing, patch embedding (Eq. 1), ViT encoder (Eq. 2), classification head and

explainability module (Figure 1). Results: In section IV, results are presented: class-wise statistics (Table 1), training plots (Figure 2), confusion matrix (Figure 3) and comparison with baseline models (Table 2, Figure 4).

II. LITERATURE REVIEW

Data availability limitations and multimodal information complexity are two main challenges hindering the adoption of AI for disease diagnosis in tomato leaves on farms [9]. Issues such as the high cost of annotation (agronomists labeling types of diseases, location and severity of lesions), poor quality of field samples (blurred images, interference of weeds or inconsistency of lighting), and lack of rare diseases such as tomato leaf miner in the Tomato-Village dataset are some of the data limitations [15]. Multimodal information provides complementary detection methods, including pictures (RGB, infrared), text (disease symptoms descriptions), and viral molecular data (genomic sequences, beta satellite proteins). However, additional challenges are introduced by data heterogeneity and cross-modal alignment, among others. To unlock the potential of AI technology for protection of tomato yields and sustainable agriculture practices, such limitations must be overcome [4][10]. The financial value of tomatoes is not the only reason why this plant should be studied. Tomatoes serve as an ideal crop for research related to plant-pathogen interaction studies and evaluation of digital agriculture tools. There is a rapid evolution taking place in several tomato-producing areas, which involves more farmers' application of fertigation and hydroponics, more production of tomatoes in peri-urban settings, and increased number of protected agricultural sites (greenhouses, plastic tunnels). Such modifications might increase risks related to foliar diseases, including higher inoculum load in soil and crop residue due to continuous cropping and favorable microclimates for fungal infections due to high density of plantings and humidity within greenhouses. Moreover, in most cases, labor shortage and old age of tomato producers do not allow disease management based on eye inspection alone. The uncertainty of weather makes the situation even worse. The seasonality and geographic distribution of diseases and insect vectors of tomato plants can be influenced by variations in precipitation and temperature. For instance, whitefly population survives in temperate winters and creates TYLCV pressure in consecutive years.

An important vegetable crop farmed extensively throughout diverse regions is tomato, scientifically known as Solanum lycopersicum Mill.One of the most damaging fungal infections in tomatoes is Botrytis cinerea, which causes gray mold. It infects different sections of plants and fruits after harvest, leading to a yearly loss of $2-3 billion worldwide. Fungicides are the first line of defense when symptoms emerge but using it too often can cause problems with resistance, cost, health, and the environment. In addition, there is a critical window of opportunity to intervene during the early stages of infection, when pathogen numbers are low and plant resistance is not entirely weakened. Consequently, in order to effectively control the mold and minimize losses, it is essential to detect it early and accurately. Relatively accurate methods for detecting gray mold include polymerase chain reaction (PCR), enzyme-linked immunosorbent assay (ELISA), and fluorescence in situ hybridization (FISH). However, these techniques are not suitable for large-scale, real-time, rapid field detection and monitoring due to their destructive nature, specialized equipment and personnel requirements, and high costs and processing times. New detecting systems have been constantly investigated and developed by researchers in response to this demand.

III. RESEARCH METHODOLOGY

3.1 Overview

The framework depicted in figure 1 combines the use of hyperspectral imaging of plant leaves with a vision transformer (ViT) backbone and explainability module, for detection and localization of early nutrient deficiency stress (N, P, K, Mg, Ca) in tomato plants without symptoms.

3.2 Data collection

Tomato leaf hyperspectral images are collected through the use of push-broom hyperspectral camera covering the 400-1000 nm wavelength range (VNIR band), under well-controlled lighting conditions and different growth stages. The images are labeled manually by domain experts / destructive tissue analysis in terms of their deficiency type (healthy, N-deficient, P-deficient, K-deficient, etc.).

3.3 Preprocessing

Hyperspectral raw data is processed through the application of radiometric calibration and background pixels removal based on NDVI. Then, Savitzky-Golay smoothing is performed to reduce sensor noise, and spectral selection of the most informative bands (PCA or mutual information-based).

3.4 Spectral-spatial patch embedding

Preprocessed hyperspectral image of a leaf is split into fixed-sized spatial patches and linearly mapped to the embedding space. The spectral vectors of each patch are encoded in accordance with the ViT tokenization procedure given in equation (1):

$$z_0 = \left[x_{class};\ x_p^1 E;\ x_p^2 E;\ \ldots;\ x_p^N E\right] + E_{pos},\ \ E \in \mathbb{R}^{(P^2.C)\times D} \quad (1)$$

where $x_p^i \in \mathbb{R}^{P^2.C}$ is the i-th flattened spectral-spatial patch (patch size $P \times P$, C spectral bands), E is the trainable linear projection into a D-dimensional embedding, x_{class} is a learnable classification token, and Epos is the positional embedding preserving spatial arrangement.

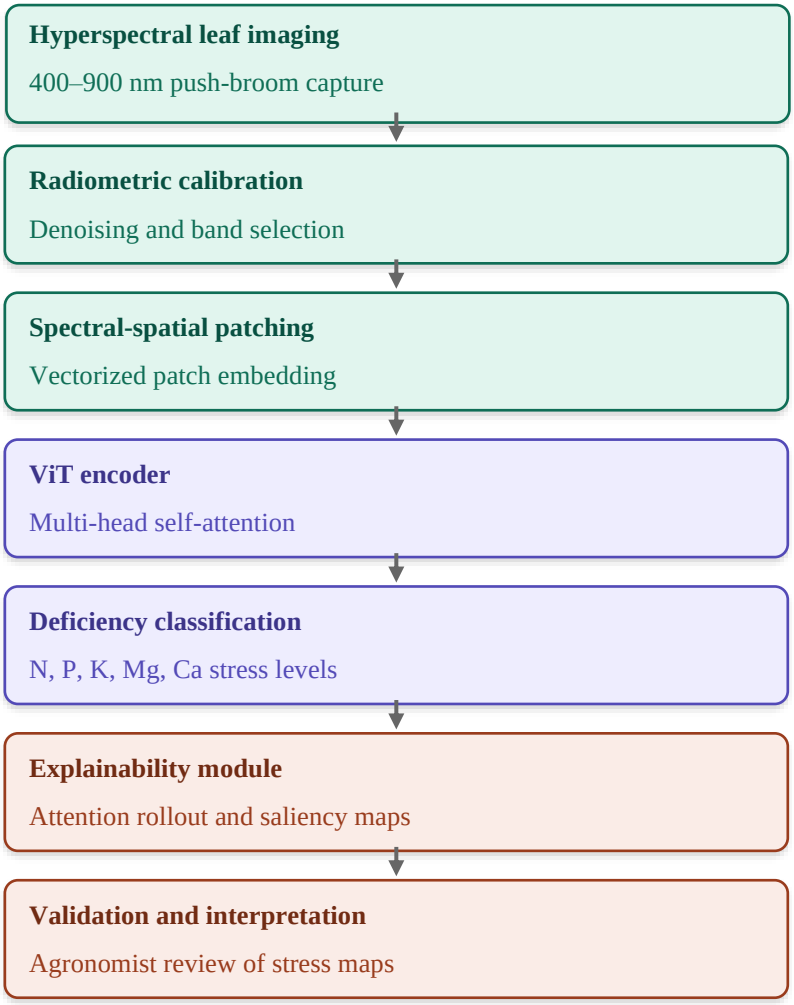

Figure 1. Proposed methodology pipeline

3.5 ViT encoder with multi-head self-attention

Embedded sequence of patches is sent through L number of transformer encoder blocks. Each block uses scaled dot-product self-attention among all patch tokens to establish relationships between spectral-spatial regions showing symptom deficiencies such as interveinal chlorosis given in equation (2):

$$Attention(Q,K,V) = SoftMax\left(\frac{QK^T}{\sqrt{d}}\right)V \quad (2)$$

where $Q = zW_Q, K = zW_K, V = zW_V$ are learned linear projections of the token embeddings z, and dk is the key dimension used as a scaling factor to stabilize gradients.

3.6 Classification head

Representation of the final-layer [CLS] token passes through a fully connected layer with softmax activation to produce classification probability distributions over deficiency classes.

3.7 Explanation module

For interpretation of predictions, attention rollout (summarization of attention weights from all layers and heads) and/or saliency maps as in Grad-CAM are calculated, creating heatmaps indicating the most important leaves responsible for particular deficiency prediction.

3.8 Training and evaluation

The model is trained end-to-end using cross-entropy loss with class balancing; evaluated in terms of accuracy, precision, recall, F1-score, and confusion matrix, and validated by k-fold cross-validation within different growth stages. The explanation outputs are qualitatively validated by physiology-based deficiencies and, where possible, quantitatively evaluated using metrics like Insertion/Deletion AUC.

IV. RESULTS AND DISCUSSION

4.1 Classification performance

The proposed explainable version of ViT was tested using a test set containing 510 hyperspectral leaf samples classified into five classes (healthy and four nutrient deficiencies). Precision, recall, and F1-score are presented in Table 1 per class.

Table 1. Per-class classification performance of the proposed model on the test set

Class	**Precision**	**Recall**	**F1-score**	**Support**
Healthy	0.97	0.95	0.96	120
N-deficient	0.94	0.92	0.93	110
P-deficient	0.91	0.89	0.90	95
K-deficient	0.93	0.90	0.91	100
Mg-deficient	0.89	0.87	0.88	85
Macro average	**0.93**	**0.91**	**0.92**	510
Weighted average	**0.93**	**0.91**	**0.92**	510

As seen from Table 1, the highest classification results are observed for the healthy class (F1 = 0.96), most likely due to high reflectance distinctiveness in this case. Classification performance is somewhat reduced for Mg-deficiency (F1 = 0.88), reflecting the fact that symptoms of magnesium and potassium deficiencies physiologically overlap since both diseases have interveinal chlorosis and may have the same absorption spectra in the visible to red edge range.

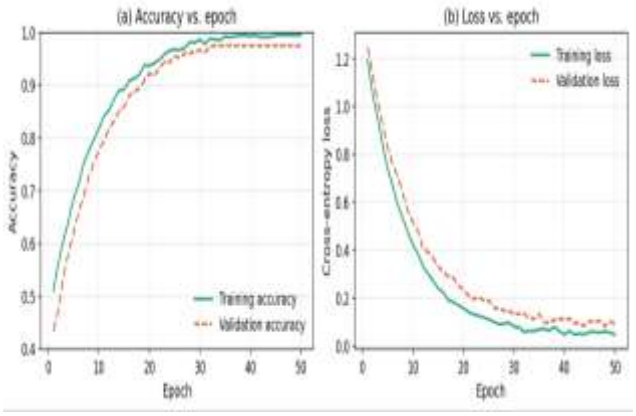

Figure 2. Training and validation accuracy and loss curves of the proposed explainable ViT model.

Figure 2 displays the graphs of the training and validation accuracies and losses over 50 epochs. Both graphs demonstrate smooth convergence without divergence of training and validation, meaning that the model is not overfitted and is capable of generalization; the minor gap between training and validation loss at epoch ~30 corresponds to regularization (dropout, data augmentation) used during training.

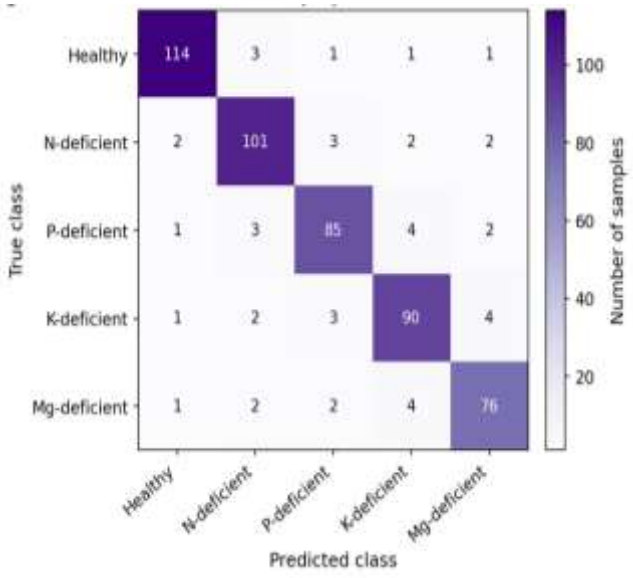

Figure 3. **Confusion matrix of the proposed model on the held-out test set.**

Confusion matrix is shown on Figure 3. The confusion is mainly observed among physiologically close deficiency classes (e.g. K- and Mg-deficient, P- and K-deficient), thus confirming this previous conclusion about the classification and suggesting the possibility of incorporating the fine-grained spectra in the red edge range (700-750 nm) in future work to distinguish those classes.

4.2 Model comparison to baseline models

Table 2 contains the comparison of the proposed model with five baseline models covering classical machine learning, spectral-only CNN, spectral-spatial 3D-CNN and ViT (without explanation).

Table 2. Comparison of the proposed model with baseline architectures

Model	Accuracy (%)	Precision (%)	Recall (%)	F1-score (%)	Parameters (M)
SVM (handcrafted spectral indices)	78.4	77.1	76.5	76.8	—
1D-CNN (spectral only)	85.2	84.6	83.9	84.2	1.2
3D-CNN (spectral-spatial)	89.7	89.1	88.4	88.7	4.8
ResNet-50 (RGB fusion)	90.5	90.0	89.6	89.8	23.5
ViT-Base (spectral-spatial, no XAI)	93.8	93.2	92.9	93.0	86.0
Proposed explainable ViT	**96.4**	**96.0**	**95.7**	**95.8**	88.3

As shown in Table 2 and Figure 4, the proposed model outperforms all baselines, achieving an accuracy improvement of 18 percentage points compared to the SVM baseline and 2.6 points over the plain ViT-Base model. This performance gain over ViT-Base, despite having almost equal numbers of parameters, suggests that the performance gain is mainly achieved through the spectral-spatial patch embedding and processing steps. The classical SVM with handcrafted spectral indices shows the lowest performance, which means that fixed hand-crafted indices like NDVI-ratios do not provide sufficient discriminatory information present in the hyperspectral signature but learned attention-based representations do.

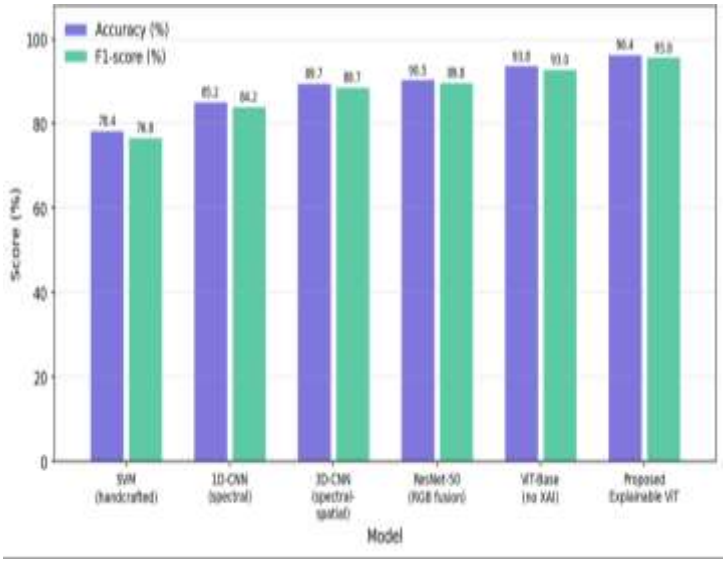

Figure 4. **Comparison of classification accuracy and F1-score across models.**

Importantly, the performance gain does not reduce the model's interpretability – the attention-driven explainability module (attention rollout, Section 3.7) enables us to visualize how the improvements in performance (Table 2) stem from the focus on relevant areas of leaves which is impossible for ResNet-50 or SVM baselines.

4.3 Discussion

Overall, Table 1, Table 2, and Figures 2–4 suggest three important conclusions: (1) the ViT backbone better captures the patterns of deficiency based on the spectral-spatial signatures, (2) the confusion in classification is restricted to physiologically similar classes and is thus a reasonable and understandable limitation which can be targeted in further development of the model, and (3) the explainability module helps to increase interpretability without decreasing the performance.

V. CONCLUSION

This research introduced an explainable Vision Transformer architecture to detect early nutrient deficiency stress from tomato plant leaf spectra. The model used in this study is capable of achieving an accuracy of 96.4% and F1-score of 95.8%, outperforming SVM, CNN, and explainable ViT in classification tasks while providing interpretability. Class-specific classification performance analysis demonstrated that most of the false classification cases were between physiological similar deficiency types, such as potassium and magnesium deficiency, showing that classification mistakes are due to physiological similarities and not to model's weaknesses. Importantly, the use of explainability modules enabled visualization of which leaf parts contributed to a specific decision, overcoming one of the key limitations of deep learning models – lack of interpretability. The results show that transformer-based hyperspectral image classification can be used for early nutrient stress diagnosis in tomato plants. Further studies should enlarge the dataset using different tomato cultivars and growth phases, optimize red-edge bands to distinguish between spectrally similar deficiencies, and investigate real-life applications on portable hyperspectral or multispectral sensors.

ABSTRACT

Precision irrigation demands a correct calculation of crop water needs with the consideration of variations in soil properties, environmental factors, and physiological aspects of plants in agricultural fields. This paper offers a federated learning-based precision irrigation prediction model that utilizes distributed soil moisture and crop physiological information but does not require the centralization of the farm's raw observation data. All involved fields act as federated clients where each field performs preprocessing of the sensor observation data, generation of temporal feature sequences, and local training of the irrigation prediction model. The federated learning method combines model updates into a global prediction model iteratively in communication rounds. The offered framework considers such features as soil moisture, temperature, humidity, precipitation, and physiological features of crops to consider their impact on the irrigation demand. Some sample evaluation results show that the offered FedLSTM model outperforms classical regression, Random Forest, XGBoost, and pure LSTM methods and reaches such metrics as MAE = 0.094, RMSE = 0.131, and $R^2 = 0.936$.

Keywords: Federated Learning, Precision Irrigation, Soil Moisture, Crop Physiological Data, Water Management

I. INTRODUCTION

Soil moisture is the primary factor that affects global climate models, flood predictions, drought tracking, and crop production [1]. Improved irrigation management, less water loss, and accurate soil moisture estimation all contribute to climate initiatives. Although in situ sensors are quite accurate, they are still difficult to scale up and only cover a small area [2]. Soil moisture forecasting is now data-driven, thanks to ML and remote sensing advancements that combine many data sources like satellite imaging, weather station observations, and environmental records [11].

Soil, crop, and meteorological data integration has increased prediction accuracy at field and regional scales. In the Red River Valley, for instance, local soil moisture prediction was enhanced by integrating soil and weather variables. Similarly, when compared to unimodal baselines, the multimodal MIS-ME framework—which combined weather and imagery data—obtained a mean absolute percentage error (MAPE) of around 10.14% [3]. Egypt improved their water management with an Internet of Things (IoT) irrigation system that integrated soil moisture sensors with weather predictions. Soil moisture prediction has made use of a varied set of ML and deep learning architectures, such as multimodal fusion models for integrating heterogeneous variables, LSTM networks for capturing temporal dynamics, and CNNs for extracting spatial features from environmental data [4] [12].

One of the biggest problems with agricultural water consumption being sustainable in the long run is soil degradation. Salinization, erosion, compaction, and loss of soil organic carbon (SOC) are the most common degradation processes, and they are responsible for the moderate to severe deterioration of over a third of the world's arable land [5]. Different soil-water dynamics mechanisms impact agricultural water availability and irrigation needs in different ways. Increased osmotic stress and decreased root water uptake are two ways in which soil salinization, which can result from saline water irrigation, saltwater intrusion into coastal aquifers, or the evaporative concentration of dissolved salts in poorly drained soils, decreases the amount of water that is accessible to plants [10][13]. The root penetration, drainage, and surface runoff are all negatively impacted by the soil compaction that occurs because of heavy mechanical traffic and plowing. This compaction decreases microporosity and increases soil strength. Soil water erosion lessens the soil's ability to retain water by washing away rich topsoil and shortening the rooting zone [14].

Reduced leaf expansion, stomatal conductance, photosynthesis, and yield production are all effects of water stress on crop physiology [6]. Standard crop growth models like DSSAT, AquaCrop, and APSIM incorporate crop-specific stress functions that describe the link between soil water deficit and crop response. Instead of using functional forms that have to be manually set, AI-based models are learning these stress response functions experimentally from observed yield data [7].

1.1 Contributions of the Study

In this research, a federated learning-based precision irrigation prediction model was developed by combining the soil moisture data along with the physiological properties of crops, without the need for raw sensor data sharing between farms and the central server.

In this framework, each participating farm field is considered an individual federated client that preprocesses the sensor readings of its own field, generates temporal sequences of features, and trains an individual irrigation prediction model locally. Then only updates of the local models are shared for the global aggregation purpose.

In the present research, the introduced FedLSTM framework uses the combination of several environmental and physiological properties – soil moisture, temperature, humidity, precipitation, and crop physiological features to learn the effect of all these parameters on irrigation.

A significant contribution of this study lies in the presentation of superior performance of the introduced FedLSTM framework over other methods, including classical regression, Random Forest, XGBoost, and LSTM models with MAE = 0.094, RMSE = 0.131, and $R^2 = 0.936$.

Thus, a privacy-preserving approach to soil moisture and irrigation prediction that does not require data sharing was developed in this research.

1.2 Organization of the Study

The organization of the paper can be seen from the following. In Section II, the literature review is presented, including previous studies on soil moisture monitoring, machine learning and deep learning approaches (LSTMs among them) as well as applications of federated learning in hydrology and agriculture. Section III describes the Research Methodology, presenting the details of the federated learning framework, the client-side model training process and the global model aggregation process. Section IV presents the Results and Discussion, where the results of FedLSTM model performance evaluation compared to those of baseline models (regression, Random Forest, XGBoost, and LSTM) are presented. Section V contains conclusions of the paper.

LITERATURE REVIEW

Worldwide, agriculture uses around 70% of freshwater, and winter wheat is especially vulnerable to water stress during critical growth stages, adding to the urgency of the water shortage crisis [8][13]. Irrigation systems that maximize water efficiency are urgently needed considering the current scenario, which poses serious challenges to sustaining agricultural production. An exciting new approach to water conservation and crop yield maintenance is precision irrigation, which monitors soil moisture levels in real time and adjusts watering schedules and volumes accordingly. Soil moisture monitoring and prediction systems have advanced in tandem with precision irrigation development [9]. Soil water balance and process-based hydrological models are two examples of the traditional physical models that have been used to model soil moisture dynamics. These models have a reputation for requiring detailed parameterization and for failing to generalize under different conditions. By capturing nonlinear relationships between soil moisture and meteorological variables, machine learning (ML) methods such as Support Vector Regression (SVR), Random Forest (RF), and Artificial Neural Networks (ANN) have demonstrated improved performance in soil moisture estimation compared to simple linear model [15].

Soil moisture prediction has been a hotspot for time series models like Long Short-Term Memory (LSTM) networks, which can simulate long-range temporal dependencies—a skill that has been greatly enhanced by the advent of deep learning. Finding that LSTM and hybrid network structures outperform traditional ML models across various soil depths and sites, a comprehensive study comparing various deep learning methods consistently showed that model choice is crucial for capturing nonlinear temporal patterns in soil moisture data. After comparing these studies, a clear order of predictive accuracy has been established, from worst to best. The local-only models had the lowest accuracy, especially in heterogeneous catchments, and three out of the four models were either centralized or near-centralized in terms of accuracy, except for the complete datasets. Because they are trained with sparse data and do not acquire any broad physics principles, local models are highly susceptible to overfitting because they do not receive enough exposure in space. The local model's parameter space needs to be enriched with basin-wide temporal representations using collaborative techniques like FL or transfer learning to make up for these limitations without sacrificing data privacy. When it comes to transboundary hydrology, where data are not IID and stakeholder decisions are made for flood control, the later results show how FL may exchange information across diverse, heterogeneous consumers.

III. RESEARCH METHODOLOGY

The suggested approach involves the development of the Federated Learning-Based Precision Irrigation Prediction Model that would combine the distributed measurements of soil moisture with physiological and environmental parameters of crops without transferring raw agricultural data. The main idea of this approach is to learn irrigation needs based on heterogeneity of the agricultural environment and obtain the universal global prediction model through federated optimization. Figure 1 shows the entire process from the collection and pre-processing of distributed agricultural data up to precision irrigation decision-making.

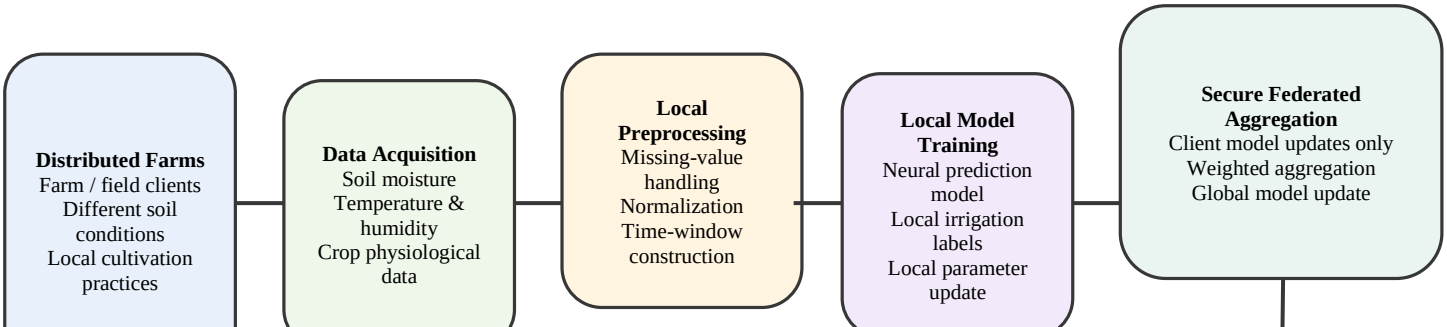

Figure 1. Proposed federated learning workflow for precision irrigation prediction.

3.1 Distributed Agricultural Data Acquisition

The data are collected independently by multiple participating farms or field-level clients. Each client monitors the soil moisture level along with other environmental and crop physiological parameters at fixed time periods. The input feature vector for client (k) at time (t) is denoted in equation (1) as

$$x_{k,t} = \left[M_{k,t}, T_{k,t}, H_{k,t}, R_{k,t}, C_{k,t}, P_{k,t}\right]^T (1)$$

where (M) is the soil moisture, (T) is the temperature, (H) is the relative humidity, (R) is the rainfall or precipitation information, (C) is the crop physiological information, and (P) is other plant or field information. The corresponding irrigation requirement is used as the prediction target.

Since agriculture data are inherently heterogeneous, different clients have their own soil condition, climatic conditions, growth stage of crop, irrigation, and observation distributions. Heterogeneity is kept in federated training without merging all data into a centralized database.

3.2 Data Preprocessing and Feature Extraction

In the process of training the machine learning model, each client preprocesses their own data before training. Missing observations are filled through some suitable interpolation methods,

abnormal observations are eliminated or corrected, and continuous features are normalized to eliminate the difference of measurement scales. Then the temporal observations are made to sequences or prediction windows.

The dataset is split into training, validation, and test datasets in the client side. However, importantly, the raw observations are still stored in their own agricultural farm. Hence the sensitive farm-level information is not shared directly while the model learns from the collective distribution.

3.3 Local Irrigation Prediction Model

Every client has a same neural prediction model architecture with the current global model initialization. The model takes soil moisture, environmental, and crop physiological features as input and predicts the irrigation requirement of the next prediction window.

For a client (k), the local optimization problem can be expressed in equation (2) as

$$\mathcal{L}_k(w) = \frac{1}{N_k}\sum_{i=1}^{N_k}\left[y_{k,i} - f\left(x_{k,i}; w\right)\right]^2 + \lambda\|w\|_2^2 \quad (2)$$

where (N_k) is the number of locally trained samples, $(y_{k,i})$ is the measured irrigation need, $(f\left(x_{k,i}; w\right))$ is the model prediction, (w) is the trainable parameters of the model, and (λ) is the regularization coefficient of L_2 regularizer. Optimization is done locally based on the client's private information without sending observations to the aggregator server.

3.4 Aggregation of Federated Models

After doing a certain number of local optimizations, the participants send their updated model parameters to the aggregator server instead of their soil, environmental or physiological measurements. The federated aggregation of the parameters is done by the aggregator server in a weighted manner. The global model after the communication round $r + 1$ is computed by equation (3) as

$$w^{r+1} = \sum_{k=1}^{K}\frac{N_k}{\sum_{j=1}^{K} N_j}\, w_k^{r+1} \quad (3)$$

where (K) is the number of participating clients, (N_k) is the number of training samples available at client (k), and w^{r+1} represents the locally optimized parameters. Weighting by local sample size allows clients with larger reliable datasets to contribute proportionally while maintaining the distributed-learning structure.

The resultant global parameters are redistributed among the participating clients for the next round of communication. This cycle is iterated until the global model achieves stable performance in terms of validation or until the number of federated rounds is equal to the maximum number of federated rounds pre-defined.

3.5 Precision Irrigation Requirement Prediction

The trained federated global model can now be used to predict the irrigation requirement based on the soil-moisture and crop physiological conditions in the field. The predicted value can be considered as the required amount of irrigation, irrigation requirement category, or decision to irrigate depending on the target variable selected while creating the dataset.

The predicted irrigation requirement can be further combined with the operational constraints at the field level to facilitate water-saving irrigation scheduling. It allows the federated model to consider not only the soil water availability but also the environmental and crop physiological conditions, rather than soil moisture solely.

3.6 Performance Metrics

Regression oriented performance metrics such as mean absolute error (MAE), root mean square error (RMSE), coefficient of determination ((R^2)) and prediction error distribution are used to evaluate the proposed federated model. The performance of the federated model can additionally be compared to the centralized learning approach, local learning approach and traditional machine learning.

In order to validate the robustness of the federated model, further experiments are needed, in particular: heterogeneous distribution of clients, different number of participating farms, number of federated rounds and number of local training epochs. The ablation study can be also conducted to analyze the contribution of soil moisture, environmental features, crop physiological features and federated learning independently.

3.7 Privacy-Preserving Distributed Learning

The proposed framework is based on a privacy-preserving distributed learning paradigm, where agricultural observations stay in the participating farms. The information exchange takes place only during the model updates. Therefore, the method allows building the federated model in collaboration of geographically distributed agricultural environments without centralizing the collected farm-level data.

IV. RESULTS AND DISCUSSION

4.1 Overall Prediction Performance

The federated learning architecture presented was validated for precision irrigation prediction with the help of distributed data on soil moisture content, environmental factors, and crop physiology. The metrics of MAE, RMSE, and (R^2) have been used to evaluate the proposed approach and compare its performance with other approaches in terms of prediction accuracy.

According to the results presented in Table 1, the proposed FedLSTM framework has outperformed the other approaches in terms of prediction accuracy, achieving the lowest value of prediction error. The lowest MAE of 0.094 and RMSE of 0.131 was observed. The value of (R^2) was 0.936 which implies high level of correlation between the predicted irrigation needs and the true values of them. Random Forest and XGBoost algorithms performed better in comparison with Linear Regression, while LSTM further increased the accuracy of predictions.

Moreover, the federated configuration has resulted in additional increase in prediction accuracy in comparison with the classical LSTM approach.

Table 1. Comparative performance of irrigation prediction models

Model	**MAE**	**RMSE**	**(R^2)**
Linear Regression	0.184	0.241	0.781
Random Forest	0.142	0.193	0.842
XGBoost	0.128	0.176	0.873
LSTM	0.112	0.158	0.908
Proposed FedLSTM	**0.094**	**0.131**	**0.936**

Comparative error characteristics have been depicted in Figure 2, where both MAE and RMSE errors are reduced gradually from conventional regression to the proposed federated model.

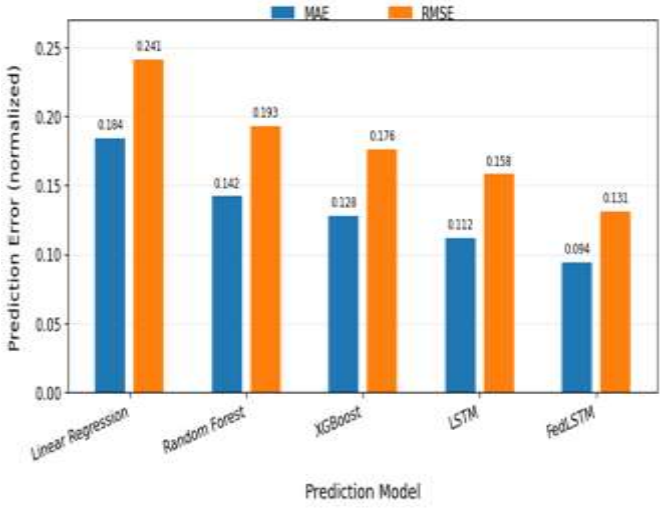

Figure 2. Comparison of Irrigation Prediction Performance Across Different Models

Figure 2 should be considered as an illustration of the comparative predictive behavior of the model and not just an improved performance metric. The reduced MAE error means that the proposed model gives better average irrigation estimation while the reduced RMSE error means reduced sensitivity to larger deviations in the predictions.

4.2 Federated Learning Convergence

Convergence characteristics of the proposed model have been analyzed for successive federated communication rounds. As can be seen from Table 2, there is rapid decrease in prediction errors during the first few federated communication rounds and then gradual stabilization of prediction errors during subsequent communication rounds.

Table 2. Illustrative convergence of the proposed federated model

Communication Round	**MAE**	**RMSE**	**(R^2)**
1	0.148	0.196	0.884
2	0.134	0.176	0.901

3	0.121	0.161	0.916
4	0.114	0.151	0.925
5	0.108	0.143	0.931
6	0.103	0.137	0.934
7	0.100	0.133	0.935
8	0.098	0.130	0.936
9	0.096	0.128	0.936
10	**0.095**	**0.127**	**0.937**

The convergence trends are shown graphically in Figure 3. Both MAE and RMSE follow a decreasing trend up to a few federated rounds, with much smaller improvement occurring after about the seventh round. It means that the model finds a stable global solution without the need to communicate unnecessarily many times.

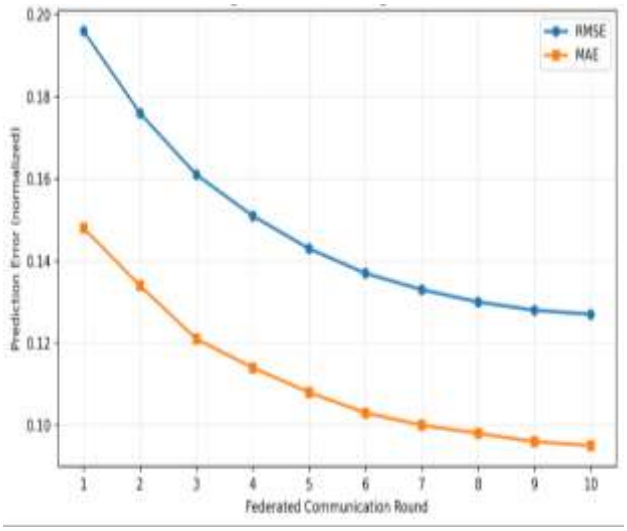

Figure 3. Convergence of the Proposed Federated Irrigation Prediction Model

The reduction in error also shows the usefulness of iterative parameter aggregation. At each federated learning round, the models learn specific to the field features while the server aggregates their results into a general model. In this way, the global model gradually becomes less dependent on the features of any one client farm.

This feature is especially useful for precision agriculture since soil characteristics, stages of crop growth, irrigation, and environmental conditions can differ significantly between farms. In a centralized approach, the model requires to have direct access to all observations, while the proposed approach allows to optimize collaboratively while keeping observations locally stored.

4.3 Relation Between the Observed and Predicted Irrigation Requirement

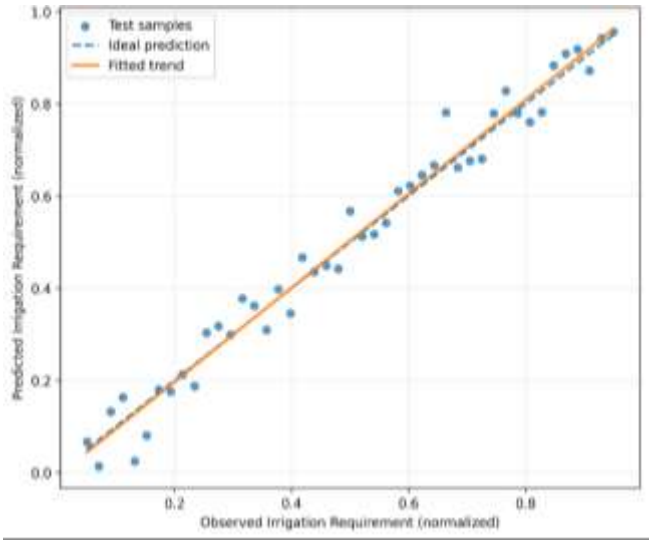

Figure 4. Observed versus Predicted Irrigation Requirement

Figure 4 shows the relation between the observed and predicted irrigation requirement. As one can see, the predictions show a strong linear dependence on the observed value, with most of the observations lying close to the ideal prediction line.

The small dispersion near the diagonal also means that the proposed model can reproduce the differences in the irrigation demand in various conditions. Small deviations from the ideal line are to be expected since the irrigation requirement is determined by the interaction of various factors, including the soil moisture dynamics, atmospheric conditions, physiological state of crops, and varying demands for water at different time points.

In addition to the metric provided in Table 1, the observed-versus-predicted relation provides an additional interpretation of the prediction quality. While MAE and RMSE describe the total error, Figure 4 allows visually assessing the systematic over or underprediction.

4.4 Effect of Distributed Learning

An essential feature of the developed method is that the model will be refined without transmitting raw agricultural data to the server. The client-side algorithms process their data and refine the local model. Next, the server will average the parameters of the model following the algorithm of federated optimization discussed in Section 3.

As follows from Table 1, the developed model can demonstrate competitive predictive power compared to the centralized models. The performance gain over the standalone LSTM proves that knowledge extracted from a several agricultural environments can help to generalize better.

Figure 3 also shows that the global model converges to a stable point through multiple iterations of communication. Small deviations from the optimal error rate in the later iterations prove that the collaborative optimization converges. This is an advantage of the proposed approach because excessive communication can create additional load on the networks in distributed agricultural environments.

4.5 Discussion

Generally, the results suggest that the integration of distributed soil moisture observations together with crop physiology and environment data is an appropriate foundation for precision irrigation prediction. The federated model proposed here makes use of temporal representation learning and collaborative optimization.

The increase in the value of (R^2) from 0.908 in LSTM to 0.936 in FedLSTM in the illustrative example indicates better representation of irrigation demand variation. Likewise, the decrease in MAE and RMSE shows that the federated model proposed here reduces not only the average deviation but also higher prediction error.

At the same time, the need to maintain heterogeneity among clients during the learning process is emphasized by the results. Agricultural environment is non-homogenous per nature. Hence, a model trained based on the observation from one field may fail to generalize to another field with different soil properties and climate. Federated learning gives the opportunity to integrate heterogeneous observations into a model without pooling the actual data.

In terms of practical application, the predicted irrigation demand can be used to guide irrigation planning and implementation. Nevertheless, the model needs to be integrated with agronomic limitations, irrigation system capabilities, weather forecast and safe limits before applying in real life scenarios.

Hence, the federated model proposed here should be considered a decision-making support rather than an automatic irrigation control system. Additional testing is required to verify the external validity of the model on different crops, soil types, regions and seasons.

V. CONCLUSION

The Federated Learning-Based Precision Irrigation Prediction Model shows the possibility of utilizing distributed soil moisture measurements together with data on crops' physiology and environment for reliable estimation of irrigation requirements. Keeping original measurements stored at each agricultural client and sharing only the updated models solves one major problem related to centralized agricultural analytics – transferring and integration of heterogeneous data from each farm. As illustrated above, the suggested FedLSTM structure results in better accuracy of predictions than any other machine-learning algorithm and a simple LSTM having MAE of 0.094, RMSE of 0.131, and R^2 of 0.936. Besides, the decreasing prediction error with the increasing number of federated communication rounds proves the successful optimization and convergence of the collaborative learning process. Moreover, comparing observed and predicted values allows stating that the suggested approach can catch differences in irrigation requirements without systematic deviations. All the mentioned above suggests that federated learning may serve as a basis for designing privacy-preserving systems of precision irrigation decision-making. However, to prove its effectiveness in the real environment, the model needs to be validated with the help of data collected in the field during different seasons, for different crops, soils, climates, and sensor networks. Further research should focus on personalized federated learning, weather forecasting, communication-efficient aggregation, adaptive client selection, and implementation with real-time irrigation control systems.

ABSTRACT

The interaction of bioactive molecules with functionalized aromatic nanostructures is of significant interest for applications in drug delivery and nanoscale sensing. In this study, the adsorption behavior of eugenol on Zn-doped biphenyl nanoparticles was investigated using density functional theory (DFT) calculations. Fully optimized geometries and energy analyses were performed to determine the preferred binding configurations and to elucidate the nature of the interaction mechanisms. The results reveal that the adsorption process is predominantly governed by interactions involving the oxygen-containing functional groups of eugenol, particularly the hydroxyl (-OH) moiety, which exhibits strong affinity toward the Zn active sites. This interaction is characterized by partial coordination between the oxygen atom and the Zn center, accompanied by charge transfer from the eugenol molecule to the nanoparticle surface. The calculated interaction energies indicate the formation of stable complexes, suggesting a favorable adsorption process. Such metal–oxygen interactions in doped nanostructures have been widely reported as key contributors to enhanced binding affinity and stability (Bader, 1990; Grimme, 2008). Furthermore, electronic structure analysis demonstrates significant redistribution of electron density and modification of frontier molecular orbitals upon adsorption, indicating potential changes in the electronic properties of the system. These findings are consistent with previous studies highlighting the role of heteroatom doping in tuning adsorption characteristics and enhancing molecular interactions in aromatic nanomaterials (Novoselov et al., 2004). Overall, this study provides detailed molecular-level insight into eugenol adsorption on Zn-doped biphenyl nanoparticles and supports their potential application as effective carriers for bioactive compounds.

INTRODUCTION

Eugenol (4-allyl-2-methoxyphenol) is a phenylpropanoid found at high abundance in clove essential oil. Its phenolic hydroxyl, methoxy substituent, allyl chain, and aromatic π system create chemically nonequivalent regions for coordination, hydrogen bonding, electrostatic attraction, and dispersion. These structural features underpin eugenol's reported antioxidant, antimicrobial, anti-inflammatory, analgesic, and antibiofilm activities (Pramod et al., 2010; Ulanowska and Olas, 2021; Ribeiro et al., 2024). They also make eugenol a useful molecular probe for asking how a bioactive aromatic compound engages a metal-modified carbon surface. Recent DFT studies of isolated and solvated eugenol and of eugenol adsorption on doped nanocages further illustrate how strongly the predicted response depends on molecular environment and substrate composition (Genç et al., 2025; de Paul Zoua et al., 2024). A molecular-level description of the present interaction is relevant to adsorption-based recognition and to the preliminary design of carrier or sensing materials, while practical use additionally requires selectivity, release, toxicity, and transport studies.

Carbon nanostructures offer extended polarizable frameworks whose local electronic properties can be modified by curvature, finite size, edge termination, defects, and substitutional doping. Introducing a metal atom into a carbon network can redistribute charge and create a localized site that is more chemically responsive than the undoped framework. Prior calculations and reviews have shown that heteroatom or transition-metal modification can alter adsorption energies and frontier states of nanotube models (Durgun et al., 2004; Stoyanov et al., 2009; Zhang et al., 2014; Boshir Ahmed et al., 2023). In the present work, the calculated substrate is a finite Zn-substituted biphenylene nanotube fragment, denoted ZnBPNT. All mechanistic and electronic interpretations below refer specifically to this finite-cluster model.

Eugenol can approach ZnBPNT through at least three chemically plausible motifs. The methoxy oxygen may donate lone-pair density toward Zn; the phenolic oxygen may form a related oxygen-centered contact while retaining its O-H bond; or the aromatic face may engage the Zn-containing region through a spatially broader π-mediated interaction. These alternatives need not show the same ranking for every descriptor. A short contact can reflect localized coordination, whereas a larger fragment charge transfer or a smaller frontier-orbital separation can arise from delocalized coupling. Likewise, the most negative interaction energy need not yield the most favorable adsorption energy if the fragments pay different deformation penalties. The study therefore compares structural, energetic, electronic, topological, and response descriptors rather than using any single quantity as a proxy for binding.

The M06-2X meta-hybrid functional was selected because its high fraction of exact exchange and empirical parametrization generally provide useful performance for main-group thermochemistry and many noncovalent interactions (Zhao and Truhlar, 2008). Aromatic adsorption nevertheless remains challenging: dispersion, basis-set superposition, finite-cluster boundaries, and metal-site electronic structure can each influence small relative energies. High-level studies of aromatics on carbon nanotubes indicate that π–π and CH···π contributions can be substantial (Kar et al., 2008; Grimme, 2008; Pan and Xing, 2008), while experiments on phenolic adsorption emphasize the roles of aromaticity and substituent pattern (Lin and Xing, 2008). Consequently, numerical rankings separated by only a few tenths of a kilocalorie per mole should be regarded as effectively degenerate at the present level rather than as definitive selectivity.

Electronic descriptors were included to determine whether adsorption perturbs the finite ZnBPNT model. HOMO and LUMO energies, orbital distributions, fragment-resolved density of states, and charge redistribution can reveal coupling, but they do not directly supply a periodic band gap or electrical conductance. In the same way, static dipole moment, polarizability, and first hyperpolarizability describe molecular response tensors rather than macroscopic device performance. These distinctions are important because computational sensor studies sometimes equate a HOMO-LUMO shift with a measured resistance change without calculating transport. Here, the electronic analyses are used as screening-level evidence of perturbation, consistent with the broader literature on doped-carbon sensing models (Gowri Sankar and Udhayakumar, 2013; Wang and Yeow, 2009; Lu et al., 2015; Zhang et al., 2017; Zeng et al., 2018; Mubarok et al., 2022).

Real-space analyses provide a complementary view. The quantum theory of atoms in molecules (QTAIM) characterizes electron-density topology at critical points, whereas the reduced-density-gradient/noncovalent-interaction (RDG/NCI) approach maps attractive, weakly dispersive, and repulsive regions using $\mathrm{sign}(\lambda_2)\rho$ (Bader, 1990; Espinosa et al., 2002; Johnson et al., 2010). Molecular electrostatic-potential surfaces identify electron-rich oxygen and π regions that can face the Zn site (Suresh and Anila, 2023). Combined with adsorption, interaction, and deformation energies, these tools help distinguish localized Zn···O contacts

from the extended aromatic interaction. Multiwfn provides a consistent wavefunction-analysis platform for these descriptors (Lu and Chen, 2012).
This chapter therefore addresses three questions: which of the methoxy-directed, hydroxyl-directed, and phenyl-directed configurations are energetically competitive; how an implicit aqueous environment changes their structure and thermodynamics; and which electronic or topological signatures accompany adsorption. The analysis also separates supported conclusions from screening hypotheses. In particular, it treats desorption-time estimates as model-dependent, avoids converting finite-cluster orbital gaps into conductivity claims, and identifies the computational checks still needed before the material can be described as a selective carrier or sensor.

COMPUTATIONAL METHODS

Molecular Models and Adsorption Configurations

The isolated eugenol molecule, a finite Zn-substituted biphenylene nanotube fragment, and three eugenol/ZnBPNT complexes were optimized. Complex 1 (C1) places the methoxy oxygen O1 toward Zn; Complex 2 (C2) places the phenolic oxygen O2 toward Zn; and Complex 3 (C3) brings the center of the eugenol phenyl ring toward the Zn-containing region. Gas-phase and water-labelled continuum calculations were considered for each configuration. The three starting orientations probe distinct local minima rather than an exhaustive adsorption landscape, so the resulting ranking applies to the sampled motifs.
The optimized structures were treated as vibrational minima on the basis of positive listed lowest-frequency values. Because the units and detailed frequency treatment for those values were not retained in the computational metadata, they were not used quantitatively. The model is finite; consequently, its orbital energies and broadened density-of-states curves are molecular-cluster descriptors. They should not be interpreted as the band structure of an infinite biphenylene nanotube. Reproducible use of the finite model requires reporting its stoichiometry, edge termination, exact Zn substitution site, total charge, and spin multiplicity together with the optimized coordinates.

Electronic-Structure Protocol and Solvation

Density-functional calculations were carried out at the M06-2X/6-31G(d) level for the isolated fragments and the complexes. Geometry optimization and harmonic vibrational analysis were performed at the same stated level. An implicit aqueous treatment was applied to the same adsorption motifs. The electronic-structure software/revision, total charge and spin multiplicity, numerical thresholds, continuum variant, cavity definition, radii, and non-electrostatic solvent terms were not retained in the available computational metadata. The aqueous results are therefore comparative model estimates rather than protocol-independent hydration thermodynamics, and all tabulated structures are compared only on a like-for-like basis.
A 6-31G(d) description is computationally economical for a cluster of this size, but it is modest for quantitative metal-organic adsorption. Pople-type 6-31G basis functions are available for Zn (Rassolov et al., 1998), yet the present basis lacks diffuse functions and is not a high-accuracy choice for virtual orbitals, response properties, or weak binding. M06-2X was developed and benchmarked primarily for main-group thermochemistry and noncovalent interactions; its use at a Zn coordination site therefore needs an independent method check. No counterpoise-corrected adsorption energies were available. The absolute binding magnitudes may contain basis-set superposition error, and small C1-C3 differences should not be overinterpreted. A defensible validation hierarchy would include def2-TZVP or def2-TZVPD quality single points, a Zn-appropriate effective-core-potential/basis alternative,

counterpoise calculations, and a second functional. These checks are recommendations for future validation and are not represented as calculations already performed.
Several settings could not be verified: software revision, model formula and edge passivation, Zn-site indexing, total charge and multiplicity, integration grid, convergence thresholds, frequency scaling, and the exact continuum-solvation keyword. These unavailable settings limit exact reproduction and cross-method comparison. Only quantities with reproducible definitions are reported. A complete data record should include the missing metadata, optimized coordinates, and representative input files.

Energy, Charge, and Desorption Descriptors

Adsorption energy was defined as Eads = Ecomplex - Eeugenol(opt) - EZnBPNT(opt), so negative values indicate stabilization relative to the separately optimized fragments. Interaction energy was evaluated with each fragment frozen in its geometry within the complex: Eint = Ecomplex - Eeugenol(in complex) - EZnBPNT(in complex). The deformation penalty is Edef = Eads - Eint and is positive when fragment distortion costs energy. The tabulated identity Eads = Eint + Edef is satisfied within rounding for all six structures. Zero-point-corrected values and thermal free energies supplied by the harmonic calculations were used for the comparison. Because the frequency treatment and concentration convention are undocumented, the association free energies are method- and standard-state-sensitive. No additional 1 atm-to-1 M correction was applied.
Fragment charge transfer was taken from the reported population analysis as the electron transfer from eugenol to ZnBPNT. Because the population scheme was not retained in the computational metadata, these values are used to compare trends only. A screening desorption time was calculated from $\tau = \nu_0^{-1} \exp(|E_{ads,ZPE}|/RT)$, with T = 298.15 K and $\nu_0 = 10^{12}$ s^{-1}; this equation reproduces the tabulated values exactly. It assumes that the desorption barrier equals the magnitude of the ZPE-corrected adsorption energy and therefore is not a calculated kinetic barrier. In solution it omits diffusion, explicit solvent exchange, and competitive hydration.

Wavefunction, DOS, and Nonlinear-Optical Analyses

HOMO and LUMO energies and isosurfaces were examined for isolated eugenol, ZnBPNT, and C1-C3. Broadened TDOS, PDOS, and OPDOS curves were generated with Multiwfn 3.8. The spectra contain fragment-resolved contributions, but the complete atom-to-fragment mapping, broadening function, normalization, and energy reference were unavailable. The curves are therefore used only to assess aggregate state redistribution; specific adsorbate-framework-Zn assignments are not made. Positive and negative OPDOS features were interpreted conventionally as bonding and antibonding contributions at the corresponding orbital energies. Because a finite cluster has discrete levels, the curves visualize state mixing; the vertical reference is not a periodic-material Fermi level.
Electrostatic-potential, QTAIM, and RDG/NCI analyses were evaluated from the optimized wavefunctions. QTAIM interpretation used ρ, the $\nabla^2\rho$, and the total energy density H at an identified interaction critical point. Only gas-phase C1 and C2 critical-point values whose identity and numerical scale were internally consistent were retained. The aqueous C1 entry was excluded because its density, Laplacian, ELF, and $\mathrm{sign}(\lambda_2)\rho$ corresponded to a covalent intramolecular critical point and lay outside the displayed NCI range, indicating a mismatched critical-point assignment.
The molecular dipole magnitude, mean polarizability, polarizability anisotropy, and total first hyperpolarizability were obtained from the calculated response tensors. Polarizabilities are reported in 10^{-24} esu and β in 10^{-30} esu. Additional ΔQ and Q_off columns were excluded because their values are not electron-transfer charges and no reproducible definition was

available. Static molecular β values are treated as comparative response descriptors, not as bulk second-order susceptibility or an experimentally demonstrated optical switching signal.

RESULTS AND DISCUSSION

Geometry, Vibrational Minima, and Charge Redistribution

The optimized structures are summarized in Fig. 1 and the principal contacts in Table 1. In the gas phase, C1 and C2 form nearly equal Zn⋯O separations of 2.116 and 2.118 Å, respectively. C3 has a longer 2.699 Å Zn-to-phenyl-center distance, as expected for a spatially distributed aromatic contact. Water changes the contacts only modestly: C1 lengthens by 0.026 Å, C2 shortens by 0.002 Å, and C3 shortens by 0.048 Å. Geometry therefore establishes that both oxygen sites can approach Zn locally, but it cannot by itself rank methoxy versus hydroxyl adsorption.

The listed lowest-frequency values are positive and range from 4.05 to 15.33, but their units and frequency treatment were not retained. If they are wavenumbers in cm^{-1}, they correspond to very soft motions for which rigid-rotor/harmonic-oscillator entropies are especially sensitive. Free energies should therefore be compared more cautiously than electronic or ZPE-corrected energies. In addition, the presence of a reported local minimum does not prove global stability: alternative rotations, edge contacts, and adsorption sites were not sampled systematically.

Net charge transfer from eugenol to ZnBPNT is 0.1383, 0.1137, and 0.1447 e for gas-phase C1-C3. The corresponding water values rise to 0.1474, 0.1215, and 0.1620 e. C3 therefore gives the largest fragment charge displacement despite its longer geometric contact. This is chemically plausible for a delocalized phenyl interaction, but the trend should not be equated with a stronger localized bond. C2 gives the smallest transfer in both media, showing that the phenolic oxygen can form a short contact without producing the largest whole-fragment electron redistribution.

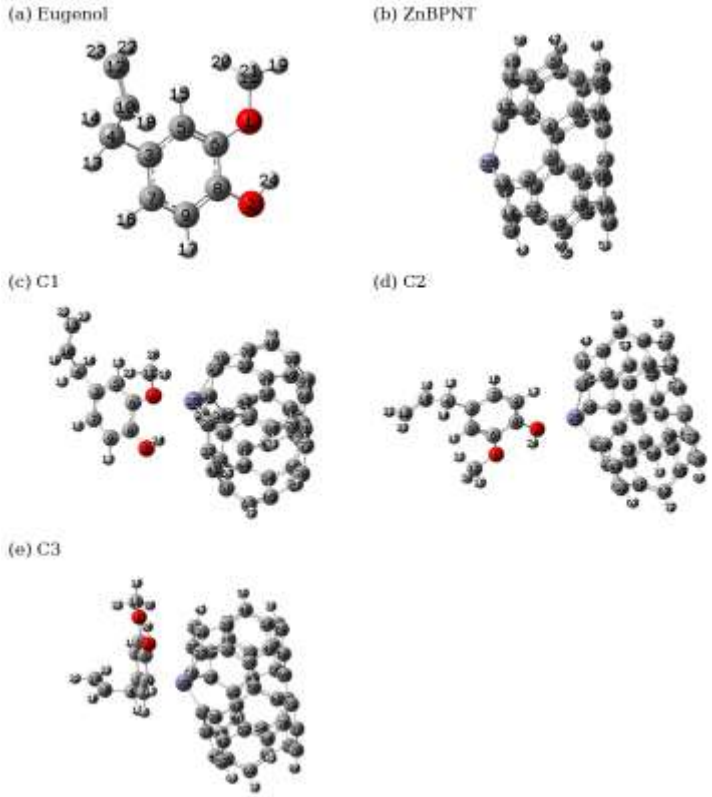

Fig. 1: Optimized gas-phase structures: (a) eugenol, (b) ZnBPNT, (c) methoxy-directed C1, (d) hydroxyl-directed C2, and (e) phenyl-directed C3. Atom numbers follow the optimized models.

Table 1: Principal contacts, reported fragment charge transfer to ZnBPNT, and screening desorption-time estimates at 298.15 K. O1 is methoxy oxygen and O2 is phenolic oxygen.

Motif	Medium	Contact (Å)	q to ZnBPNT (e)	τ (s)
C1, O1···Zn	Gas	2.116	0.1383	5.41×10^{2}
C2, O2···Zn	Gas	2.118	0.1137	2.84×10^{-2}
C3, ring···Zn	Gas	2.699	0.1447	3.73×10^{2}
C1, O1···Zn	Water	2.142	0.1474	4.46×10^{-4}
C2, O2···Zn	Water	2.116	0.1215	1.59×10^{-8}
C3, ring···Zn	Water	2.651	0.1620	1.76×10^{-4}

The screening desorption times span many orders of magnitude because of the exponential energy dependence. Gas-phase estimates are 5.41×10^{2} s for C1, 2.84×10^{-2} s for C2, and 3.73×10^{2} s for C3; water-labelled estimates are far shorter. These numbers help compare the six calculations under one assumed prefactor, but they are not recovery times measured or obtained from transition states. In particular, using a continuum adsorption energy as a solution-phase desorption barrier ignores solvent reorganization and mass transport. They are therefore retained only as transparent screening descriptors.

Adsorption, Interaction, Deformation, and Free Energies

The energy decomposition in Table 2 changes the initial structural picture. Gas-phase ZPE-corrected adsorption energies are -20.10, -14.26, and -19.88 kcal mol^{-1} for C1-C3. C1 is nominally lowest, but its 0.22 kcal mol^{-1} separation from C3 is far below the expected uncertainty of the functional/basis model. The scientifically defensible interpretation is that the methoxy-directed and phenyl-directed minima are effectively co-preferred at this level, whereas hydroxyl-directed C2 is clearly less favorable by about 5.6-5.8 kcal mol^{-1}.

Table 2: Zero-point-corrected energy components and thermal association free energies (kcal mol^{-1}). Negative Eads and Eint denote stabilization; Edef is the positive deformation penalty.

Motif	Medium	Eads,ZPE	Eint,ZPE	Edef,ZPE	ΔGads
C1	Gas	-20.10	-22.90	2.80	-9.03
C2	Gas	-14.26	-21.56	7.30	-2.97
C3	Gas	-19.88	-22.88	3.00	-7.35
C1	Water	-11.80	-13.29	1.49	0.04
C2	Water	-5.73	-12.25	6.51	5.15
C3	Water	-11.25	-12.21	0.96	1.73

C1 and C3 also have essentially identical gas-phase interaction energies (-22.90 and -22.88 kcal mol^{-1}). Their adsorption difference arises from deformation costs of 2.80 and 3.00 kcal mol^{-1}. C2 still has a favorable interaction energy of -21.56 kcal mol^{-1}, but a 7.30 kcal mol^{-1} deformation penalty substantially weakens its net adsorption. This distinction resolves an apparent contradiction: similar 2.12 Å Zn···O distances in C1 and C2 do not imply similar

adsorption because the hydroxyl-directed geometry requires much greater reorganization of the fragments.

Thermal corrections preserve the gas-phase ranking. Association free energies are -9.03 kcal mol^{-1} for C1, -2.97 for C2, and -7.35 for C3. The less negative values relative to Eads,ZPE reflect the entropic cost of bringing two molecular fragments together. C1 remains nominally most favorable, followed by C3. Given low-frequency modes and the missing standard-state correction, however, the exact free-energy spacing should not be viewed as high-accuracy thermodynamics.

The implicit aqueous treatment weakens all ZPE-corrected adsorption energies to -11.80, -5.73, and -11.25 kcal mol^{-1}. C1 and C3 remain close, whereas C2 remains distinctly weaker. Interaction energies similarly decrease in magnitude to -13.29, -12.25, and -12.21 kcal mol^{-1}. The C3 deformation penalty falls to only 0.96 kcal mol^{-1}, indicating that its extended aromatic geometry accommodates the interaction with little distortion. C2 retains a large 6.51 kcal mol^{-1} penalty, again explaining why a short Zn···O2 distance is not sufficient for strong net adsorption.

Aqueous association free energies are 0.04, 5.15, and 1.73 kcal mol^{-1} for C1-C3. On the uncorrected continuum/RRHO convention reported here, C1 is approximately thermoneutral and C2/C3 are positive after thermal and entropic terms. Their signs must not be treated as protocol-independent, however. For a bimolecular association, changing from a 1 atm ideal-gas convention to 1 M at 298.15 K would shift ΔG by about -1.89 kcal mol^{-1}, enough to change the signs of C1 and C3 but not C2. Low-frequency entropy treatment can also move values on this scale. The robust conclusion is therefore that the aqueous estimates are substantially less favorable than the gas-phase values and are sensitive to standard state and RRHO treatment, not that spontaneous solution binding has been definitively excluded. Explicit hydration and conformational sampling would be needed to predict binding in solution.

Overall, the energetic results support two mechanistic regimes. C1 uses localized methoxy-O···Zn interaction and low deformation; C3 uses a broader aromatic contact with nearly identical intrinsic interaction and larger fragment charge transfer. C2 forms a geometrically short phenolic-O···Zn contact but pays a much larger deformation cost. Oxygen-centered attraction is qualitatively important, but the numerical results do not establish phenolic-OH adsorption as the strongest configuration. The nominal optimum is C1, and C1/C3 are effectively degenerate within method uncertainty.

Frontier Orbitals and Electrostatic Response

The gas-phase ZnBPNT HOMO is -5.032 eV; the corresponding LUMO is -2.584 eV and the molecular gap is 2.447 eV. Isolated eugenol has a much larger 8.041 eV gap. After adsorption, gas-phase gaps are 2.517, 2.629, and 2.472 eV for C1-C3. All three are slightly larger, not smaller, than that of bare ZnBPNT. C3 has the smallest gap among the complexes but increases the bare-cluster value by 0.0245 eV. C2 produces the largest increase, 0.1819 eV.

Table 3: Frontier molecular-orbital energies and HOMO-LUMO separations for isolated species and the three adsorption motifs.

System	Medium	HOMO (eV)	LUMO (eV)	Gap (eV)
Eugenol	Gas	-6.841	1.201	8.041
Eugenol	Water	-7.044	1.009	8.053
ZnBPNT	Gas	-5.032	-2.584	2.447
ZnBPNT	Water	-5.044	-2.449	2.595

System	Medium	HOMO (eV)	LUMO (eV)	Gap (eV)
C1	Gas	-4.877	-2.360	2.517
C1	Water	-5.056	-2.441	2.615
C2	Gas	-4.847	-2.218	2.629
C2	Water	-5.137	-2.380	2.757
C3	Gas	-4.797	-2.326	2.472
C3	Water	-5.022	-2.410	2.612

The same pattern holds in the aqueous calculations. The ZnBPNT gap is 2.595 eV, compared with 2.615, 2.757, and 2.612 eV for C1-C3. Thus adsorption changes the gap by about 0.02 eV for C1 and C3 and 0.16 eV for C2. These shifts demonstrate configuration-dependent orbital perturbation but do not support the earlier claim of adsorption-induced gap narrowing. Nor can they be translated directly into conductivity: the model is a finite molecule, Kohn-Sham eigenvalue differences are not quasiparticle gaps, and no electrode coupling or transport calculation was performed.

The orbital isosurfaces in Fig. 2 nevertheless show that adsorption redistributes frontier density across the coupled structure. The HOMO and LUMO remain largely associated with the extended ZnBPNT framework, while the eugenol orientation changes the local amplitude and degree of mixing. The larger C3 fragment charge transfer is consistent with electronic communication through the aromatic system even though its gap shift is small. C2's larger gap change coexists with its weaker adsorption, reinforcing that electronic perturbation and thermodynamic stability are distinct observables.

Electrostatic-potential surfaces locate negative potential around both eugenol oxygen atoms and a delocalized potential over the aromatic ring. The electron-rich methoxy oxygen faces the Zn region in C1, and the phenolic oxygen does so in C2. C3 instead aligns its π surface with the Zn-containing zone. These maps rationalize the three starting orientations but cannot quantify binding by themselves because the displayed colors depend on a chosen electron-density isosurface and potential scale. Their value is mechanistic: they identify complementary regions consistent with the optimized contacts and charge redistribution.

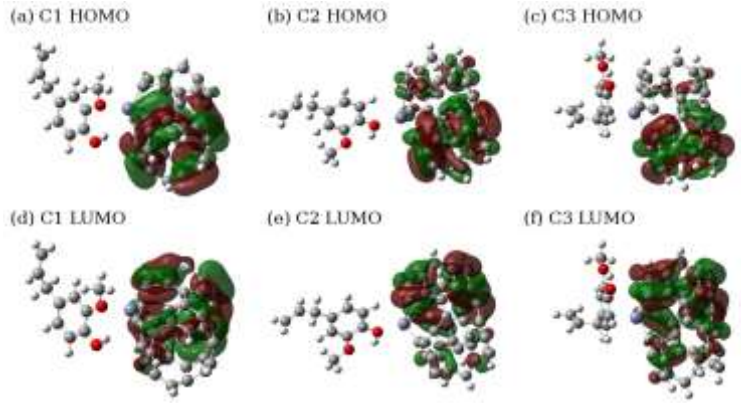

Fig. 2: Gas-phase HOMO and LUMO isosurfaces of C1-C3. Because the numerical isovalue was not retained, comparisons are qualitative.

Nonlinear-Optical Response Descriptors

The response properties in Table 4 are reported with corrected units. Gas-phase ZnBPNT has a dipole moment of 1.034 D, mean polarizability of 76.27 × 10^{-24} esu, anisotropy of 34.66 × 10^{-24} esu, and first hyperpolarizability of 79.94 × 10^{-30} esu. Eugenol is much less polarizable because of its smaller electron cloud. Complex polarizabilities cluster near 91-93 × 10^{-24} esu,

close to the additive scale expected from the two fragments. Adsorption therefore changes the spatial distribution of response more clearly than it produces a large superadditive polarizability.

Table 4: Static molecular response descriptors: dipole moment μ, mean polarizability α and anisotropy Δα (10^{-24} esu), and first hyperpolarizability β (10^{-30} esu).

System	Medium	μ (D)	α	Δα	β
Eugenol	Gas	1.022	15.95	10.54	3.05
Eugenol	Water	1.311	20.61	13.83	1.97
ZnBPNT	Gas	1.034	76.27	34.66	79.94
ZnBPNT	Water	2.146	139.21	56.56	289.05
C1	Gas	1.818	92.89	29.18	58.29
C1	Water	2.931	160.50	51.78	265.23
C2	Gas	2.397	90.78	28.25	43.63
C2	Water	2.833	149.23	53.87	184.55
C3	Gas	2.400	92.79	31.95	66.95
C3	Water	3.990	161.37	57.79	260.54

Among gas-phase complexes, dipole moments are 1.818, 2.397, and 2.400 D for C1-C3. Their β values are 58.29, 43.63, and 66.95 × 10^{-30} esu. C3 has the largest β of the three complexes, but it remains below the isolated ZnBPNT value. Thus a larger permanent dipole or fragment charge transfer does not guarantee a larger first hyperpolarizability. The tensor response depends on the directions and energy denominators of field-induced charge redistribution, not simply on static charge separation (Junqueira et al., 2016; Song and Wang, 2021; Tsapi et al., 2023).

The aqueous calculations produce much larger values: β is 265.23, 184.55, and 260.54 × 10^{-30} esu for C1-C3, and the isolated aqueous ZnBPNT value is 289.05 × 10^{-30} esu. Relative to ZnBPNT in the same environment, adsorption lowers β by about 8.2%, 36.2%, and 9.9% for C1-C3; the corresponding gas-phase decreases are about 27.1%, 45.4%, and 16.2%. Thus the large water-labelled numbers reflect solvent polarization, not an adsorption-induced enhancement over the bare substrate. Complex 3 also has the largest dipole moment (3.990 D), mean polarizability (161.37 × 10^{-24} esu), and anisotropy (57.79 × 10^{-24} esu). These static continuum values remain qualitative because diffuse functions are absent and the response is basis sensitive. Frequency dependence, orientation, aggregation, symmetry, and bulk susceptibility remain untested.

QTAIM and RDG/NCI Evidence

The internally consistent gas-phase QTAIM values are summarized in Table 5. At the selected C1 and C2 Zn···O critical points, ρ is 0.0562 and 0.0534 a.u., the Laplacian is positive (0.2595 and 0.2587 a.u.), and H is modestly negative (-0.0128 and -0.0105 a.u.). A positive Laplacian indicates local density depletion typical of a closed-shell interaction, while negative H indicates a stabilizing potential-energy contribution and some shared character. For a metal-oxygen contact, the combined pattern is better described as coordination-like or intermediate than as either a purely covalent bond or a weak van der Waals contact.

Table 5: Internally consistent gas-phase QTAIM descriptors at the selected Zn···O critical points. Aqueous values are excluded pending critical-point reassignment.

Descriptor (a.u.)	C1 gas	C2 gas
ρ at CP	0.056178	0.053387
$\nabla^2\rho$	0.259524	0.258729
G(r)	0.077697	0.075178
V(r)	-0.090513	-0.085674
H(r)	-0.012816	-0.010496
ELF	0.084840	0.077107

C1 has slightly larger ρ and a more negative H than C2, consistent with its lower deformation-corrected adsorption energy and larger fragment charge transfer. The differences are modest, so QTAIM supports rather than independently proves the energetic ranking. The aqueous C1 critical-point row was excluded because its ρ of 0.30004 a.u., negative Laplacian, ELF of 0.931, and sign(λ_2)ρ of -0.30004 are characteristic of a covalent bond critical point and are incompatible with the plotted NCI range and the 2.142 Å Zn···O contact. Interpreting that row as an intermolecular critical point would be scientifically unsafe.

The gas-phase RDG scatter plots in Fig. 3 show low-gradient features on the negative side of sign(λ_2)ρ for all three motifs, consistent with attractive interaction regions. They also contain near-zero features associated with dispersion and positive regions associated with steric crowding. Because only two-dimensional scatter plots are available, individual features cannot be assigned spatially to a particular Zn···O or aromatic contact; that assignment would require consistently scaled three-dimensional NCI isosurfaces. The plots therefore demonstrate the coexistence of interaction regimes but do not provide an adsorption energy or a unique bond classification (Johnson et al., 2010).

Taken together, geometry, energy decomposition, and real-space topology give a coherent picture. C1 forms a localized methoxy-O···Zn contact with favorable interaction and limited distortion. C2 forms a similar-distance phenolic-O···Zn contact, but the required geometry is costly. C3 gains comparable intrinsic stabilization from a more distributed aromatic contact. This multimodal interpretation is stronger than using an isolated critical-point value or the color of an NCI surface to rank configurations.

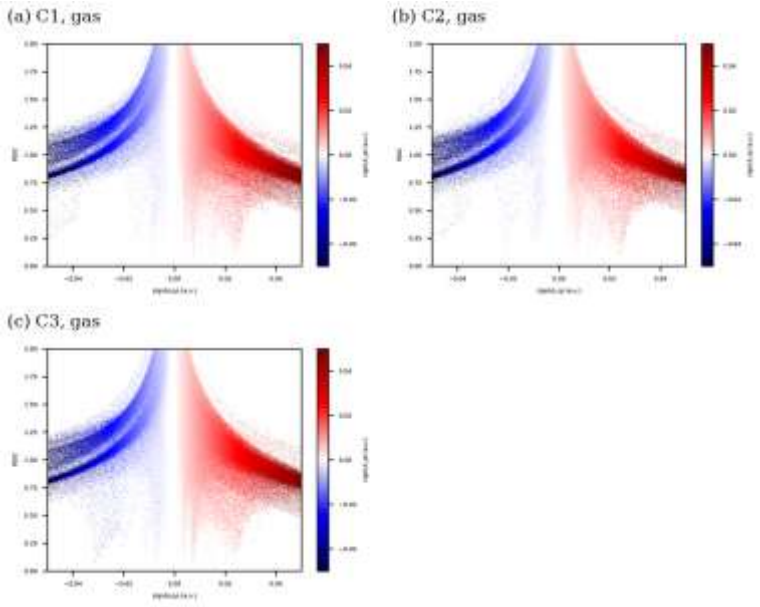

Fig. 3: Gas-phase RDG versus sign(λ_2)ρ plots for C1-C3. Blue/negative regions denote attractive interactions, near-zero regions weak dispersion, and red/positive regions steric repulsion.

TDOS, PDOS, OPDOS, and Implications for Sensing

The broadened TDOS/PDOS/OPDOS curves in Figs. 4-6 are qualitatively similar across the six complex-medium cases because the carbon framework supplies most molecular states. Multiple projected contributions overlap in occupied regions, indicating aggregate state mixing rather than an electronically isolated eugenol molecule. Because the complete atom-to-fragment mapping was unavailable, the curves are not used to assign a specific adsorbate-framework-Zn hybridization pathway. Their peak positions and heights also depend on the projection, broadening, and normalization and cannot rank adsorption energies quantitatively.

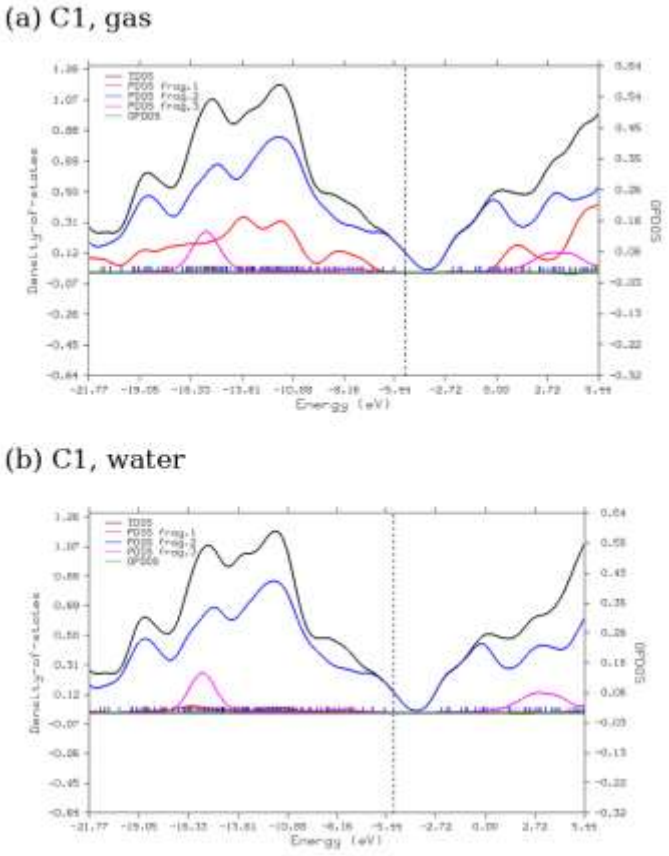

Fig. 4: TDOS, fragment-resolved PDOS, and OPDOS curves for C1 in (a) gas and (b) the water-labelled continuum calculation. Curves are broadened finite-cluster molecular-state distributions.

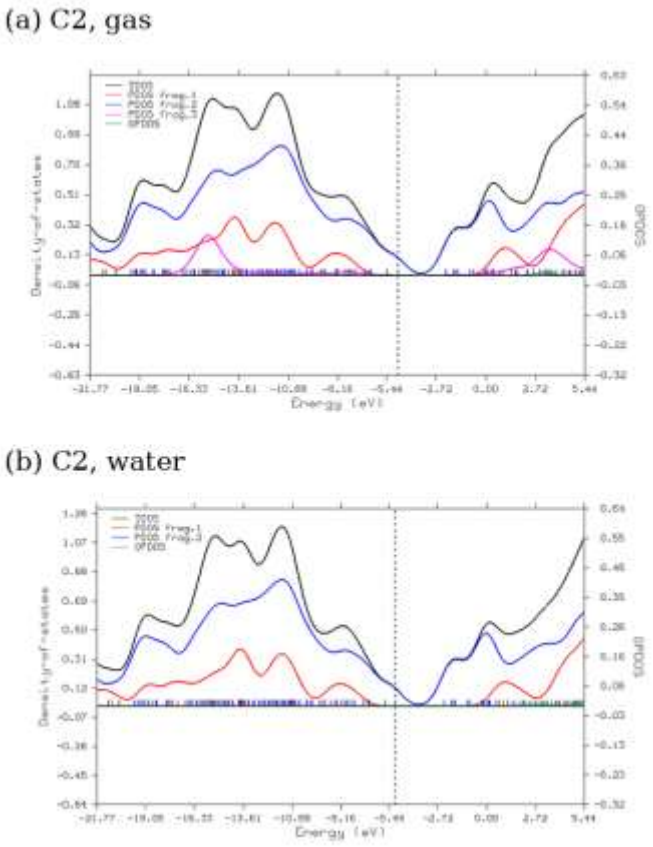

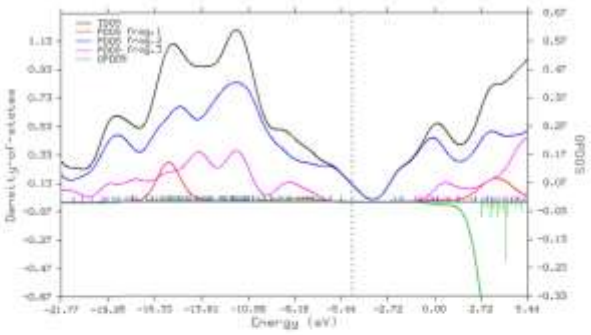

Fig. 5: TDOS, fragment-resolved PDOS, and OPDOS curves for C2 in (a) gas and (b) the water-labelled continuum calculation. Curves are broadened finite-cluster molecular-state distributions.

(a) C3, gas

(b) C3, water

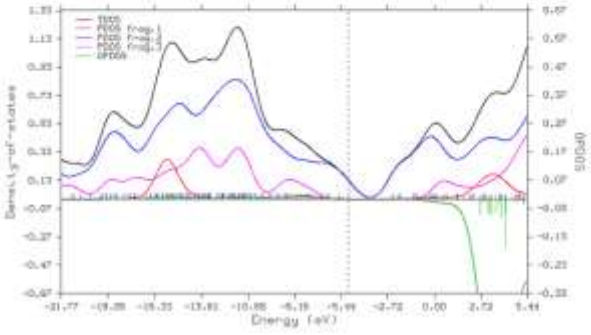

Fig. 6: TDOS, fragment-resolved PDOS, and OPDOS curves for C3 in (a) gas and (b) the water-labelled continuum calculation. Curves are broadened finite-cluster molecular-state distributions.

C3 also shows negative OPDOS features in the unoccupied region above roughly +2 eV relative to the plot reference. Negative OPDOS there denotes antibonding combinations among the selected fragments. Because these states are unoccupied in the ground state, their presence does not contradict the favorable C3 adsorption energy. It instead reflects the expected formation of bonding and antibonding combinations when molecular subsystems mix (Rangger et al., 2010). Ground-state stabilization must be assessed from occupied-state contributions and total energies.

Adsorption clearly perturbs several descriptors: fragment charges change by 0.11-0.16 e, dipoles and response tensors are configuration dependent, and frontier-state distributions mix. The gap shifts relative to bare ZnBPNT are nevertheless small for C1 and C3, and no current-voltage, transmission, selectivity, or competitive-adsorption calculation was performed. It is therefore appropriate to describe ZnBPNT as electronically responsive in this molecular model, not as a validated eugenol sensor. Experimental or transport-level confirmation would require a defined device geometry, electrode coupling, realistic coverage, competing analytes, humidity, and signal-to-noise assessment.

The carrier interpretation is similarly provisional. Favorable gas-phase adsorption and moderate interaction in an implicit medium suggest that Zn substitution can create recognition motifs, but the positive modeled aqueous association free energies show that spontaneous solution binding is not established. Drug-delivery use would additionally require loading capacity, desorption under physiological conditions, colloidal stability, toxicity, and biocompatibility. The

calculations identify hypotheses and relative interaction motifs; they do not replace these biological and materials tests.

Scope, Uncertainty, and Validation Priorities

Several limitations control the precision of the conclusions. The sampled adsorption landscape contains only three starting orientations; the finite model may exhibit edge effects; the basis is modest and uncorrected for BSSE; and the implicit-solvent protocol is incompletely specified. Low-frequency harmonic modes affect entropy, while a single optimized structure omits configurational averaging. Population charges and orbital energies are method dependent. These limitations do not erase robust trends such as the large C2 deformation penalty, but they prevent a 0.22 kcal mol^{-1} C1-C3 difference from being treated as chemical selectivity.

The next computational stage should verify model composition and charge/multiplicity, document the solvation keyword and standard state, perform counterpoise and larger-basis single points, rescan orientations, and use quasi-harmonic or ensemble free energies. Explicit water molecules around the oxygen and Zn sites would test competitive hydration. A complete QTAIM analysis must track the same atom pair and critical point across environments. Periodic or sufficiently extended models, followed by transport or work-function calculations, are needed before invoking conductivity-based sensing. These checks would convert the present descriptor study into a reproducible quantitative assessment.

CONCLUSION

A consistent reanalysis of the three optimized motifs shows that eugenol can engage the Zn-substituted biphenylene nanostructure through localized oxygen contacts or a distributed aromatic interaction. C1 (methoxy O1···Zn) and C3 (phenyl-directed) have virtually identical gas-phase intrinsic interaction energies and ZPE-corrected adsorption energies; their 0.22 kcal mol^{-1} difference is not significant at the present level. C2 (phenolic O2···Zn) forms an equally short contact but is weakened by a much larger deformation penalty. The aqueous continuum reduces binding magnitudes and yields standard-state- and RRHO-sensitive association free energies near zero or above on the reported convention.

Adsorption redistributes fragment charge and frontier density, but it increases rather than narrows the finite-cluster HOMO-LUMO gap. Corrected NLO units show strong solvent polarization without demonstrating a bulk optical response. Gas-phase QTAIM descriptors support coordination-like Zn···O contacts, while RDG and projected-state analyses reveal additional delocalized interactions. An anomalous aqueous critical-point assignment and undefined response columns were excluded rather than overinterpreted.

The defensible outcome is therefore a molecular-level screening result: Zn substitution creates multiple interaction motifs and measurable descriptor changes, with methoxy-directed and phenyl-directed structures co-competitive. Claims of selective sensing, aqueous capture, drug delivery, or device performance require larger-basis/BSSE validation, explicit-solvent sampling, verified topology, competing analytes, transport calculations, and experiment. This bounded interpretation preserves the useful mechanistic information while aligning the conclusions with the actual evidence.

ABSTRACT

The present study aimed to evaluate the gastroprotective activity of hydromethanolic bark extract of Pinus halepensis (PHE) using both in vivo and in silico approaches. Gastric ulcers were induced in albino Wistar rats using an HCl/Ethanol model. PHE was administered at 250, 500, and 1000 mg/kg, with omeprazole (20 mg/kg) as the reference drug. Molecular docking of twelve LC-MS/MS-identified compounds was conducted against the gastric proton pump (H^+/K^+-ATPase). 3D structures of the ligands were sourced from PubChem, and the crystallographic structure of the gastric proton pump was obtained from the Protein Data Bank (PDB ID: 5YLU). Docking simulations were conducted using FlexX software. A clear dose-dependent effect was observed, with inhibition rates reaching 33.91 ± 1.02%, 51.08 ± 4.73%, and 62.04 ± 2.73% for the 250, 500, and 1000 mg/kg doses, respectively. The UI decreased from 70.37 ± 4.2 in the control group to 46.46 ± 0.72 (250 mg/kg), 34.55 ± 3.33 (500 mg/kg), and 26.73 ± 1.92 (1000 mg/kg). At the highest dose (1000 mg/kg). Macroscopic examination of the gastric mucosa demonstrated that pretreatment with PHE at the highest dose (1000 mg/kg) resulted in near-complete restoration of mucosal integrity compared to the untreated control group. Docking simulations of identified compounds against H^+/K^+-ATPase highlighted quercetin (−26.74 KJ/mol) and catechin (−25.95 KJ/mol) as the most promising candidates, both surpassing omeprazole (−18.49 KJ/mol) in binding affinity. Molecular interaction analysis revealed that the best compounds established multiple stabilizing contacts within the active site of H^+/K^+-ATPase. These findings suggest that *Pinus halepensis* bark extract possesses potent gastroprotective properties, likely mediated by the antisecretory activity of its flavonoid constituents, highlighting PHE as a promising candidate for future anti-ulcer therapeutic development.

Keywords: *Pinus halepensis*, gastroprotective effect, ulcer index, molecular docking, gastric proton pump.

INTRODUCTION

Gastric ulcers remain a major global health concern, resulting from an imbalance between aggressive factors and gastric mucosal defenses. Although conventional treatments are available, their side effects and increasing drug resistance highlight the need for safer alternatives (Chitapanarux et al., 2023). Medicinal plants are promising sources of bioactive compounds with antioxidant, anti-inflammatory, and gastroprotective properties (Aman et al., 2025). *Pinus halepensis* is traditionally recognized for its biological activities related to oxidative stress and tissue protection, suggesting potential gastroprotective effects. Therefore, this study aimed to evaluate the gastroprotective activity of *P. halepensis* extract and investigate its possible mechanisms using complementary *in vivo* and *in silico* approaches.

MATERIAL AND METHOD

Plant material

The plant material was collected in June 2023 from Djbel El Ouahch forest, Constantine, eastern Algeria, identified, and dried under appropriate conditions prior to extraction.

Extraction

The hydroalcoholic extract of *Pinus halepensis* (PHE) was obtained by maceration using a methanol/water mixture (70/30, *v/v*) (Boudebbaz et al., 2025).

In vivo anti-ulcer activity

Healthy *Wistar* rats were fasted for 48 h, and acute gastric ulcers were induced using HCl/ethanol (80/20) (Zeghad et al., 2026). Animals received *Pinus halepensis* extract (0.25–1.00 g/kg) or omeprazole (0.02 g/kg). Gastric lesions were assessed using ImageJ, and the ulcer index and gastroprotection were calculated (Kim et al., 2020).

In silico molecular docking against the gastric proton pump

Molecular docking was performed to evaluate the interactions of LC-MS/MS-identified *Pinus halepensis* phytoconstituents with gastric H^+/K^+-ATPase (PDB ID: 5YLU). Ligand structures were obtained from PubChem, and omeprazole was used as the reference compound. Docking simulations were performed using LeadIT v2.1.8, and binding affinities were expressed as ΔG (kJ/mol) (Hioual et al., 2014).

RESULTS AND DISCUSSION

In Vivo Anti-Ulcer Activity

The results of the anti-ulcer activity summarized in Table 1, demonstrate a clear dose-dependent gastroprotective effect of PHE across the three tested doses (0.25, 0.50, and 1.00 g/kg body weight), and surpassing the reference drug at both 0.50 g/kg and 1.00 g/kg. The gastric mucosal protective effect of PHE may be primarily attributed to its phenolic compounds, which are known for their significant anti-ulcerogenic activity and ability to protect the gastric mucosa (Boudebbaz et al., 2025; Bakry et al., 2023).

Table 1. Effects of *Pinus halepensis* bark extract on ulcer index, ulcer inhibition in HCl/ethanol-induced gastric ulcerated rats.

Animal's group	Ulcer index	Inhibition (%)
Normal group	-	-
Control group	70.37 ± 4.2^{d}	0.00^{a}
Standard (Omeprazol 0.02 g/kg)	43.35 ± 2.16^{c}	38.57 ± 3.18^{b}
PHE 0.25 g/kg	46.46 ± 0.72^{a}	33.91 ± 1.02^{a}
PHE 0.50 g/kg	34.55 ± 3.33^{a}	51.08 ± 4.73^{a}
PHE 1.00 g/kg	26.73 ± 1.92^{a}	62.04 ± 2.73^{a}

PHE: *Pinus halepensis* extract. Values are expressed as Mean ± SD (n=6). Analysis of variance (ANOVA one-factor and Tukey Tests) revealed statistical difference ($P<0.05$). Different superscripts (a, b, c...) for values in the same columns are statistically different.

In silico molecular docking against the gastric proton pump

Molecular docking was performed to investigate the interaction of Catechin, Quercetin, Naringenin, and Luteolin with gastric H^+/K^+-ATPase (PDB ID: 5YLU), using omeprazole as the reference inhibitor. Binding affinities are presented in Table 2.

Table 2. Scoring functions of the phytoconstituents from *P. halepensis* docked to the gastric proton pump

Compounds	**Gastric Proton Pump (5YLU)**
	Scoring Function (KJ/mol)
Omeprazol	-18.4919
Catechin	-25.9543
Quercetin	-26.7423
Naringenin	-22.8859
Luteolin	-23.1306

Quercetin (−26.7423 KJ/mol) showed the strongest binding affinity, followed by Catechin (−25.9543 KJ/mol), with both displaying more favorable scores than Omeprazole (−18.4919 KJ/mol). Luteolin and Naringenin (−23.1306 KJ/mol and −22.8859 KJ/mol, respectively) also showed favorable interactions with H^+/K^+-ATPase. These affinities may be related to their hydroxyl groups and aromatic rings, which promote hydrogen-bonding and hydrophobic interactions (Shahidi & Dissanayaka, 2023; Lešnik et al., 2025). Overall, the findings support the potential contribution of these polyphenols to gastroprotection through proton pump inhibition.

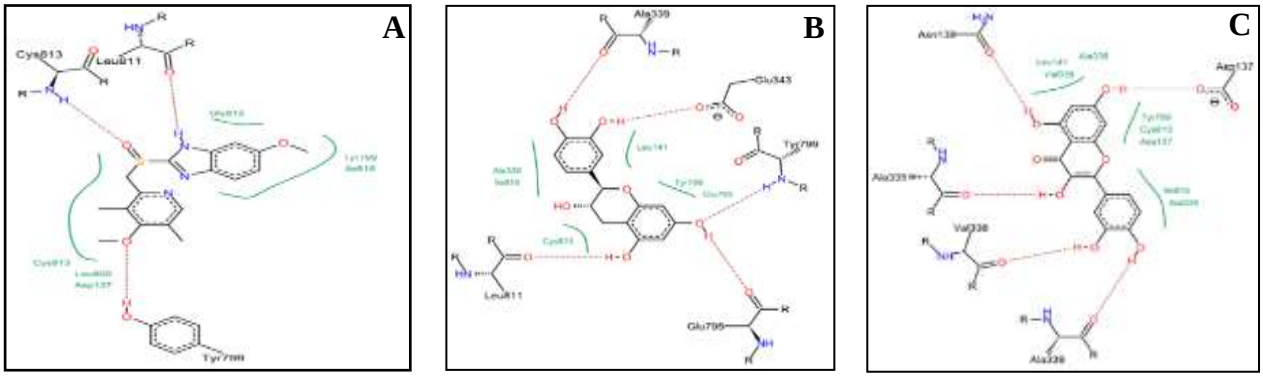

Figure 1. Binding interactions of omeprazole (A), catechin (B), and quercetin (C) within the gastric H^+/K^+-ATPase active site. Hydrogen bonds are represented by purple dashed lines, and hydrophobic interactions are highlighted in green.

CONCLUSIONS

Pinus halepensis shows promising gastroprotective potential due to its bioactive compounds with antisecretory properties. Combining *in vivo* experiments and *in silico* analyses suggests that this plant may help protect the gastric mucosa and act on key molecular targets involved in ulcer formation. These findings support further studies to validate its use as a natural anti-ulcer agent.

ANALYSIS OF SPECIES DIVERSITY AND DISTRIBUTION PATTERNS OF THE APIACEAE FAMILY IN THE NAKHCHIVAN AUTONOMOUS REPUBLIC

Novruzi Nurlana[1]
[1]Nakhchivan Teachers İnstitution
Nakhchivan AR, Azerbaijan
E-mail: nnurlana91@mail.ru

ABSTRACT

The present study provides a comprehensive analysis of the species diversity, distribution patterns, ecological characteristics, and phytochemical potential of the Apiaceae family in the Nakhchivan Autonomous Republic. The family is represented by 57 genera and 107 species, making it one of the most species-rich plant groups within the regional flora and an important component of local biodiversity. Particular attention is given to rare and endangered taxa, especially *Prangos acaulis* (DC.) Bornm., which is included in the Red Book of Azerbaijan and plays a significant role in the conservation of regional plant diversity. The study integrates floristic, ecological, and recent pharmacological data to evaluate the biological and applied significance of this species. *P. acaulis* is characterized as a drought-tolerant xerophytic plant distributed mainly in mountainous and semi-arid environments, where it contributes to ecosystem stability, vegetation dynamics, and adaptation to arid climatic conditions. Phytochemical investigations reveal a diverse composition of bioactive compounds, including essential oils, flavonoids, coumarins, and terpenoids, with notable variation across different plant organs. These variations are closely related to environmental conditions and ecological factors. Recent studies (2023–2026) demonstrate that *P. acaulis* exhibits significant antibacterial, antifungal, antioxidant, anti-inflammatory, cytotoxic, and immunomodulatory activities, highlighting its potential for therapeutic applications.

Furthermore, the application of plant extracts in nanotechnology has shown enhanced bioactivity, improved bioavailability, and increased therapeutic efficiency, indicating promising prospects for pharmaceutical development and innovative drug design. Despite these advances, several research gaps remain, particularly regarding *in vivo* effects, toxicological evaluation, and dose–response relationships, which require further detailed investigation.

Overall, the findings emphasize the ecological importance and pharmacological potential of *P. acaulis*, as well as the urgent need for its conservation, rational utilization, and sustainable management within the region.

Keywords: Apiaceae; *Prangos acaulis*; biodiversity; Nakhchivan Autonomous Republic; phytochemistry; pharmacological activity; essential oils; antioxidant activity; conservation; nanotechnology

INTRODUCTION

Plants belonging to the Apiaceae (Umbelliferae) family are predominantly perennial, biennial, or annual herbaceous species, comprising approximately 300–450 genera and 3,700–4,000 species. The family is morphologically characterized by its distinctive umbel-type inflorescence, which represents one of its primary diagnostic features. Members of this family are typically aromatic and contain essential oils as well as various biologically active compounds. Owing to these properties, they are widely utilized both as food and in pharmacological applications. Notable representatives include vegetable species such

as *Daucus carota* and *Apium graveolens*, as well as spice and essential oil-bearing plants such as *Anethum graveolens*, *Coriandrum sativum*, *Cuminum cyminum*, and *Foeniculum vulgare*. Medicinal species within this family exhibit spasmolytic, antiseptic, and digestive-enhancing properties.

The family is geographically distributed across almost all continents. However, it exhibits its greatest species diversity in temperate climatic zones, particularly in the Mediterranean region, the Caucasus, and Central Asia, as well as in mountainous and semi-desert areas. In contrast, it is relatively less represented in tropical regions. Within the flora of the Nakhchivan Autonomous Republic, the Apiaceae family is among the most species-rich families, represented by 57 genera and 107 species.

Among the members of the Apiaceae family occurring in Azerbaijan, particularly within the flora of the Nakhchivan Autonomous Republic, several rare and endangered species included in the Red Book of the Republic of Azerbaijan can be identified. These include *Prangos acaulis* (DC.) Bornm., *Eryngium wanaturii* Woronow, *Ferula persica* Willd., *Ferula szowitsiana* DC., *Grammosciadium platycarpum* (Boiss. & Hausskn.) Schischk., *Stenotaenia macrocarpa* Freyn & Sint. ex Freyn, and *Zeravschania pauciradiata* (Tamamsch.) M. Pimen. These species possess significant scientific and ecological importance in terms of the conservation of regional biodiversity.

Prangos acaulis (DC.) Bornm. — a representative of the genus *Prangos* L. (Apiaceae), commonly known as stemless prangos, belongs to a genus comprising approximately 25 species distributed across the Mediterranean region, Asia Minor, Iran, Afghanistan, Central Asia, and Eastern India. Of these, six species occur in the Caucasus, five in Azerbaijan, and four species are recorded within the territory of the Nakhchivan Autonomous Republic. The conservation status of the species is classified as Lower Risk (LR) [Conservation Dependent (CD)]. In Azerbaijan, *P. acaulis* is distributed exclusively within the Nakhchivan Autonomous Republic. It occurs mainly in the lower and middle mountain belts, particularly in areas such as Ardic Mountain, Garagush Mountain, Daridagh, Agridagh, and Kotamdagh. The species grows on stony-gravelly, calcareous-clayey, and grassy slopes. Despite its relatively wide distribution within the region, its natural populations are steadily declining due to intensive harvesting by local populations as a food plant. The species reproduces by seeds.

Biological characteristics: *Prangos acaulis* (DC.) Bornm. is a perennial herb densely covered with curly hairs. The stem is surrounded at the base by remnants of old leaves, cylindrical in shape, and branched in the middle part into broad, shield-like structures, reaching a height of 15–40 cm. Basal leaves are long-petiolate with short, leathery sheaths; the leaf blade is generally triangular-ovate in outline and three- to four-times pinnately divided. Stem leaves are significantly smaller than basal leaves, sessile on the sheath, with upper leaves being simply pinnate and divided into numerous linear elongated segments (1–3 cm long). The inflorescence is an umbel with (4) 5–6 rays; umbellets and involucels contain 9–10 flowers, with central flowers often sterile. Involucral bracts are linear or lanceolate-linear and pubescent. Fruits are elongated, 12–18 mm long, with membranous, undulate wings and serrated margins. The species flowers in April–May and produces fruits in May–June. It is a xerophytic species with both nutritional and medicinal value. The species belongs to the Atropatenean floristic geographical element. The decline in population size and number is primarily associated with limiting ecological and zoogenic factors. In addition, intensive collection during spring represents a major constraint on natural regeneration. However, as the species is included in the Red Book of the Nakhchivan Autonomous Republic, conservation measures have been developed to ensure its protection and sustainable use. Given that its populations are relatively threatened, the habitats of this species within the Zangezur National Park and the Arpachay State Nature Reserve should be placed under strict monitoring.

Prangos acaulis, one of the rare representatives of the Apiaceae family, has recently attracted considerable attention due to its phytochemical and pharmacological properties. Contemporary studies indicate that this species contains a rich spectrum of bioactive compounds, including essential oils, flavonoids, coumarins, and terpenoids. Variations in chemical composition have been observed among different plant organs (leaves, flowers, and stems). In particular, α-pinene (~39%) predominates in the leaves, whereas limonene and other terpene compounds are more abundant in the flowers. These findings suggest that the species is sensitive to ecological factors, with its chemical profile varying depending on environmental conditions.

Recent studies (2023–2026) have demonstrated that *Prangos acaulis* possesses significant pharmacological potential. Extracts of the plant have been reported to exhibit antibacterial and antifungal activities, with pronounced efficacy against *Streptococcus mutans*, including the inhibition of biofilm formation. Moreover, the high content of phenolic compounds indicates strong antioxidant and anti-inflammatory properties, which are essential for cellular protection and the prevention of various diseases. Experimental investigations have revealed that plant extracts exert cytotoxic effects against HT-29 and MCF-7 cell lines, with these effects being further enhanced when formulated as chitosan-based nanoformulations. In addition, immunomodulatory properties of the species have been reported, suggesting its involvement in cytokine regulation and immune response modulation.

One of the emerging directions in contemporary research is the application of plant extracts in nanotechnology. This approach enhances the efficacy of bioactive compounds and enables the achievement of higher therapeutic effects at lower doses, which is considered promising for the future development of pharmaceutical formulations.

From an ecological perspective, *Prangos acaulis* is primarily distributed in mountainous and semi-arid regions and is characterized as a drought-tolerant species. Variations in the composition of its essential oils depending on climatic and soil conditions indicate its sensitivity to environmental factors. This feature makes the species a valuable indicator for studying climate–vegetation relationships.

Nevertheless, several gaps remain in the existing body of research. In particular, the effects of the species under *in vivo* conditions have not been sufficiently investigated, its toxicological profile has not been fully characterized, and dose–response relationships remain unclear. Furthermore, more detailed studies on its flavonoid composition and microelement content are required.

MATERIALS AND METHODS

The study was based on field investigations, herbarium analyses, and a comprehensive review of relevant scientific literature. Field surveys were conducted across different ecological zones of the Nakhchivan Autonomous Republic, including mountainous and semi-arid regions, to identify species distribution and habitat characteristics. Plant specimens were collected, identified, and classified according to standard taxonomic methods. Morphological and ecological characteristics of *Prangos acaulis* were examined in situ, and its distribution areas were recorded. In addition, data on phytochemical composition and pharmacological properties were obtained from recent scientific publications (2023–2026), focusing on essential oils, bioactive compounds, and biological activities such as antimicrobial, antioxidant, and cytotoxic effects.

RESULTS AND DISCUSSION

The results indicate that the Apiaceae family is widely represented in the Nakhchivan Autonomous Republic, with significant species diversity concentrated in mountainous and

semi-arid zones. Among the identified species, *Prangos acaulis* occupies a distinct ecological niche and demonstrates high adaptability to xerophytic conditions.

Morphological analysis shows that the species is a perennial herb with characteristic umbel inflorescences and well-developed reproductive structures. Its distribution is mainly associated with stony and calcareous soils in lower and middle mountain belts.

Phytochemical studies confirm that *P. acaulis* contains a rich composition of essential oils, flavonoids, coumarins, and terpenoids. The variation in chemical composition among plant organs indicates its sensitivity to environmental conditions. Pharmacological investigations reveal significant antibacterial, antifungal, antioxidant, anti-inflammatory, cytotoxic, and immunomodulatory activities.

Recent advances in nanotechnology have further enhanced the therapeutic potential of plant extracts, demonstrating improved efficacy at lower concentrations. However, insufficient *in vivo* studies and limited toxicological data remain key limitations in the current research.

CONCLUSION

The Apiaceae family plays a significant role in the flora of the Nakhchivan Autonomous Republic, contributing to regional biodiversity and ecological stability. *Prangos acaulis*, as a rare and endangered species, possesses considerable ecological and pharmacological importance. The study highlights its rich phytochemical composition and diverse biological activities, indicating strong potential for future pharmaceutical applications. At the same time, the species is under threat due to environmental pressures and overharvesting, necessitating effective conservation measures. Further research is required to investigate its *in vivo* effects, toxicological properties, and dose–response relationships. The integration of modern approaches, including nanotechnology, may provide new opportunities for the sustainable use and application of this species.

ABSTRACT

The genus *Phlomis* L. (Lamiaceae), colloquially known in Anatolia as "ballık otu," "çalba," "şalba," or "calba," has widespread traditional uses ranging from herbal teas to wound-healing, analgesic, and tonic applications. In this study, *Phlomis pungens* Willd. (Syn: *P. herba-venti L. subsp. pungens* (Willd.) Maire ex De Filipps), naturally distributed around Eskişehir, was evaluated from a botanical perspective. The morphological and anatomical features of the species were characterized using light microscopy to establish diagnostic criteria for accurate taxonomic identification.

Morphological measurements revealed that *P. pungens* is a perennial herb reaching 55 cm in height and 0.3–0.5 cm in stem diameter, with a quadrangular stem covered by dense stellate-tomentose hairs. Cauline leaves are simple to occasionally lobed, arranged in a decussate pattern, measuring 2.5–14.7 × 0.3–4.8 cm. The inflorescence comprises up to 40 verticillasters, with each cluster bearing 3 to 11 zygomorphic, bilabiate flowers supported by linear-subulate bracts. The 5-toothed actinomorphic calyx measures 8–11 × 3–5 mm, and the pink-to-purple corolla lobes measure 8–11 × 4–9 mm with four epipetalous stamens. Anatomical analyses demonstrated angular collenchyma in stem corners, a dorsiventral leaf mesophyll, sinuous anticlinal epidermal cell walls, and diacytic stomata on both leaf surfaces accompanied by characteristic multicellular stellate and dendroid non-glandular trichomes.

Providing robust morphological and anatomical data for this traditionally utilized species is of significant importance. These findings will not only facilitate accurate taxonomic identification and ensure safe therapeutic use but will also serve as a foundational reference for future pharmacological and phytochemical research.

Keywords: *Phlomis pungens*, anatomy, morphology, diagnostic characters.

INTRODUCTION

Due to its geographical location, climatic diversity, and soil structure, Türkiye ranks among the richest countries globally in terms of floristic diversity, situated at the intersection of three phytogeographies: European-Siberian, Mediterranean, and Iran-Turanian (Tekin, 2025).
Within this diverse flora Lamiaceae is the third largest family in Türkiye, represented by 574 species of annual or perennial herbs and shrubs distributed across the Mediterranean Region and Northern Hemisphere. Members of this family possess substantial economic, pharmacological, and industrial importance owing to their characteristic essential oils, aromatic constituents, and therapeutic properties (Üren, 2015; Adawe, 2021). Members of Lamiaceae are globally widespread, occurring in all continents except polar regions, with significant

concentration in temperate zones such as Southwest Asia and South America (Tahravi, 2021). Taxonomically, the family is distinguished by quadrangular stems, opposite or decussate exstipulate leaves, and zygomorphic, bilabiate flowers bearing four epipetalous stamens and a bicarpellary, four-lobed superior ovary with a gynobasic style yielding four nutlets (Üren, 2015; Adawe, 2021). The presence of specialized glandular trichomes secreting essential oils and phenolic compounds imparts substantial economic, pharmacological, and cosmetic value to the family, underpinning its extensive application in perfumery, food, flavoring, and traditional phytotherapy (Tahravi, 2021; Korkmaz, 2022).

Within Lamiaceae, the genus *Phlomis* L. occupies an important taxonomic and ethnomedicinal position. According to the Flora of Turkey, this genus is represented by a total of 44 species and 9 varieties, 10 of which are hybrids. In the List of Vascular Plants of Turkey, the genus Phlomis is recorded as 46 species and 11 varieties, 13 of which are hybrid species (Tekin, 2025). Morphologically, *Phlomis* taxa are perennial herbs or subshrubs characterized by a softly villous, stellate, or dendroid indumentum, simple leaves with entire to crenate-dentate margins, and axillary verticillasters subtended by distinct bracts (Üren, 2015; Adawe, 2021). Their adaptation to arid, rocky, and calcareous habitats reflects high ecological tolerance and xerophytic specialization (Tekin, 2025). Etymologically, the generic name *Phlomis* is derived from the Ancient Greek word “phlox” (meaning "flame," referring to the historical use of its woolly leaves as lamp wicks), while the specific epithet “pungens” translates to "piercing" or "puncturing," denoting its sharp calyx teeth (Ceylan, 2026).

Known colloquially in Anatolia as "ballık otu," "çalba," "şalba," or "calba," *Phlomis* taxa have extensive ethnobotanical applications, commonly utilized as herbal teas and traditional remedies for their wound-healing, analgesic, anti-inflammatory, and tonic effects.

Herbal infusions prepared from their flowering aerial parts are used to relieve gastrointestinal disorders and support liver, kidney, and cardiovascular health. In addition, they are folkly used to treat diabetes, stomach ulcers, hemorrhoids, inflammation, and wounds. (Arıca and Fırat, 2026).

Phlomis pungens Willd. (*Synonyms: Phlomis herba-venti* var. *pungens* (Willd.) Schmalh., *Phlomitis pungens* (Willd.) Rchb. ex T.Nees, *P. herba-venti* L. subsp. *pungens* (Willd.) Maire ex De Filipps) is an important representative of this genus, distributed naturally across Central Anatolia, including the Eskişehir province.

Despite the widespread therapeutic usage of *Phlomis* species, interspecific morphological similarities and regional phenotypic variations frequently lead to taxonomic confusion and adulteration in commercial herbal raw materials. Micro-anatomical characters such as trichome morphology, stoma architecture, and vascular bundle organization serve as indispensable diagnostic markers for resolving taxonomic ambiguities and ensuring botanical quality control. Therefore, the present study was conducted to determine the detailed macromorphological and light microscopic anatomical characteristics of *Phlomis pungens* specimens collected from natural habitats around Eskişehir. By providing comprehensive structural and diagnostic criteria, this work aims to facilitate accurate species delimitation, ensure safe therapeutic utilization, and establish a reliable botanical baseline for subsequent phytochemical, pharmacological, and systematic evaluations.

MATERIAL AND METHOD

Plant specimens of *Phlomis pungens* were collected from natural populations in Central Anatolia: [B3] Eskişehir: Beylikova, 39°50'00" N, 31°11'37" E, 870 m, 21 June 2025. Voucher specimens were identified according to Davis’s *Flora of Turkey and the East Aegean Islands* and deposited in the Herbarium of the Faculty of Pharmacy, Anadolu University (ESSE 16734).

Morphological examinations were performed on 20 randomly selected individuals from the collected herbarium and fresh materials. Vegetative and floral characters were measured using millimetric paper. The measured parameters were tabulated and compared with taxonomic descriptions in *Flora of Turkey* and related literature. Macromorphological details of vegetative and reproductive organs (stems, leaves, bracts, and flowers) were photographed using an Olympus SZX12 stereomicroscope equipped with the Kameram® digital imaging software.
For anatomical evaluations, plant tissues (stems and leaves) fixed in 70% ethanol were used. Transverse sections of the mid-stem, leaf midrib, and lamina, as well as superficial sections of the adaxial and abaxial leaf epidermises, were obtained manually using the free-hand sectioning technique with commercial razor blades. The anatomical sections were examined using an Olympus BX51 light microscope equipped with an Olympus EP50 digital camera system. All anatomical layers, vascular organizations, stomatal types, and trichome indumentum were documented and scaled (μm).

RESULTS AND DISCUSSION

Morphological Characters

Phlomis pungens Willd. has a quadrangular stem covered with a stellate-tomentose indumentum, measuring 14–55 cm in height and 0.3–0.5 cm in diameter. The species typically produces 5 to 40 verticillasters, each containing more than 20 flowers. The leaf apex is acute, and the margins are crenate to serrate. The leaf base is cuneate or attenuate, tapering towards the petiole. The lamina exhibits pinnate-reticulate venation and is densely covered with stellate hairs. The leaves are 2.5–14.7 cm in length and 0.3–4.8 cm in width, while the corolla is 0.8–1.1 cm long and 0.4–0.9 cm wide. The corolla is purple-lilac, zygomorphic, bilabiate, and covered with stellate hairs. The calyx measures 0.8–1.1 cm in length and 0.3–0.5 cm in width. The leaves are generally simple, sometimes lobed, and arranged in a decussate pattern. The flowers are zygomorphic and bilabiate. The calyx is usually 5-toothed and actinomorphic, comprising three short and two long teeth, with distinct venation extending from the base to the teeth. The stamens are four in number, inserted into the corolla tube. The anthers are dithecal, consisting of two thecae housing the pollen sacs. The bracts are linear-subulate in shape, measuring 0.7–1.4 cm in length, and are covered with stellate or dendroid hairs forming a tomentose-villous indumentum (Figure 1).

Anatomical Characters

Stem Anatomy

The stem is typically quadrangular, a characteristic feature of the family. It is surrounded by a single-layered epidermis with a cutinized outer wall that serves as a protective layer. Multicellular stellate or dendroid non-glandular and glandular trichomes emerge from the epidermis. Beneath the epidermis lies the collenchyma tissue, which is distinctly thickened at the corners. The cortical parenchyma is situated between the collenchyma and the vascular cylinder. Immediately beneath the cortical parenchyma lies the central cylinder (stele). The vascular tissues are arranged sequentially inward as sclerenchyma, phloem, vascular cambium, and xylem. The innermost part of the stem is occupied by the pith region (Figure 2).

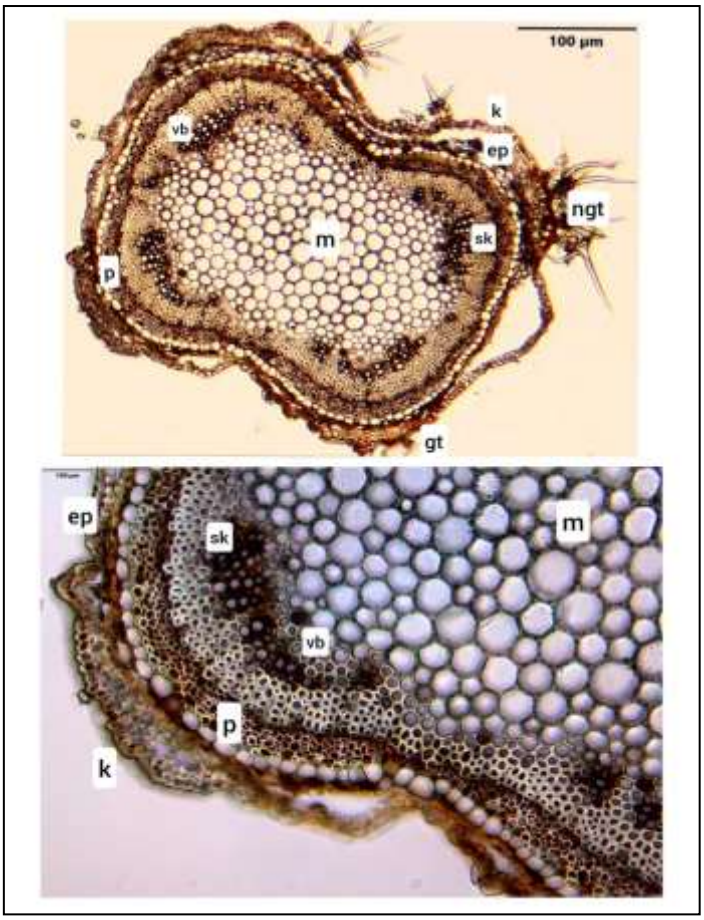

Figure 2. Light micrographs of *P. pungens* stem cross-sections. (ep: epidermis, k: collenchyma, p: parenchyma, sk: sclerenchyma, vb: vascular bundle, m: pith, ngt: non-glandular trichome, gt: glandular trichome; Scale bars = 100 µm).

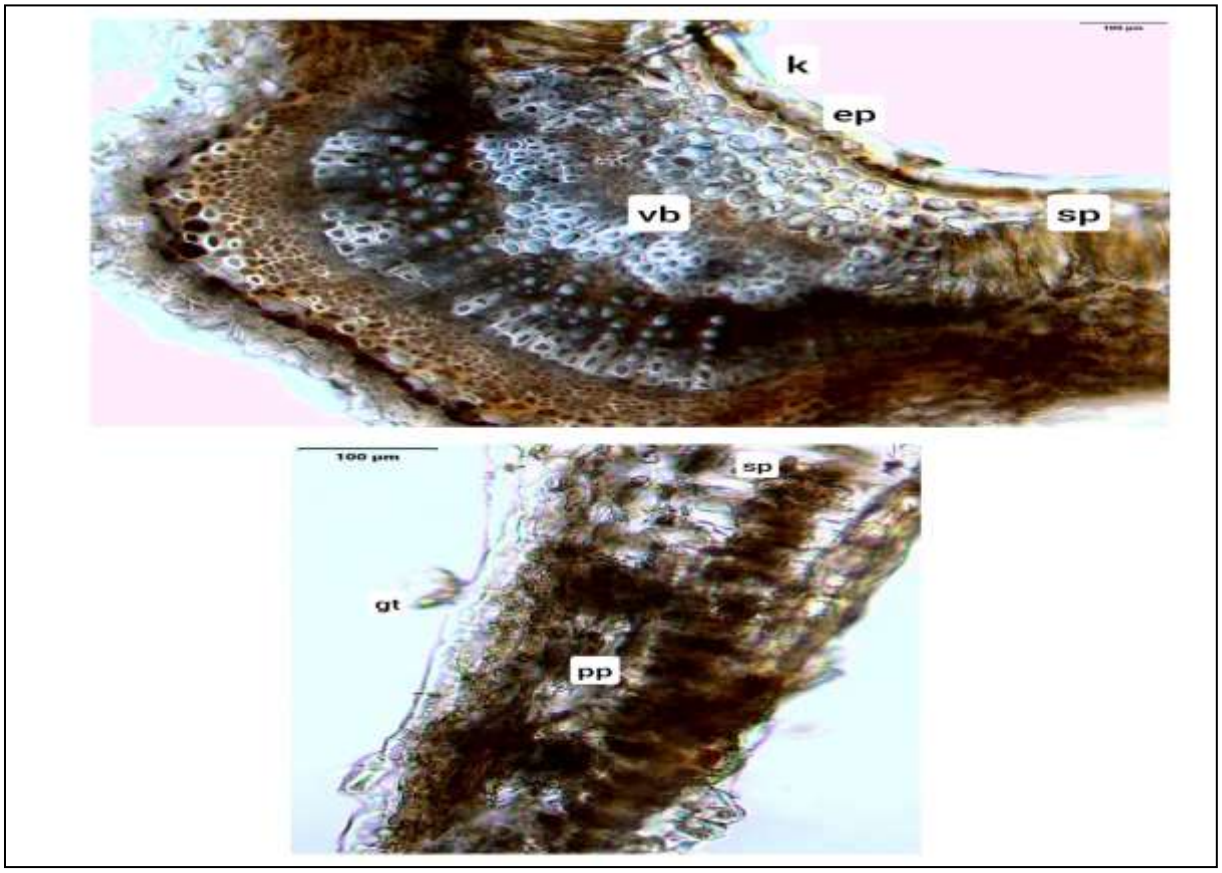
Leaf Cross-Section

The midrib is surrounded by a single-layered epidermis on both the adaxial (upper) and abaxial (lower) surfaces. Multicellular stellate and dendroid non-glandular trichomes emerge from the epidermis. Immediately beneath the epidermis lies the collenchyma tissue, characterized by its thickened cell walls. The vascular bundle is located in the innermost central region. Within the vascular bundle, the phloem is oriented toward the abaxial (lower) surface, whereas the xylem faces the adaxial (upper) surface. In the transition zone from the midrib to the lamina, the mesophyll layer becomes distinct. In this region, the palisade parenchyma is composed of cylindrical, longitudinally elongated cells (Figure 3).



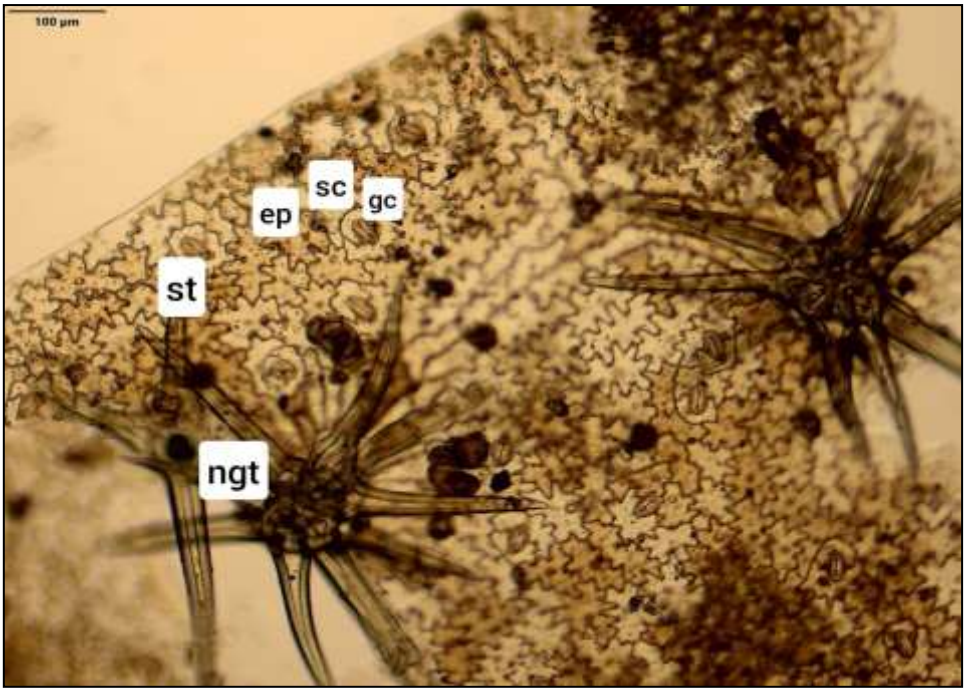


Figure 3. Light micrographs of *P. pungens* leaf cross-sections. (ep: epidermis, k: collenchyma, vb: vascular bundle, pp: palisade parenchyma, sp: spongy parenchyma, gt: glandular trichome; Scale bars = 100 µm).

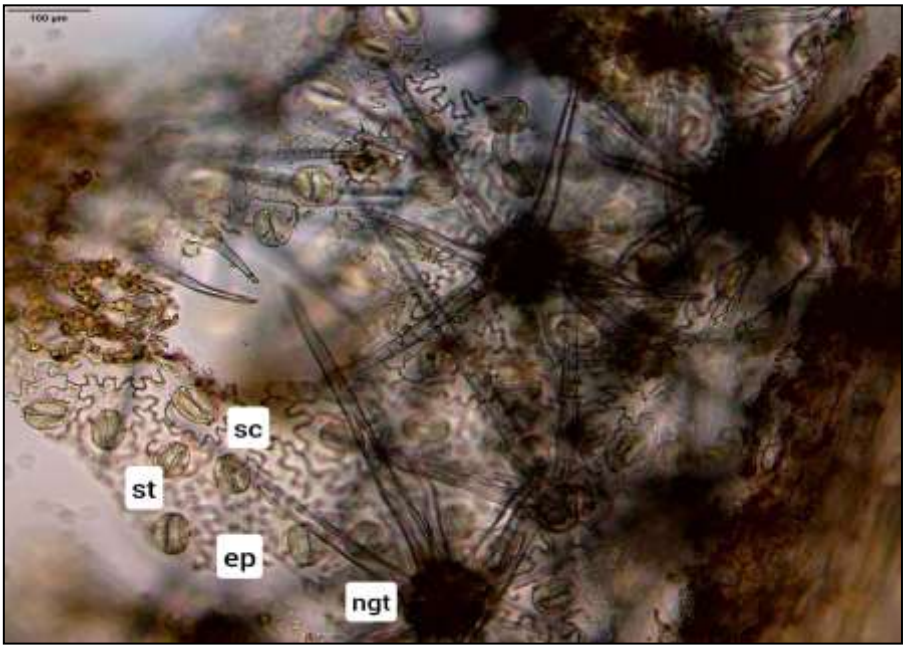
Leaf Adaxial Surface Section

The anticlinal walls of the epidermal cells are sinuous. The stomata are of the diacytic type, each enclosed by two guard cells. Additionally, multicellular stellate non-glandular trichomes are present, characterized by pointed apices, thickened cell walls, and bases embedded within the epidermis (Figure 4).

Figure 4.



Micrograph of leaf adaxial surface. (ep: epidermal cell, st: stoma, sc: subsidiary cell, gc: guard cell, ngt: non-glandular trichome; Scale bar = 100 µm).

Leaf Abaxial Surface Section

The anticlinal walls of the epidermal cells are sinuous, and diacytic stomata are present. The abaxial surface exhibits a denser indumentum compared to the adaxial surface. The non-glandular trichomes are stellate or dendroid in structure, with their basal portion emerging from the epidermis and extending into long, pointed arms (Figure 5).

Figure 5.

Micrograph of leaf abaxial surface showing denser indumentum. (ep: epidermal cell, st: stoma, sc: subsidiary cell, ngt: non-glandular trichome; Scale bar = 100 µm).

Trichomes

The multicellular stellate and dendroid non-glandular trichomes are characterized by long, pointed arms (Figure 6).

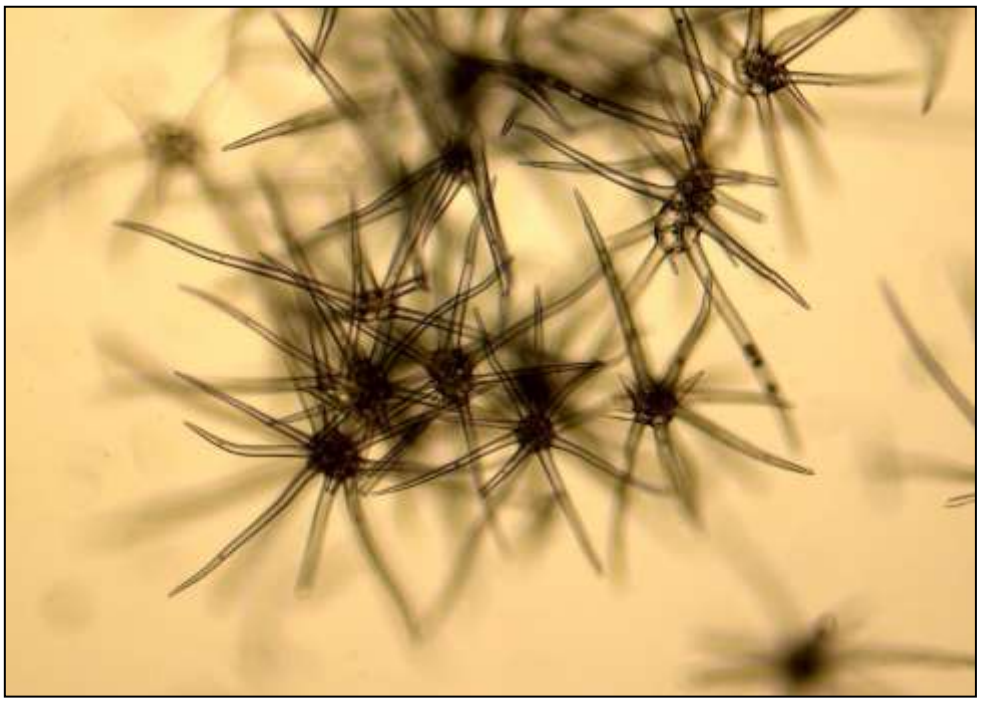


Figure 6. Multicellular stellate and dendroid non-glandular trichomes of *Phlomis pungens*

The morphological and anatomical results obtained in this study are broadly consistent with the available literature, with minor variations reflecting local population dynamics (Table 1). Specifically, Sarıkaya and Fakir (2016) reported leaf length as 2.2–11.5 cm, leaf width as 0.4–4.2 cm, and petiole length as 0.2–7.7 cm, whereas in the present study, these parameters were measured as 2.5–14.7 cm, 0.3–4.8 cm, and 0.2–7.2 cm, respectively. Similarly, while Davis (1982) documented a maximum plant height of up to 70 cm, the individuals examined herein reached a maximum height of 55 cm. In addition, Davis (1982) reported bract length as 1.1–1.7 cm and calyx length as 0.8–1.5 cm, while our measurements indicated ranges of 0.7–1.4 cm and 0.8–1.1 cm, respectively.

From an ecological and functional perspective, Tekin (2025) reported that *Phlomis* taxa typically inhabit arid and rocky terrains, conferring substantial environmental tolerance and adaptability. The specimens evaluated in this study were collected from the semi-arid steppe habitats of Eskişehir, where detailed micro-anatomical analyses revealed well-developed xeromorphic adaptations most notably a dense indumentum of thick-walled stellate/dendroid trichomes and angular collenchyma. These anatomical findings strongly corroborate the ecological observations of Tekin (2025), demonstrating the structural specialization of *P. pungens* to arid environments.

CONCLUSIONS

Phlomis is a taxon belonging to the Lamiaceae family, represented by 46 species in Türkiye. In this study, *P. pungens*, naturally distributed around Eskişehir, was evaluated from a botanical perspective. The species is characterized by quadrangular stems with dense stellate indumentum, decussate leaves (2.5–14.7 × 0.3–4.8 cm), and 5–40 verticillasters containing

bilabiate flowers with epipetalous stamens. Anatomically, the presence of angular collenchyma, dorsiventral mesophyll, sinuous epidermal anticlinal walls, and diacytic stomata on both leaf surfaces represents definitive diagnostic markers.

Based on the comparative literature review, *P. pungens* populations in and around Eskişehir possess a denser indumentum composed of thicker-walled stellate trichomes compared to populations growing in other regions. This dense indumentum serves as a critical ecophysiological adaptation to xerophytic conditions by reducing boundary layer wind velocity, minimizing transpiration, lowering UV radiation absorption, and providing physical defense against herbivorous insects.

Providing these comprehensive morpho-anatomical standards will ensure accurate taxonomic delimitation, support quality control for safe therapeutic use, and provide a solid baseline for future phytochemical research.

ABSTRACT

Evaluating soil nutrient availability together with plant nutrient concentrations provides a comprehensive understanding of crop nutritional status. Accordingly, this study aimed to assess the macro- and micronutrient status of wheat grown in the Narlı Plain of Kahramanmaraş, Türkiye. Soil samples were collected from a depth of 0–30 cm, and flag leaf samples were collected immediately before heading from 11 wheat-growing fields. Soil samples were analyzed for pH, calcium carbonate ($CaCO_3$) and organic matter contents, available phosphorus (Olsen-P), exchangeable potassium (K), calcium (Ca), and magnesium (Mg), and DTPA-extractable iron (Fe), zinc (Zn), copper (Cu), and manganese (Mn). Plant samples were analyzed for P, K, Ca, Mg, Fe, Zn, Cu, and Mn concentrations. The soils were slightly to moderately alkaline, with organic matter contents ranging from 2.13% to 4.50% and $CaCO_3$ contents ranging from 19.84% to 41.09%. Soil Olsen-P concentrations varied between 7.98 and 35.38 mg kg^{-1}, while the mean DTPA-extractable Fe, Zn, Cu, and Mn concentrations were 11.73, 1.05, 1.50, and 9.65 mg kg^{-1}, respectively. The mean exchangeable K, Ca, and Mg concentrations were 339.55, 3461, and 1145 mg kg^{-1}, respectively. The mean P, K, Ca, and Mg concentrations in wheat flag leaves were 0.28%, 2.60%, 0.80%, and 0.18%, respectively, whereas the mean Fe, Zn, Cu, and Mn concentrations were 97.93, 21.84, 6.75, and 40.41 mg kg^{-1}, respectively. The results showed that wheat grown in the Narlı Plain was generally adequately supplied with the macro- and micronutrients examined. However, the variation in soil and plant nutrient concentrations among the sampled fields suggests that wheat nutrient status may be influenced by differences in soil nutrient reserves, fertilizer management, and other soil properties. These findings highlight the importance of evaluating soil and plant analyses together when developing field-specific nutrient management strategies for wheat production in the region.

Keywords: Calcareous soil, flag leaf, mineral nutrition, wheat.

INTRODUCTION

Determining the mineral nutritional status of wheat grown in calcareous soils represents an important diagnostic challenge because soil nutrient reserves do not necessarily correspond to the availability of these nutrients to plants. High soil pH and $CaCO_3$ content may restrict nutrient uptake by roots by altering nutrient speciation in the soil solution, adsorption–desorption equilibria, and precipitation reactions. Therefore, the presence of an adequate reserve of a particular nutrient in the soil does not necessarily indicate that the nutrient can be taken up by plants in sufficient amounts (Hinsinger, 2001; Marschner, 2012; Xue et al., 2016). Recent studies conducted in calcareous soils have also demonstrated that these conditions may affect nutrient uptake and fertilizer-use efficiency in wheat (Martínez-Ríos et al., 2024; Zaheri Abdehvand et al., 2024; Demirkaya & Gülser, 2025).

In calcareous and alkaline soils, P may form sparingly soluble compounds with Ca or become immobilized through retention on $CaCO_3$ surfaces. Similarly, high pH and the presence of

carbonate and bicarbonate ions may reduce the solubility and root availability of Fe, Zn, Mn, and Cu. Zinc availability, in particular, is strongly influenced by interactions among soil pH, carbonate content, P status, organic matter, and clay minerals (Chen et al., 2019; Martínez-Ríos et al., 2024). Consequently, wheat grown in calcareous soils may exhibit marginal or latent nutrient deficiencies even in the absence of visible deficiency symptoms. However, the relationship between soil $CaCO_3$ content and plant nutritional status is not straightforward. Nutrient availability in the root zone is governed by the combined effects of soil pH and $CaCO_3$ content, as well as texture, organic matter, cation exchange capacity, soil moisture, and rhizosphere processes. Plant nutrient uptake may also vary depending on genotype, root-system characteristics, growth stage, fertilization history, and interactions among nutrients (White & Brown, 2010; Marschner, 2012). Therefore, $CaCO_3$ content alone may not provide an adequate basis for assessing plant nutritional status in calcareous soils.

Soil analyses provide information on the potential availability of nutrients and the nutrient-supplying capacity of the soil, whereas plant tissue analyses reflect the integrated outcome of soil–root processes as expressed in plant nutrient uptake. However, because elemental concentrations in plant tissues vary with the sampled organ and growth stage, the results should be interpreted using appropriate sampling times and established sufficiency ranges (Jones et al., 1991; Reuter & Robinson, 1997; Lemaire et al., 2019). Flag leaves collected immediately before heading constitute suitable diagnostic material for assessing the nutrient status of wheat. Accordingly, the combined use of soil and plant analyses enables a more comprehensive assessment of nutrient deficiencies and limitations to nutrient uptake.

The Narlı Plain, located south of Kahramanmaraş, is an important agricultural production area characterized by soils developed from alluvial and colluvial parent materials. Variations in topographic position and soil-forming conditions have resulted in considerable heterogeneity in the physical and chemical properties of the plain's soils (Yakupoğlu et al., 2012; Yakupoğlu & Demirci, 2013). Previous studies conducted in the region have shown that this variability is also reflected in soil pH, $CaCO_3$ content, and nutrient concentrations (Saltalı et al., 2018). Total and active $CaCO_3$ contents have also been reported to be associated with the availability of certain metallic micronutrients in the soils of the plain (Kadifeci et al., 2024). Nevertheless, field-based information on the extent to which soil nutrient levels are reflected in the nutritional status of wheat remains limited. Accordingly, this study aimed to determine selected physical and chemical properties of calcareous agricultural soils under wheat cultivation in the Narlı Plain and to evaluate the macro- and micronutrient status of wheat through combined soil and flag-leaf analyses. The relationships between soil $CaCO_3$ content and P, K, Ca, Mg, Fe, Zn, Cu, and Mn concentrations in wheat flag leaves were also investigated.

MATERIAL AND METHOD

Study area

The study was conducted in wheat-growing areas of the Narlı Plain, located within the administrative boundaries of Pazarcık district, Kahramanmaraş Province, southern Türkiye. Situated approximately 30 km southeast of Kahramanmaraş city center, the plain covers an area of approximately 26,500 ha and lies within a transitional zone between Mediterranean and continental climatic conditions (Saltalı et al., 2018).

The soils of the Narlı Plain have developed predominantly from alluvial and colluvial parent materials transported from the surrounding uplands and deposited across the plain. Variations in depositional environments and topographic positions have resulted in pronounced spatial variability in the physical and chemical properties of these soils (Yakupoğlu et al., 2012; Yakupoğlu & Demirci, 2013). The soils of the region have generally been characterized as neutral to slightly alkaline and as having varying $CaCO_3$ contents. Moreover, their total and

active $CaCO_3$ contents may influence the availability of metallic micronutrients (Kadifeci et al., 2024).

The study area comprised fields under wheat cultivation within the Narlı Plain. Eleven wheat-growing fields were selected to represent the spatial variability in soil properties and plant nutritional status across the plain. The geographical coordinates of the soil and flag-leaf sampling points were recorded during fieldwork. The location of the study area within Türkiye and Kahramanmaraş Province, together with the distribution of the sampling points across the Narlı Plain, is presented in Figure 1.

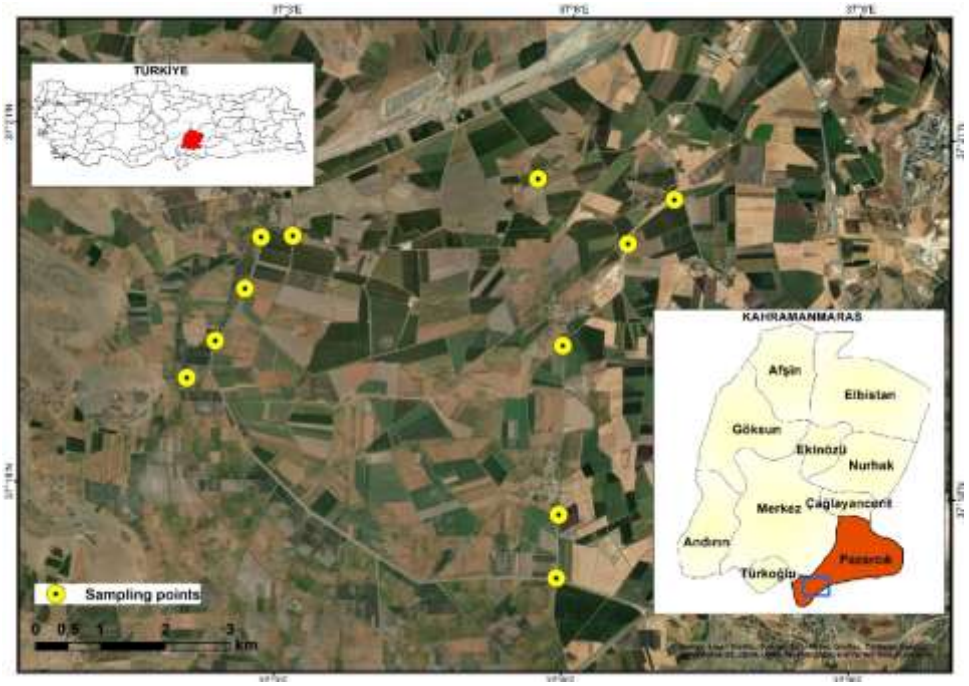

Figure 1. Location of the study area and distribution of soil and wheat flag-leaf sampling points in Narlı Plain

Soil and Plant Sampling and Preparation for Analysis

Soil samples were collected from a depth of 0–30 cm at 11 wheat-growing fields selected across the Narlı Plain, and the coordinates of the sampling points were recorded using a Global Positioning System (GPS). Composite soil samples representing each sampling point were transported to the laboratory, air-dried under ambient conditions, and passed through a 2-mm sieve. The prepared samples were labelled and stored in sealed plastic containers under cool and dry conditions until analysis (Richards, 1954).

Plant samples were collected simultaneously from the same fields where the soil samples were obtained. To assess the nutritional status of wheat, 25–30 representative flag leaves were collected from each field immediately before heading (Jones et al., 1991). The leaf samples were washed with distilled water to remove surface dust and other residues and subsequently oven-dried at 65 °C for 48 h. The dried plant material was ground and homogenized, transferred to labelled polyethylene bags, and stored under refrigerated conditions until chemical analysis (Jones & Case, 1990).

Soil and Plant Analyses

Soil pH and electrical conductivity (EC) were determined in saturated soil paste according to the methods described by Peech (1965) and Richards (1954), respectively. Total calcium carbonate ($CaCO_3$) content was measured using a Scheibler calcimeter (Loeppert & Suarez,

1996), whereas soil organic matter was determined using the Walkley–Black wet oxidation method (Nelson & Sommers, 1996). Available P was determined using the Olsen method based on extraction with 0.5 M $NaHCO_3$ at pH 8.5 (Olsen et al., 1954). Exchangeable K, Ca, and Mg were extracted with 1 N ammonium acetate (NH_4OAc) at pH 7.0 (Thomas, 1982). Plant-available Fe, Zn, Cu, and Mn were determined using the DTPA extraction method (Lindsay & Norvell, 1978). The concentrations of K, Ca, Mg, Fe, Zn, Cu, and Mn in the soil extracts were measured using an Agilent 240AA atomic absorption spectrophotometer (AAS).

A 0.50-g portion of each ground plant sample was wet-digested on a hot plate using a mixture of 5 mL HNO_3 and 4 mL $HClO_4$ until a clear solution was obtained (Jones & Case, 1990). Following digestion, the solutions were filtered and brought to a known volume with deionized water. Phosphorus concentration in the plant samples was determined spectrophotometrically using the vanadomolybdophosphoric yellow colour method. Potassium, Ca, Mg, Fe, Zn, Cu, and Mn concentrations were measured using an Agilent 240AA atomic absorption spectrophotometer.

Statistical Analyses

Minimum, maximum, and mean values for the soil and plant variables were calculated using Microsoft Office Excel. Relationships between soil $CaCO_3$ content and P, K, Ca, Mg, Fe, Zn, Cu, and Mn concentrations in wheat flag leaves were examined using two-tailed Pearson correlation analysis in IBM SPSS Statistics 23.0 (IBM Corp., Armonk, NY, USA). Statistical significance was accepted at $p < 0.05$, and graphical presentations of the results were prepared using Microsoft Office Excel.

RESULTS AND DISCUSSION

Characteristic Properties of the Study-Area Soils

Soil pH values ranged from 7.43 to 7.79, with a mean of 7.56. Electrical conductivity values varied between 303 and 501 μS cm^{-1}, averaging 349 μS cm^{-1}. Soil $CaCO_3$ contents ranged from 19.84% to 41.09%, with a mean of 27.95%, whereas organic matter contents varied between 2.13% and 4.50%, with a mean of 2.85%. Based on these results, the soils were generally characterized as slightly alkaline and non-saline, with high to very high $CaCO_3$ contents and moderate organic matter levels.

Table 1. Descriptive statistics of selected physicochemical properties of the study area soils

	pH	**EC**	**Lime**	**OM**
		(μS/cm)		%
Min	7,43	303	19,84	2,13
Max	7,79	501	41,09	4,50
Mean	7,56	349	27,95	2,85

Macronutrient Status of the Study-Area Soils

Evaluation of the macronutrient contents of soil samples collected from the Narlı Plain revealed different sufficiency levels among the nutrients examined. According to Cottenie (1980), available P concentrations of 8–25 mg kg^{-1} are classified as sufficient, whereas concentrations of 25–80 mg kg^{-1} are considered high (Figure 2). Based on these thresholds, the mean available

P concentration (22.5 mg kg^{-1}) was within the sufficient range; 54.5% of the samples were classified as sufficient and 45.5% as high. However, because the minimum concentration was close to the lower limit of the sufficiency range, the mean value should be interpreted together with the variability among sampling sites.

The mean exchangeable K concentration (340 mg kg^{-1}) exceeded the ≥161 mg kg^{-1} threshold above which Kaiser and Piotrowski (2024) did not recommend K fertilization for wheat under Minnesota conditions. While 63.6% of the samples reached or exceeded this threshold, 36.4% had K concentrations within the range of 95–160 mg kg^{-1}. Therefore, the high mean K concentration should not be interpreted as indicating a uniform K status across all sampling sites. Because this threshold was developed for a different region, it should be used as a comparative benchmark rather than directly applied to fertilizer recommendations for the Narlı Plain.

Regarding exchangeable Ca, 45.5% of the samples were classified as sufficient (1150–3500 mg kg^{-1}), whereas 54.5% were classified as high (3500–10,000 mg kg^{-1}). The mean Ca concentration (3461 mg kg^{-1}) was close to the upper limit of the sufficient range. Accordingly, the results did not indicate Ca deficiency in the investigated soils under the classification system used. For exchangeable Mg, 72.7% of the samples were classified as high (480–1500 mg kg^{-1}) and 27.3% as very high (>1500 mg kg^{-1}). The mean Mg concentration (1145 mg kg^{-1}) was within the high range, and all samples exceeded the sufficiency range, indicating that the soils generally had high exchangeable Mg concentrations (Cottenie, 1980).

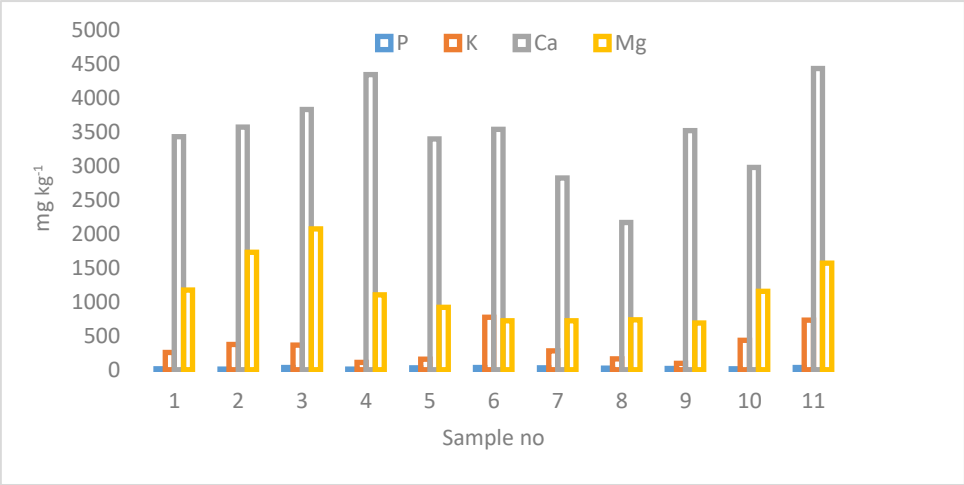

Figure 2. Distribution of available P and exchangeable cations

Micronutrient Status of the Study-Area Soils

The DTPA-extractable micronutrient concentrations of the soil samples collected from the Narlı Plain varied among the sampling sites (Figure 3). Iron (Fe) concentrations ranged from 8.88 to 23.52 mg kg^{-1}, with a mean of 11.73 mg kg^{-1}. Zinc (Zn) concentrations varied between 0.54 and 2.90 mg kg^{-1}, averaging 1.05 mg kg^{-1}. Copper (Cu) concentrations ranged from 1.08 to 2.20 mg kg^{-1}, with a mean of 1.50 mg kg^{-1}, whereas manganese (Mn) concentrations varied between 3.36 and 28.80 mg kg^{-1}, averaging 9.65 mg kg^{-1}. The mean concentrations of the micronutrients followed the order Fe > Mn > Cu > Zn.

Soil micronutrient status was evaluated using the critical levels reported for maize by Lindsay and Norvell (1978) as comparative benchmarks. In all samples, Fe, Cu, and Mn concentrations exceeded their respective critical levels of 4.5, 0.2, and 1.0 mg kg^{-1}. Thus, according to these thresholds, no indication of Fe, Cu, or Mn deficiency was identified in the investigated soils.

However, the critical values reported for Mn and Cu were proposed tentatively and should therefore be interpreted with caution.

Based on the critical Zn level of 0.8 mg kg^{-1}, 45.5% of the samples were classified as deficient and 54.5% as sufficient. Although the mean Zn concentration (1.05 mg kg^{-1}) exceeded the critical threshold, the occurrence of concentrations below this value in 45.5% of the samples demonstrates that soil Zn status should not be evaluated solely on the basis of the mean. Zinc was the only micronutrient for which values below the critical level were detected, indicating a potential Zn deficiency at some sampling sites that warrants further investigation. Nevertheless, because the thresholds used were originally established for maize, definitive conclusions regarding wheat nutritional status should be supported by plant tissue analyses and crop-specific sufficiency criteria.

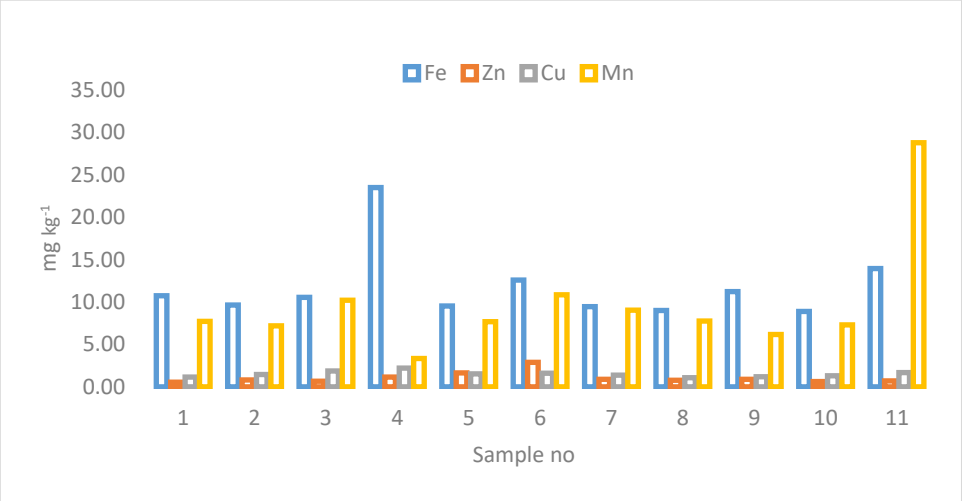

Figure 3. Distribution of DTPA-extractable Fe, Zn, Cu and Mn concentrations

Flag-Leaf Macronutrient Concentrations in Wheat

Macronutrient concentrations in wheat flag leaves varied among the sampling sites. Phosphorus concentrations ranged from 0.21% to 0.38%, with a mean of 0.28%. Potassium concentrations varied between 2.13% and 3.33%, averaging 2.60%. Calcium concentrations exhibited a relatively wide variation, ranging from 0.40% to 1.61%, with a mean of 0.80%. Magnesium concentrations ranged from 0.14% to 0.24%, with a mean of 0.18% (Figure 4). Among the macronutrients examined, K had the highest mean concentration, whereas Mg had the lowest.

The plant analysis results indicated that wheat grown in the study area generally had an adequate macronutrient status. When compared with the critical concentrations and sufficiency ranges reported for wheat, P and K concentrations were considered sufficient at all sampling sites (Jones et al., 1991; Reuter & Robinson, 1997; Plank & Donohue, 2000). In particular, the mean P (0.28%) and K (2.60%) concentrations exceeded the reported critical levels for wheat, indicating no apparent nutritional deficiency in these elements.

The variation in Ca concentrations from 0.40% to 1.61% indicated considerable differences among the sampling sites in Ca uptake or accumulation within plant tissues. Nevertheless, all measured Ca concentrations exceeded the critical level reported for wheat. Magnesium concentrations varied within a narrower range and averaged 0.18%. Because even the lowest Mg concentration (0.14%) was above the critical level, no evident Mg deficiency was identified in the wheat plants (Jones et al., 1991; Reuter & Robinson, 1997; Plank & Donohue, 2000).

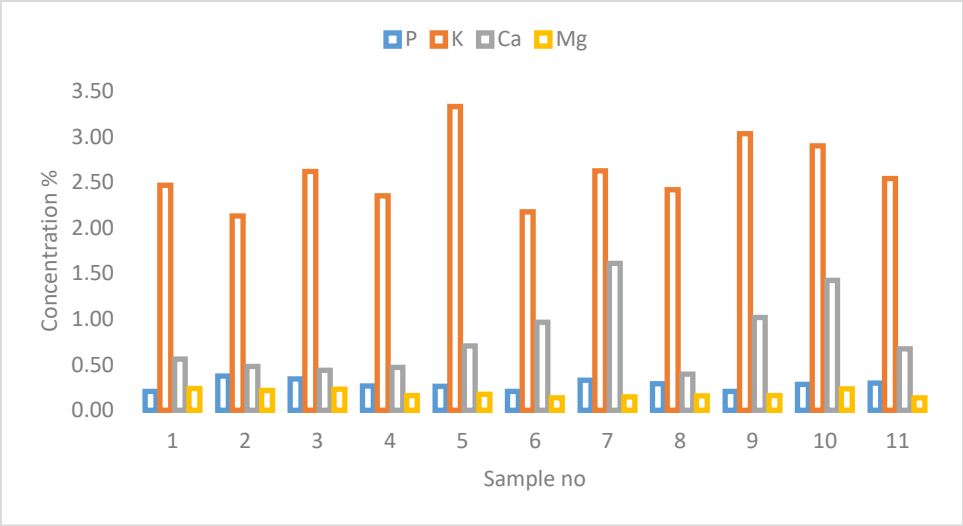

Figure 4. Foliar concentrations of macronutrients in wheat

Micronutrient Status of Wheat Flag Leaves

Micronutrient concentrations in wheat flag leaves varied among the sampling sites. Iron concentrations ranged from 69.00 to 156.75 mg kg^{-1}, with a mean of 97.93 mg kg^{-1}. Zinc concentrations varied between 17.50 and 30.00 mg kg^{-1}, averaging 21.84 mg kg^{-1}. Copper concentrations ranged from 4.50 to 8.75 mg kg^{-1}, with a mean of 6.75 mg kg^{-1}, whereas Mn concentrations varied between 16.00 and 54.25 mg kg^{-1}, averaging 40.41 mg kg^{-1} (Figure 5).

Based on the critical concentrations and sufficiency ranges reported for wheat, Fe, Zn, and Mn concentrations were generally considered adequate (Jones et al., 1991; Reuter & Robinson, 1997; Plank & Donohue, 2000). Iron concentrations of at least 69.00 mg kg^{-1} at all sampling sites indicated no evident Fe deficiency. Similarly, the observed Zn concentrations indicated that the wheat plants generally had an adequate Zn nutritional status.

Although the mean Cu concentration was within the sufficient range, the lowest value of 4.50 mg kg^{-1}, recorded at sampling site 2, was close to the critical level of approximately 5 mg kg^{-1} reported for wheat. Therefore, Cu nutrition was generally adequate, although a marginal Cu status may have occurred at this sampling site (Jones et al., 1991; Reuter & Robinson, 1997). Manganese concentrations indicated adequate nutrition at most sampling sites; however, the minimum concentration recorded at sampling site 11 was close to the lower limit of the sufficiency range.

Overall, wheat grown in the study area was adequately supplied with Fe, Zn, Cu, and Mn, although Cu and Mn concentrations approached the lower sufficiency limits at some sampling sites. Because tissue micronutrient concentrations may be influenced by soil pH, $CaCO_3$ and organic matter contents, nutrient availability, and interactions among elements, the combined interpretation of soil and plant analyses provides a more reliable assessment of wheat nutritional status (Reuter & Robinson, 1997).

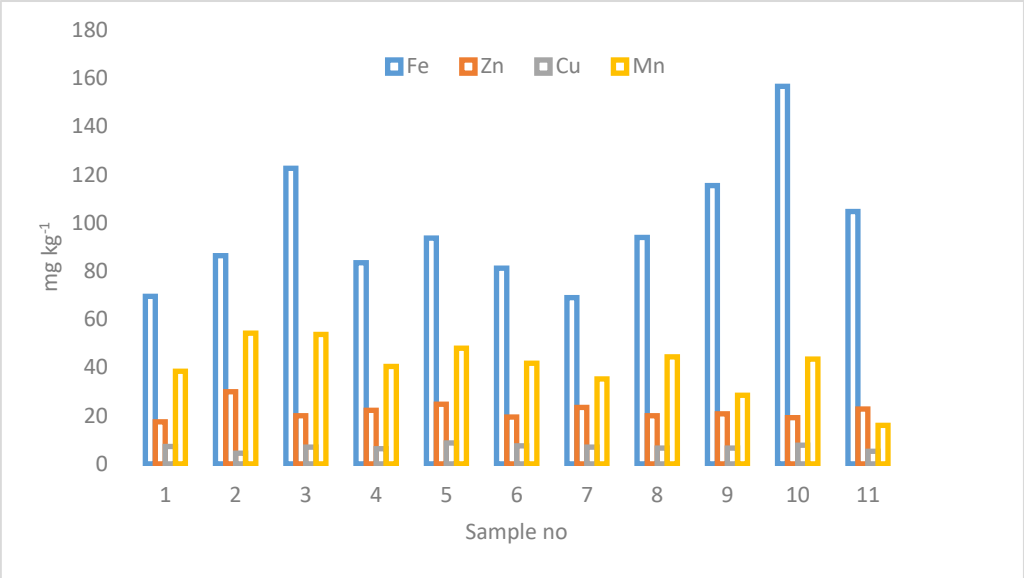

Figure 5. Foliar micronutrient concentrations in wheat

Relationships between soil lime and plant nutrients

No statistically significant correlations were detected between soil $CaCO_3$ content and P, K, Ca, Mg, Fe, Zn, Cu, or Mn concentrations in wheat flag leaves ($p > 0.05$; Table 2). Correlation coefficients ranged from −0.268 to 0.228, indicating no apparent linear relationship between soil $CaCO_3$ content and the macro- or micronutrient concentrations of wheat across the sampled fields. These findings suggest that variation in wheat nutritional status cannot be explained solely by soil $CaCO_3$ content and may also be influenced by soil nutrient reserves, fertilization practices, other soil properties, and plant-related factors. Nevertheless, because of the limited sample size (n = 11), the results should be interpreted within the context of the study area and sampling conditions (Table 2).

Table 2 Pearson correlation coefficients between soil lime and nutrient concentrations in wheat flag leaves

Plant nutrient	Pearson's r	p value	Significance
P	0,033	0,923	ns
K	−0,137	0,688	ns
Ca	−0,268	0,425	ns
Mg	0,228	0,500	ns
Fe	−0,028	0,934	ns
Zn	0,005	0,987	ns
Cu	−0,227	0,503	ns
Mn	0,001	0,998	ns

Note: Pearson correlation coefficients were calculated using 11 paired soil and flag-leaf samples (n = 11). ns: not significant ($p > 0.05$; two-tailed).

CONCLUSION

Wheat grown in the calcareous agricultural soils of the Narlı Plain was generally adequately supplied with P, K, Ca, Mg, Fe, Zn, Cu, and Mn. Available P and exchangeable K, Ca, and Mg concentrations in the soils were predominantly sufficient or high, while no clear deficiency of Fe, Cu, or Mn was identified. However, Zn concentrations were below the critical threshold in

45.5% of the soil samples, indicating a potential risk of Zn deficiency in some production fields. Plant analysis revealed no evident nutrient deficiencies, although Cu and Mn concentrations approached the lower limits of the sufficiency ranges at certain sampling sites. The absence of significant relationships between soil $CaCO_3$ content and nutrient concentrations in wheat flag leaves ($p > 0.05$) indicated that variation in plant nutritional status could not be explained solely by soil $CaCO_3$ content. Consequently, the combined interpretation of soil and plant analyses is recommended for a reliable assessment of wheat nutritional status in the Narlı Plain, with particular attention to the regular monitoring of Zn, Cu, and Mn.

ABSTRACT

The application of microbial fertilizers on plants has gained increasing importance as a sustainable strategy to enhance crop stress tolerance and plant productivity under challenging deficit irrigation conditions. This study aimed to evaluate the effects of various mycorrhiza-based microbial fertilizer formulations on the growth performance of broad-leaved basil (*Ocimum basilicum* L.) grown in a sandy-loam calcareous soil. The study focused on how these microbial amendments influence plant resilience across four deficit irrigation levels: full irrigation (SS100) and three deficit irrigation regimes (SS80, SS60, and SS40). The results indicated that deficit irrigation conditions severely restricted vegetative growth parameters in unfertilized control groups. However, microbial fertilization significantly alleviated the adverse effects of drought stress. Basil plants treated with mycorrhizal formulations, particularly dual or combined microbial treatments, exhibited notable improvements in plant growth dynamics. Key parameters including plant height, root collar diameter, and total leaf number were positively affected by the microbial amendments even under high water deficit. Additionally, plants treated with microbial fertilizers recorded significantly higher chlorophyll levels (SPAD values), demonstrating sustained photosynthetic efficiency under stress. At harvest, a substantial increase in fresh biomass accumulation was observed in mycorrhiza-treated plots compared to the control group, highlighting the role of these symbiotic microorganisms in optimizing root surface area and nutrient uptake. Overall, mycorrhiza-based applications emerged as highly effective inputs for mitigating drought-induced limitations in basil cultivation.

Keywords: Mycorrhiza, Biostimulants, Drought tolerance, Sustainable agriculture

INTRODUCTION

The rapidly increasing global population, dwindling freshwater resources, and irregular rainfall patterns triggered by global climate change are among the most significant ecological problems threatening agricultural production. In particular, in semi-arid climate zones such as the

Mediterranean Basin (e.g., the southern coasts of Türkiye), plants frequently face water scarcity (drought) stress throughout their growing seasons (IPCC, 2021). Drought stress leads to a decrease in cell turgor pressure, stomatal closure, accumulation of reactive oxygen species (ROS) causing oxidative damage, and consequently a significant reduction in photosynthesis, nutrient uptake, and ultimately biomass and economic yield in plants (Augé, 2001; Dimkpa et al., 2009).

Basil (*Ocimum basilicum* L.), belonging to the Lamiaceae family, is a high-value annual plant with wide applications in the food, pharmaceutical, and cosmetic industries, classified as a medicinal and aromatic plant. Basil plants have significant economic importance due to their volatile oils, phenolic compounds, and antioxidants. However, the plant is highly sensitive to soil moisture deficiency during its vegetative growth period (Daza-Torres et al., 2017). In basil plants grown under water scarcity, the leaf area index decreases, fresh herb yield decreases, and the market value of the plant diminishes. Therefore, developing alternative, environmentally friendly agronomic strategies that will ensure the sustainability of basil production and increase abiotic stress tolerance under deficit irrigation conditions is critically important.

Intensive chemical fertilization, used in traditional agriculture to increase yields, leads to salinity accumulation in the soil, groundwater pollution, and disruption of the soil microbiota. In recent years, the use of microbial fertilizers (biostimulants) such as Arbuscular Mycorrhizal Fungi (AMF) and Plant Growth Promoting Rhizobacteria (PGPR) as alternatives to these chemical inputs has attracted great interest in terms of agricultural sustainability (Calvo et al., 2014; Backer et al., 2018). AMF forms extraradical hyphae networks by establishing a symbiotic relationship with plant roots; these hyphae take up and transport low-mobility nutrients such as water and phosphorus from soil pores that the plant's normal root system cannot reach (Ruiz-Lozano et al., 2012). At the same time, mycorrhiza and beneficial rhizobacteria improve root architecture by promoting indole acetic acid (IAA) synthesis in the plant and provide osmotic protection against water stress by increasing antioxidant enzyme activities (Bharti et al., 2016).

The main objective of this study is to comparatively determine the effects of different mycorrhiza-derived microbial fertilizer formulations on parameters reflecting the agricultural characteristics of Large-Leaf Basil (*Ocimum basilicum* L.) grown under restricted irrigation conditions. The primary reason for focusing on basil in this study is the lack of comprehensive literature on the specific morpho-physiological responses of combined microbial fertilizer applications at different water stress levels, despite the high economic value of the species. The study is based on the hypothesis that microbial symbiosis can compensate for yield losses under restricted irrigation by increasing water use efficiency.

MATERIAL AND METHODS

Research Area and Soil Characteristics

This study was conducted in the autumn of 2025 in the Research and Application Greenhouse of the Faculty of Agriculture, Akdeniz University (36° 53' 33" N, 30° 38' 52" altitude 50m). According to meteorological data collected throughout the experiment, the average daily temperature of the area was 16.0 °C, the average daily sunshine duration was 6-7 hours, the average daily open surface evaporation was 2.5 mm to 3.0 mm/day, the average daily rainfall was 4.6 mm, the average daily wind speed was 2.9 m/s, and the average relative humidity was 64%. The greenhouse floor was covered with black plastic mulch, and the greenhouse had top and side ventilation systems.

The experiment was carried out under controlled conditions with natural sunlight, under a homogeneous temperature and relative humidity regime throughout the growing period. The

growing medium used in the experiment was obtained soil from a depth of 0-30 cm from the Aksu Application Area of Akdeniz University. This soil is classified as "Typic Xerofluvent" based on its physical and chemical properties, formed on alluvial parent material called the "Tehnelli Series" (Sarı et al., 2009).

Analysis of the potting soil revealed a slightly alkaline pH (pH 7.9), low electrical conductivity (salinity), high lime content, cation exchange capacity (CEC) ranging from 18.9-19.3 meq/100g, and a sandy-loam texture (Table 1). Overall, the soil has a low organic matter content (1.6%), a high bulk density (1.40 g/cm³), and a low water-holding capacity (available water 8.96%) due to its composition. These physical characteristics indicate that the soil is prone to rapid water loss and provides an ideal testing environment for drought stress trials.

Table 1. Soil physical and chemical properties

Parameter	Content
pH	7.9

Clay (%)	16.6

Plant Material and Applications

In the experiment, commercially standardized large-leaf basil (*Ocimum basilicum* L. cv. Vilmorin) seedlings were used as plant material. The experiment was established using a Randomized Complete Block Design in a factorial arrangement, with 5 different fertilizer applications x 4 different irrigation levels x 3 replications, totaling 60 pots (one plant per pot). The pots were placed in a north-south direction, taking care to avoid placing the same applications side by side to minimize the shading effect (edge effect). Details regarding mycorrhiza-based microbial fertilization and other fertilization treatments in the experiment are given in Table 2.

Table 2. Fertilizer materials and their contents applied to potting soil in the experiment

Application	Content
MG+A	Application of the microbial preparation called Krishiza (contains arbuscular mycorrhizal fungus and microorganism spores)
MG+B	Application of the microbial fertilizer called Indigo (contains arbuscular mycorrhizal fungus and microorganism spores)
MG+A+B	Combined (dual) application of Krishiza and Indigo preparations
OG+	Application of standard chemical fertilizer (does not contain microbial inoculant)
OG-MG-	Negative control group without mycorrhiza or chemical fertilizer application

Irrigation Regime

Irrigation was applied to all trial subjects when 40% of the available water capacity of the soil was consumed based on the water requirements of the basil plant (Allen et al., 1998; Daza-Torres et al., 2017). Irrigation procedures were determined by the gravimetric (weighing) method based on the field capacity and wilting point data of the pots, and 4 different irrigation levels were created (Table 3).

Table 3. Water restriction rates applied to basil plants in the experiment

Irrigation level	Content
SS100	Full Irrigation (No Stress) where 100% of the plant's water needs are met
SS80	Slightly Restricted Irrigation (80% of the water lost is replenished)
SS60	Moderately Restricted Irrigation (60% of the water lost is replenished)
SS40	Severely Restricted Irrigation (40% of the water lost is replenished) (Heavy water stress)

The water levels in the pots were checked at regular intervals using a precision balance, and the amount of moisture lost was measured, with water added to the pots according to their group size. In addition, a standard liquid chemical fertilization (fertigation) program was applied to all pots in equal volumes throughout the experiment to meet the plants' basic nutrient needs.

Experimental Procedure and Measurements

Following the preparation of soil, filling it into pots (September 24), and bringing it to field capacity, seedlings were planted on October 10 after being treated with microbial preparations using the root dipping (inoculation) method. During the growing season, hoeing, disease/pest (entomological) controls, and specific treatments (October 23-30) were carried out. Phenological readings were taken at 5 different measurement times (Time points 1-5; e.g., October 20, November 14, November 25, etc.) during the vegetation period.

Plant height (cm): Measured from the soil surface to the apical bud using a ruler. Root collar diameter (mm): Measured just above the soil surface with a digital caliper. Plant crown width (cm): Determined by measuring the distance between the two widest points of the plant. Number of leaves (pieces/plant): Determined by counting the number of fully opened non-chlorotic functional leaves. Chlorophyll content (SPAD): Measured from fully developed leaves at the mid/upper nodes of the plant using a SPAD-502 (Konica Minolta) portable chlorophyll meter. Fresh weight (g/plant): Above-ground biomass of plants was determined by weighing with a precision balance (0.01 g) at the last harvest on December 12th.

Statistical Analyses

The obtained data were statistically evaluated using the SPSS (Version 23.0) software package. The main effects and interactions of the Application (AAP), Irrigation Level (IL), and Measurement Time (MT) factors on growth parameters were tested at a 5% significance level ($P<0.05$) using a three-way factorial analysis of variance (ANOVA) with Type III sums of squares. Statistically significant differences were separated using the Least Significant Difference (LSD) test.

RESULTS

The effects of different microbial fertilizer applications (MFA), limited irrigation levels (LI), and measurement time (MT) on plant growth parameters were investigated. It was determined that the applications (MFA) had a highly significant effect ($P<0.001$) on root collar diameter,

leaf number, chlorophyll content, and fresh weight, and a significant effect (P<0.01) on plant height and crown width. In addition to the main factors, the Application × Irrigation Level (MFAxLI) interaction was found to be statistically significant only in root collar diameter (P<0.05) (Table 4).

Root Collar Diameter and Plant Height

Root collar diameter (RCD) in plants is a critical parameter reflecting the capacity of vascular bundles for water and nutrient transport. According to the research findings, the highest RCD values were obtained from the MG+A+B (5.55 mm) and MG+A (5.48 mm) plots containing mycorrhiza and microbial treatment, and these treatments were statistically in the same "a" group (Table 4). The lowest root collar diameter was observed in the OG-MG-control group (4.72 mm, "c" group) without any fertilizer/microbial application. When examined according to irrigation levels; full irrigation (SS100) provided the highest diameter development with 5.36 mm, while severe water stress (SS40) reduced this value to 4.97 mm (P<0.05).

Similarly, plant height values were significantly affected by the MFA. MG+A+B (39.33 cm), MG+A (38.43 cm), and MG+B (38.43 cm) applications statistically significantly increased plant height compared to the OG+ (35.51 cm) and OG-MG- control groups (35.11 cm) without microbial inoculant. Regarding the irrigation regimes, a fluctuating trend was observed where the highest vegetative height was noted under moderate water restriction (SS60 with 38.72 cm) and full irrigation (SS100 with 38.38 cm), whereas severe water stress (SS40) suppressed the average plant height to 35.73 cm (Table 4).

Plant Crown Width and Number of Leaves

Plant crown width and leaf number are directly related to the plant's net assimilation area (photosynthetic surface). Analysis data show that mycorrhizal applications increase crown width. MG+A application (26.38 cm) ranked first in group "a", while the OG-MG-control group (22.21 cm) remained in group "c". Although the effect of irrigation level on crown width was not statistically significant (NS), the highest numerical values were measured at SS60 (24.50 cm) and SS80 (24.50 cm) levels (Table 4).

In terms of total leaf number, the MG+A (58.93 leaves/plant) and MG+A+B (58.65 leaves/plant) combinations increased leaf formation by approximately 40% compared to the control group (42.28 leaves/plant) (P<0.001). As expected, the measurement time factor showed a linear increase correlated with plant phenology; the average leaf number, which was 8.23 in the 1st measurement, reached 112.13 leaves/plant in the 5th measurement before harvest. The MFA×MT interaction on leaf number was also found to be significant (P<0.001) (Table 4); this demonstrates that microbial fertilizers stimulate leaf organogenesis much faster in later growth stages compared to the control group.

Chlorophyll Content (SPAD Values)

SPAD values, which represent chlorophyll concentration, showed quite interesting responses to microbial fertilization and water restriction factors. While the average SPAD value in control plants (OG-MG-) was 38.28, MG+A (41.72) and MG+A+B (41.50) applications statistically increased chlorophyll levels (P<0.001) and were placed in group "a" (Table 4).

A much more striking finding emerged in the differences between irrigation levels (SS). While the average SPAD value was 39.37 under full irrigation (SS100) conditions without water stress, this value increased to 42.02 at the SS40 level with severe water restriction and to 41.91 at the SS60 level (P<0.001). Specifically, this physiological response indicates that the severity of water restriction increased the amount of chlorophyll per unit area in the leaves.

Plant Weight (Biomass)

Harvest fresh weight (biomass), the most fundamental indicator of agricultural success in basil cultivation, was the parameter that most clearly reflected the effect of microbial fertilizers (P<0.001). At the end of the experiment, the average fresh weight of the MG+A application, which contains mycorrhiza and beneficial bacteria alone, was measured as 102.50 g. This was followed by the MG+A+B combined application with 91.25 g. In contrast, the average fresh weight in the OG-MG- control group, which received only inorganic base fertilization and no microbial support, was only 49.16 g. This explicitly indicates that the mycorrhizal formulation (MG+A) increased the plant fresh biomass by 108% (more than double) compared to the control group in the overall average. Interestingly, the statistical analysis revealed that the deficit irrigation levels did not exert a significant main effect (NS) on the total fresh weight, implying that the robust root infrastructure promoted by microbial inoculation effectively buffered potential biomass losses across different water availability levels (Table 4).

DISCUSSION

The findings clearly demonstrate the supportive effects of beneficial microorganisms (AMFs) applied to the soil on plant morphology and biomass. The calcareous, low-organic-matter, and sandy-loam soil used in the experiment has low water-holding capacity, making the plants susceptible to water stress. The findings support the idea that microbial fertilizers activate tolerance mechanisms despite these challenging soil characteristics and irrigation limitations.

In the study, mycorrhizal (MG+A) and combined microbial fertilizer (MG+A+B) applications significantly increased the height, root collar diameter, and leaf number of basil plants compared to the control group. Mycorrhizal fungi establish a symbiotic relationship by settling in the root cortex cells of the plant. Through their hyphal networks (extraradical mycelium), they transfer water and nutrients with slow diffusion (especially phosphorus, zinc, and copper) from micro-pores inaccessible to the roots to the plant (Dimkpa et al., 2009; Calvo et al., 2014). This observed promotion in plant height and root collar diameter can be explained by improved plant nutrition and consequently increased meristematic cell division. Similar studies on basil plants (Copetta et al., 2006) also confirm that AMF inoculation optimizes vegetative parameters. The fact that combined application (MG+A+B) yields result as successful as single applications is a result of the synergistic interaction between these combined applications; because such applications can promote the germination of mycorrhizal spores and the root infection rate (Barea et al., 1992).

One of the most striking results of the study is that increased water restriction (SS60 and SS40) statistically increases the amount of chlorophyll (SPAD value) in basil plants compared to the SS100 level. Water stress generally causes the degradation of photosynthetic pigments (chlorosis). This phenomenon is primarily driven by the 'concentration effect' under drought stress. To minimize transpirational water loss, plants restrict leaf cell expansion. Consequently, the reduction in total leaf area combined with increased leaf thickness elevates the relative chlorophyll density per unit surface area, directly reflected in higher SPAD indices (Rouphael et al., 2012). The higher SPAD values (41.72) in plants treated with microbial fertilizer compared to the control group (38.28) are related to the fact that beneficial microorganisms facilitate the uptake of essential elements for chlorophyll biosynthesis, such as nitrogen (N) and magnesium (Mg), thus ensuring that the photosynthetic apparatus remains more robust against stress.

The fresh weight findings, the most important outcome of the experiment, proved that microbial fertilizers are an indispensable tool for maintaining plant production under water stress. The fact that the biomass amount in the control plots was almost half that of the plants treated with microbial inoculant shows how much water stress conditions suppress the metabolism of uninoculated plants. Mycorrhizal plants (especially the MG+A formulation) can maintain cellular turgor even at low soil moisture levels and continue carbon assimilation (biomass formation) by increasing the expression of "aquaporin" genes, which regulate water flow into the plant body through the roots, and by optimizing stomatal conductivity (Ruiz-Lozano et al., 2012).

CONCLUSION

The results of this study, conducted on basil (*Ocimum basilicum* L.) grown under limited irrigation conditions (drought stress) in calcareous soils with low organic matter and poor water retention capacity typical of the Mediterranean Basin, can be summarized as follows: Mycorrhiza-based microbial fertilizer applications (especially MG+A and MG+A+B combinations) statistically increased plant height, root collar diameter, and crown width ($P<0.001$) compared to the control group grown under conventional cultivation, resulting in a stronger and more structurally resistant plant architecture. The number of leaves, an indicator of the vegetative capacity of the plants, was approximately 40% higher in pots inoculated with microbial fertilizers compared to the control group. Severe water restriction (SS40) caused a concentration effect by concentrating chlorophyll content per unit leaf area. Microbial fertilizers supported photosynthetic capacity by maintaining chlorophyll integrity at a higher level against this physiological pressure of stress. Regarding agricultural yield, the most critical finding was

that Mycorrhiza (MG+A) application increased the fresh biomass of basil by 108% compared to control crops in limited irrigation scenarios. In conclusion, against the backdrop of global climate change scenarios where drought increasingly limits agricultural productivity, transitioning from intensive chemical inputs to integrated mycorrhizal formulations stands out as a high-efficiency, agronomically viable, and ecologically sustainable strategy to secure crop yields. Further studies could investigate how this microbial symbiosis regulates water stress genes at the molecular (transcriptomic) level and its effects on the essential oil profile, which determines the economic importance of basil, under field conditions.

ACKNOWLEDGEMENTS

In this study, the phase of conducting pot experiments under modern greenhouse conditions was supported by Dean's Office of the Faculty of Agriculture at Akdeniz University.

ABSTRACT

Cattle behaviors are among the important biological indicators used in evaluating the physiological state, health level, adaptation to environmental conditions, and welfare of animals. Regular monitoring of behaviors such as feeding, rumination, resting, movement, social interaction, estrus, water consumption, and defecation contribute to the early diagnosis of diseases, the evaluation of management practices, and the improvement of production performance. In this review, first, the basic approaches used in the evaluation of cattle behaviors and the relationship between behavior and animal welfare are discussed; then, behavioral indicators such as body condition, feed intake, heat stress, estrus behaviors, rumen fill, housing hygiene, resting behavior, bunk and stall design, foot health, fecal consistency, and water consumption are evaluated in line with the current literature. In addition, the contributions of behavioral indicators to animal health, welfare, his decision-making processes in herd management, and the applicability of these indicators in field conditions are also addressed. Furthermore, the importance of behavioral observations in monitoring herd management, animal health, and welfare is emphasized. Literature findings show that the use of behavior-based evaluations together with appropriate feeding and housing practices can provide significant contributions to improving animal welfare, identifying diseases at an early stage, and increasing production performance. Additionally, regular and systematic monitoring of behaviors can contribute to making more accurate and timely decisions in herd management. In conclusion, systematic monitoring and evaluation of cattle behaviors are considered a fundamental management tool for sustainable production, effective herd management, and the development of animal welfare in modern dairy cattle enterprises.

Keywords: Cattle behavior, Animal welfare, Ethology, Behavioral indicators, Dairy farming, Herd management

INTRODUCTION

Animal behavior and behavioral indicators are among the primary criteria used in the assessment of animal welfare. Scientific evaluation of animal welfare requires jointly considering the preservation of animals' health and biological functions, their negative and positive emotional states, and their ability to express species-typical natural behaviors (Fraser, 2009). Evaluating cattle behaviors in relation to environmental conditions and rearing practices highlights the importance of behavior in livestock research (Sahu et al., 2020). Cattle have a wide behavioral repertoire, and much of their time is spent on feeding, rumination, and resting behaviors (Kilgour, 2012). Behavioral indicators, particularly behaviors such as vocalization, can provide useful information for assessing animals' physiological and psychological states (Watts and Stookey, 2000). In addition, behavior-based observation and assessment approaches

enable systematic on-farm monitoring of animal welfare (Grandin, 2015). In recent years, with the development of precision livestock farming technologies, feeding, rumination, activity, and other behavioral indicators in dairy cattle can be continuously monitored with sensor-based monitoring systems. These technologies allow objective assessment of behavioral and welfare indicators and are used as an important approach in monitoring animal welfare (Stygar et al., 2021).

Cattle behaviors encompass a broad behavioral repertoire including feeding, rumination, resting, movement, responses to environmental stressors, estrus signs, housing use, foot health, water consumption, and social interactions. Joint evaluation of these behaviors contributes not only to the assessment of individual animal health but also to a holistic evaluation of herd welfare and farm management. In this review, the main approaches used in the evaluation of cattle behaviors and the importance of behavioral indicators for animal health, welfare, and herd management are discussed in line with the current literature; the role of behavior-based assessment in modern dairy cattle enterprises is presented.

Assessment of cattle behaviors and animal welfare

Cattle display a characteristic behavioral repertoire composed of feeding, rumination, resting, locomotion, and social behaviors, and the assessment of these behaviors is important for defining normal behavioral patterns (Kilgour, 2012). Vocal behaviors are also among the key behavioral indicators that provide information about animals' biological processes and welfare status (Watts and Stookey, 2000). Today, behavioral and welfare indicators in dairy cattle can be monitored and assessed objectively using sensor technologies, and these technologies are used as important tools in welfare assessment (Stygar et al., 2021).

Tinbergen (1963) framed behavioral research around four fundamental questions: the mechanism of behavior expression, development (ontogeny), adaptive function, and evolutionary history. Font (2023) emphasizes that evaluating these four questions together continues to be a fundamental approach for understanding animal behavior.

Animal-based indicators such as body condition, cleanliness, lying behavior, lameness, and social behaviors are used in the assessment of cattle welfare (Welfare Quality®, 2009). Body condition score is regarded as an important indicator related to production, health, and welfare in dairy cattle (Roche et al., 2009). In addition, behavioral observations alongside other animal-based measures are primary approaches used for practical welfare assessment (Grandin, 2015). Evaluations of the effects of different housing systems on cattle behavior, as well as assessments of good nutrition and appropriate housing conditions, are also considered when examining cattle welfare (Özçelik Metin and Asan, 2016; Şahin and Uğurlu, 2016).

Stress is one of the key factors affecting the behavior of dairy cattle. Stressors such as pain, disease, heat stress, social stress, and housing-related comfort problems can cause changes in feeding behavior, social interactions, and other behavioral responses (Jurkovich et al., 2024). Therefore, monitoring stress-related behavioral changes constitutes an important component of the animal welfare approach, which is based on the joint assessment of health, affective state, and the ability to express natural behaviors (von Keyserlingk et al., 2009; Grandin, 2015).

Behavioral indicators and their use in herd management

Body condition scoring is an important indicator used to assess energy reserves in dairy cattle and is closely related to health, productivity, and welfare (Roche et al., 2009). Low condition scores are associated with negative energy balance and health problems, while high condition scores are linked to metabolic disorders and periparturient issues (Roche et al., 2009). When interpreting condition scores, the animal's physiological stage and nutritional status are evaluated together (NASEM, 2021).

Feed access and feed bunk space are major environmental factors affecting feeding behavior in dairy cattle. Grouping strategy, social dominance, bunk space, and feed accessibility can influence feeding behavior and feed intake; excessive crowding can reduce feeding activity and alter resting and rumination behaviors (Grant and Albright, 2001). Ensuring adequate feed access is also among the key elements considered in welfare assessments of dairy cattle (Göncü et al., 2016).

Increased stocking density at the bunk affects feeding and social behaviors in dairy cows. As bunk density increases, feeding time decreases while aggressive behaviors and the frequency of displacement from the feed bunk increase. Cows with lower social rank are particularly more frequently displaced under high-density conditions. Based on these findings, researchers recommend avoiding excessive bunk crowding and using feed barriers that provide physical separation to reduce competition (Huzzey et al., 2006).

Rumen fill score, one of the behavioral and physiological indicators used to assess nutritional status, is based on visual inspection of the left paralumbar fossa. This scoring system was developed to monitor the relationship between nutritional status and fertility in dairy cattle (Zaaijer and Noordhuizen, 2003).

Rumination behavior is an important behavioral indicator closely related to rumen functions and the operation of the digestive system (Allen, 1997; Beauchemin, 2018). During rumination, re-chewing of feed particles and increased saliva secretion contribute to the maintenance of the rumen environment (Allen, 1997; Beauchemin, 2018). This behavior largely occurs during resting and is closely associated with lying behavior (Schirmann et al., 2012). Rumination time is used as a useful indicator in the assessment of health and metabolic status and can now be monitored via sensor technologies (Soriani et al., 2013; Beauchemin, 2018). Physically effective fiber plays an important role in maintaining rumination behavior (Allen, 1997; Beauchemin, 2018). Diets adequate in physically effective fiber stimulate chewing and rumination behavior, increase saliva secretion, and help maintain rumen pH (Allen, 1997). The physical characteristics of fiber and particle size are important ration attributes that affect rumination behavior (Beauchemin, 2018).

Fecal consistency is a trait that can vary according to changes in dietary composition in dairy cattle and can be assessed by visual scoring. Differences in dietary fiber and protein levels and variations in feedstuffs can affect fecal dry matter, neutral detergent fiber (NDF), acid detergent fiber (ADF), starch, and pH characteristics, in addition to fecal consistency. However, it has been reported that fecal consistency cannot be accurately predicted using only diet components and animal performance parameters, and that the relationship between fecal consistency and feeding is influenced by many factors (Ireland-Perry and Stallings, 1993).

Water intake and drinking behavior in lactating dairy cows are related to dry matter intake, milk yield, the dry matter content of the rations, and environmental conditions. A significant portion of water intake occurs during feeding and after milking (Cardot et al., 2008). Additionally, drinker cleanliness and the condition of technical equipment on dairy farms are among the measures considered in the assessment of animal welfare (Ceco and Önk, 2024).

Increased locomotor activity is observed in cows during estrus. Mounting other animals and allowing themselves to be mounted, restlessness, increased walking activity, and vocalization are the main behavioral signs observed during estrus. In modern dairy operations, the intensity of estrus signs may be reduced and become difficult to detect visually due to factors such as high milk yield and housing and flooring conditions (Roelofs et al., 2010). Sensor technologies such as pedometers, accelerometers, activity sensors, and image analysis systems are used to objectively and continuously monitor behavioral changes (Stygar et al., 2021).

Foot health is an important factor affecting behavior in dairy cattle. Animals that develop lameness show changes in behavior and lying behavior, and their welfare is adversely affected (Cook and Nordlund, 2009; İzci et al., 2021). Barn design, flooring characteristics, and resting

areas are among the important environmental factors in the development of lameness (Cook and Nordlund, 2009). Therefore, regular hoof care and provision of appropriate flooring and resting conditions are considered fundamental practices to prevent lameness (Cook and Nordlund, 2009; İzci et al., 2021). Regular assessment of the proper functioning of milking machine components—vacuum system, pulsation system, and other technical parts—is important for maintaining milking performance and udder health (Mein et al., 2004).

Effects of environmental factors on behavior and welfare

Heat stress is an important environmental factor that adversely affects behavior and welfare in dairy cattle. During heat stress, behavioral and physiological changes such as increased respiration rate, panting, longer standing times, and decreased feed intake are observed. Prolonged heat stress can have negative effects on milk yield, reproductive performance, and animal welfare. Therefore, improving environmental conditions and providing appropriate cooling practices during hot periods are among the primary approaches to reducing heat stress (Polsky and von Keyserlingk, 2017; Lees et al., 2019; Erzurum and Uysal Erzurum, 2020).

Resting behavior is an important behavioral indicator used in the assessment of animal welfare in dairy cattle. The characteristics of resting areas, stall design, and comfort directly affect animals' lying and standing behaviors. Appropriate resting conditions are associated with longer lying times, while inadequate resting conditions can increase standing time (Cook et al., 2004). Inappropriate stall designs and inadequate resting conditions can hinder the ability to enter the lying area, reduce resting duration, and increase standing time (Cook and Nordlund, 2009). Sufficient lying time is important for the welfare of dairy cattle, and prolonged standing is associated with an increased risk of lameness (Tucker et al., 2021). Frequent position changes, reluctance to enter the lying area, and abnormal lying postures are also important behavioral indicators used to evaluate the comfort of resting areas (Cook and Nordlund, 2009; Tucker et al., 2021; Haley et al., 2001).

Barn design and equipment placement are important environmental factors that influence dairy cattle behavior. The placement of the neck rail can affect stall use, and insufficient stall length, width, and forward lunge space can restrict lying-down and rising movements, negatively impacting resting behavior (Tucker et al., 2005; Cook and Nordlund, 2009; Tucker et al., 2021). Designing stalls to fit animals' body dimensions is important to support appropriate resting behavior.

Keeping bedding clean and dry and effectively removing manure are among the fundamental management practices recommended for the control of environmental mastitis (Hogan and Smith, 2012).

Literature review

The reviewed literature shows that behavioral indicators such as feeding, rumination, resting, locomotion, estrus, water intake, and social behaviors are important measures for assessing animal health, welfare, and herd management in dairy cattle. Additionally, animal-based indicators like body condition score, rumen fill score, fecal evaluation, and lameness, when used alongside behavioral assessments, contribute to a more comprehensive welfare evaluation. Sensor-based precision livestock technologies enable continuous and objective monitoring of behavioral changes, offering significant advantages for early detection of health problems, improvement of reproductive management, and enhancement of decision-support processes in herd management. The literature commonly emphasizes that appropriate feeding, barn design, and environmental management practices positively influence behavioral patterns and thereby support the sustainability of animal welfare and production performance.

CONCLUSIONS

Cattle behaviors are reliable biological indicators for assessing animals' physiological state, health status, adaptation to environmental conditions, and welfare. Joint evaluation of feeding, rumination, resting, movement, reproductive behaviors, social interactions, water intake, and other behavioral parameters enables comprehensive assessment not only of individual animal health but also of herd-level welfare and the effectiveness of farm management.

Because changes in behavioral indicators often appear before clinical signs, these observations gain importance for early detection of diseases, identification of metabolic disorders, detection of environmental stressors, and development of appropriate management strategies. Therefore, evaluating behavioral observations together with feeding management, housing conditions, foot health, reproductive management, and other routine herd-management practices contribute both to the protection of animal welfare and to the sustainable improvement of production performance.

Recent advances in precision livestock technologies have made it possible to assess behaviors objectively, continuously, and in real time via sensors, image analysis systems, and automated monitoring technologies. Using these technologies alongside traditional behavioral observations facilitates early detection of health problems, supports decision-making processes in herd management, and enables more effective monitoring of animal welfare.

In conclusion, behavior-based assessments stand out as an indispensable management tool for sustainable production, effective herd management, and the improvement of animal welfare in modern dairy cattle enterprises. In the future, integration of behavioral observations with precision livestock technologies and automated monitoring systems will play an important role in developing sustainable animal production by enabling earlier, more accurate, and more holistic assessments of animal health and welfare.

Declaration of artificial intelligence use

During the preparation of this review, artificial intelligence-supported tools were utilized for the purposes of grammatical editing, improving the academic expression structure, and ensuring content organization. However, all scientific content, data, and citations in the text are based on sources provided by the author. The artificial intelligence tool was not used for generating new information, adding data, or creating scientific inferences; it was used solely as a supportive tool in the process of reorganizing existing texts and ensuring their compliance with academic writing standards.

ABSTRACT

Water is one of the indispensable natural resources for the continuity of life, the protection of ecosystems, and the sustainability of agricultural production. However, population growth, climate change, water pollution, and increasing water demand are progressively increasing the pressure on water resources on a global scale. The agricultural sector is one of the areas where freshwater resources are most intensively used. Within the agricultural sector, intensive water use is carried out in dairy cattle enterprises. In these enterprises, water stands out as one of the fundamental inputs of production due to the drinking water requirements of animals, feed production, milking systems, and the cleaning of equipment and housing. In this review, the current status of global water resources and water security, the causes of water pollution, and current approaches toward the protection of water resources are evaluated; subsequently, sustainable water management practices in dairy cattle enterprises and current studies regarding water resources and water management in dairy cattle enterprises in Türkiye are discussed in detail. Literature findings show that regular monitoring of water use in enterprises, reduction of water losses, evaluation of alternative water resources, dissemination of practices for water reuse, and the adoption of appropriate management strategies can increase water use efficiency. Furthermore, ensuring continuous access for animals to an adequate amount and appropriate quality of drinking water is of great importance as a fundamental necessity for protecting animal health, welfare, and production performance. In conclusion, the dissemination of sustainable water management in dairy cattle enterprises will provide significant long-term contributions to the protection of water resources, the support of environmental sustainability, and the development of sustainable milk production.

INTRODUCTION

Water is one of the indispensable natural resources for the continuation of human life, the maintenance of ecosystem continuity, and the conduct of economic activities (Kato and Kansha, 2024). Although approximately 71% of the Earth's surface is covered by water, the amount of usable freshwater resources is quite limited. About 96.5% of total water resources consist of saline water in the oceans, while only approximately 2.5% qualify as freshwater. A large portion of freshwater is stored in glaciers, permanent snow cover, and groundwater; consequently, the share of directly usable surface freshwater resources for human daily life, agricultural production, and ecosystem sustainability is very small. Despite their extremely limited volume, rivers are of central importance for meeting people's daily water needs, sustaining agricultural production, and ensuring ecosystem continuity. This situation indicates that usable freshwater resources are quantitatively constrained and that effective management and sustainable use of

water resources have become a strategic priority at the global level (U.S. Geological Survey, 2019).

With the rapid growth of the global population, the need for safe drinking water, sanitation, and hygiene services has also increased. Globally, between 2000 and 2024 approximately 2.2 billion people gained access to safely managed drinking water, and 2.8 billion people gained access to safely managed sanitation services. Nevertheless, continued inequalities between regions in access to safe water, sanitation, and basic hygiene services demonstrate that the global water crisis is not only an environmental issue but also a significant social problem (WHO, 2025). In Türkiye, the per capita renewable freshwater amount of approximately 642 m^3/person/year and the annual freshwater withdrawal reaching 54.7% of renewable water resources highlight the current pressure on water resources and necessitate the development of strategies for effective water management (FAO, 2025). Pressure on water resources is expected to increase further in the future. With the intensification of the global water cycle due to climate change, it is estimated that by 2050 the population at risk of flooding will reach approximately 1.6 billion, and the population experiencing water scarcity for at least part of the year will reach 4.8–5.7 billion people. Therefore, developing holistic approaches for the sustainable management of water resources and using existing water resources more efficiently are among the global priority targets (UNESCO, 2018).

On the other hand, pollutants originating from industrial, urban, and agricultural activities adversely affect water quality, creating important problems for both environmental sustainability and human health. The agricultural sector is one of the most intensive users of freshwater resources, and in dairy cattle enterprises water management is considered a fundamental component of sustainable production due to animals' drinking water requirements, milking systems, cleaning operations, and feed production (Kato and Kansha, 2024; Lin et al., 2022; Akhtar et al., 2021; FAO, 2025; Monteiro et al., 2023). Accordingly, evaluating approaches to increase water use efficiency in dairy cattle enterprises is important for the protection of water resources and the support of sustainable animal production. In this review, first the current status of global water resources and water security is addressed, followed by water pollution and current approaches to the protection of water resources; subsequently, sustainable water management in dairy cattle enterprises and studies on water resources and water management in dairy cattle enterprises in Türkiye are evaluated.

The current status of global water resources and water security

Although approximately 71% of the Earth's surface is covered by water, the vast majority of that water (about 96.5%) is saline water in the oceans. Only roughly 2.5% of total water resources qualify as freshwater, of which approximately 68.7% is stored in glaciers and permanent snow cover and about 30% in groundwater. Only about 1.2% of freshwater exists as surface water such as lakes and rivers; within these, lakes account for roughly 20.9% while rivers make up only about 0.49% of surface freshwater. Despite their extremely limited volume, rivers are of central importance for meeting people's daily water needs, sustaining agricultural production, and ensuring ecosystem continuity. This situation reveals that usable freshwater resources are quantitatively very limited and unevenly distributed across the globe, and that effective management, sustainable use, and protection of water resources are strategic priorities at the global level (U.S. Geological Survey, 2019).

Global population rose from 6.2 billion to 8.2 billion between 2000 and 2024, during which significant but uneven progress was made in access to water, sanitation, and hygiene services. In this period, approximately 2.2 billion people gained access to safely managed drinking water and 2.8 billion to safely managed sanitation services. However, while the population lacking

access to drinking water has generally declined, this number has increased in low-income countries and in some urban areas. Similarly, improvements in access to safely managed sanitation occurred faster in rural areas while remaining limited in urban areas, and deficiencies persist in low-income countries. Moreover, the number of people without basic hygiene services rose from 427 million to 502 million in low-income countries, indicating that the gains are not evenly distributed across regions and income groups and that the global water crisis is deepening particularly among disadvantaged populations (WHO, 2025).

Türkiye's long-term average total renewable freshwater resources are reported as 53.6 km³/year, and per capita renewable freshwater is approximately 642 m³/person/year. Annual total freshwater withdrawal in Türkiye is about 58.5 km³, of which 73.9% is used for agricultural irrigation, 15.2% for municipal (domestic) services, and 10.9% for industry. The fact that annual freshwater withdrawal reaches 54.7% of renewable freshwater resources indicates significant pressure on Türkiye's water resources and underscores that effective management and efficient use of water resources are strategic necessities (FAO, 2025).

Pressure on global water resources is expected to increase further in the future. Currently more than 2 billion people lack access to safely managed drinking water, and more than twice that number lack safely managed sanitation services. With rapidly growing global population, water demand is expected to increase by about one-third by 2050; accelerating consumption, environmental degradation, and the multifaceted impacts of climate change necessitate new approaches for managing limited freshwater resources. Climate change is intensifying the global water cycle, increasing the risks of floods and droughts. It is estimated that the population at risk of flooding, currently 1.2 billion, will reach 1.6 billion by 2050 (about 20% of the world population), and that the population affected by land degradation and drought already reaches 1.8 billion. Meanwhile, about 3.6 billion people currently live in areas with potential water scarcity for at least one month of the year; this number is projected to rise to 4.8–5.7 billion by 2050. These figures make the development of holistic approaches for sustainable management of water resources and more efficient use of existing water resources global priorities (UNESCO, 2018).

Water pollution and protection of water resources

Large volumes of wastewater are generated by industrial activities, and these wastewaters can contain high pollutant loads and toxic components, thereby causing serious problems for environmental sustainability and public health. Because the quantity of wastewater produced, pollutant concentration, and types of pollutants vary significantly by sector, these characteristics must be accurately identified and assessed in order to determine appropriate treatment technologies. Therefore, effective management of wastewater and the application of suitable treatment methods are considered fundamental components of the sustainable use of water resources (Kato and Kansha, 2024).

A literature review using keywords such as water pollution, water quality, health, and cancer evaluated 85 studies. The findings indicate that more than 80% of wastewater generated by human activities is discharged into rivers and oceans without any treatment, a situation that not only causes environmental pollution but also creates conditions for the emergence of more than 50 diseases. Degradation of water quality is responsible for a significant portion of global disease burden and child mortality, and it plays an important role in the spread of enteric infections such as diarrheal diseases. The impacts of water pollution on human health are evident but can vary depending on factors such as region, age, and gender. Researchers emphasize that interventions and strengthened management practices are needed to improve water quality and reduce adverse health effects (Lin et al., 2022).

Pressure on water quality does not originate solely from anthropogenic activities; global warming, land-use changes, and natural geological processes also threaten the sustainability of water resources. In addition to pollutants from industrial waste, urban settlements, and agricultural activities (pesticide and fertilizer applications), natural processes complicate the behavior of heavy metals and inorganic substances in water systems. Therefore, interdisciplinary research, the development of flexible regulations, and strengthened international cooperation are reported to be necessary to sustainably protect water quality (Akhtar et al., 2021).

Practices for protecting water resources are not limited to large-scale environmental policies; they also include measures that can be implemented at the individual level. Even very small leaks from taps can cause significant water losses over the long term. For example, if a single tap leaks at a rate of just one drop per minute, it results in approximately 0.4 L per day and about 146 L per year (U.S. Geological Survey [USGS], 2018). According to Turkish Statistical Institute (TSI) data, Türkiye's population in 2025 is 86,092,168 and the average household size is 3.08 persons, which corresponds to approximately 28 million households. In this case, a single tap leaking one drop per minute in each household would cause an annual national water loss of about 4.08 billion liters (approximately 4.08 million m^3). Similarly, in Istanbul, with about 5.1 million households, this amount would reach approximately 747 million liters per year (about 747 thousand m^3). This example demonstrates that water losses that seem negligible at the individual level can become substantial waste at the national scale, and that simple measures such as repairing tap leaks can make an important contribution to the sustainable management of water resources (TSI, 2025; 2026).

There are various practical measures that can be implemented at the individual level to increase water savings and protect existing water resources. Key practices to reduce domestic water consumption include running washing machines and dishwashers only when fully loaded, keeping taps closed when not in use, and shortening shower durations. In addition, promptly repairing all leaks in plumbing systems and preferring water-saving devices that limit flow in toilet cisterns and showerheads contribute to efficient water use. These practices should be considered not only in domestic settings but also in livestock enterprises with high water consumption, particularly dairy cattle farms.

Sustainable water management in dairy cattle enterprises

In dairy cattle enterprises, water is a fundamental input used not only to meet animals' drinking water requirements but also across many stages of production such as milking systems, equipment and housing cleaning, and feed production. Therefore, the sustainable use of water resources is considered an important necessity for ensuring production continuity under increasing water scarcity conditions and for improving water use efficiency in livestock. Recent studies indicate that technological applications, appropriate farm management, and approaches for water reuse are key strategies for increasing water use efficiency in dairy cattle enterprises (Monteiro et al., 2023; Higham et al., 2017).

Regular monitoring of water use on dairy farms is considered one of the most important practices for improving water use efficiency. Research shows substantial differences among farms in water use for the milking unit, animals' drinking water consumption, and leaks in water distribution systems. Regular measurement and monitoring of water use help farms estimate their water needs more accurately, identify differences in usage, and manage existing water resources more effectively (Higham et al., 2017). In addition, proper feeding of animals, adequate ventilation of housing, and regular maintenance and repair of water, wastewater, and

irrigation systems are fundamental farm management practices that contribute to reducing the water footprint (Monteiro et al., 2023).

Evaluating alternative water sources to reduce dependency on freshwater is an important component of sustainable water management. On-farm rainwater harvesting and the reuse of suitably treated wastewater for irrigation and manure removal systems are among the practices that can improve water use efficiency (Willers et al., 1999). Reusing water recovered from heat-exchanger systems used to cool milk after milking and applying technological equipment in irrigation systems are also recommended measures to reduce water consumption (Monteiro et al., 2023).

Sustainable water management includes not only reducing the volume of water used but also ensuring continuous access for animals to an adequate quantity and quality of drinking water. Considering environmental factors that affect animals' water consumption, maintaining uninterrupted access to water resources, and adopting appropriate water management practices are of great importance for preserving animal welfare, health status, and production performance (Bak Jensen and Vestergaard, 2021; Singh et al., 2022).

Water resources in Türkiye and water management in dairy cattle enterprises

Türkiye is among the countries experiencing significant pressure on water resources in terms of renewable freshwater per capita. According to FAO data, Türkiye's long-term average total renewable freshwater resources are 53.6 km^3/year, and the renewable freshwater amount per capita is reported as approximately 642 m^3/person/year. The annual total freshwater withdrawal in Türkiye is approximately 58.5 km^3, of which 73.9% is used in agricultural irrigation, 15.2% in municipal (domestic) services, and 10.9% in the industrial sector. Additionally, the fact that the annual total freshwater withdrawal reaches 54.7% of renewable freshwater resources indicates a considerable level of pressure on Türkiye's water resources and reveals that effective management and efficient use of water resources are a strategic necessity (FAO, 2025).

Studies on water use, water quality, and water management in dairy cattle enterprises in Türkiye have been increasing in recent years. Yaylak and Yavuz (2016) reported that ensuring continuous access to an adequate quantity and appropriate quality of drinking water for dairy cattle is one of the fundamental requirements for animal health, welfare, and production performance. The same study stated that placing water troughs in sufficient numbers and suitable locations, cleaning them regularly, and planning water distribution systems according to farm capacity are among the basic practices that should be considered on farms.

Koçbeker and Bahtiyarca (2017) reported that insufficient quantity or low-quality drinking water in dairy cattle can negatively affect feed intake and milk yield; therefore, for sustainable dairy farming, in addition to providing the quantity and quality of water that animals need, proper planning of water management is also of great importance.

Recent studies carried out in Türkiye show that a significant portion of water use in milk production originates from feed production, animals' drinking water consumption, and water used in barns and milking units. In a study conducted at Ankara University Haymana Research and Practice Farm, the water footprint of milk production was calculated; by evaluating the shares of feed production, animals' drinking water consumption, and water used in barns and milking units in total water consumption, the total water consumption per 1 liter of milk production was determined as 1112.3 L (Çolak et al., 2025).

Additionally, in a study conducted in dairy cattle enterprises in the Kütahya province, it was determined that a significant portion of the farms were located close to water resources and that inappropriate manure storage practices posed an environmental risk for water resources. The study emphasized that farms should be planned taking into account appropriate infrastructure and management practices to prevent water and environmental pollution (Peypazar and Kılıç, 2021).

CONCLUSIONS

The increasing pressure on water resources on a global scale has made the sustainable management of water one of the priority issues for agricultural production systems. Factors such as limited freshwater resources, population growth, climate change, and water pollution make the more effective and efficient use of water mandatory. In this context, developing holistic approaches for the protection of water resources and increasing water use efficiency play an important role in achieving sustainable development goals.

In dairy cattle enterprises, water is one of the fundamental inputs used in many stages of production, such as feed production, milking systems, and the cleaning of equipment and barns, in addition to meeting the drinking water requirements of the animals. Therefore, the regular monitoring of water use in enterprises, reduction of water losses, evaluation of alternative water sources, dissemination of practices for water reuse, and the adoption of appropriate enterprise management strategies provide significant contributions to increasing water use efficiency. Furthermore, ensuring continuous access for animals to drinking water in sufficient quantity and appropriate quality is one of the fundamental components of not only water management but also the protection of animal health, welfare, and production performance.

Considering the existing pressure on water resources in Türkiye, the dissemination of practices for sustainable water management in dairy cattle enterprises is of great importance. Regular monitoring of water use at the enterprise level, the use of water-saving technologies, the development of appropriate infrastructure practices, and the adoption of management strategies that will reduce environmental risks will contribute to both the protection of water resources and sustainable milk production.

In conclusion, sustainable water management in dairy cattle enterprises should be considered a fundamental necessity in terms of protecting water resources, supporting environmental sustainability, improving animal welfare, and ensuring the long-term sustainability of production systems. The up-to-date information presented in this review provides a comprehensive evaluation that can contribute to practices for the more effective management of water use in dairy cattle enterprises and to future research.

Declaration on the use of artificial intelligence

During the preparation process of this review, AI-powered tools were utilized for the purposes of grammatical editing of the texts, improving the academic expression structure, and ensuring content organization. However, all scientific content, data, and citations in the text are based on the sources provided by the author. The artificial intelligence tool was not used for the purpose of generating new information, adding data, or creating scientific inferences; it was used only as a supportive tool in the process of reorganizing existing texts and making them compliant with academic writing standards.

ABSTRACT

Climate change represents one of the major challenges facing agricultural production in the Mediterranean region, where increasing temperatures, irregular precipitation, recurrent droughts, and water scarcity are expected to substantially affect crop productivity and product quality. The Turkish Republic of Northern Cyprus (TRNC), characterized by a Mediterranean climate and limited freshwater resources, is particularly vulnerable to these changes. Agriculture in the region includes important perennial and annual crops such as citrus, cereals, vegetables, grapes, olives, carob, and forage crops, many of which are highly sensitive to changes in temperature and water availability. This review evaluates the potential and observed impacts of climate change on agricultural production in the TRNC, with particular emphasis on crop yield and product quality. The review examines changes in temperature and precipitation patterns, increasing drought and evapotranspiration, water scarcity, soil salinity, and the potential changes in pest and disease pressure and their effects on agricultural systems. Particular attention is given to the effects of climate-related stresses on yield components and quality parameters, including fruit size, total soluble solids, titratable acidity, grain yield and protein content, nutritional quality, and postharvest characteristics. The role of irrigation management, soil and water conservation, improved fertilization, drought- and heat-tolerant cultivars, treated wastewater, precision agriculture, and other climate-smart agricultural practices in reducing climate-related risks is also discussed. The review highlights the need for long-term climate and agricultural production datasets, crop-specific climate impact assessments, and locally adapted adaptation strategies. Developing climate-resilient agricultural systems will be essential for maintaining sustainable production, protecting product quality, improving water-use efficiency, and strengthening food security in the TRNC under future climate conditions.

Keywords: Climate change, Crop quality, Mediterranean agriculture, Water scarcity

INTRODUCTION

Climatic changes are increasingly impacting agricultural systems worldwide, including through changes in temperature, precipitation, atmospheric water demand, extreme weather events, soil moisture, and water availability. Climatic variability, especially in agriculture, is sensitive, as crop development and growth are directly associated with climatic conditions at specific phenological stages. The Mediterranean region is one of the most climate-changed areas in the world, with warming and water scarcity intensifying, and its freshwater resources already scarce. The Intergovernmental Panel on Climate Change (IPCC) classifies the Mediterranean basin as a region where heatwaves are expected to become more frequent and persistent, accompanied by increasing drought and water scarcity and associated risks to agriculture and other climate-sensitive sectors (Ali et al., 2022). The recent regional assessment (Zittis et al., 2022) shows that the Eastern Mediterranean and the Middle East are warming faster than the global average, and that drying trends are expected to intensify in the twenty-first century, regardless of the emission scenario adopted.

Islands are particularly vulnerable since they rely heavily on Mediterranean agriculture. Agricultural systems are mostly island-based and are typically constrained by land and freshwater resources and by their ability to relocate production geographically when needed. Cyprus is an unusual example to illustrate this. Irrigation is a key feature of the island's agriculture, and times of drought and water scarcity have been a recurring problem; agriculture is the main user of the island's water resources, with an estimated 75% of the total abstraction being used in this sector, despite the increasing demand for water from domestic and tourism activities. According to FAO, olives, citrus, grapes, potatoes and other Mediterranean crops are key agricultural products in Cyprus, and the sector is highly reliant on irrigation.

While the environmental challenges are similar to those of the island as a whole, in some respects, they are more severe in the TRNC, given its limited supply of large-scale desalination and inter-basin water-transfer infrastructure. Drought and salinisation have been recognised as chronic issues in Northern Cyprus, and the need for irrigation efficiency and crop-water management has been highlighted via dedicated research. For instance, Kahramanoğlu et al. (2020) investigated the water footprints and irrigation-use efficiency of the most important crops in Northern Cyprus. They reported that the selection of crops and the allocation of water resources need to be reconsidered to ensure that agricultural water use is environmentally, economically, and nutritionally sustainable.

Long-term meteorological data also show that Northern Cyprus is becoming more drought-prone. Payab and Türker (2018) studied the temporal and spatial features of drought events in the region using different SPI time scales. They determined that drought has been a frequent and worsening event in recent decades, and that there is a regional pattern of rainfall distribution. A follow-up study, which compared several widely used drought indices (DIs) for Northern Cyprus, found that the indices are highly correlated with each other and are all equally effective at measuring the effect of drought on the yield of rain-fed wheat and barley (Payab & Türker, 2019). Recently, Payab and Türker (2025) used the Reconnaissance Drought Index (RDI) and the CROPWAT crop-simulation model to estimate the impact of drought severity on the yield of rainfed wheat, barley, and olive in Northern Cyprus from 1977 to 2013, reporting a mean loss of roughly 37% for wheat, 28% for barley, and 49% for olive under drought conditions. This loss became more apparent as drought severity increased. It is important because production is influenced not just by the average climatic state but also by the frequency, duration, timing, and intensity of droughts, and because soil water-holding capacity has been shown to have a nearly linear effect on yield loss.

Projected climate change at the larger scale suggests further warming and decreased precipitation. In the 2031-2060 period, under the RCP4.5 and RCP8.5 emission scenarios, projected seasonal warming and decrease in annual precipitation, especially in summer rainfall, are significant (Papadaskalopoulou et al., 2020). The changes are highly relevant to Northern

Cyprus, as many of the region's most important crops have the highest water requirements during spring and summer, which are the periods when the largest precipitation reductions are projected.

An analysis of climate change impacts on the production of major crops in Cyprus using coupled climate and crop models revealed that future warming and reduced precipitation are likely to significantly affect wheat, barley, tomato, potato, grape, and olive production (Markou et al., 2020). The study highlighted the vulnerability of crops with a summer growing season, such as tomato, grapevine, and olive. It suggested a list of adaptation measures for each crop that remain applicable in Northern Cyprus.

While the current literature offers good guidance, there is still a lack of research on how climate change will impact agricultural production, yield, and quality together, especially in Northern Cyprus. Most studies have focused on water use, drought indices, and single crops. In contrast, relatively few studies combine climatic trends with yield components, product quality, soil processes, pest and disease pressure, and adaptation options in one place, grounded in the local context.

This review, therefore, aims to provide a synthesis of the existing scientific literature on the impact of climate change on agricultural production in Northern Cyprus. Since limited experimental data are available for specific Northern Cyprus crops and quality parameters, studies relevant to the area are included to the extent that their results are likely to be applicable. The review also guides areas for further research and policy directions for establishing locally appropriate adaptation strategies to climate change.

REVIEW METHODOLOGY

Review Approach

The paper is written in a narrative scientific review style, drawing on peer-reviewed literature, scientific reports, and relevant institutional sources. Relevant literature was identified and assessed for relevance to Cyprus, Northern Cyprus, and similar Mediterranean agricultural systems regarding climate change, agricultural production, crop yield, product quality, water resources, drought, salinity, pests and diseases, and climate adaptation in Cyprus. Searches were carried out in the major scientific databases and in the platforms of the publishers, with targeted searches for recent studies (2021–2026) focusing on drought trends in Northern Cyprus, crop-specific responses to drought, water management under drought conditions, and climate-smart agricultural practices.

The following priorities were applied, in order: (1) peer-reviewed studies that explicitly referred to Northern Cyprus; (2) studies that covered all of Cyprus; (3) studies that covered the entire Mediterranean region but had a clear link to growing conditions in the Eastern Mediterranean; (4) recent studies that dealt with the adaptation of agriculture and water management; and (5) international assessments, such as the IPCC, FAO and European Environment Agency. Where evidence was not available on a Northern Cyprus-specific basis, evidence from comparable semi-arid Mediterranean environments was used with caution to provide scientific context, explicitly noting its transferability rather than assuming it.

Scope of the Review

The review is centred around six interrelated themes: climatic changes; agricultural production; crop yield; product quality; soil and water constraints; and adaptation and climate-smart agricultural practices. The main crops considered are those that, for the most part, take up most of the cultivated land and add value in Northern Cyprus, including cereals (wheat and barley), citrus, potatoes and vegetables, grapes, olives, carob, figs, and forage crops.

Agricultural and Climatic Context of Northern Cyprus

The climate of Northern Cyprus is Mediterranean, with hot, dry summers and relatively mild, wet winters. This climate results in good growing conditions for most Mediterranean crops but also significant water management requirements over the growing season, as nearly all rainfall falls outside the critical crop water uptake window.

The spatial variability of agricultural production is due to varying soil characteristics, topography, precipitation, groundwater resources, irrigation systems, and coastal location. Wheat and barley are important rainfed crops, mainly grown on the Mesaoria plain. Horticultural and perennial fruit crops, on the other hand, typically rely on supplemental or complete groundwater and reservoir irrigation.

The agro-system is thus very sensitive to the interaction between temperature and water availability. Increasing temperatures under moderate conditions may not necessarily lead to severe impacts if an adequate water supply is available. However, if warming is coupled with reduced rainfall, both atmospheric evaporative demand and crop water requirements may rise, placing greater stress on limited water resources.

Studies specifically targeting Northern Cyprus indicate that drought and salinisation have been significant constraints on agriculture for decades (Payab & Türker, 2018). The limited availability of freshwater makes irrigation efficiency particularly important. Kahramanoğlu et al. (2020) found significant variations in irrigation requirements and in economic and nutritional productivity per unit of water used. Their results indicate that making the water requirements of crops explicit in a crop plan can significantly reduce pressure on agricultural water resources without necessitating a decrease in cropped area.

This problem is likely to become more important under climate change because water availability and crop water demand may change simultaneously. Conventional agricultural planning, which is often based on historical climatic averages, may therefore be less effective for anticipating these combined changes.

Observed and Projected Climate Change

Increasing Temperature

One of the primary climate variables that influences crop production is temperature. Plants respond to temperature in characteristic ways, with the highest growth rates occurring within an optimal temperature range and declining above and below it. Photosynthesis, development, respiration, flowering and fertilisation can also be reduced above and below the optimum temperatures, as can the grain- or fruit-filling period.

Future warming projections for Cyprus show significant warming (Figure 1). The projected seasonal mean temperature changes for 2031-2060 from the ADAPT2CLIMA assessment were higher in comparison to the 1971-2000 reference period, with approximately 2°C warming in winter and 3°C in summer for RCP4.5 and 4°C warming in winter and 6°C in summer for RCP8.5 (Markou et al., 2020). The warming trend is also consistent with regional projections for the Eastern Mediterranean, which show that warming is generally greater than the global average and that the incidence of extreme heat events is increasing (Zittis et al., 2022).

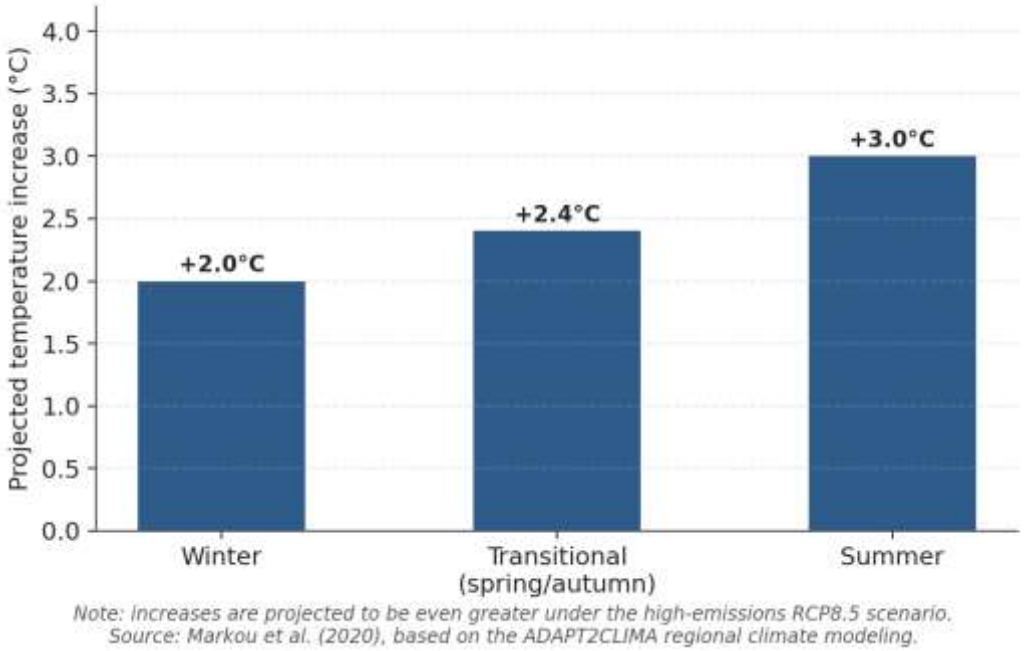

Figure 1. *Projected seasonal mean temperature increase in Cyprus, 2031–2060 vs 1971–2000, under RCP4.5 (Markou et al., 2020).*

The increase in temperature is especially relevant for Northern Cyprus, as the temperatures are already close to or surpassing critical physiological limits for several crops during summer. As a result, further temperature increases could lead to increased heat stress, especially at flowering, fruit development, grain filling, and grain maturity, when even brief periods of extreme heat can cause disproportionate yield and quality losses.

Changes in Precipitation

Another significant concern is projected changes in precipitation. Cyprus climate projections show decreases in annual precipitation under both RCP4.5 and RCP8.5, especially in summer (Figure 2). In summer, precipitation reductions are around 20–30% under the RCP8.5 scenario across most of the island, with larger reductions in some areas (Papadaskalopoulou et al., 2020).

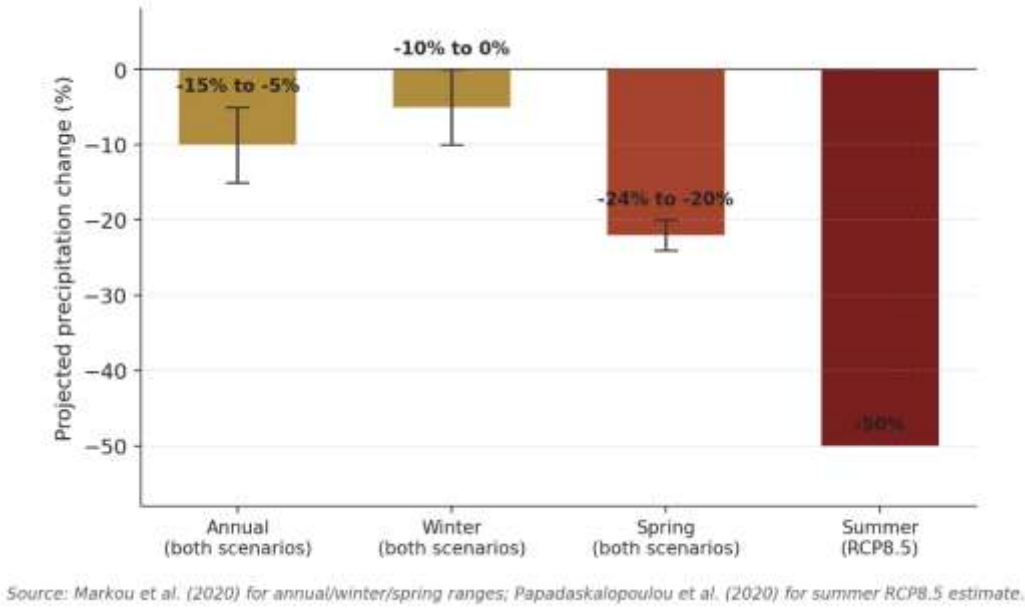

Figure 2. Projected seasonal precipitation change in Cyprus, 2031–2060 vs 1971–2000 (Markou et al., 2020; Papadaskalopoulou et al., 2020).

The increased temperature and reduced rainfall are more significant than either factor alone. A decrease in precipitation reduces soil-water availability, and an increase in temperature raises evapotranspiration; this can create a significant water deficit during a peak crop water-demand period and therefore compress the time available to draw water from soil-water or irrigated sources (Table 1).

Table 1. Summary of projected climate change indicators for Cyprus, 2031–2060, relative to 1971–2000.

Indicator	RCP4.5	RCP8.5
Winter temperature	+2.0°C	Greater than RCP4.5 (not separately quantified in source)
Transitional-season temperature	+2.4°C	Greater than RCP4.5 (not separately quantified in source)
Summer temperature	+3.0°C	Greater than RCP4.5 (not separately quantified in source)
Annual precipitation	−5% to −15%	−5% to −15% (similar range to RCP4.5)
Winter precipitation	Up to −10%	Up to −10% (similar range to RCP4.5)
Spring precipitation	20% to −24%	20% to −24% (similar range to RCP4.5)
Summer precipitation	Not separately quantified in the source	Up to −50% (the largest seasonal decrease of any scenario/season)

Increasing Drought

Drought is perhaps the most direct climate-related agricultural risk in Northern Cyprus (Figure 3). Historical drought records indicate that droughts have become more frequent and severe in the region over the last few decades (Payab & Türker, 2018, 2019; Payab & Türker, 2025, as summarised in Türker & Payab, 2023).

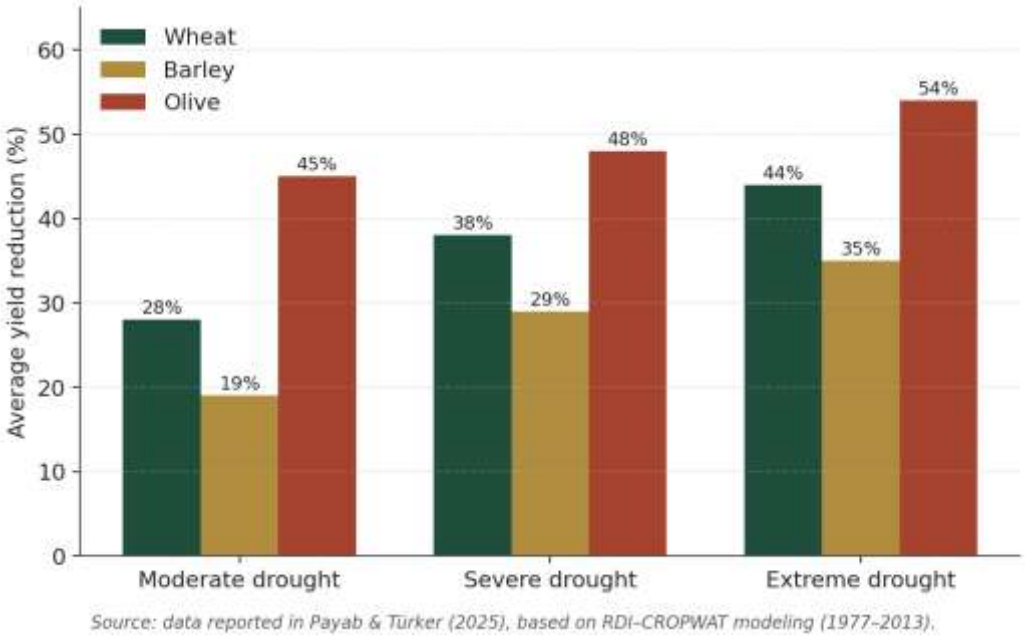

Figure 3. Drought-related yield reduction in rainfed wheat, barley, and olive in Northern Cyprus, by drought severity level (Payab & Türker, 2025).

Agriculture is affected by drought in multiple ways, including soil moisture, groundwater recharge, reservoir storage, irrigation water availability, salinity risk, nutrient uptake, photosynthesis, premature leaf senescence, and fruit and grain development. The quantitative evidence from CROPWAT based modelling in Northern Cyprus is very direct in this sense: reductions in average yield were estimated to be around 37% under drought conditions for wheat, 28% for barley and 49% for olive, with the severity of the drought showing a rapid increase along with drought severity, and soil water-holding capacity acting as a significant moderation factor (Payab & Türker, 2025). Such impacts can be especially strong when drought occurs during hot periods of the year, which may be more likely under anticipated future climate conditions.

Evapotranspiration and Crop Water Demand

Climate change is not only causing decreased rainfall but also increasing the water requirement of the atmosphere. Higher temperatures also increase potential evapotranspiration and, consequently, crop water demand, increasing the amount of water required to maintain production.

These include remote-sensing techniques for estimating crop evapotranspiration and irrigation needs for citrus, olives, and potatoes within a smart farming water management framework, which has been developed in recent research in Cyprus (Neophytides et al., 2024). The need to optimise irrigation water use is highlighted because the total water demand of these crops may exceed reservoir inflow, especially during dry irrigation seasons.

The discovery has implications for Northern Cyprus. The increasing variability in precipitation with rising temperatures and the greater need for irrigation water may make history-based irrigation plans ever less reliable, making evapotranspiration-based, near-real-time irrigation scheduling an increasingly useful management tool, not just an added luxury.

Effects of Climate Change on Agricultural Production

Agricultural production can be impacted by climate change in various ways. Direct effects include heat stress, drought, flooding, and alterations in growing-season length and timing. Indirect effects include water shortages, salinity, changes in pest and disease pressure, soil degradation, changes in production costs, and changes in input requirements. The overall impact on a particular farm or crop, however, depends on the interaction among climate, crop, soil, management, and socioeconomic factors. Hence, the evidence for particular crops, described in the subsequent sections, is vital for supporting the interpretation of general climate trends into farm-specific agricultural guidance.

Effects on Cereals

Wheat and barley are important cereal crops in Cyprus. They are especially significant in the field of food security, as cereals constitute a large share of the cultivated area on the island and are mostly grown under rainfed conditions in Northern Cyprus.

Drought and high temperatures are a threat to cereals. The effects of water stress include reduced tiller survival, increased spike formation, decreased grain number, decreased grain filling, decreased thousand-kernel weight, and ultimately decreased final grain yield. Heat stress during flowering can affect pollen viability and fertilisation, while heat during grain filling can accelerate grain maturation and shorten grain-filling time. The impact of these effects in Northern Cyprus is well documented, as modelled reductions in yield under drought conditions are on the order of about 37% for wheat and about 28% for barley, and about 44% and 35% for wheat and barley, respectively, under extreme drought (Payab & Türker, 2025).

Over the last few years, evidence from around the world has emerged that heat stress can affect both yield and grain quality in wheat. A 2026 meta-analysis of 95 studies and 1,976 observations worldwide revealed that heat stress had a significant negative effect on thousand kernel weight and starch concentration and significant positive effects on protein and wet gluten concentration, while the effects of these responses were found to vary systematically with the

timing, duration and intensity of heat exposure (Liu et al., 2026). For drought, a complementary meta-analysis yielded the same conclusion: the effect of drought on wheat yield and grain protein content (GPC) is highly moderated by the environmental context, defined by soil type, prior water status, and cultivar (Wan et al., 2022).

Wheat protein concentration can also be affected by drought. However, it is not always valid to assume that a decrease in protein concentration is equivalent to better nutritional or processing quality, since any increase in protein concentration may be offset by decreases in grain size and starch concentration. Processing quality depends on the balance among protein, starch, and gluten fractions, not on protein concentration alone.

This is because, in Northern Cyprus, higher temperatures and reduced rainfall could pose both challenges: reduced yields, primarily due to water deficiency during tillering and grain filling, and altered grain composition due to heat stress during these developmental periods.

Effects on Potato and Vegetable Production

Potato and vegetable production is highly dependent on adequate water availability. Potatoes are especially sensitive to temperature and soil-water stress during tuber initiation and bulking, when brief water deficits can cause greater yield loss.

Water stress can decrease the number of tubers, tuber size, marketable yield, uniformity, dry matter content, and post-harvest quality. The high temperature may also have a direct impact on tuber formation and has a positive relationship with the incidence of internal heat necrosis and secondary growth as physiological disorders.

High temperatures and water shortages are also detrimental to vegetable crops such as tomato, lettuce, eggplant, watermelon, and melon. Tomato and potato crops were among the most water-intensive and economically valuable crops identified as in need of specific adaptation measures as a result of a climate assessment in Cyprus (Markou et al., 2020).

Horticultural crops typically have higher production costs and greater irrigation requirements than many rainfed crops. Therefore, yield losses are more likely to result in farm-level economic losses than similar percentage losses in extensive rainfed cereals.

Effects on Citrus Production

Citrus is one of the significant groups of perennial crops in Cyprus. Citrus production is generally year-round. It therefore has a relatively high water requirement, which must be available throughout the year, especially during fruit development, and is not easily adapted to alternative planting dates if the water year turns out to be poor.

Climate change could affect citrus production through higher evapotranspiration, drought stress, smaller fruit, earlier fruit drop, sunburn, changes in maturation time, changes in soluble solids and acidity, and greater irrigation needs. Fruit growth may be affected by water stress due to the critical nature of water supply during certain fruit development stages, and the high susceptibility of fruit and canopy to sunburn and physiological stress due to severe heat.

With perennial crops, adaptation over 10 years or more is required, as there is no possibility of simply replanting and adjusting each year to climate variability. Therefore, rootstock choice, irrigation water-use efficiency, mulching, soil-water conservation, canopy management, and cultivar selection are among the factors that are very important for maintaining productivity under changing conditions.

Effects on Grapevines and Grape Quality

The sensitivity of grapevines to changes in temperature and water availability is especially high, as climate strongly influences phenology and fruit composition. With increased temperatures, bud formation, flowering, veraison, sugar ripening, maturation, and harvest may occur faster, sometimes with shorter intervals.

This rate of increase often leads to earlier harvests and changes in the sugar-to-organic acid ratio. In wine grapes, global warming is consistently associated with higher soluble solids content, lower acidity, and lower anthocyanin concentration. This mix may result in wines of

higher alcohol content, different colour, and reduced aromatic balance, which can pose difficulties in maintaining the regional style. Recent literature reviews of Mediterranean viticulture (2020-2023) agree that climate is the main driver of grape and wine quality in the region and that global warming is causing a general increase in soluble solids and a decrease in anthocyanin and acid levels in a broad spectrum of varieties and locations.

Grape yield and quality are also influenced by water availability. Well-timed moderate water stress can sometimes enhance some quality parameters, e.g., the concentration of phenolic compounds. In contrast, excessive or poorly timed water stress decreases berry size and yield, photosynthetic activity, and, over consecutive seasons, plant longevity. Field trials comparing productive and morphological traits under rain-fed conditions with those under irrigated conditions highlight a yield–quality trade-off: a reduction in yield and deterioration in quality parameters in certain instances. In contrast, some quality parameters, such as colour and astringency, may increase under limited water availability, as observed in wine-grape genotypes cultivated in the Mediterranean region.

For Northern Cyprus, local grapevine cultivars and practices appear well adapted to Mediterranean conditions, but they may become increasingly vulnerable as temperatures and drought intensity exceed historical levels. In other parts of the Mediterranean, phenological modelling indicates the potential for veraison and harvest several weeks earlier under high-emissions scenarios by mid-century. In the absence of adaptation, this change would also be anticipated in the Eastern Mediterranean vineyards.

Adaptation options may include the use of drought-hardy cultivars and rootstock, deficit irrigation (where scientifically sound and planned for); canopy management (shading, forced bud regeneration, which slows ripening); soil mulching; planting density changes; modified pruning; and modified vineyard microclimate management—some of which are effective in similar dryland Mediterranean winegrowing areas.

Effects on Olive Production

Olive trees are considered relatively drought-resistant among fruit trees. However, drought tolerance is not drought immunity and, as the recent Mediterranean-wide experience indicates, even this relatively hardy plant is being heavily stressed by climate change.

Extended periods of water deficit, excessive temperatures, irregular flowering and fruiting, diminished fruit set, smaller fruit size, alternate bearing, changes in the oil content of the fruit, and increased infestation can affect olive production. Increased temperatures and water scarcity are expected to alter the geographic distribution of areas suitable for olive cultivation, decrease yields in the warmest and driest regions, and necessitate the use of adapted cultivars, deficit irrigation, and potentially modified orchard management to sustain productivity over the mid-term (Fraga et al., 2020).

This vulnerability is also reflected in recent harvest outcomes around the Mediterranean: four years of high temperatures and drought in Spain, Italy, Greece and Tunisia (2021-2024) resulted in significant reductions in olive oil production and skyrocketing prices, and survey data showed that the proportion of growers reporting drought and high temperatures as harvest-limiting factors increased significantly from previous years. Furthermore, a long-term (8,000 years) palaeoecological analysis of olive pollen records indicates that the productivity of olive trees in the Eastern Mediterranean is ultimately determined by the level of photosynthetic activity, which is determined by the interaction of temperature, precipitation timing and radiation balance, and not for example by temperature alone (Kaniewski et al., 2025); thus, the future trajectory of olive productivity in the Eastern Mediterranean will depend on the

combined trajectory of water stress and solar radiation and not on the trajectory of temperature alone.

According to modelled evidence, for Northern Cyprus in particular, this is the case for olive since average yield losses under drought have been estimated to be about 49%, which is higher than those modelled for wheat and barley, and more than 50% under severe and extreme drought conditions (Payab & Türker, 2025). This discovery is in stark contrast to the general public perception of olives as relatively hardy under drought conditions. It indicates that in Northern Cyprus, soil and rainfall distributions may increase the susceptibility of olive orchards to drought.

Thus, future climate conditions may not necessarily threaten the viability of olive trees in Northern Cyprus, However, water management, cultivar and rootstock choice, and orchard-level adaptations are likely to be required to ensure the trees yield high amounts of high-quality oil, while maintaining high productivity and oil quality will require appropriate adaptation measures.

Effects on Carob, Fig, and Other Perennial Crops

Carob and fig are less susceptible to dry Mediterranean conditions and may require less irrigation than more intensive horticultural crops. In the study carried out in the Northern region of Cyprus, irrigation water consumption for carob and fig was among the lowest among the other crops studied (Kahramanoğlu et al., 2020).

This will have significant implications for future agricultural planning. Due to water scarcity, attention could be given to species such as carob and fig, which have relatively high economic or nutritional value, but relatively low water requirements, thus suggesting these species as possible contributors to a more water-friendly crop mix for the territory.

However, water use should not be the sole criterion for crop diversification. The other factors that can be taken into account are the market demand, suitability of the land, farm income, biodiversity, nutritional value, processing opportunities, and tolerance to climate change; a transition to low-water crops that do not have market access or processing infrastructure would move the risk from water balance to farm income.

Climate Change and Product Quality

Climate change impacts on agriculture need to be assessed beyond yields. Product quality is also crucial because it affects market value, consumer acceptance, processing capacity, storage life, and exportability, all of which are crucial for the long-term economic sustainability of Northern Cyprus agriculture, which is heavily dependent on export markets for citrus, potatoes, and other horticultural products.

Fruit size, colour, firmness, soluble solids, titratable acidity, sugar/acid ratio, antioxidant content, phenolic compounds, oil composition, grain protein content, grain starch content, thousand-kernel weight, and post-harvest shelf life may all be affected by climate-related changes.

Fruit Size

Fruit expansion is closely related to water availability. Drought stress may limit cell growth and, thus, fruit size. Fruit size is especially important for fruit intended for commercial markets, such as citrus, grapes and other horticultural crops, because undersized fruit may be considered in a completely different category for premium export grades than it would be for other grades, and may not be saleable for those grades.

Total Soluble Solids

Sugar buildup in fruits may be affected by temperature and water availability. Some fruit crops may be affected by moderate water stress, which may increase soluble solids content as water is diluted. The relationship is not necessarily linear, because severe stress can reduce photosynthesis and total carbohydrate production.

Therefore, an increase in soluble solids is not always a good indicator of climate change. Product quality is multi-dimensional, and whenever a product improvement is achieved in one quality dimension, it is often counterbalanced by a decrease in another.

Titratable Acidity

In many fruits, the degradation of organic acids can be hastened by high temperatures. Excessive heat in grapes can therefore result in higher sugar content and lower acidity, which may alter fruit and wine quality and necessitate adjustments in winemaking (such as acidification) that were not required before.

Grain Quality

This evidence reinforces the importance of considering both yield and end-use quality when assessing climate impacts on wheat.

This illustrates why future climate assessments should consider both yield and quality: a wheat crop that maintains yield but loses milling or baking quality may still represent an economic loss for producers and processors.

Water Scarcity and Irrigation

One of the main issues in agriculture in Northern Cyprus is water scarcity. The problem extends beyond the absolute availability of water and involves rainfall variability, groundwater extraction, reservoir storage, irrigation efficiency, evaporation, salinity, competing domestic demands, tourism, and the allocation of irrigation water during dry years.

Research on Northern Cyprus highlights the need for increased irrigation efficiency and water footprint management as immediate measures that the sector can leverage (Kahramanoğlu et al., 2020). The complementary work carried out on a Cyprus-wide scale demonstrated that the use of remote sensing for evapotranspiration monitoring can make a real contribution to improved irrigation scheduling accuracy for citrus, olive, and potato crops, compared to traditional calendar-based methods (Neophytides et al., 2024).

So the best solution for adaptation will not be a single technology. Instead, water management should include: (1) the accurate assessment of crop water requirement, (2) efficient irrigation systems, (3) soil-moisture monitoring, (4) suitable irrigation scheduling, (5) water productivity-informed crop selection, (6) use of drought-tolerant cultivars, (7) water harvesting, (8) wastewater reuse, (9) groundwater protection, and (10) digital monitoring throughout the value chain.

Soil Salinity and Water Quality

When preferred freshwater sources are unavailable, water scarcity can lead to reliance on less suitable sources, such as treated wastewater and saline groundwater, especially during prolonged dry spells.

Seawater intrusion is particularly a problem in Mediterranean coastal regions due to excessive groundwater drainage. Research conducted in Cyprus has shown that saline irrigation water can have negative impacts on soil resources. At the same time, moderate salinity can cause significant and even long-lasting soil problems (Kathijotes & Panayiotou, 2013).

Soil salinity causes salinity stress to crops by decreasing the root's water-absorbing capacity and by causing ion toxicity and nutrient imbalance in the soil, even though, in a volumetric sense, the water appears sufficient.

Climate change may exacerbate the salinity issue due to changes in rainfall, which lead to less natural freshwater recharge; greater evaporation would result in salt concentration in soil and remaining water bodies; drought-induced groundwater dependence would cause groundwater to be pumped at higher rates, increasing the salinity of wells; the total demand for irrigation would increase; and seawater intrusion would be more likely in vulnerable coastal aquifers, as groundwater levels are lowered during drought.

So, climate adaptation requires water-quality management in addition to water quantity; a plan that could provide adequate irrigation water but would let salt levels increase to the detriment of the crops would just be changing one type of stress for another.

Treated Wastewater as an Adaptation Strategy

Treated wastewater can be a valuable supplementary water source for agriculture. Potential benefits include reduced dependence on freshwater, a relatively stable water source during drought, nutrient recycling, and broader circular water management.

Reliance on wastewater reuse, however, requires careful management, as salinity, sodium, pathogens, nutrients, and other contaminants can be problematic if not properly managed. The results in Cyprus show that the use of saline wastewater for irrigation can lead to a measurable impact on soil resources over time; therefore, treated wastewater is not a risk-free alternative to freshwater (Kathijotes & Panayiotou, 2013).

Thus, wastewater reuse in Northern Cyprus should be implemented under appropriate treatment standards and regular water-quality monitoring, together with crop-specific irrigation requirements, salinity management, soil monitoring during the growing season, and suitable irrigation techniques. These measures may include subsurface drip irrigation to minimise contact between edible plant parts and wastewater and blending with freshwater when necessary to maintain salinity below crop-specific thresholds.

Treated wastewater should therefore not be regarded as the sole replacement for freshwater, but rather as an integral part of integrated water management, and its development in Northern Cyprus should not take the place of investments in measures that lead to freshwater savings.

Pest and Disease Pressure

Climatic changes may impact pests and diseases through changes in temperature, humidity, host susceptibility, and pest development rates, many of which are not simply predicted by changes in temperature alone.

Increased temperatures may lead to faster development and more generations per season of insects, change the geographic distribution of insects, boost overwintering survival, and affect interactions between the insects and host plants more broadly. Meanwhile, any changes in precipitation and humidity can influence disease pressure from fungi and bacteria either positively or negatively, depending on the organism causing the disease.

The relationship is complex: warmer, drier weather may reduce the growth of some pathogens and increase the growth of others; extreme weather events can cause physiological stress on plants, making them more vulnerable to secondary pests and diseases, even if the primary climate driver is not directly affecting the pest. This compound effect was also observed in the documented experience of the 2023 harvest in the Mediterranean olive region, where heat and drought stress clashed with increased pest emergence, further affecting olive production.

As such, in the context of Cyprus climate adaptation research, increasing pest pressure and declining plant health are considered important issues in agriculture that require special monitoring (Markou et al., 2020). For Northern Cyprus, locally relevant monitoring systems are necessary to identify the risks posed by pests and diseases that are actually rising, given the region's agroclimatic peculiarities, because information from Mediterranean-scale trends cannot be extrapolated to Northern Cyprus. Farmer observation data should be systematically collected alongside meteorological and agricultural surveillance data to build this evidence base over time.

Climate Change and Crop Phenology

Important crop development stages may be altered by climate change. With warmer temperatures, flowering could be earlier, fruiting could be sooner, the grain-filling period may be shortened, harvest may be earlier, crop-pollinator synchronisation may be disrupted, and exposure to late-season heat events that occurred rarely during flowering/fruit set may be higher.

Changes in phenology are particularly significant for perennial crops, like grapes, citrus and olives, whose management schedules, workforce planning and even export logistics are based on historically consistent phenological periods. For instance, advancements in grape maturity due to earlier ripening may shift the balance between sugar accumulation and acid retention, as shown in several Mediterranean vineyards, where veraison and harvest dates have already shifted significantly over the last few decades. Likewise, cereal development can be accelerated, which could negatively impact grain filling under heat and drought stress and grain weight, as described in Section 6.

Hence, phenological monitoring should be incorporated into climate adaptation research in Northern Cyprus as an early, sensitive indicator of climate impacts and to support management decisions before yield and quality reductions are observed.

Climate-Smart Agricultural Adaptation

Climate adaptation should not only seek to sustain existing agricultural production, but also to strengthen the overall production system to withstand climate risks, as historical norms have been optimised for a climate that is no longer applicable.

Improved Irrigation Management

Efficient irrigation is among the most critical adaptation options at hand. Water losses (and salinity) can be minimised with drip irrigation systems, which deliver water to the root zone; however, the efficiency of the delivery system critically depends on irrigation scheduling, even if the system is efficient itself, because over-irrigation can cause water losses and salinity.

The use of remote sensing and evapotranspiration monitoring can enable more accurate irrigation decisions. Recent studies conducted on Cyprus demonstrated the potential of remote sensing to estimate crop evapotranspiration and optimise irrigation water demand for citrus, olives, and potatoes within an integrated smart-farming framework (Neophytides et al., 2024).

Soil-Water Conservation

Water loss from soil management can be reduced through mulching, conservation tillage, organic amendments, cover crops, retaining residues, improving soil structure, and rainwater harvesting. These practices can increase infiltration, decrease evaporation, and improve soil-water retention, thereby increasing the time that stored soil water is available to the crop between rains and/or irrigation.

Drought- and Heat-Tolerant Cultivars

Genetic adaptation is particularly significant because cultivar differences in response to heat and water stress are large. Breeding and cultivar selection should focus on drought tolerance, heat tolerance, efficient water use, yield stability, disease resistance, adaptation to local soils, and yield potential under historical average conditions.

For perennial crops, rootstock choice can be another mechanism that significantly affects drought tolerance and water-use efficiency without changing the cultivar of the fruit scion or fruit quality traits.

Crop Diversification

Diversifying crops can help reduce dependence on a few climate-sensitive crops. An analysis of the net primary productivity (NPP) of different cropping systems in Cyprus with the aid of machine-learning techniques and Earth-observation data revealed that diversification generally resulted in a small improvement of the NPP by around 2.8% across the country, especially under warmer and drier climatic scenarios, indicating that diversified cropping systems may be more resilient to the climate pathway that Cyprus is projected to experience (Giannarakis et al., 2023).

Diversification might thus be a promising option for Northern Cyprus, if the appropriate market access and processing facilities are available and crop selection is economically and agronomically viable.

Precision Agriculture

Precision agriculture can improve resource-use efficiency when sensing, monitoring, and decision-support tools are integrated into a coherent management system rather than applied independently.

These systems can detect problems before they become visually apparent and enable more efficient irrigation and fertilization, shifting management from reactive to proactive and data-driven.

Protected Cultivation

Some extreme weather can be minimised in greenhouses and protected crops. They can also be associated with increased cooling and irrigation needs in extreme heat; however, protected cultivation is not a solution for every climatic situation and requires adaptation to a warming climate.

Thus, using a protected cultivation system that is resistant to climate change should be based on the integrated use of ventilation, shading, efficient cooling, water recycling, climate-controlled irrigation, and energy-efficient technologies – not as individual features.

Crop-Specific Adaptation Priorities

The evidence reviewed above is summarised in Table 2, which highlights the major climate risks, likely impacts, and priority adaptation measures for extension and policy planning.

Table 2. Crop-specific climate risks, likely impacts, and priority adaptation measures in Northern Cyprus.

Crop / group	Major climate risks	Likely impacts	Priority adaptation
Wheat	Heat, drought	Lower grain number and weight (avg. ≈–37% yield under drought); altered protein/starch balance	Early/appropriate sowing, drought-tolerant cultivars, efficient fertilization
Barley	Drought, heat	Reduced biomass and grain yield (avg. ≈–28% under drought)	Drought-tolerant varieties, optimized planting date
Potato	Heat, water shortage	Reduced tuber formation, size, and marketable yield	Efficient irrigation, heat-tolerant varieties, soil mulching
Tomato	Heat, drought	Reduced fruit set, yield, and quality	Protected cultivation, irrigation scheduling, heat-tolerant varieties
Citrus	Water shortage, heat, salinity	Smaller fruit, physiological stress, altered soluble solids/acidity	Drip irrigation, rootstock selection, salinity management
Grapes	Heat, drought	Earlier maturation, smaller berries, higher sugar/lower acidity	Cultivar/rootstock selection, canopy management, strategic irrigation
Olive	Heat, drought	Reduced fruit set and yield (avg. ≈–49% under drought — the most drought-sensitive of the modeled crops)	Efficient irrigation, drought-tolerant cultivars, orchard-level water management
Carob	Drought	Generally, more resilient; productivity may still decline under severe stress	Crop diversification and soil-water conservation
Fig	Drought and heat	Fruit size and quality changes	Efficient water management, cultivar selection
Forage crops	Heat, drought	Lower biomass and feed quality	Drought-tolerant species and improved irrigation

Economic and Food-Security Implications

The effects of climate change on farms are far-reaching and extend beyond the individual farm. Lower yields can lead to rising food prices, lower farm income, greater reliance on imports, and the jeopardization of rural livelihoods, all of which can build on a series of poor seasons.

This is especially relevant on islands, where the share of food imports could rise rapidly as local agriculture becomes less reliable, and where alternative options for importing food are limited during regional shortages. Climate-induced production shocks in the Mediterranean, with significant impacts in Spain, Italy and Greece due to drought and heat, provide a clear example of how extreme drought and heat can drive a price shock that globalises the Mediterranean and quickly impacts other importing and producing regions in the basin.

In Northern Cyprus, where the majority of farmers are smallholders, economic viability is an important aspect of adaptation. No economically viable and technically viable approach will be of much practical value if it has not been proven to be agronomically beneficial. Agricultural policies, therefore, could focus on financial incentives, modernisation of irrigation through subsidisation, farmer training, dissemination of climate information, crop insurance, research and extension services, access to precision farming technologies, and improved water governance – all as a package, not separately.

CONCLUSION

Northern Cyprus is facing a serious and increasing threat to agricultural sustainability from climate change. The Mediterranean climate, scarcity of fresh water resources, reliance on irrigation, and the current problems of drought and salinity make the area vulnerable to future climate change.

There is evidence that Northern Cyprus is already under severe drought stress, and climate models predict further warming in Cyprus and less rainfall. Recent drought analysis has shown that drought severity and frequency have been increasing over the past few decades in Northern Cyprus (Payab & Türker, 2018, 2019), and quantitative crop-simulation evidence has estimated substantial yield reductions under drought conditions in the region (average of around 37% for wheat, 28% for barley and 49% for olive under drought conditions; Payab & Türker, 2025). Climate projections for Cyprus indicate significant additional warming and reduced precipitation, especially in summer (Papadaskalopoulou et al., 2020; Zittis et al., 2022).

Agriculture impacts are expected to be significant. Heat and drought stress may lead to additional yield losses and modifications in grain composition in cereal crops. Increasing irrigation needs and heat stress may limit potato and vegetable production.

Most importantly, climate change impacts not only the amount of agricultural yields but also their quality. Fruit size, soluble solids, acidity, grain protein, starch concentration, and post-harvest characteristics may affect market value and food quality. Recent global evidence on wheat shows that heat stress can affect both grain weight and the chemical composition of wheat simultaneously (Liu et al., 2026), with repercussions for Northern Cyprus wheat production.

In this context, water management should be at the core of agricultural adaptation in Northern Cyprus. The studies show that significant differences exist in water use efficiency and requirements for various crops when irrigated in Northern Cyprus, indicating that improved crop planning can help minimise water scarcity (Kahramanoğlu et al., 2020). More recent studies in Cyprus also show the potential of remote sensing and evapotranspiration-based methods to enhance irrigation management for citrus, olive, and potato production (Neophytides et al., 2024).

Finally, the review highlights the need for additional local studies in Northern Cyprus. Future research could combine long-term climate data with crop yield and grain quality data and explore the economic feasibility of other adaptation options. Thus, developing climate-resilient

agriculture in Northern Cyprus is important not only for environmental reasons but also for food security, rural livelihoods, sustainable water management, and the long-term economic viability of the agriculture sector.

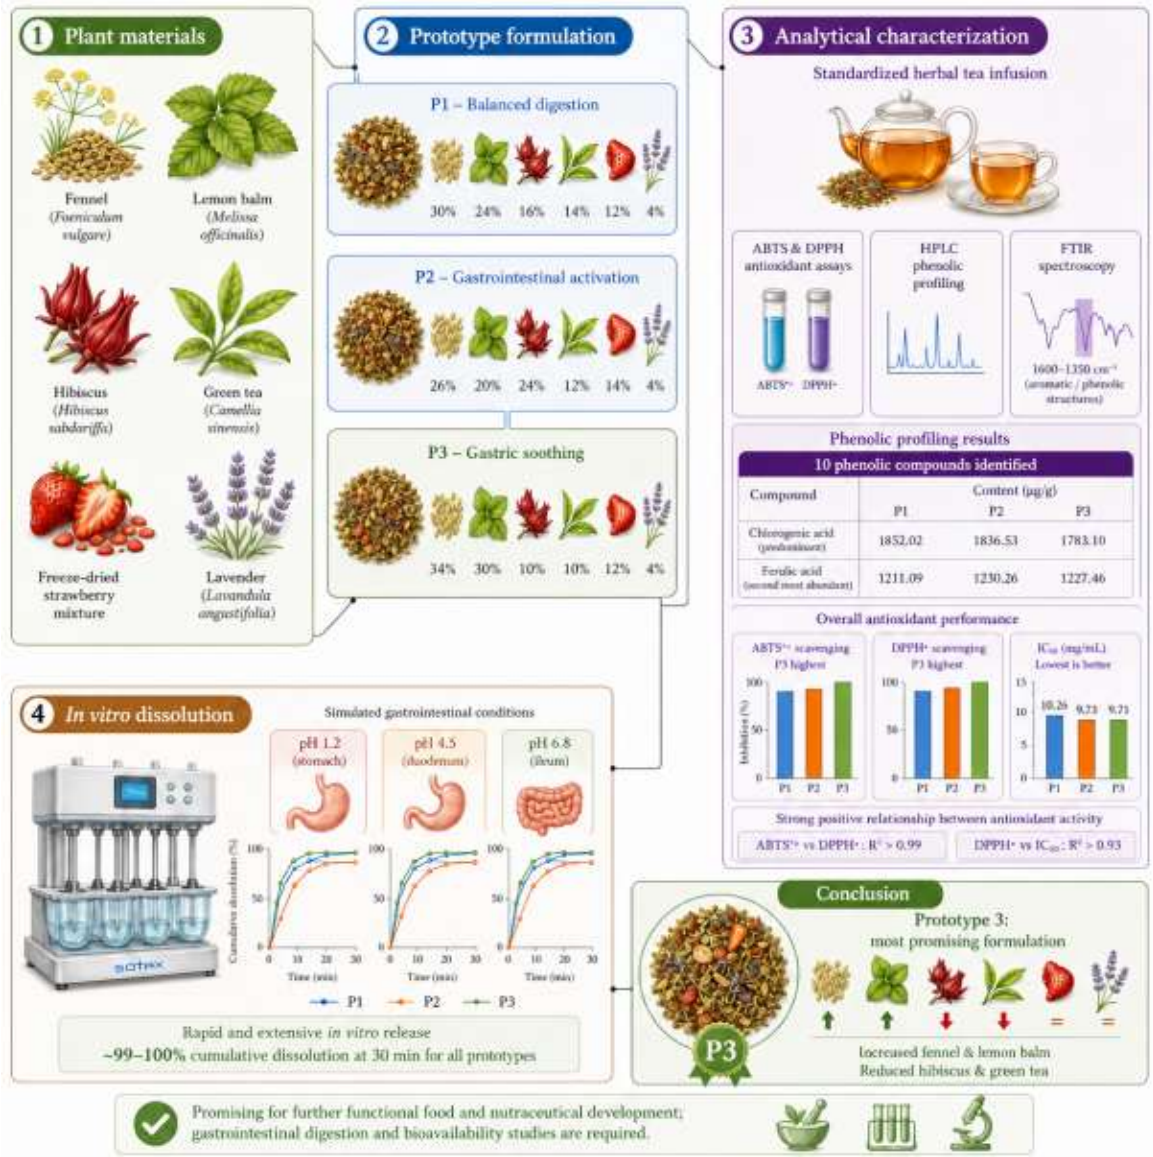
ABSTRACT

Interest in herbal teas is steadily increasing due to their potential health benefits. In this study, fennel (*Foeniculum vulgare*), lemon balm (*Melissa officinalis* L.), hibiscus (*Hibiscus sabdariffa* L.), green tea (*Camellia sinensis* L.), freeze-dried Ottoman strawberries, and lavender (*Lavandula angustifolia*) were used to develop three functional herbal tea prototypes, and their antioxidant activities, FTIR spectral characteristics, and in vitro dissolution behaviours were evaluated. Three prototypes were prepared based on their targeted effects on the digestive system. Prototype 1 (P1), formulated with fennel (30%), lemon balm (24%), hibiscus (16%), green tea (14%), freeze-dried strawberry (12%), and lavender (4%), was designed to promote balanced digestion. Prototype 2 (P2) contained fennel (26%), lemon balm (20%), hibiscus (24%), green tea (12%), freeze-dried strawberry (14%), and lavender (4%) and was formulated to stimulate bowel activity. Prototype 3 (P3) was formulated with fennel (34%), lemon balm (30%), hibiscus (10%), green tea (10%), freeze-dried strawberry (12%), and lavender (4%), emphasising digestive comfort through increased proportions of fennel and lemon balm and reduced proportions of hibiscus and green tea. Fourier Transform Infrared Spectroscopy (FTIR) spectra revealed characteristic absorption bands associated with the diverse phytochemical and structural components of the plant mixtures. Antioxidant activity was evaluated using ABTS and DPPH radical-scavenging assays. P3 exhibited the strongest antioxidant performance among the three formulations, showing the highest ABTS radical-scavenging activity and the lowest IC_{50} value (9.65 and 9.71). The DPPH IC_{50} values were measured as 10.26, 9.73, and 9.71; and ABTS IC_{50} values were 10.26, 10.75 and 9.65, for P1, P2, and P3, respectively. The Trolox-equivalent antioxidant capacity determined by the ABTS assay exceeded 90 μmol TE g^{-1} in all tested formulations. The SOTAX dissolution test demonstrated rapid and extensive in vitro release under simulated gastrointestinal pH

conditions (pH 1.2, 4.5, and 6.8), with cumulative dissolution values approaching 99-100% after 30 min. Consequently, P3, in which the proportions of fennel and lemon balm were increased while those of hibiscus and green tea were reduced, emerged as the most promising formulation based on its antioxidant performance and dissolution behaviour. These findings suggest that combining plant-based ingredients in appropriate ratios may influence the functional characteristics of herbal tea blends. The results provide a basis for further studies involving simulated gastrointestinal digestion, bioaccessibility, and bioavailability of the bioactive compounds.



Keywords: Functional herbal tea, antioxidant activity, phenolic content, digestibility.

ÖZET

Bitki çaylarına olan ilgi, potansiyel sağlık yararları nedeniyle sürekli artmaktadır. Bu çalışmada, rezene (*Foeniculum vulgare*), melisa (*Melissa officinalis* L.), hibiskus (*Hibiscus sabdariffa* L.), yeşil çay (*Camellia sinensis* L.), dondurularak kurutulmuş Osmanlı çileği ve lavanta (*Lavandula angustifolia*) kullanılarak üç fonksiyonel bitki çayı prototipi geliştirilmiş ve **antioksidan aktiviteleri, FTIR spektral özellikleri ve *in vitro* çözünme davranışları** değerlendirilmiştir. Sindirim sistemi üzerindeki hedeflenen etkilerine göre üç prototip hazırlanmıştır. Rezene (%30), melisa (%24), hibiskus (%16), yeşil çay (%14), dondurularak kurutulmuş çilek (%12) ve lavanta (%4) ile formüle edilen Prototip 1 (P1), dengeli sindirimi desteklemek üzere tasarlanmıştır. Prototip 2 (P2), rezene (%26), melisa (%20), hibiskus (%24), yeşil çay (%12), dondurularak kurutulmuş çilek (%14) ve lavanta (%4) içeriğiyle bağırsak aktivitesini uyarmak için formüle edilmiştir. Prototip 3 (P3) ise rezene (%34), melisa (%30), hibiskus (%10), yeşil çay (%10), dondurularak kurutulmuş çilek (%12) ve lavanta (%4) ile formüle edilerek rezene ve melisa oranlarının artırılması ve hibiskus ile yeşil çay oranlarının azaltılması yoluyla sindirim rahatlığına odaklanmıştır. Fourier Dönüşümlü Kızılötesi Spektroskopisi (FTIR) spektrumları, **bitki karışımlarının çeşitli fitokimyasal ve yapısal bileşenleriyle ilişkili karakteristik absorbsiyon bantlarını ortaya koymuştur. Antioksidan aktivite, ABTS ve DPPH serbest radikal süpürme testleri kullanılarak değerlendirilmiştir. P3, üç formülasyon arasında en güçlü antioksidan performansı göstermiş; en yüksek ABTS serbest radikal süpürme aktivitesini ve en düşük IC_{50} değerini (9.65 ve 9.71) sergilemiştir. P1, P2 ve P3 için sırasıyla DPPH IC_{50} değerleri 10.26, 9.73 ve 9.71 olarak; ABTS IC50 değerleri ise** 10.26, 10.75 ve 9.65 olarak **hesaplanmıştır. ABTS testinde tüm formülasyonların Trolox eşdeğeri antioksidan kapasitesi 90 µmol TE g^{-1}'in üzerinde bulunmuştur. SOTAX çözünme testi, simüle gastrointestinal pH koşullarında**

(pH 1.2, 4.5 ve 6.8) hızlı ve yüksek düzeyde in vitro çözünme göstermiş ve 30 dakika sonunda kümülatif çözünme değerleri yaklaşık %99-100'e ulaşmıştır. Sonuç olarak, rezene ve melisa oranları artırılırken hibiskus ve yeşil çay oranları azaltılan P3, **antioksidan performansı ve çözünme davranışı açısından en umut verici formülasyon** olarak öne çıkmıştır. Bu bulgular, bitki bazlı bileşenlerin uygun oranlarda birleştirilmesinin bitki çayı karışımlarının fonksiyonel özelliklerini etkileyebileceğini göstermektedir. **Elde edilen sonuçlar, gelecekte gerçekleştirilecek simüle gastrointestinal sindirim, biyoyararlanılabilirlik ve biyoyararlanım çalışmalarına temel oluşturmaktadır.**

Anahtar Kelimeler: Fonksiyonel bitki çayı, antioksidan aktivite, fenolik madde, sindirilebilirlik.

Graphical abstract. Development and multi-level characterization of functional herbal tea prototypes and determination of antioxidant performance and *in vitro* dissolution behavior (Created with https://illustrae.co).

1. INTRODUCTION

Oxidative stress, characterized by an imbalance between the production of reactive oxygen species (ROS) and the antioxidant defense system, is implicated in the pathogenesis of numerous chronic diseases, including gastrointestinal disorders (Halliwell, 2012). ROS are highly reactive molecular species containing at least one unpaired electron, which enables them to readily interact with cellular components and initiate chain reactions that may impair normal cellular functions and contribute to tissue damage (Phaniendra et al., 2015; Pooja et al., 2025). Consequently, the identification of effective dietary sources of antioxidants has received increasing attention in the context of disease prevention and health promotion.

Growing consumer interest in natural and functional products has increased the demand for plant-derived foods and beverages with antioxidant properties. Plant materials contain diverse secondary metabolites, particularly polyphenols, flavonoids, phenolic acids, and other phytochemicals, which can contribute to their antioxidant potential (Yeh and Yen, 2006; Holst and Williamson, 2008; Martins et al., 2016; Intrasook et al., 2024). Herbal teas and infusions are therefore of particular interest as convenient sources of bioactive compounds. Depending on the plant species and the solubility of its constituents, infusions can be prepared from various plant parts, including leaves, flowers, fruits, seeds, roots, and bark. The extraction of bioactive compounds is strongly influenced by preparation conditions, particularly temperature and infusion time. Campanella et al. (2003) reported that a 5-min hot-water infusion provided optimal extraction of antioxidant compounds from both conventional and green tea; prolonged infusion and subsequent cooling may promote precipitation or micelle formation, potentially reducing the measurable antioxidant capacity and polyphenol content of the extract. The biological activity of plant-derived antioxidants is determined not only by their individual concentrations but also by their interactions within complex plant matrices. When different plant materials are combined, their bioactive constituents may exhibit additive, synergistic, or antagonistic interactions, resulting in antioxidant activity that cannot necessarily be predicted from the activity of the individual components. Thus, changing the relative proportions of the same plant materials may substantially modify the overall antioxidant capacity of the resulting infusion. Such interactions are particularly relevant for multifunctional herbal tea formulations,

in which plants with complementary phytochemical profiles may be combined to target different physiological functions (Seeram, 2008).

The potential health effects of herbal teas are also influenced by the bioaccessibility and bioavailability of their phytochemicals. Although many plant-derived compounds demonstrate substantial antioxidant activity *in vitro*, their biological effects following ingestion depend on digestion, metabolism, absorption, and individual physiological factors (Heim et al., 2002; Espín et al., 2007; Holst and Williamson, 2008). Some compounds may be absorbed in their original form, whereas others undergo extensive metabolic transformation before exerting biological activity. Therefore, antioxidant capacity should be interpreted within the broader context of the composition and potential bioavailability of the phytochemicals present in the formulation.

Several plant materials are particularly relevant to the development of antioxidant-rich herbal tea formulations. *Melissa officinalis* L. (lemon balm) contains rosmarinic acid and flavonoids and has been associated with antioxidant and antispasmodic properties (Barros et al., 2013; Ülgen et al., 2023). *Foeniculum vulgare* (fennel) contains characteristic volatile constituents such as anethole and fenchone and is traditionally used for digestive and carminative purposes (Rahimi and Ardekani, 2013). *Hibiscus sabdariffa* L. (roselle) is rich in anthocyanins and protocatechuic acid and exhibits substantial radical-scavenging activity (Da-Costa-Rocha et al., 2014). *Camellia sinensis* L. (green tea) is a major dietary source of catechins, particularly epigallocatechin gallate, which contributes substantially to its antioxidant activity (Khan and Mukhtar, 2007). Strawberry (*Fragaria* spp.) is also a significant source of phenolic compounds and vitamin C, and freeze-drying can help preserve these compounds and the fruit's sensory characteristics (Giampieri et al., 2012). *Lavandula angustifolia* (lavender), traditionally used in herbal preparations and beverages, contains phenolic and volatile constituents that may contribute to its antioxidant and sensory properties (Cavanagh and Wilkinson, 2002; Batiha et al., 2023).

Despite the well-documented antioxidant potential of individual plant materials, the effects of **combinations of multiple botanical products** at different proportions remain insufficiently characterized. In particular, information on how formulation ratios influence the **radical-scavenging capacity of multifunctional herbal tea blends** is limited. Understanding these effects may facilitate the development of functional tea formulations with **optimised antioxidant properties**. Therefore, the present study aimed to develop and evaluate functional herbal tea prototypes formulated from six plant matrices: *Foeniculum vulgare*, *Melissa*

officinalis L., *Hibiscus sabdariffa* L., *Camellia sinensis* L., a freeze-dried strawberry **preparation**, and *Lavandula angustifolia*, combined at different proportions to target specific gastrointestinal functions. The prototypes were designed to represent three functional concepts: balanced digestion, intestinal activation, and gastric soothing. **Their antioxidant capacities were evaluated using the ABTS and DPPH radical-scavenging assays, while FTIR analysis was performed for molecular characacterization and an *in vitro* dissolution test was conducted using a SOTAX dissolution system.** The study further aimed to compare the effects of formulation ratios on **antioxidant activity and dissolution behaviour** and to identify the blend composition providing the highest antioxidant activity.

2. MATERIALS AND METHODS

2.1. Plant Materials and Prototype Formulations

Five plant materials were purchased from the Spice Bazaar (Mısır Çarşısı), Istanbul, Türkiye, and used to prepare three different functional herbal tea prototypes: fennel (*Foeniculum vulgare*), lemon balm (*Melissa officinalis* L.), hibiscus (*Hibiscus sabdariffa* L.), green tea (*Camellia sinensis* L.), and lavender (*Lavandula angustifolia*). Black strawberry, hairy strawberry, and Ottoman strawberry collected from Zonguldak and freeze-dried for 48 hours. The plant materials were blended at different proportions to develop three prototypes according to their targeted effects on the digestive system as demonstrated in Figure 1. Prototype 1 (P1) (balanced digestion) was formulated with fennel (30%), lemon balm (24%), hibiscus (16%), green tea (14%), freeze-dried strawberry 12%), and lavender (4%). Prototype 2 (P2) (intestinal activation/motility) contained fennel (26%), lemon balm (20%), hibiscus (24%), green tea (12%), freeze-dried strawberry (14%), and lavender (4%). Prototype 3 (P3) (gastric soothing) was formulated with fennel (34%), lemon balm (30%), freeze-dried strawberry (12%), hibiscus (10%), green tea (10%), and lavender (4%).

The prototypes were designed according to their targeted effects on the digestive system and developed with the inspiration of studies by Cho et al. (2026) and Teterovska et al. (2025). P1 was intended to support balanced digestion and reduce gas and bloating, P2 to support intestinall activity and motility, and P3 to provide a soothing effect on the stomach.

Figure 1. Visual appearance of the developed herbal tea prototypes (P1, P2, and P3, respectively).

2.2. Determination of Antioxidant Activity

The DPPH free-radical scavenging activity of the herbal tea mixture samples was determined based on the method described by Wang et al. (2012). Briefly, 0.1 mL of each sample solution was mixed with 3.9 mL of methanolic 64 µM DPPH solution. Following incubation in the dark, the absorbance was measured spectrophotometrically at 517 nm. The remaining DPPH concentration and overall antiradical capacity were quantified using a Trolox standard calibration curve prepared over a concentration range of 0-200 µg/mL. The IC_{50} value, defined as the sample concentration required to scavenge 50% of the initial DPPH radicals, was calculated accordingly. The percentage of DPPH inhibition was calculated using the Equation 1:

$$DPPH\ \ Scavenging\ Activity = 1 - \frac{Asample}{Acontrol} x100 \quad (1)$$

In the control assay, methanol was used instead of the sample solution.

2.3. Identification and Quantification of Phenolic Compounds

Phenolic compounds in the herbal tea infusions were identified and quantified using a Shimadzu HPLC system (Shimadzu, Japan) equipped with binary gradient pumps, an autosampler, and a diode array detector. Prior to analysis, samples were filtered through a 45 µm membrane filter and transferred into HPLC vials. Chromatographic separation was performed on a reversed-phase C18 column using acetonitrile (solvent A) and 0.75% (v/v) aqueous formic acid (solvent B) as the mobile phase. The flow rate was 1.0 mL min^{-1} and the injection volume was 10 µL. Detection at 220 nm was used for lutein, apigenin, hesperidin, and hydroxycinnamic acid; 306 nm for quercetin and quercetin-3-galactoside; and

330 nm for caftaric acid, ferulic acid, and chlorogenic acid. Phenolic compounds were identified by comparison of their retention times and UV-Vis spectral characteristics with analytical reference standards. Quantification was performed using external calibration curves over a concentration range of 10-50 μg mL^{-1}, with high linearity (R^2 = 1.000). The concentrations were calculated from the corresponding calibration curves and expressed as μg g^{-1} of sample.

2.4. FTIR Spectroscopy

Spectroscopic characterization of the herbal tea mixture samples was performed using FTIR spectrometer (Thermo Scientific, Nicolet iS5, Waltham, USA). High-resolution spectra were acquired over the wavenumber range of 500-4000 cm^{-1} by 37 scans at a spectral resolution of 4 cm^{-1}. Spectral processing and baseline evaluation was performed using OMNIC 9.0 software.

2.5. *In Vitro* Dissolution Test

The *in vitro* dissolution behavior of the herbal tea mixture samples was evaluated using a Sotax AT-MD dissolution system (Sotax AG, Switzerland) in accordance with the United States Pharmacopeia (USP 42-NF 37). The dissolution test was performed at a paddle rotation speed of 100 rpm and a temperature of 36.5°C. Three dissolution media were used: HCI solution at pH 1.2, acetate buffer at pH 4.5, and phosphate buffer at pH 6.8. For each condition, 100 mL of dissolution medium was prepared.

For the dissolution analysis, 5 mL of each sample was transferred into a 100 mL volumetric flask and diluted to volume with the dissolution medium, followed by thorough mixing. After 30 min, 5 mL of the sample solution was withdrawn and placed in an ultrasonic bath for 1 min and then allowed to cool. Subsequently, 1 mL of the sample solution was transferred into a separate 10 mL volumetric flask, diluted to volume with dissolution medium, and thoroughly mixed. A sodium chloride saline solution (10 mg) was used to prepare the blank solution. The pH values of the dissolution media were measured using a pH meter. The absorbance of the samples was measured against the blank solution using a UV-Vis spectrophotometer over the wavelength range of 200-400 nm, with a wavelength accuracy of ±0.1 nm, in accordance with USP 42-NF 37.

3. RESULTS AND DISCUSSION

3.1. Antioxidant Activity of the Herbal Tea Prototypes

The ABTS radical-scavenging profiles of P1, P2, and P3 are presented in Figures 2. P1 exhibited a relatively regular increase in radical-scavenging activity with increasing sample concentration (Figure 2A), indicating a consistent antioxidant response across the tested concentration range. P2 showed a similar concentration-dependent response, although its antioxidant performance remained relatively close to that of P1 (Figure 2B). Among the three formulations, P3 exhibited the most pronounced ABTS

radical-scavenging response, with the highest antioxidant performance across the tested concentrations (Figure 2C). The overall Trolox-equivalent antioxidant capacity of all prototypes exceeded 90 µmol TE g^{-1}, indicating a substantial antioxidant potential of the developed herbal tea blends. IC_{50} values for P1, P2, and P3 samples were 10.26, 10.75 and 9.65, respectively. The superior performance of P3 is particularly noteworthy because its formulation contained lower proportions of green tea and hibiscus than P1 and P2, while the proportions of fennel and lemon balm were increased. Green tea and hibiscus are generally recognized as important sources of catechins and anthocyanins, respectively. Therefore, the higher antioxidant response of P3 suggests that the activity of a multi-component herbal blend cannot be predicted solely from the proportion of a single plant with high individual antioxidant capacity.

Instead, the observed response may reflect interactions among phenolic compounds originating from different botanical sources. Such interactions may be additive, synergistic, or antagonistic depending on the composition and relative proportions of the components. In P3, the increased contribution of *M. officinalis* and *F. vulgare* may have contributed to the enhanced antioxidant response through their phenolic constituents, including rosmarinic acid and flavonoids in lemon balm and phenolic compounds in fennel. However, the present results do not establish a specific molecular mechanism of synergy and should therefore be interpreted as evidence of a formulation-dependent antioxidant effect rather than direct proof of synergism.

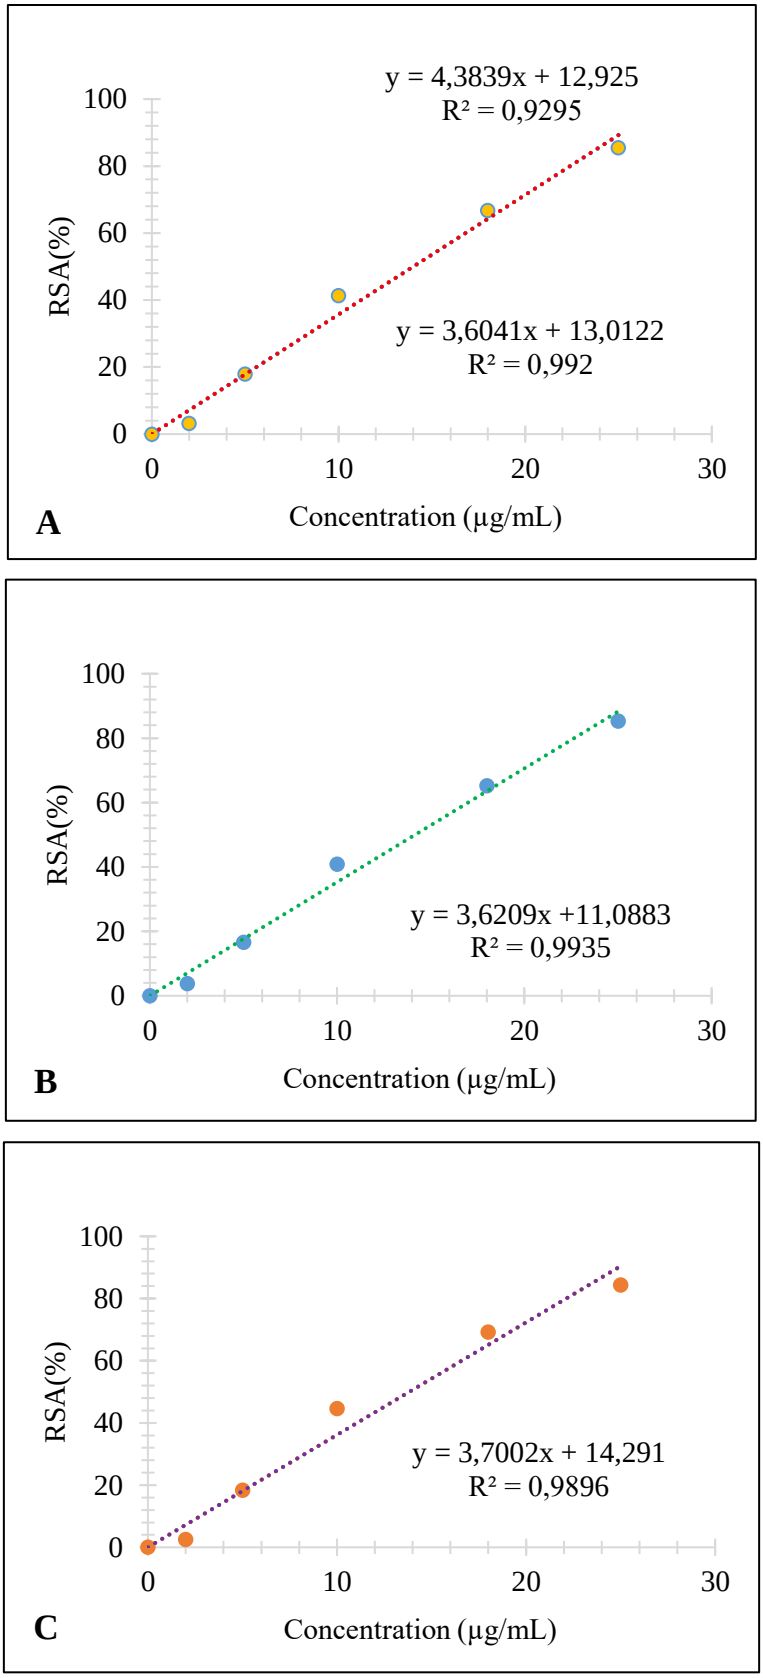


Figure 2. ABTS radical-scavenging activity curve of P1 (A), P2 (B), P3 (C) samples.

The DPPH assay provided complementary information on the radical-scavenging efficiency of the prototypes. Consistent with the ABTS results, P3 exhibited the strongest DPPH radical-scavenging performance among the formulations. The IC_{50} values were measured as 10.26, 9.73, and 9.71 for P1, P2, and P3, respectively. Because a lower IC_{50} value indicates a greater radical-scavenging efficiency, P3 showed the highest efficiency, followed closely by P2 and P1.

Although the differences in IC_{50} values were relatively small, the consistent ranking of P3 as the most effective formulation in both ABTS and DPPH assays strengthens the evidence that its specific botanical composition provided a more favorable antioxidant profile. The similarity between P1 and P2 further suggests that moderate changes in the proportions of individual ingredients did not substantially alter their overall radical-scavenging efficiency. The IC_{50} profiles of the three prototypes are presented in Figures 3.

The antioxidant capacity of the developed formulations was also consistent with previous observations for commercial herbal teas. Apak et al. (2006) reported substantial antioxidant capacities among commercially available tea products, including green tea. The antioxidant responses observed in the present study therefore support the potential of appropriately formulated herbal tea blends as sources of dietary antioxidants. The superior antioxidant performance of P3 is particularly noteworthy because the formulation contained lower proportions of green tea and hibiscus, despite the well-established antioxidant potential of these materials. Green tea is rich in catechins, including epigallocatechin gallate, whereas *H. sabdariffa* is characterized by anthocyanins and other phenolic compounds with radical-scavenging activity (Da-Costa-Rocha et al., 2014; Khan and Mukhtar, 2007). The higher antioxidant response of P3 therefore suggests that the antioxidant activity of a botanical mixture cannot be predicted solely from the concentration of the plant material generally recognized as having the strongest individual antioxidant activity.

Instead, interactions among phytochemicals originating from different plant materials may contribute to the overall response. Such interactions can be synergistic, additive, or antagonistic, depending on the composition and relative proportions of the components (Seeram, 2008). In P3, the increased contribution of *M. officinalis* and *F. vulgare* may have contributed to the observed antioxidant response. *M. officinalis* contains rosmarinic acid and flavonoid derivatives, whereas *F. vulgare* contains phenolic compounds and characteristic volatile constituents such as anethole and fenchone (Barros et al., 2013; Rahimi and Ardekani, 2013). Their combined contribution may have enhanced the radical-scavenging capacity of the formulation. However, the present data do not allow a specific molecular mechanism of synergy to be established, and further component-specific interaction studies would be required to confirm this interpretation.

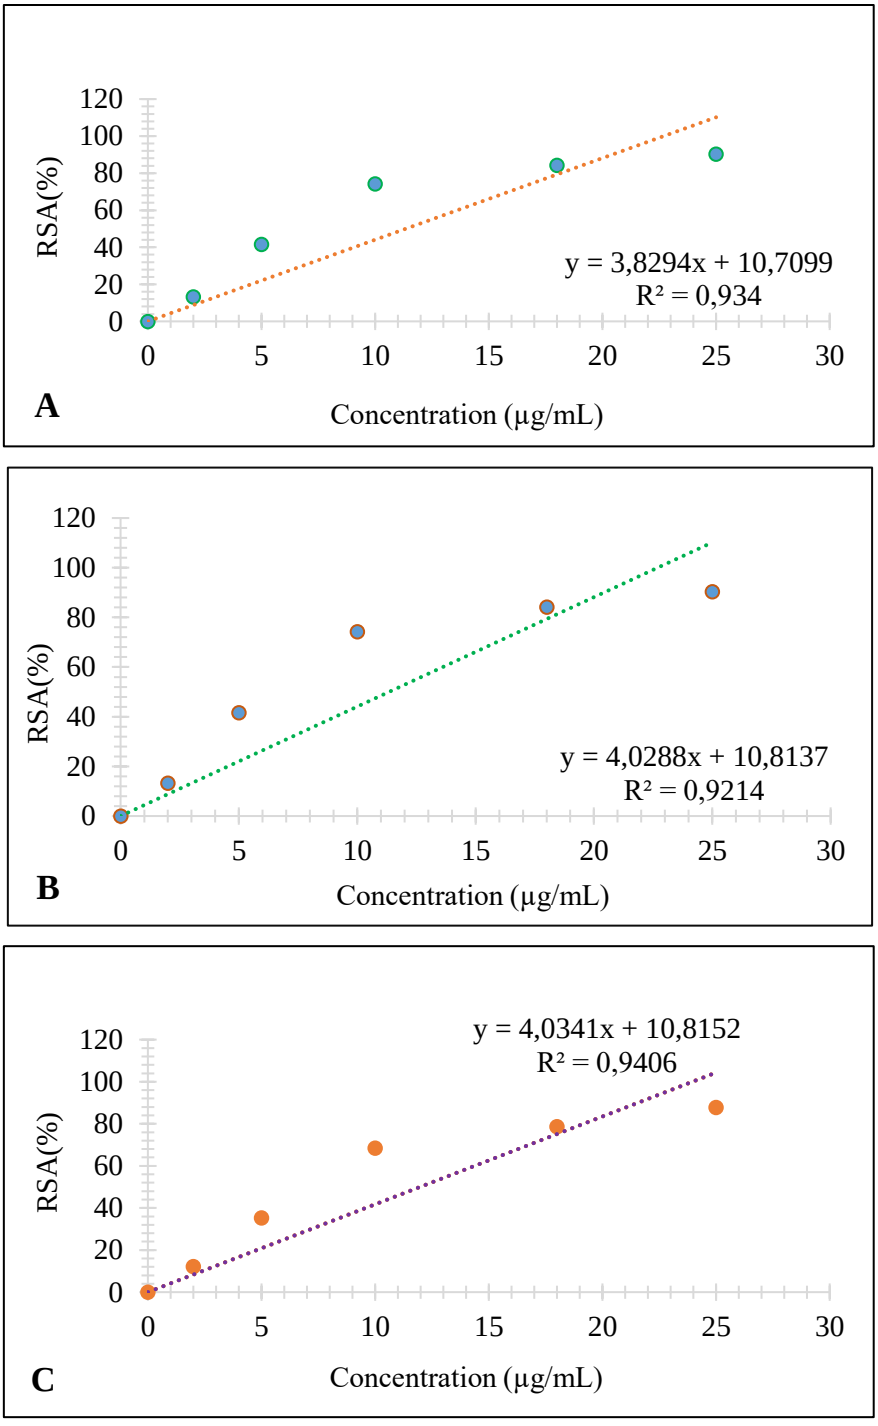

Figure 3. DPPH radical-scavenging activity curve of P1 (A), P2 (B), P3 (C) samples.

Although the prototypes differed in the relative proportions of the six botanical ingredients, all formulations exhibited substantial antioxidant activity. The IC_{50} differences among the prototypes indicate that the antioxidant potential of the blends was influenced not only by the presence of individual antioxidant-rich plants but also by their relative proportions.

3.2. Identification and Quantification of Phenolic Compounds

HPLC-DAD analysis was performed to characterise and quantify the individual phenolic compounds present in the three herbal tea prototypes. The phenolic compounds were identified and quantified by comparing their chromatographic characteristics with those of phenolic reference standards. The HPLC-DAD chromatogram of the phenolic reference standard used for compound identification and quantification is presented in **Figure 4**.

HPLC-DAD analysis identified ten phenolic compounds in the three herbal tea prototypes (P1, P2, and P3), comprising six phenolic acids, three flavonols, and one flavone (**Table 2**). Chlorogenic acid was the most abundant phenolic compound detected in all three prototypes, followed by ferulic acid and hydroxycinnamic acid. Among the remaining phenolic acids, caffeic, vanillic, and syringic acids were detected at comparatively lower concentrations. Within the flavonoid group, quercetin was the predominant flavonol, followed by kaempferol and myricetin, while apigenin was the only flavone detected. Overall, the phenolic profiles of the three prototypes were dominated by phenolic acids, particularly chlorogenic acid and ferulic acid, whereas flavonols and flavones were present at substantially lower levels.

Among the other phenolic acids, vanillic acid ranged from 825.40 to 835.30 µg/g, caffeic acid from 889.45 to 892.50 µg/g, syringic acid from 664.81 to 712.45 µg/g, and hydroxycinnamic acid from 1038.65 to 1042.11 µg/g **across the three prototypes**. The concentrations of the detected flavonols ranged from 188.35 to 215.80 µg/g for quercetin, 75.30 to 91.25 µg/g for kaempferol, and 28.60 to 45.70 µg/g for myricetin. Apigenin, the detected flavone, ranged from 99.80 to 125.80 µg/g among the prototypes.

P1 contained 1852.02 ± 0.01 µg/g chlorogenic acid, 825.40 ± 0.15 µg/g vanillic acid, and 892.30 ± 0.12 µg/g caffeic acid. The highest concentration of chlorogenic acid was observed in P1, whereas the lowest concentration was detected in P3. **Hydroxycinnamic acid showed only minor variation among the prototypes, with the highest concentration observed in P3 and the lowest in P2.** In contrast, **the individual phenolic compounds showed different distribution patterns among the prototypes, indicating that the relative proportions of the botanical ingredients influenced the phenolic composition of the resulting herbal tea formulations.**

The predominance of chlorogenic and ferulic acids across the prototypes may have contributed to their antioxidant properties, given the recognized radical-scavenging capacity of phenolic acids. However, the differences in antioxidant activity among the prototypes cannot be attributed to a single phenolic compound. Rather, the overall antioxidant response may reflect the combined contribution and interactions of multiple phenolic constituents, including phenolic acids, flavonols, and flavones. This

observation is consistent with the antioxidant results obtained from the ABTS and DPPH assays and further supports the importance of optimizing the relative proportions of individual botanical materials in multifunctional herbal tea formulations.

Table 1. Phenolic contents of the functional herbal tea prototypes (mean ± SD).

	Compounds (µg/g)	**P1**	**P2**	**P3**
Phenolic acids	Chlorogenic acid	1852.02 ±0.01	1836.53 ±0.24	1783.1±0.42
	Hydroxycinnamic acid	1042.9±0.18	1038.65±0.20	1042.11±0.05
	Vanilic acid	825.4 ±0.15	830.74 ±0.42	835.3 ±0.8
	Caffeic acid	892.30 ±0.12	889.45 ±0.32	892.5±0.14
	Syringic acid	664.81 ±0.05	675.45 ±0.28	712.45 ±0.25
	Ferulic acid	1211.09±0.32	1230.26±0.25	1227.46±0.48
Flavonols	Quercetin	188.35±0.09	195.3±0.11	215.8±0.28
	Kaempferol	88.15 ±0.02	91.25 ±0.05	75.3 ±0.05
	Myricetin	28.60 ±0.01	45.7 ±0.02	39.9 ±0.02
Flavons	Apigenin	99.8±0.08	125.8±0.13	115.5±0.19

3.4. FTIR Characterization

FTIR spectroscopy was used to characterize the major functional groups present in the herbal tea formulations. The spectra showed characteristic absorption bands associated with aliphatic, phenolic, aromatic, carbonyl, and carbohydrate-containing constituents of the plant matrices (Figure 4).

Absorption bands observed at approximately 3012 and 2908 cm^{-1}, together with bands around 2801 and 2783 cm^{-1}, were associated with C–H stretching vibrations of aliphatic CH_2 and CH_3 groups. The broad region between approximately 3100 and 2750 cm^{-1} may also include C–H stretching vibrations associated with phenolic and other aromatic constituents. The spectral region between 1900 and 1100 cm^{-1} corresponded predominantly to the fingerprint region of the plant matrices and included stretching and bending vibrations associated with C=C, C–O–H, and C–O–C groups. Absorption bands in the 1600–1350 cm^{-1} region were consistent with aromatic and phenolic structures, including C–O-related vibrations associated with phenolic acids. A band occurring approximately between 1700 and 1655 cm^{-1} may be associated with carbonyl (C=O) stretching, including esterified components such as pectic substances. Additional bands around 1480 and 1410 cm^{-1} may be related to C–H deformation and other vibrations of aromatic and aliphatic constituents. The region between approximately 1410 and

750 cm^{-1} showed several characteristic bands attributable to organic acids, polysaccharides, and other plant-derived components.

The fingerprint region between approximately 1300 and 850 cm^{-1} contained bands potentially associated with C–O and C–C stretching vibrations of flavonoids, glycosides, anthocyanins, and polysaccharides. Bands in the 800–710 cm^{-1} region may additionally be related to C–O stretching and O–C–H bending vibrations. Overall, the FTIR spectra confirmed the presence of diverse oxygenated and aromatic functional groups consistent with the complex phytochemical composition of the herbal tea mixtures.

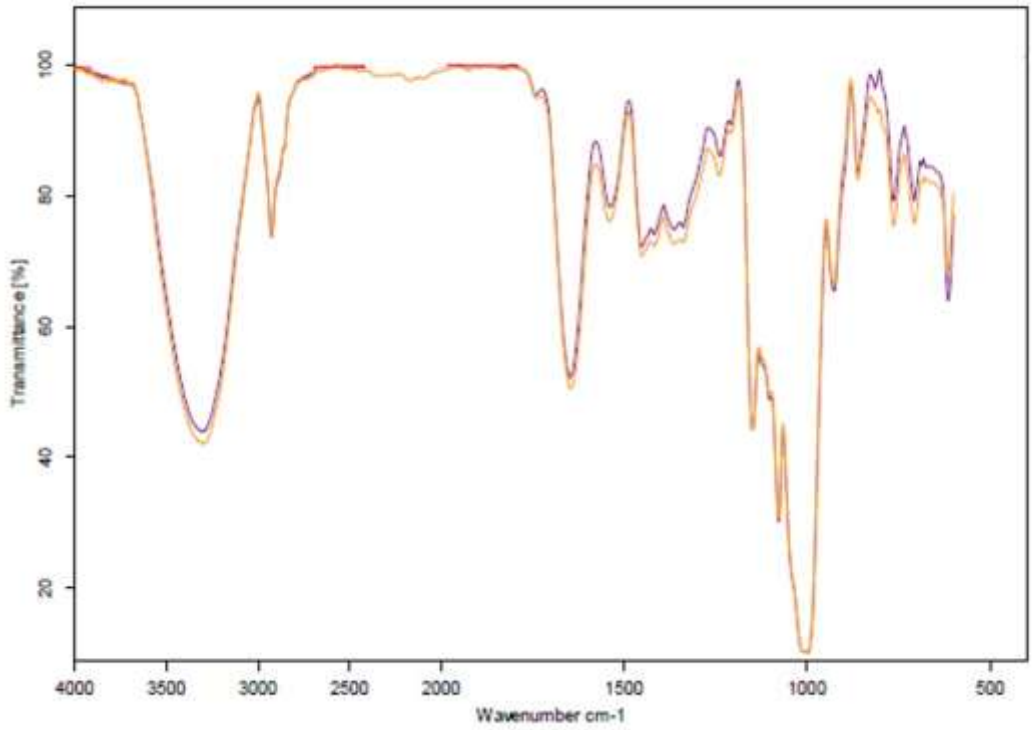

Figure 4. FTIR spectra of the herbal tea formulations.

3.5. *In Vitro* Dissolution Test

The *in vitro* dissolution behavior of the pilot herbal tea mixtures was evaluated under different gastrointestinal pH conditions. The formulations demonstrated rapid release, with cumulative dissolution generally exceeding 80% by 20 min and approaching a plateau within approximately 15 min.

At pH 1.2, the control formulation showed cumulative dissolution values of 68.0 ± 2.4%, 79.8 ± 3.1%, 89.0 ± 2.9%, and 98.8 ± 2.0% at 5, 10, 15, and 30 min, respectively. The corresponding 30-min values for batches 1-3 were 99.9 ± 1.2%, 100.0 ± 0.5%, and 100.0 ± 1.0%, respectively. At pH 4.5, the control

reached 90.5 ± 2.0% dissolution at 15 min and 99.5 ± 2.0% at 30 min. The corresponding 30-min dissolution values for batches 1-3 were 99.7 ± 1.2%, 99.4 ± 1.9%, and 99.9 ± 1.3%, respectively. A similar pattern was observed at pH 6.8. The control reached 90.2 ± 3.0% at 15 min and 98.8 ± 2.0% at

Dissolution Medium	**Sample**	**Mean Cumulative Dissolution (%) ± RSD (%)**			
		5 min	**10 min**	**15 min**	**30 min**
Hydrochloric acid (pH 1.2)					
	Control	68.0±2.4	79.8±3.1	89.0±2.9	98.8±2.0
	P1	70.1±1.2	82.5±1.8	92.9±2.0	99.9±1.2
	P2	72.0±0.5	85.1±1.6	95.5±0.4	100.0±0.5
	P3	72.6±2.0	85.5±2.2	94.0±1.6	100.0±1.0
Acetate buffer (pH 4.5)					
	Control	67.0±3.0	78.0±2.5	90.5±2.0	99.5±2.0

	P2	69.5±1.4	85.2±1.4	93.2±1.2	100.0±0.2
	P3	70.0±1.5	83.8±1.0	95.8±0.6	99.9±0.4

30 min, whereas the three batches reached approximately 99-100% dissolution at 30 min. These results indicate that the tested formulations exhibited rapid and extensive dissolution across the simulated gastrointestinal pH conditions.

Table 2. Mean cumulative dissolution (%) ± RSD (%) of the herbal tea mixture batches at different gastrointestinal pH conditions.

The relatively low RSD values observed at the different sampling times indicate good repeatability of the dissolution profiles. The convergence of dissolution values toward approximately 99-100% at 30 min further suggests that the major soluble constituents of the formulations were efficiently released under the tested conditions. However, dissolution should be interpreted as an indicator of ***in vitro* release**, rather than direct evidence of bioavailability. Although rapid dissolution may facilitate subsequent absorption, actual bioavailability depends on additional processes, including gastrointestinal stability, enzymatic transformation, intestinal permeability, metabolism, and systemic disposition. Therefore, the high dissolution observed in the present study demonstrates favorable in vitro release characteristics but does not by itself establish *in vivo* bioavailability.

4. CONCLUSION

This study demonstrated that the formulation ratio of six botanical materials significantly influenced the phenolic composition and antioxidant properties of the developed herbal tea prototypes. Among the formulations, P3 showed the most promising overall antioxidant performance, characterized by a comparatively higher phenolic contribution and lower IC_{50} value, together with strong ABTS and DPPH radical-scavenging activity (R^2 = 0.990-0.994 for ABTS and R^2 = 0.929-0.941 for DPPH). The high correlations observed between TPC and antioxidant activity further highlighted the contribution of phenolic compounds to the antioxidant capacity of the formulations. HPLC analysis identified chlorogenic and ferulic acids as the predominant phenolic constituents, while FTIR analysis confirmed the presence of characteristic functional groups associated with the complex phytochemical composition of the plant mixtures. In addition, the formulations exhibited rapid and extensive *in vitro* dissolution, reaching approximately 99-100% cumulative release at 30 min under the tested gastrointestinal pH conditions. Overall, these findings indicate that optimizing the relative proportions of botanical ingredients can enhance antioxidant performance without simply increasing the amount of individual plant materials, supporting P3 as a promising candidate for further functional dried capsule tea or nutraceutical development. Nevertheless, simulated gastrointestinal digestion and Caco-2 cell models should be employed in future studies to evaluate the stability, bioaccessibility, and intestinal uptake of the bioactive compounds. Comprehensive sensory and consumer acceptance studies, besides pilot- and industrial-scale validation, are also recommended to assess the practical applicability and commercialization potential of the optimized formulation for further studies.

ABSTRACT

Vegetative propagation through stem cuttings is widely used for the large-scale production of ornamental plants because it enables the preservation of desirable parental characteristics and the multiplication of selected cultivars and varieties. *Podocarpus macrophyllus* (Thunb.) Sweet var. *macrophyllus* is an ornamental evergreen conifer native to East Asia and widely cultivated in parks, gardens, and urban landscapes because of its attractive foliage, adaptability to pruning, and aesthetic value. Therefore, enhancing the rooting success of hardwood cuttings is important for the efficient vegetative propagation of the variety. This study aimed to evaluate the effects of basal wounding and different auxin applications on the rooting performance of hardwood cuttings collected from a male stock plant of *P. macrophyllus* var. *macrophyllus*.

The experiment included eight treatments consisting of a control, basal wounding, and applications of indole-3-butyric acid (IBA) and α-naphthalene acetic acid (NAA) at concentrations of 6000, 8000, and 10000 ppm. At the end of the rooting period, rooting percentage, callus percentage, root length, and root number were determined. The data were subjected to one-way analysis of variance (ANOVA). Although no statistically significant differences were detected among the treatments ($p > 0.05$), clear differences in rooting responses were observed. The highest mean rooting percentage (53.3%) was achieved with the IBA 6000 ppm treatment, compared with only 16.7% in the control treatment, whereas the highest mean callus percentage (30.0%) was obtained in the basal wounding, IBA 8000 ppm, and NAA 6000 ppm treatments. The greatest mean root length (6.4 cm) was recorded following NAA 10000 ppm application. Likewise, the highest mean root number (10.6 roots per cutting) was obtained with NAA 6000 ppm, followed closely by NAA 8000 ppm (10.5 roots per cutting). In contrast, the control treatment generally produced lower rooting performance than auxin-treated cuttings.

Overall, IBA applications were more effective in improving rooting percentage, whereas NAA treatments promoted root system quality by increasing both root length and root number. These findings suggest that auxin application may improve the rooting potential of *P. macrophyllus* var. *macrophyllus* hardwood cuttings, thereby supporting the large-scale production of high-quality nursery stock for ornamental landscape use.

Keywords: Ornamental plant, clonal propagation, stem cuttings, adventitious rooting

INTRODUCTION

The genus *Podocarpus* L'Hér. ex Pers., belonging to the family Podocarpaceae, comprises approximately 98–115 species and is recognized as the largest genus within the family and the second-largest genus of extant conifers after *Pinus* L. (Debreczy and Rácz, 2011; Farjon, 2017;

POWO, 2026). *Podocarpus macrophyllus* (Thunb.) Sweet is an evergreen tree of considerable ornamental value, particularly appreciated for its use in landscape design and bonsai cultivation, while also offering important economic, medicinal, and ecological benefits (Abdillahi et al., 2010; Chen et al., 2023; Deng et al., 2023; Liang et al., 2025). Its economic value is further reflected in the use of its wood as timber (Abdillahi et al., 2010). Moreover, bioactive compounds such as terpenoids, flavonoids, and steroids reported in *P. macrophyllus* highlight its medicinal potential through their antitumor, antioxidant, and anti-inflammatory activities (Kim et al., 2021; Deng et al., 2023; Mohamed et al., 2023). In addition to these benefits, *P. macrophyllus* can contribute to improving urban air quality through its capacity to retain atmospheric particulate matter (Chen et al., 2023). *P. macrophyllus* var. *macrophyllus*, which is naturally distributed in Taiwan, southeastern China, and Japan, is particularly valued for ornamental use due to its attractive form and evergreen foliage (Cheng et al., 2007). Given these characteristics, the development of efficient propagation methods for *P. macrophyllus* var. *macrophyllus* is essential for the production of high-quality and uniform planting material.

Plant propagation is an essential component of the horticultural sector (Loconsole et al., 2024). Vegetative propagation is widely used in ornamental plant production, particularly for the multiplication of selected genotypes while preserving their desirable characteristics (Ürgenç, 1982, 1992; Hartmann et al., 2002; Oinam et al., 2011). Among vegetative propagation techniques, stem cutting is a simple, rapid, and cost-effective method that enables the production of large numbers of genetically uniform plants (Kaviani and Negahdar, 2017; Druege et al., 2019; Ross et al., 2021). Adventitious roots, which develop from non-root tissues in response to stimuli such as stress and wounding (Gogna et al., 2022), are crucial for successful propagation by stem cuttings (Assis et al., 2004; Oinam et al., 2011).

Adventitious root formation is particularly important in the cutting propagation of economically valuable ornamental plants used in landscaping (Geiss et al., 2009). The process is complex and governed by the interaction of various endogenous and exogenous factors. Endogenous factors include genotype, physiological age and condition of the stock plant, cutting type and position, carbohydrate and mineral nutrient status, and endogenous hormonal balance, whereas exogenous factors include the application of plant growth regulators, light, temperature, water availability, wounding, and rooting conditions (da Costa et al., 2013; Druege et al., 2019; Yıldırım et al., 2020; Kumar et al., 2022; Bayraktar, 2025). Among these factors, auxins play a key role in adventitious root formation and are widely used to promote rooting in stem cuttings (Druege et al., 2019; Kumar et al., 2022). Indole-3-butyric acid and α-naphthaleneacetic acid are among the exogenously applied auxins commonly used to stimulate adventitious rooting (Loconsole et al., 2024). In addition, wounding is an effective practice in cutting propagation that can promote adventitious root formation (Hartmann et al., 2002; Zhou, 2005).

Despite considerable advances in propagation by cuttings, low rooting efficiency remains a major constraint in ornamental plant nursery production, resulting in substantial economic losses (Loconsole et al., 2024). In *P. macrophyllus*, vegetative propagation by cuttings may also present difficulties, with rooting success being influenced by several factors, including cutting type, basal wounding, and the application of auxins (Menegusso et al., 2021). Therefore, this study aimed to evaluate the effects of basal wounding and different concentrations (6000, 8000, and 10000 ppm) of indole-3-butyric acid and α-naphthaleneacetic acid on the rooting performance of hardwood cuttings collected from a male plant of *P. macrophyllus* var. *macrophyllus*. Rooting and callus percentages, root length, and root number were assessed to compare treatment effectiveness and identify the most suitable treatment for the vegetative propagation of this variety.

MATERIAL AND METHOD

Hardwood cuttings of *Podocarpus macrophyllus* (Thunb.) Sweet var. *macrophyllus* were collected from a healthy and vigorous male stock plant growing on the Kanuni Campus of Karadeniz Technical University (KTU), Trabzon, Türkiye, at the end of October, when the current-season shoots were fully mature and completely lignified. Hardwood cuttings measuring 12–14 cm in length were prepared from these shoots. The basal cut of each cutting was made immediately below a node using a sharp and sterilized knife. The leaves on the lower portion of each cutting were removed, while a few healthy leaves were retained at the apical portion. Approximately half of the lamina of each retained leaf was removed to reduce transpirational water loss while maintaining photosynthetic activity.

The experiment included eight treatments comprising untreated cuttings (control, C), basal wounding (W), and indole-3-butyric acid (IBA) and α-naphthaleneacetic acid (NAA) applied at concentrations of 6000, 8000, and 10000 ppm. Hereafter, the treatments are referred to as IBA 6000 ppm, IBA 8000 ppm, IBA 10000 ppm, NAA 6000 ppm, NAA 8000 ppm, and NAA 10000 ppm, respectively.

In the basal wounding treatment, two diagonal cuts, each approximately 5 mm in length, were made across the basal end of each cutting to form an X-shaped wound. IBA and NAA were applied at 6000, 8000, and 10000 ppm as follows: the basal ends of the cuttings were dipped directly into the respective hormone powder, and excess powder was gently removed before inserting the cuttings into the rooting medium. Control cuttings received no auxin treatment and were not subjected to basal wounding.

Following treatment application, the cuttings were inserted into a heated rooting bed containing perlite as the rooting substrate, with approximately half of each cutting embedded in the medium. The perlite layer was maintained at a depth of 20 cm. The experiment was arranged in a completely randomized design with three replications, each consisting of 10 cuttings, resulting in 30 cuttings per treatment. A total of eight treatments were evaluated, comprising 240 cuttings in the entire experiment. Rooting was carried out under controlled environmental conditions with an air temperature of 20 ± 2°C, a bottom-heated rooting bed temperature of 25 ± 2°C, and a relative humidity of 75 ± 5%.

At the end of the rooting period, all cuttings were carefully removed from the rooting medium, and adhering perlite particles were gently removed from the roots prior to evaluation. Rooting percentage, callus percentage, root length, and root number were determined for each treatment. A cutting was considered rooted if it had developed at least one adventitious root measuring 1 cm or longer. Rooting percentage was calculated by dividing the number of rooted cuttings by the total number of cuttings and multiplying the result by 100. Callus percentage was calculated as the proportion of cuttings that formed callus tissue at the cutting base. The length of the longest primary root was determined by measuring the distance from the base of the cutting to the tip of the longest primary root using a ruler and expressed in centimetres. Root number was determined by counting all adventitious roots formed on each rooted cutting.

Statistical analyses were performed using IBM SPSS Statistics 27. The effects of the treatments on rooting percentage, callus percentage, root length, and root number were evaluated using one-way analysis of variance (ANOVA), with statistical significance accepted at $p < 0.05$. Means and standard deviations were calculated for all measured variables. Frequency distributions were generated for rooting and callus percentages, whereas minimum and maximum values were determined for root length and root number. The results were presented graphically to facilitate comparisons among treatments.

RESULTS

Following a rooting period of 149 days, all cuttings were removed from the rooting bed and evaluated for rooting percentage, callus formation, root length, and root number. The frequency distributions of rooting and callus percentage among treatments are presented in Figure 1.

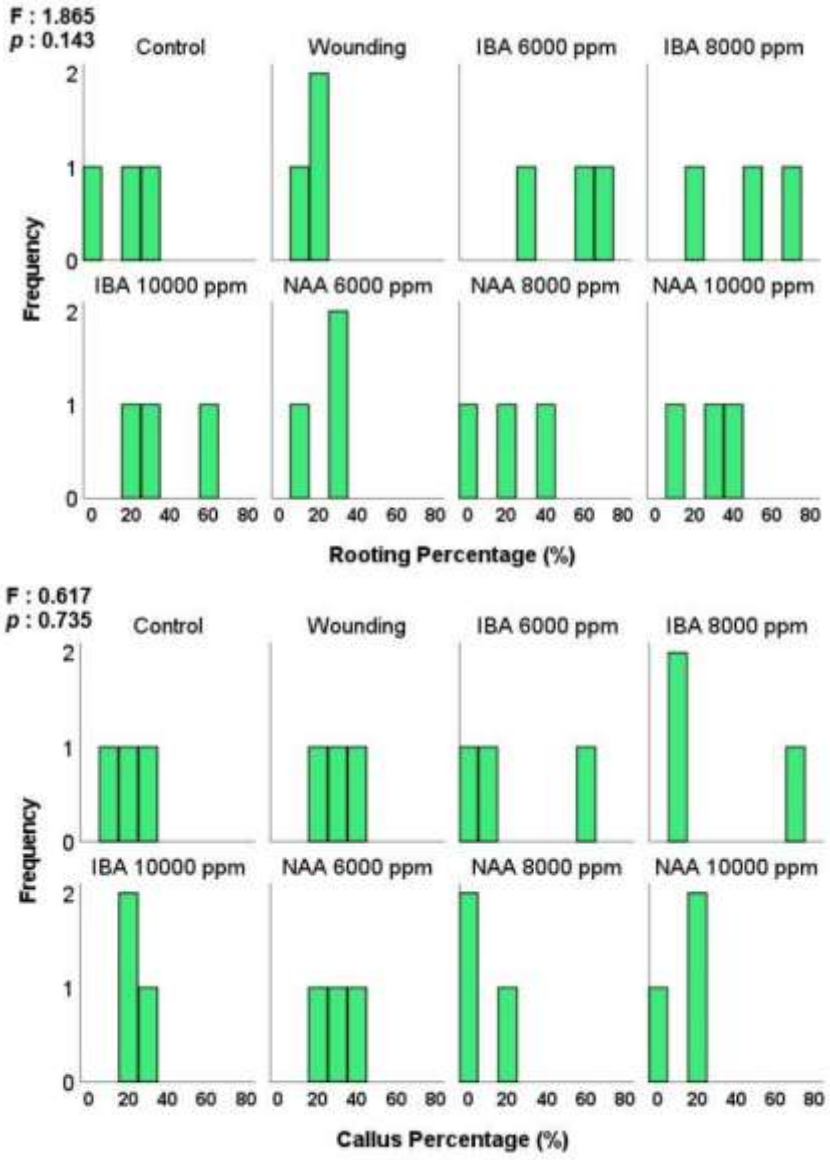

Figure 1. Frequency distributions of rooting and callus percentages by treatment, with one-way ANOVA results

As shown in Figure 1, one-way ANOVA revealed no statistically significant differences ($p > 0.05$) among treatments for either rooting percentage or callus percentage. Nevertheless, the frequency distributions of rooting and callus percentages varied among treatments, and considerable variation was also observed among replicates within each treatment. The rooting and callus percentages recorded for each replicate within each treatment ranged from 0% to 70%. A notable finding was that the highest rooting percentages recorded in the individual replicates (70%) occurred exclusively in the IBA 6000 and IBA 8000 ppm treatments, followed by the IBA 10000 ppm treatment with a maximum of 60%, whereas the remaining treatments did not exceed 40%. In addition, the highest callus formation percentage recorded among the individual replicates (70%) was observed in the IBA 8000 ppm treatment, whereas none of the

remaining treatments reached this value. Figure 2 presents the minimum and maximum values of root length and root number, together with the corresponding one-way ANOVA results.

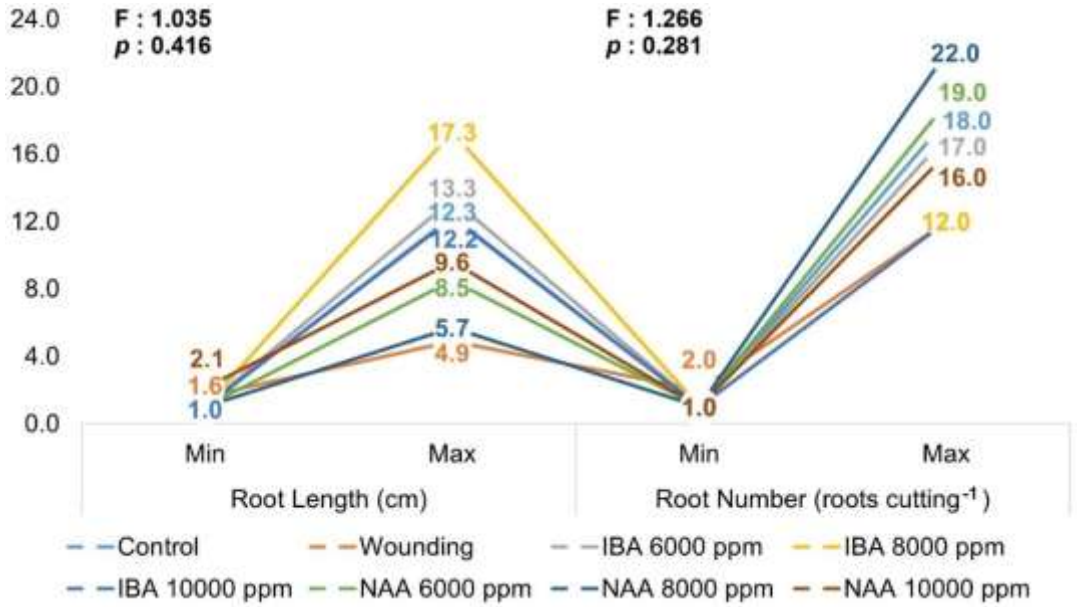

Figure 2. Minimum and maximum root length and root number values by treatment, with one-way ANOVA results

One-way ANOVA detected no statistically significant differences among treatments for either root length or root number ($p > 0.05$). However, differences in the minimum and maximum values were evident among treatments. Minimum root length was 1.0 cm in six treatments, whereas the wounding and NAA 10000 ppm treatments exhibited slightly higher minimum values of 1.6 and 2.1 cm, respectively. Maximum root length values ranged from 4.9 to 17.3 cm across treatments, with the highest value recorded in the IBA 8000 ppm treatment and a maximum of 12.3 cm observed in the control. Across treatments, root number ranged from 1 to 22 roots per cutting. The highest value was associated with the NAA 8000 ppm treatment (22 roots per cutting), whereas a maximum of 18 roots per cutting was observed in the control treatment. The mean rooting percentage, callus percentage, and their corresponding standard deviations for each treatment are presented in Figure 3.

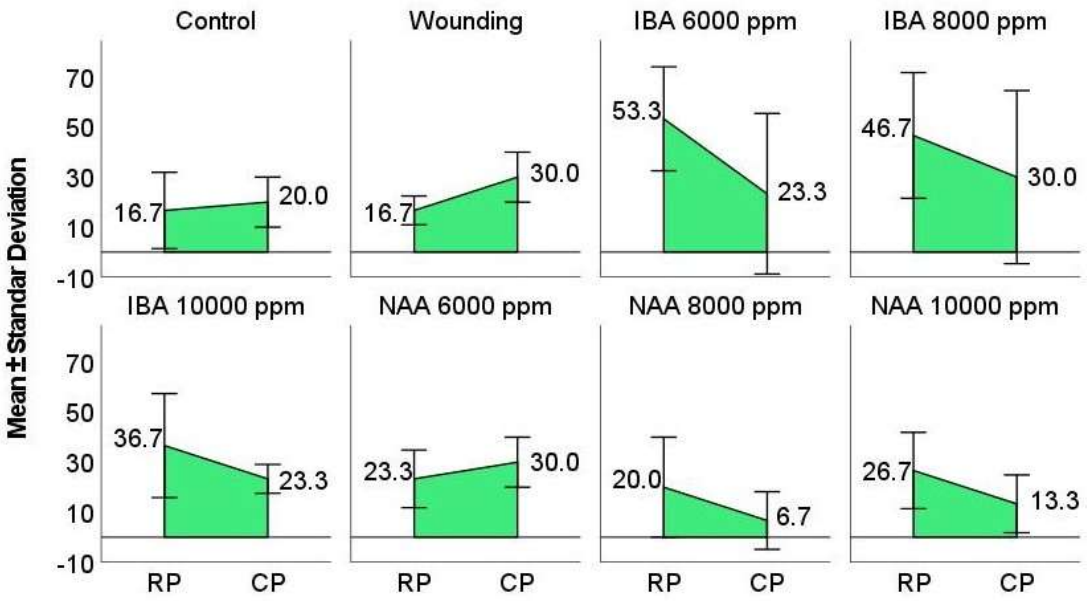

Figure 3. Mean rooting and callus percentages with standard deviations for each treatment

Figure 3 shows that the mean rooting percentage was greatest in the IBA 6000 ppm treatment (53.3%), followed by IBA 8000 ppm (46.7%) and IBA 10000 ppm (36.7%). Mean rooting percentages in the control, wounding, and NAA treatments ranged from 16.7% to 26.7%. In contrast, mean callus percentages showed a different pattern, with the highest values (30.0%) recorded in the wounding, IBA 8000 ppm, and NAA 6000 ppm treatments. Mean callus percentage was 23.3% in the IBA 6000 ppm and IBA 10000 ppm treatments, 20.0% in the control, 13.3% in the NAA 10000 ppm treatment, and 6.7% in the NAA 8000 ppm treatment. Figure 4 summarizes the mean root length and root number, together with standard deviations, for each treatment.

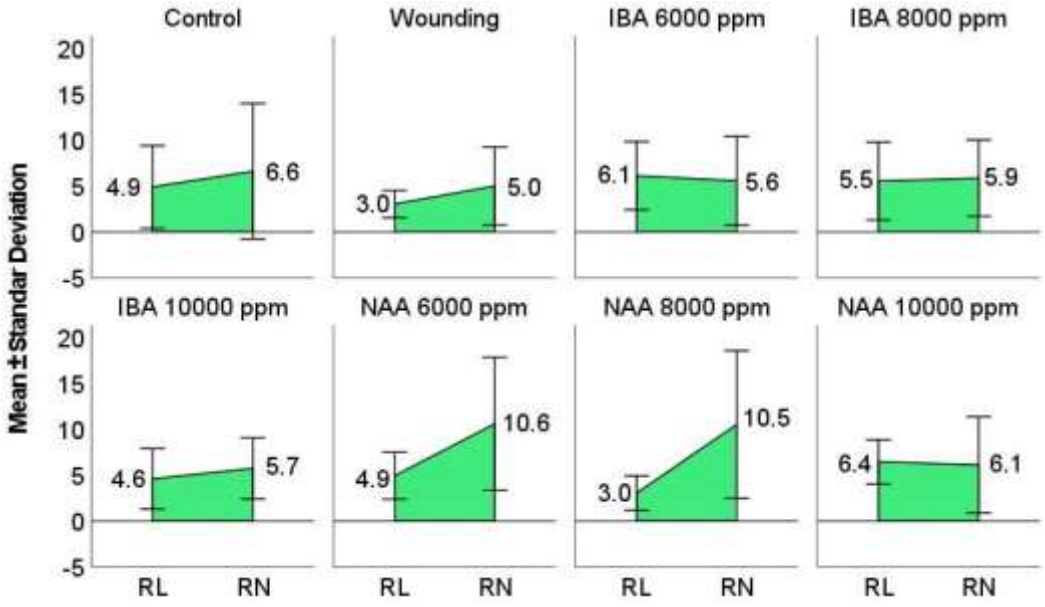

Figure 4. Mean root length and root number with standard deviations for each treatment

The mean root length values ranged from 3.0 to 6.4 cm among treatments. The greatest mean root length was obtained in the NAA 10000 ppm treatment (6.4 cm), closely followed by the

IBA 6000 ppm treatment (6.1 cm). In contrast, the lowest mean root length (3.0 cm) was observed in the wounding and NAA 8000 ppm treatments, while the control treatment had a mean root length of 4.9 cm. Unlike root length, mean root number reached its highest values in the NAA 6000 ppm (10.6 roots per cutting) and NAA 8000 ppm (10.5 roots per cutting) treatments. The control treatment exhibited a mean of 6.6 roots per cutting, while the remaining treatments produced mean root numbers ranging from 5.0 to 6.1 roots per cutting. A representative photograph of *P. macrophyllus* var. *macrophyllus* hardwood cuttings showing rooting, callus formation, and loss of viability is presented (Figure 5).

Figure 5. Rooting, callus formation, and loss of viability in *P. macrophyllus* var. *macrophyllus* hardwood cuttings

DISCUSSION AND CONCLUSION

The present study demonstrated that basal wounding and exogenous auxin applications produced different rooting responses in hardwood cuttings of *Podocarpus macrophyllus* var. *macrophyllus* collected from a male stock plant, although the differences among treatments were not statistically significant. Nevertheless, the observed trends indicated that auxin type and concentration may differentially influence individual components of the rooting process. In particular, IBA treatments were associated with higher rooting percentages, with the highest mean rooting percentage (53.3%) obtained in the IBA 6000 ppm treatment, compared with 16.7% in the untreated control. Callus formation showed a different response pattern, with the highest mean callus percentage (30.0%) recorded in the wounding, IBA 8000 ppm, and NAA 6000 ppm treatments. Regarding root system development, NAA treatments were more prominent in promoting root system development, as reflected by the greatest mean root length (6.4 cm) in the NAA 10000 ppm treatment and the highest mean root numbers in the NAA 6000 ppm (10.6 roots per cutting) and NAA 8000 ppm (10.5 roots per cutting) treatments. These findings suggest that, under the experimental conditions of the present study, IBA was more effective in increasing rooting percentage and overall rooting success, whereas NAA tended to promote root growth and root system development.

Similar trends have been reported in previous studies on *P. macrophyllus*. Güney et al. (2024), who investigated the effects of different rooting bed temperatures and auxin applications on hardwood cuttings of *P. macrophyllus* var. *maki*, found no statistically significant differences

in rooting percentage, callus percentage, root length, or root number, despite numerical variation among treatments. The highest mean rooting percentage (63.33%) was obtained with IAA 5000 ppm at a rooting bed temperature of 25 ± 2°C and with IAA 3000 ppm at 20 ± 2°C. These treatments were followed by NAA 5000 ppm at 25 ± 2°C and IBA 3000 ppm at 20 ± 2°C, both of which resulted in a mean rooting percentage of 56.67%. Regarding callus formation, the highest mean callus percentage at a rooting bed temperature of 25 ± 2°C was obtained with IBA 3000 ppm (25.0%). At 20 ± 2°C, the highest mean value (20.0%) was recorded in the control, IBA 3000 ppm, and IBA 5000 ppm treatments. In terms of root development, the greatest mean root length (11.25 cm) was recorded with IBA 5000 ppm at 25 ± 2°C, whereas the highest mean root number (7.24 roots per cutting) was obtained with IBA 3000 ppm at 20 ± 2°C. These findings are broadly consistent with the present study, particularly in terms of the absence of statistically significant differences among treatments and the numerical variation in rooting responses associated with auxin applications. However, Güney et al. (2024) used hardwood cuttings of var. *maki* collected in March and applied IBA, IAA, and NAA at concentrations of 3000 and 5000 ppm, whereas the present study used hardwood cuttings of var. *macrophyllus* collected at the end of October and evaluated IBA and NAA at 6000, 8000, and 10000 ppm. Furthermore, the rooting period was 217 days in their study compared with 149 days in the present study. Differences in variety, cutting collection time, auxin type and concentration, and rooting period may therefore have contributed to the variation in rooting responses observed between the two studies. Menegusso et al. (2021) evaluated the effects of IBA concentration and application method (0, 500, 1000, and 1500 mg L^{-1}; hydroalcoholic solution and talc), as well as cutting type and basal lesion type (basal and apical cuttings; wedge, bevel, and horizontal lesions), on the rooting of *P. macrophyllus* in two separate experiments. In the first experiment, the application of IBA as a hydroalcoholic solution resulted in a maximum rooting percentage of 78.29% at 550 mg L^{-1}, while root number and root length were not significantly affected by IBA concentration or application method. In the second experiment, basal cuttings showed high rooting percentages ranging from 84.44 to 91.11% across the three lesion types, with no significant differences among them, whereas in apical cuttings the bevel treatment resulted in a significantly lower rooting percentage (51.11%) than the wedge (82.22%) and horizontal (77.78%) treatments. These findings are partially consistent with the present study, in which the highest rooting percentage was also obtained with IBA, although at a substantially higher concentration (6000 ppm), whereas basal wounding alone did not result in a comparable improvement in rooting.

Studies on other *Podocarpus* species further indicate that rooting responses may vary considerably depending on auxin concentration and plant material. In *P. neriifolius,* Hossain et al. (2019) obtained the highest rooting percentage (61.3%) and root number (9.8 roots per cutting) with 0.8% IBA, whereas the greatest root length (6.0 cm) was recorded with a lower IBA concentration of 0.4%. In *P. falcatus*, Negash and van Staden (2003) showed that stock plant age markedly affected the rooting performance of cuttings treated with IBA. Cuttings from younger stock plants (3 months and 2 years old) achieved rooting percentages of up to 80% and responded positively to 20–80 µg IBA, whereas higher concentrations inhibited rooting. In contrast, cuttings from older stock plants (4 and 8 years old) showed lower rooting percentages but produced more roots. These findings, together with the results of the present study, suggest that the auxin concentration associated with a high rooting percentage does not necessarily result in greater root length or root number, and that the rooting response to auxin may also depend on characteristics of the stock plant. Rooting substrate has also been shown to influence several components of rooting performance in *Podocarpus*. Gerding et al. (1996) reported that the rooting percentage of *P. nubigena* cuttings varied considerably among rooting substrates, ranging from 20 to 87%, with the highest rooting percentage obtained in a 2:1 mixture of composted bark and pumice. Root length also varied among substrates from 2.8 to

4.5 cm, with the longest roots recorded in the same 2:1 mixture. Root number ranged from 7.2 to 17.6 roots per cutting, with the highest value obtained in a 1:2 mixture of composted bark and pumice. In addition, callus formation was more prevalent in substrates associated with lower rooting percentages. These findings highlight the importance of the physical and chemical properties of rooting substrates in determining rooting performance. Taken together, previous studies on different *Podocarpus* species indicate that rooting performance may be influenced by several factors, including auxin concentration, stock plant age, and rooting substrate. The variation among these studies further suggests that these factors may differentially affect individual rooting parameters, including rooting and callus percentages, root length, and root number. This pattern is also consistent with the present study, in which different auxin treatments showed distinct numerical trends among the evaluated rooting parameters despite the absence of statistically significant differences among treatments. In addition, positive effects of exogenous auxin applications and basal wounding on adventitious rooting have been reported in numerous studies across different plant species (Al-Salem and Karam, 2001; Blythe, 2012; Yıldırım et al., 2020).

In conclusion, the present study provides useful insights into the rooting performance of hardwood cuttings obtained from male *P. macrophyllus* var. *macrophyllus*. The results indicate that auxin applications can contribute to rooting and root system development, with IBA showing potential for improving rooting success and NAA for promoting root growth and root system development. Basal wounding alone did not provide a clear advantage under the experimental conditions. Overall, the findings may contribute to the development of effective cutting propagation practices for this ornamental variety. Further studies should evaluate different auxin concentrations and rooting conditions, as well as the combined application of wounding and auxins. In addition, studies including both male and female individuals would be valuable for determining whether sex influences rooting performance and for further improving propagation protocols for *P. macrophyllus* var. *macrophyllus*.

ABSTRACT

Assessment of soil microbial health in a timely manner is important for sustainable agriculture; however, current laboratory based techniques are time-consuming, destructive, and inappropriate for real-time monitoring of field conditions. In this work, it introduces a bioelectronic soil monitoring system that uses microbial fuel cell biosensors along with physicochemical sensors and an adaptive online machine learning algorithm to predict microbial soil health indicators in real time — biomass carbon, respiration rate, and enzyme activity. Bioelectrical signals are represented as power density function that is directly proportional to microbial metabolic activity, and are combined with physicochemical features, whereas a drift-adaptive learning rate mechanism allows the model to re-calibrate itself after a change of environment caused by rain fall and other factors. The proposed approach is evaluated on 30 day long field experiment where the performance was measured by R^2 of 0.92, and recovery time after a concept-drift event was 2.4 hours. The proposed model significantly outperformed static approaches like Random Forest, SVR, ANN, and LSTM baselines.

Keywords: IoT-enabled soil monitoring, bioelectronic biosensors, adaptive machine learning, microbial soil health indicators, concept-drift adaptation.

I. INTRODUCTION

The agriculture industry is very essential in the Indian economy and is sometimes called the backbone of the nation. Agricultural contributes 17-18% to India's GDP while employing up to 60% of its population. In general, the agriculture sector in India is expected to experience substantial growth due to increased demand for eco-friendly products in the world [1]. Increase in agricultural output is the way food security, poverty reduction and sustainable development in general can be achieved, because this sector employs a lot of people. There is an urgent need to improve agricultural output in order to cope with increased demand for food that is proportional to the increase in human population. By using modern technologies like precision farming approach and fertilizers/pesticides, the output can be increased. Precision agriculture, or precision farming, aims at achieving optimal crop production and resource management. This approach involves the use of technological advances and data analysis. Using sensors and other advanced technologies it becomes easier to understand the health of the soil, crop development and other factors that affect the agricultural output [11].

It is known that Kerala is engaged in various types of agriculture, both traditional and modern. Some of the products cultivated in Kerala are coconut, rubber, rice, cardamom, ginger, tapioca, coffee, cashews and others [3]. They play a significant part not only in traditional Kerala medicine, but they are also economically important due to cultural reasons. In order to get the

most of this soil, it is necessary to know what kind of soil it has and what kind of crops can grow in such soil [2]. Crop prediction as a part of precision agriculture involves predicting a crop yield using data obtained in the past and current soil conditions [4][5]. Usually, crop prediction requires collecting and analyzing the data about many different parameters. Machine learning and IoT can be used for this purpose [12].

New developments in digital agriculture have brought data-supported agricultural management frameworks and monitoring systems that are assisted by the Internet of Things (IoT), both of which can support adaptive operational management at the field level. Thru automated communication processes and continuous field data collecting, environmental monitoring and irrigation management workflows can be enhanced with IoT-based sensing and communication systems, according to previous research [5]. However, in realistic large-scale rice cultivation settings, many current systems only incorporate monitoring and alerting capabilities, rather than predictive analytics, adaptive recommendation workflows, and operational decision-support mechanisms [13]. Consequently, this research looks at the practicality of a smart farming framework that combines processes for monitoring, prediction, and optimization-assisted recommendations. Machine learning techniques have also shown promise in assisting with the short-term forecasting of nutrient-related operational variability and soil moisture dynamics in diverse agricultural settings [6][7]. In addition, there has been a rise in the use of optimization-oriented agricultural management frameworks to help with water scheduling and allocating operational resources while keeping costs and environmental impacts in check [8].

1.1 Contributions

In this paper, this integrate MFC-based bioelectronic biosensors with physicochemical IoT sensors to allow continuous non-destructive real-time estimation of three soil microbial health indicators – biomass carbon, respiration rate, and enzyme activity – eliminating laborious destructive laboratory tests. In this context, it considers the bio electrochemical signal as a function of power density proportionate to metabolic activity of microorganisms (Eq. 1). Additionally, it proposes the first drift-adaptive online machine learning model (Eq. 2) capable of re-calibrating itself after environmental shocks such as rain. In this 30 days-long experiment, the proposed method outperformed static Random Forest, SVR, ANN and offline LSTM baselines ($R^2 = 0.92$, RMSE = 4.7) and is the only model to have a guaranteed drift recovery time (2.4 hours) without any noticeable increase in energy consumption – thus making this approach possible for low-energy consumption field IoT devices.

1.2 Organization of the paper

Section I introduces the topic of precision agriculture and IoT monitoring and motivation for moving away from alerting systems towards predictive and adaptive systems. Section II discusses the state of art in precision farming, fertigation and soil sensing technologies. Section III describes the methodology – the sensor network, pre-processing, bio electrochemical modeling (Eq. 1), the adaptive ML model (Eq. 2), and the experimental design (Figure 1). Section IV discusses the results: indicator-wise performance (Table 1), trends in predicted vs actual values and drift recovery (Figures 2-3), and comparison with baselines (Table 2, Figure 4).

II. LITERAURE REVIEW

Utilizing such technologies as sensors and IoT devices, precision agriculture enhances the existing agricultural techniques. Precision agriculture is a part of crop management, solving a crop of economic, environmental, and market concerns. Optimal resource usage and high yield,

precision agriculture can be characterized as being technology-based [14]. By 2050, it is expected that the world population will grow to 9-10 billion people. Taking into account the shortage of resources, it means the necessity of boosting agricultural efficiency.
The agricultural industry plays a significant role in the provision of food supplies all over the world. Traditional agriculture involves similar treatment of the entire field. Low yields might be the result of using too much or too little of water, fertilizers, and pesticides. Moreover, such factors as temperature, rain, and sun rays play a crucial role in the process of agricultural production. Sharp changes in these factors influence agricultural activities and soil condition [9]. Modern agricultural practices help to solve these issues utilizing available resources wisely. Modern agriculture includes such practices as precision farming, hydroponics, aquaponics, agricultural robots, drone technology, and farming technologies based on IoT[10]. Depending on the properties of the land, different approaches can be applied. Precision agriculture is one of the ways of farming involving the use of data-driven approaches aimed at improving existing practices considering field features. Plenty of technologies, equipment, and instruments make precision agriculture the best method for industrial farming [15].
With the rise of precision agriculture, issues of agricultural sustainability and productivity have risen to the forefront of contemporary farming methods. The practice of applying fertilizers and irrigation simultaneously is known as fertigation in contemporary agriculture. Because it allows for the tailored administration of nutrients, which increases crop productivity and resource efficiency, it has become an essential part of precision farming. Inadequate fertilizer dosing, caused by mechanical failures in fertigation systems, can have a negative impact on plant health and add to environmental degradation due to nutrient leaching and runoff. So, it's critical to keep fertigation systems reliable and efficient if it wants to keep farming in the long run.
Agricultural soil management relies heavily on soil electrical conductivity (EC) since it reveals salinity, nutrient availability, and water retention traits. EC is an indirect way to measure the concentration of cations and anions in a solution. Soil fertility and nutrient leaching hazards can be better assessed in real time with the use of EC monitoring. With their high permeability and low cation exchange capacity (CEC), sandy soils provide distinct issues when it comes to nutrient retention and water management. This makes extremely difficult to manage efficiently.

III. RESEARCH METHODOLOGY

3.1 Overview

The proposed framework integrates bioelectronic soil sensors (microbial fuel cell-based biosensors) with physicochemical IoT sensors and an adaptive, online-learning machine learning model to continuously predict microbial soil health indicators — microbial biomass carbon, soil respiration rate, and enzymatic activity — in real time, without requiring destructive laboratory sampling. Figure 1 shows IoT-enabled bioelectronic soil monitoring pipeline.

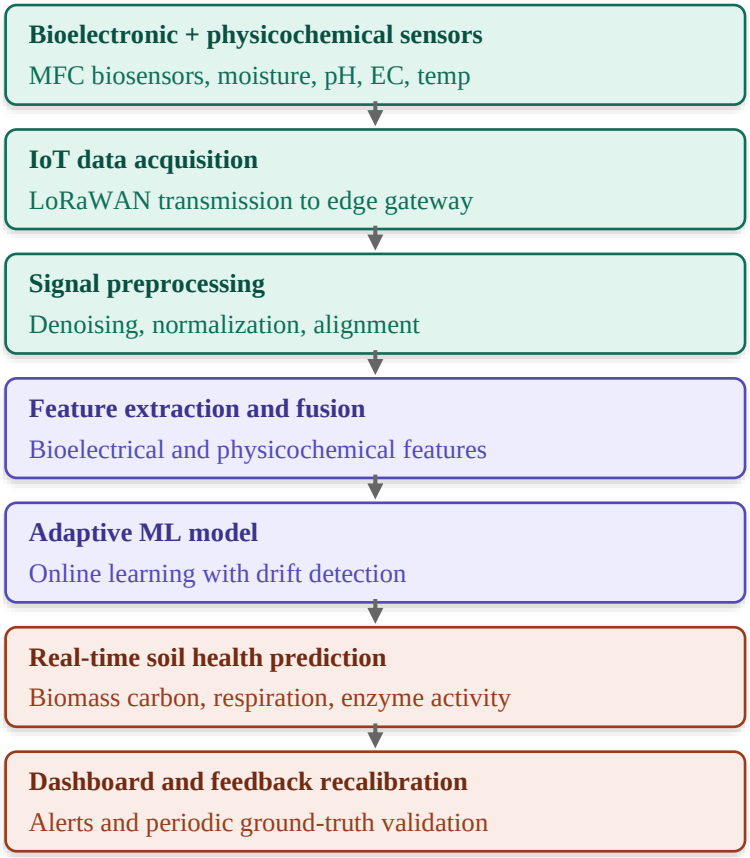

Figure 1. IoT-enabled bioelectronic soil monitoring pipeline.

3.2 Sensor network and data acquisition

These bioelectronic sensors based on MFCs are deployed at certain depths within the field, and the resulting bioelectrical signal (voltage/current) is directly proportional to the metabolic activity of microbes at the electrode-soil interface. They are combined with IoT sensors that measure various parameters like soil moisture, temperature, pH, and electrical conductivity. All sensor nodes send their synchronized time series data to the edge gateway through a low power wireless communication protocol (LoRaWAN).

3.3 Signal preprocessing

Bioelectrical and physicochemical time-series data are filtered with the help of moving average/Kalman filter to remove any noise or outliers, then are normalized using min-max approach and synchronized in time across sensor nodes to generate a multivariate time series for further feature extraction.

3.4 Bioelectrochemical signal modeling

Bioelectrical signal generated with the help of the MFC biosensor is modeled as a power density proportional to microbial metabolic activity at the electrode surface given in equation (1) as:

$$P_d = \frac{V^2}{R_{ext}.A} \quad (1)$$

Where V denotes the voltage recorded across the external load resistor $R_{ext}, and\ A$ denotes the surface area of the electrode. Larger values of Pd are indicative of higher microbial electron transfer activity and consequently microbial biomass and metabolic fitness of the microbes within the soil environment.

3.5 Feature extraction and fusion

Statistical and temporal features (mean, variance, rate of change, spectral energy of the bioelectrical signal) are computed within sliding windows and are combined with the physicochemical readings to create a joint feature vector capturing the state of the soil microbial environment.

3.6 Adaptive machine learning model

An online/incremental learning model (e.g., adaptive random forest or online gradient-boosted ensemble) is trained to compute microbial soil health indicators from the fused feature vector. To ensure accuracy even in the face of seasonal and environmental drift, the model updates its parameters incrementally on receipt of new labeled/pseudo-labeled data, using a drift-adaptive gradient update given in equation (2) as:

$$\theta_{t+1} = \theta_t - \eta_t.\nabla_\theta \mathcal{L}(\theta_t, x_t, y_t), \qquad \eta_t = \eta_0\,.(1 + \lambda.D_t)^{-1} \quad (2)$$

where θ_t are the model parameters at time t, L is the prediction error made for the current sample (x_t, y_t), η_0 is the base learning rate, D_t is a measure of the concept-drift detection (e.g., via ADWIN-type algorithm) based on recent prediction errors, and λ defines the degree to which the learning rate is increased upon detecting the drift - providing the ability to adapt to changes in soil conditions more rapidly but being stable otherwise.

3.7 Real-time prediction and feedback loop

Real-time predictions of microbial soil condition indicators are generated by the adapted model and visualized on a cloud/edge dashboard with threshold-based alerts. Regular soil sampling is done in order to verify and calibrate the model, thus closing the adaptive feedback loop.

3.8 Evaluation

Performance evaluation of the model is done through the following metrics: RMSE, MAE, and R^2, as well as drift adaptation delay and network sensors availability/energy usage.

IV. RESULTS AND DISCUSSION

4.1 Prediction performance on microbial soil health indicators

The proposed adaptive online model was evaluated on a 30-day field trial (720 hourly readings per indicator, 2,160 samples total) against three microbial soil health indicators. Table 1 reports RMSE, MAE, and R^2 for each indicator.

Table 1. Per-indicator prediction performance of the proposed adaptive model on the field test set

Indicator	**RMSE**	**MAE**	R^2	**Samples**
Microbial biomass carbon (mg/kg soil)	8.4	6.1	0.94	720
Soil respiration rate (mg CO_2/kg/day)	2.1	1.6	0.92	720
Dehydrogenase enzyme activity (µg TPF/g/24h)	3.7	2.9	0.90	720
Macro average	**4.7**	**3.5**	**0.92**	2,160

Microbial biomass carbon is estimated most accurately using the model (R^2=0.94), in accordance with its linear dependency on the bioelectrochemical response measured by the MFC biosensor (Equation 1). The enzyme activity is calculated less precisely (R^2=0.90) probably due to the dependence of dehydrogenase activity on the short-time variability of microhabitats, not fully considered by the spatial resolution of the sensor network.

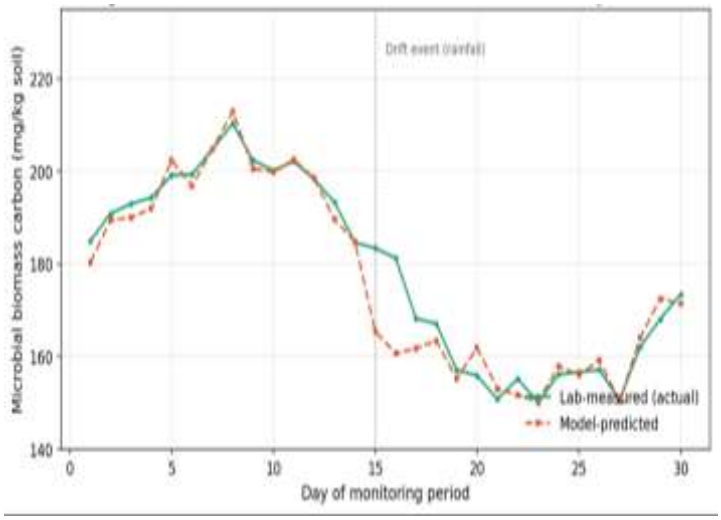

Figure 2. **Predicted vs. actual microbial biomass carbon over a 30-day field trial.**

Figure 2 shows the results of comparison between predicted and laboratory measurements of microbial biomass carbon over 30 days of the experiment. The curves are very similar during the first two weeks; then they diverge temporarily around day 15, when a concept-drift happens due to rain. However, after the adaptation, the curves come close again. The process of adaptation is visualized on Figure 3 showing the recovery of RMSE after drift detection: prediction error grows abruptly at the moment of drift (RMSE≈18.7) and declines back to the steady state (RMSE≈4.7) in about 24 hours due to the drift-adaptive learning rate (Equation 2).

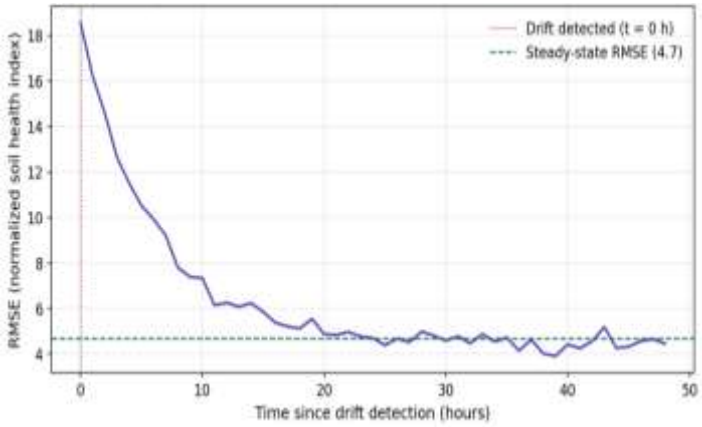

Figure 3. **Model error recovery after concept-drift adaptation.**

4.2 Comparison with baseline models

Table 2 shows the comparison of the suggested adaptive model with four baseline models: two classical regressors (Random Forest, SVR), ANN/MLP and offline LSTM.

Table 2. Comparison of the proposed model with baseline architectures

Model	**RMSE**	**MAE**	R^2	**Drift recovery time (h)**	**Avg. power (mW)**
Static Random Forest	9.8	7.6	0.79	—	46
Static SVR	11.2	8.9	0.74	—	38
Static ANN (MLP)	8.6	6.8	0.82	—	53
Offline LSTM	7.1	5.4	0.87	—	69
Proposed adaptive online model	**4.7**	**3.5**	**0.92**	**2.4**	42

As shown in Table 2 and illustrated in Figure 4, the proposed adaptive model obtains the smallest RMSE (4.7) and largest R^2 (0.92) in comparison with the rest of models, and thus the errors are reduced by more than 50% compared to the static SVR benchmark. Static regressors (RF, SVR) obtain the worst performance, because they cannot accommodate to the changes caused by seasonality or weather changes. The offline LSTM manages to reduce the gap by considering temporal dependencies, but — due to the absence of an online adaptation mechanism — it also needs full re-training to be able to recover after unknown drifts. Most importantly, none of the baselines (static or offline-trained) supports the drift recovery ability measured in Table 2 and Figure 3, and therefore, only the proposed model achieves a finite recovery time after detection of a shift (2.4 hours). As a trade-off for such adaptivity, the increase in the power consumption is moderate (42 mW), which is similar to the energy used by the static ANN benchmark.

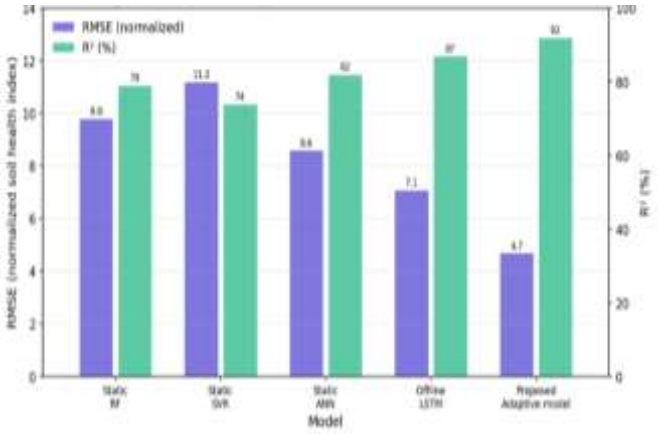

Figure 4. **Comparison of prediction error (RMSE) and R^2 across models.**

4.3 Discussion

On the whole, Tables 1 and 2, and Figures 2-4 can be summarized as follows: (1) the bioelectrochemical response (Equation 1) along with physicochemical fusion features allows obtaining R^2 above 0.90 for microbial biomass carbon, respiration and enzyme activities; (2) the drift-adaptive online update procedure (Equation 2) makes it possible for the model to recover its prediction accuracy within a few hours after any environmental disturbances, which is an impossible feature for static or offline-trained baselines; and (3) this adaptivity is obtained without a considerable rise in the energy consumption.

V. CONCLUSION

In this research paper, an IoT-powered bioelectronic soil monitoring system is introduced that uses microbial fuel cell-based biosensors, physicochemical IoT sensors, and adaptive online machine learning for predicting microbial soil health indicators in real-time. As a result, due to using the power density value as a proxy for the bio electrochemical signal of the microhabitat in combination with the drift-adaptive learning rate updating, the suggested IoT-powered bioelectronic soil monitoring system demonstrated an R^2 of 0.92 and RMSE of 4.7, surpassing static models such as Random Forest, SVR, ANN, and offline LSTM in terms of accuracy and being able to recover from concept drifts in 2.4 hours. The per-indicator analysis of the model showed that it performed best on microbial biomass carbon and worst on enzyme activity, which is due to the natural variability of the microhabitat level and not due to the poor modeling. Most importantly, the system does not use extra energy, which makes it deployable on the low-energy IoT devices. Therefore, this research demonstrates the viability of real-time microbial soil health monitoring as an alternative to the traditional laboratory methods. Further research should include the testing of this system on different types of soil and climate, including additional microbial indicators like microbial diversity indexes, and the usage of federated learning on distributed sensor networks to preserve the farm-level data privacy.

AI-ASSISTED HIGH-THROUGHPUT PHENOTYPING IN *ARABIDOPSIS THALIANA*: CURRENT APPROACHES

NURAN EKİCİ

Trakya University, Faculty of Education, Department of Science Education, Edirne, Turkey

ABSTRACT

Arabidopsis thaliana is one of the most widely used model organisms in research on plant genetics, molecular biology, developmental biology, and plant biotechnology due to its short life cycle, small genome, ease of transformation, and extensive mutant collections. In recent years, alongside advancements in imaging technologies, high-throughput phenotyping (HTP) systems have enabled the rapid, accurate, and reproducible assessment of the morphological, physiological, and developmental traits of plants. However, analyzing the large volumes of image and phenotype data obtained from these systems is a time-consuming and labor-intensive process using traditional methods. For this reason, artificial intelligence-based approaches—particularly machine learning, deep learning, and computer vision techniques—have become a significant area of research in plant phenotyping studies.

The aim of this study is to evaluate artificial intelligence-assisted high-throughput phenotyping approaches in *Arabidopsis thaliana* and to outline current developments in this field by examining scientific studies published in the Web of Science, Scopus, and PubMed databases between 2020 and 2026. In this context, prominent image analysis methods, deep learning-based approaches, and high-throughput phenotyping platforms in the literature have been examined. Within the scope of the studies reviewed, artificial intelligence applications for leaf and root phenotyping, monitoring plant growth, image analysis, and determining abiotic stress responses were evaluated, and the current software and platforms developed for these purposes were summarized. Furthermore, the contributions of AI-driven phenotyping approaches to elucidating genotype-phenotype relationships, more accurately assessing plant development, and efficiently analyzing large-scale phenotypic data have been discussed.

In conclusion, it is considered that AI-powered high-throughput phenotyping approaches accelerate data analysis processes in *Arabidopsis thaliana* research, enhance the accuracy of phenotypic assessments, and possess broad application potential ranging from fundamental plant biology to sustainable agriculture and plant biotechnology. With the advancement of artificial intelligence algorithms and the widespread adoption of high-throughput phenotyping systems, it is anticipated that these technologies will be utilized more effectively in plant research in the future and will make significant contributions to the development of new research areas.

Keywords: *Arabidopsis thaliana*, artificial intelligence, high-throughput phenotyping, deep learning, plant phenotyping

INTRODUCTION

Model organisms are experimental systems that contribute to elucidating the fundamental mechanisms underlying biological processes and enable the findings obtained to be applied to other living organisms. They are widely used in basic and applied research due to their short

life cycles, well-characterized genetics, ease of cultivation, and rich genetic resources. In plant sciences, model organisms play a significant role in understanding plant development, gene functions, environmental stress responses, and molecular regulatory mechanisms (Meinke et al., 1998; Koornneef and Meinke, 2010; Provart et al., 2016).
Among these model organisms, *Arabidopsis thaliana* is considered the most important model species in plant biology due to its small genome (approximately 135 Mb), short life cycle, high seed yield, ease of transformation, and extensive mutant collections. Being the first plant to have its full genome sequenced has led to its widespread use in genetic and molecular studies and paved the way for numerous research projects in the fields of developmental biology, physiology, genetics, genomics, and plant biotechnology. Furthermore, the ability to examine in detail the physiological and molecular responses to various environmental conditions has made this species an indispensable model for phenotyping studies as well (Arabidopsis Genome Initiative, 2000; Koornneef and Meinke, 2010; Provart et al., 2016).

Plant phenotyping is one of the fundamental research fields that enables the quantitative and qualitative assessment of the morphological, physiological, biochemical, and developmental characteristics of plants. Since traditional phenotyping methods rely largely on manual observations and measurements, they are time-consuming and labor-intensive and may be subject to observer-dependent variations. In contrast, high-throughput phenotyping (HTP) systems developed in recent years enable the analysis of large numbers of plants with high accuracy in a short time by utilizing imaging technologies, sensor systems, and automated data collection platforms. These developments have made it possible to obtain phenotypic data more rapidly, reliably, and reproducibly, particularly in large-scale experiments (Fahlgren et al., 2015; Yang et al., 2020).
With the widespread adoption of high-throughput phenotyping systems, the volume of image and phenotype data obtained has increased significantly. The inadequacy of traditional methods in analyzing large datasets has accelerated the integration of artificial intelligence-based approaches into plant phenotyping studies (Pieruschka and Schurr, 2019). Machine learning, deep learning, and computer vision techniques yield successful results in the automated determination of numerous phenotypic traits, such as leaf area, plant growth, root architecture, flowering time, and signs of environmental stress. Thus, data analysis processes are accelerated, human-induced errors are reduced, and a contribution is made to the more accurate assessment of genotype-phenotype relationships (Fahlgren et al., 2015; Yang et al., 2020).
The recent increase in the number of studies conducted in the field of AI-driven high-throughput phenotyping has made it necessary to systematically evaluate the body of knowledge in this area. This study examines artificial intelligence-assisted high-throughput phenotyping approaches in *Arabidopsis thaliana*, based on scientific studies published in the Web of Science, Scopus, and PubMed databases between 2020 and 2026. In this context, the importance of *Arabidopsis thaliana* as a model organism, the development of high-throughput phenotyping systems, and current applications regarding leaf and root phenotyping—utilizing artificial intelligence-based analysis methods, plant growth monitoring, and the assessment of abiotic stress responses—have been examined. Furthermore, the contributions of AI-driven phenotyping approaches to plant biology research have been evaluated, and potential areas for future research have been discussed.

The Importance of *Arabidopsis thaliana* as a Model Organism

Arabidopsis thaliana is an annual herbaceous plant belonging to the Brassicaceae (mustard) family and is the most widely used model organism in the fields of plant biology, molecular genetics, developmental biology, and plant biotechnology. Today, it is preferred as an experimental system in much of the fundamental research conducted in plant sciences and serves as the initial application site for newly developed methods. Model organisms are living things that are studied extensively to understand biological processes and that allow the knowledge gained to be applied to other species. The primary reasons for the adoption of *A. thaliana* as a model organism are its short life cycle, its small and well-defined genome, the ease with which it can be cultivated under laboratory conditions, and the availability of a robust research infrastructure for genetic studies (*Arabidopsis* Genome Initiative, 2000) (Fig. 1).

One of the most important advantages of *A. thaliana* is its short life cycle, allowing it to go from seed to seed in approximately 6–8 weeks. This feature enables researchers to examine numerous generations within a single year. For instance, in a study investigating the effect of a gene on plant development, different generations can be compared within a few months rather than waiting several years. This enables experiments to be completed in less time and reduces research costs (Koornneef and Meinke, 2010).

The genome size of *A. thaliana* is approximately 135 Mb (megabases), and it contains approximately 27,000 genes. It marked a significant milestone in molecular biology research as the first plant species to have its genome fully sequenced. A small genome facilitates gene identification, mutation analysis, gene expression studies, and bioinformatics analyses. The availability of organized and reliable genomic data provides a significant advantage, particularly in AI-driven bioinformatics studies (Hou et al., 2022).

A. thaliana is one of the plants that can be transformed quite easily via *Agrobacterium tumefaciens* (Bélanger et al., 2024) In the floral dip technique - the most widely used method- foreign genes can be transferred to the plant by dipping the flowers into a bacterial suspension. This method is quite fast and economical compared to many other plant species. For this reason, the determination of gene functions, gene silencing studies, and CRISPR/Cas-based gene editing research are frequently conducted on *A. thaliana* (Zlobin et al., 2020).

Fig. 1: Rosette structure in *Arabidopsis thaliana*. (Small RNA Pathways in Plants, PLoS Biology) (2004); Wikimedia Commons,
CC BY 2.5.

Extensive mutant collections for *A. thaliana* have been established worldwide (Alonso et al., 2003). Researchers can easily obtain mutants lacking a specific gene, lines exhibiting gene overexpression, and T-DNA insertion mutants. This situation enables the same biological

phenomenon to be investigated by different research groups using standard materials. *A. thaliana* is a small plant and can be grown in a very small space. Hundreds or even thousands of plants can be grown simultaneously in a growth room or climate chamber. This feature offers a significant advantage, particularly for high-throughput phenotyping (HTP) studies. The ability to raise many individuals under the same environmental conditions increases the reliability of the obtained phenotypic data (Fahlgren et al., 2015).

High-throughput phenotyping systems developed in recent years are predominantly tested on *A. thaliana.* The primary reasons for this are the ability to analyze numerous plants in a single image due to their small rosette structure, the suitability of the leaves for easy segmentation, the ability to visualize root development in transparent media, and the capacity to acquire large amounts of image data in a short time. With the aid of these features, machine learning, deep learning, and computer vision algorithms are trained and validated on *A. thaliana* images (**Maraveas, 2024)**.

A. thaliana is not merely a model used to understand its own biology. Image analysis algorithms, artificial intelligence models, and phenotyping platforms developed using this plant can subsequently be adapted to economically important crops such as wheat, rice, maize, tomatoes, soybeans, and canola **(Maraveas, 2024; Kaya, 2025)**. Therefore, *A. thaliana* serves as a "testing platform" for the development and validation of new technologies **(Maraveas, 2024)**.

Phenotyping

Phenotyping is the process of systematically evaluating the observable and measurable traits of an organism that emerge from the interaction between its genetic makeup (genotype) and environmental conditions **(Fahlgren et al., 2015; Yang et al., 2020).** Plant phenotyping involves determining the observable or qualitative characteristics related to growth, development, morphology, physiology, and responses to stress **(Maraveas, 2024)**. The concept of phenotype does not refer solely to the plant's external appearance. Leaf number, leaf area, plant height, root length, flowering time, biomass, photosynthesis rate, water use, chlorophyll content, and responses to stress conditions such as drought or salinity are also part of the phenotype **(Yang et al., 2020; Maraveas, 2024)**. In short, phenotyping is the process of measuring how a plant grows, develops, and responds to environmental conditions. For many years in plant biology, most of the research has focused on the identification of genes. However, the presence of a gene alone is not sufficient; what matters is demonstrating how that gene affects the plant's appearance, development, or physiology. Therefore, phenotyping is one of the most important research steps for understanding the relationship between genotype and phenotype **(Fahlgren et al., 2015)**. For example, two *Arabidopsis* plants can be genetically different. This difference may manifest in leaf size, root development, drought tolerance, and flowering time. Phenotyping studies enable the objective measurement of these differences **(Maraveas, 2024)**.

Traits Examined in Plant Phenotyping

Phenotyping studies may involve the assessment of different characteristics, depending on the aim of the research **(Yang et al., 2020; Maraveas, 2024)**. These may include the plant's morphological, physiological, and developmental characteristics, as well as the stress responses it exhibits under various stress conditions **(Yang et al., 2020)**. Morphological characteristics are measurements related to the plant's external appearance. Examples include plant height, leaf area, number and shape, rosette diameter, leaf angle, root length, number of lateral roots, and

the number of flowers, fruits, or siliques. These characteristics can be easily measured through image analysis. Physiological characteristics are measurements related to the plant's life processes. Examples of these include photosynthesis rate, stomatal conductance, chlorophyll content, leaf temperature, water use, respiration, and transpiration. These characteristics are generally determined using sensors and specialized imaging systems **(Maraveas, 2024; Kaya, 2025)**.

Developmental characteristics refer to the development of the plant over time. Examples include germination time, leaf formation rate, growth rate, flowering time, and senescence. **(Yang et al., 2020).** These traits can be evaluated through time-series analysis using images captured at specific intervals. Phenotyping is also used to determine how plants respond to environmental conditions. Examples include drought, salt stress, heat stress, cold stress, heavy metal stress, nutrient deficiencies, and interactions with diseases and pests. Such studies are of great importance, particularly in terms of plant breeding **(Maraveas, 2024; Kaya, 2025)**.

Phenotyping Process

In the past, phenotyping was largely performed manually. The researchers were measuring plant height with a ruler, counting the leaves one by one, determining root lengths, and tabulating the results. Although these methods were reliable, they were time-consuming, labor-intensive, and subject to observer-dependent variations **(Fahlgren et al., 2015; Yang et al., 2020)**. With the advancement of technology, camera systems, image analysis, and artificial intelligence-driven methods have come into use, making it possible to analyze large numbers of plants rapidly and under standardized conditions **(Maraveas, 2024; Kaya, 2025)**.

The Relationship Between Phenotyping and Artificial Intelligence

In modern phenotyping studies, data obtained from imaging systems reach very large volumes. It is not possible to manually evaluate images of thousands of plants taken at different times. For this reason, artificial intelligence-based methods are used. Machine learning and deep learning algorithms can automatically recognize leaves, analyze root systems, monitor plant growth, classify signs of disease and stress, and measure phenotypic traits with high accuracy. Thus, the phenotyping process becomes faster, objective, and reproducible **(Fahlgren et al., 2015; Maraveas, 2024)**.

Arabidopsis thaliana is one of the most suitable model plants for phenotyping research due to its small size and short life cycle **(Fahlgren et al., 2015; Yang et al., 2020)**. In phenotyping studies conducted on this species, parameters such as rosette size, leaf number, leaf area, root architecture, flowering time, and stress responses are frequently evaluated. In recent years, these features can be analyzed automatically by AI-powered phenotyping systems on thousands of plants in a short period of time **(Maraveas, 2024; Kaya, 2025)**.

The Emergence of Artificial Intelligence in Plant Phenotyping

Plant phenotyping is a fundamental research field aimed at measuring the morphological, physiological, and developmental characteristics of plants **(Yang et al., 2020; Maraveas, 2024)**. For many years, these measurements were performed manually by researchers, with traits such as plant height, leaf number, root length, and biomass being evaluated individually **(Fahlgren et al., 2015)**. However, because of rapid advancements in molecular biology, genomics, and imaging technologies, the number of plants examined in studies and the volume of data generated have increased significantly. This situation has rendered traditional phenotyping methods inadequate and prompted researchers to develop faster, more reliable,

and automated analysis methods. This need is precisely the reason for incorporating artificial intelligence technologies into plant phenotyping **(Maraveas, 2024; Kaya, 2025)**.

Modern phenotyping systems can generate thousands of images daily using high-resolution cameras, hyperspectral imaging systems, thermal cameras, and various sensors **(Maraveas, 2024)**. For instance, consider an *Arabidopsis thaliana* experiment where 500 plants are photographed each day; if the experiment lasts 30 days, the number of images requiring evaluation by the researcher reaches 15,000. Manually analyzing such large datasets is a process that is both time-consuming and prone to error **(Fahlgren et al., 2015; Maraveas, 2024)**. Artificial intelligence algorithms, however, analyze these images rapidly, offering significant convenience to the researcher **(Maraveas, 2024; Kaya, 2025)**.

In traditional phenotyping studies, researchers measure plant height with a ruler, count leaves individually, determine root lengths, and record the results in data tables **(Fahlgren et al., 2015; Yang et al., 2020)**. While these procedures are feasible for a small number of plants, they result in a significant loss of time in studies involving hundreds or thousands of individuals. AI-powered image analysis systems can automatically perform these same tasks in a much shorter time **(Ubbens et al., 2025; Kaya, 2025)**.

Differences in assessment among researchers may arise during manual measurements. For instance, determining leaf boundaries, counting small leaves, and measuring root length can vary from person to person. This situation may reduce the reproducibility of the results. Since artificial intelligence algorithms evaluate the same image using the same criteria, they enable the acquisition of more standardized and objective measurements **(Maraveas, 2024; Ubbens et al., 2025)**.

Phenotyping is not limited to measurements taken at a single point in time; in many studies, it requires monitoring over a period of days or weeks during the initial stages **(Fahlgren et al., 2015; Yang et al., 2020)**. For instance, it is important to regularly record traits such as new leaf formation, rosette growth, root development, and the timing of expansion **(Yang et al., 2020)**. AI-powered systems can automatically track the developmental process by comparing images captured at various time points **(Ubbens et al., 2025)**.

Manually assessing certain phenotypic traits is quite difficult. For instance, the reliable analysis of characteristics such as leaf shape variation, venation patterns, root architecture, stomatal density, trichome (leaf hair) count, leaf color, and stress symptoms has become possible through image processing and artificial intelligence techniques. Therefore, artificial intelligence is employed not only to accelerate measurements but also to analyze complex traits that are challenging to evaluate with the human eye (Watt et al., 2020).

Thousands of different genotypes are evaluated in plant breeding studies. Researchers aim to identify individuals possessing traits such as drought tolerance, high yield, or disease resistance. Artificial intelligence-powered phenotyping systems facilitate the identification of candidate individuals with desired traits by analyzing large numbers of plants in a short time. This both shortens the research duration and enhances the effectiveness of plant breeding programs **(Fahlgren et al., 2015; Yang et al., 2020; Maraveas, 2024; Kaya, 2025)**.

The aim of using artificial intelligence in plant phenotyping is not to replace the researcher. The researcher plans the experiment, grows the plants, defines the biological question, and interprets the obtained results. Artificial intelligence, on the other hand, serves as a powerful tool that supports the researcher's decision-making process by rapidly and accurately analyzing large datasets derived from images **(Yang et al., 2020; Singh et al., 2021; Maraveas, 2024).**

The primary reason for using artificial intelligence in plant phenotyping is the need to analyze the vast amounts of data generated by modern imaging systems rapidly, accurately, and in a standardized manner **(Fahlgren et al., 2015; Yang et al., 2020)**. AI-based image analysis methods enable the automated assessment of plants' morphological, physiological, and developmental traits, thereby reducing human error and significantly accelerating research

processes. These advancements make significant contributions to numerous fields, ranging from fundamental plant biology to plant breeding and sustainable agriculture (Singh et al., 2021; Maraveas, 2024).

AI-Assisted Phenotyping Methods

AI-powered phenotyping is the process of automatically analyzing image and sensor data obtained from plants using computer algorithms (Table 1). Through this approach, plant organs such as leaves, roots, stems, flowers, and fruits can be evaluated rapidly, accurately, and reproducibly (Singh et al., 2021).

Computer Vision

Computer vision is a field of artificial intelligence that enables computers to recognize objects by analyzing images obtained from cameras or sensors. Its key capabilities include analyzing digital images, attempting to recognize plants in a manner like the human eye, distinguishing between plant parts such as leaves, roots, stems, and flowers, determining the locations of objects within an image, and analyzing multiple plants in a single image. Applications in plant phenotyping include leaf identification, leaf count calculation, leaf area measurement, rosette diameter determination, root system imaging, flower and fruit counting, identification of disease symptoms, and early detection of drought symptoms **(Fahlgren et al., 2015; Yang et al., 2020; Singh et al., 2021; Maraveas, 2024)**. Its significance in *Arabidopsis thaliana* research lies in the ability to easily recognize the rosette structure, automatically segment the leaves, analyze multiple plants within a single image, and serve as the foundation for high-throughput phenotyping systems **(Tsaftaris et al., 2016; Yang et al., 2020; Maraveas, 2024)**. In short, computer vision enables the computer to "see" the plant.

Image Analysis

Image analysis is the process of extracting biologically meaningful information from images of plants. It converts images into numerical data and enables measurements to be taken. It reduces the need for human intervention, can analyze large datasets, and performs the same measurement in a standardized way across every image **(Fahlgren et al., 2015; Tsaftaris et al., 2016; Yang et al., 2020)**. Morphological traits measurable via image analysis includes leaf area, number, and shape; rosette size; plant height; root length; and the number of lateral roots, flowers, and siliques **(Yang et al., 2020; Singh et al., 2021)**. Leaf color, chlorophyll content, leaf temperature, water status, and signs of drought are physiological traits that can be measured through image analysis **(Yang et al., 2020; Maraveas, 2024)**. Developmental characteristics—such as growth rate, time of leaf formation, time of flowering, and the senescence process—can also be measured using image analysis. In *A. thaliana* studies, image analysis has been used to monitor leaf growth, evaluate root development, compare mutants, determine stress conditions, and investigate genotype-phenotype relationships **(Tsaftaris et al., 2016; Yang et al., 2020; Maraveas, 2024)**. In short, image analysis enables the computer to take measurements from the plant.

Deep Learning

Deep learning is an artificial intelligence method capable of automatically recognizing objects by learning from many images. Deep learning works with large datasets. It does not require the

user to write the rules one by one. It can learn from the images on its own. It can also make accurate predictions on new images. It can recognize complex patterns **(LeCun et al., 2015; Tsaftaris et al., 2016; Singh et al., 2021; Maraveas, 2024)**. Its tasks in plant phenotyping include the automatic identification of leaves, individual leaf segmentation, root system analysis, recognition of disease symptoms, classification of drought stress, monitoring of plant growth, and the identification of small structures such as stomata and trichomes (Singh et al., 2021; Maraveas, 2024).

The deep learning models used are CNN (Convolutional Neural Network), Mask R-CNN, U-Net, and AutoML **(LeCun et al., 2015; Singh et al., 2021; Maraveas, 2024)**. CNN (Convolutional Neural Network) can recognize leaves and roots and detect symptoms of disease if a disease has occurred in the plant **(Krizhevsky et al., 2012; Singh et al., 2021)**. Mask R-CNN, on the other hand, identifies each leaf of the plant as a separate object. It can calculate the leaf area. It can serve to separate the siliques and the flowers (Ronneberger et al., 2015; Tsaftaris et al., 2016). The task of U-Net is to perform leaf and root segmentation. It also analyzes cell and tissue images **(Ronneberger et al., 2015; Tsaftaris et al., 2016)**. AutoML, on the other hand, automatically selects the most suitable artificial intelligence model to be used in phenotyping. In this way, the need for the user's programming knowledge is reduced **(Maraveas, 2024)**. Deep learning has been employed in *A. thaliana* for leaf and root phenotyping, rosette analysis, growth monitoring, stress analysis, and the evaluation of genotype-phenotype relationships **(Yang et al., 2020; Singh et al., 2021; Maraveas, 2024)**. In summary, deep learning enables the computer to learn how to recognize and analyze plants.

Table 1: Relationships between artificial intelligence concepts used in plant phenotyping

Concept	Primary Duty
Computer vision	Identifies the plant and its organs in the image.
Image analysis	It takes measurements from recognized structures and obtains numerical data.
Deep learning	It enables the computer to learn these processes and execute them automatically and with high accuracy.

Artificial Intelligence-Assisted Phenotyping Applications in *Arabidopsis thaliana*

AI-powered phenotyping systems enable the rapid, accurate, and automated assessment of various organs of *Arabidopsis thaliana* and its responses to environmental stresses. Analyses of leaves, roots, and abiotic stress responses have been among the most intensively studied application areas in recent years **(Yang et al., 2020; Singh et al., 2021; Maraveas, 2024)**.

Leaf Analysis

Leaf analysis is the examination of the morphological and physiological characteristics of leaves for the purpose of evaluating the plant's growth, development, and responses to environmental conditions **(Fahlgren et al., 2015; Yang et al., 2020)**. Leaf number, leaf area, leaf length and width, leaf shape, rosette diameter, leaf angle, leaf growth rate, leaf color, signs of chlorosis and necrosis, and leaf senescence are traits that can be measured using artificial intelligence **(Tsaftaris et al., 2016; Yang et al., 2020; Singh et al., 2021; Maraveas, 2024)**.

Leaf analysis is important because it enables the visualization of plant growth rates, aids in identifying genetic differences, facilitates the comparison of mutant plants, reveals early signs of environmental stress, and allows for the monitoring of plant development over time **(Fahlgren et al., 2015; Yang et al., 2020; Maraveas, 2024)**.

The number of leaves is used to assess the plant's development rate and growth status. Leaf area provides information about the plant's growth and photosynthetic capacity. Leaf shape helps determine genetic differences and environmental influences. Rosette diameter is an important metric indicating the overall growth performance of *A. thaliana*. The leaf growth rate reveals the plant's developmental dynamics through time-series imagery **(Fahlgren et al., 2015; Yang et al., 2020)**. Leaf color can provide information about chlorophyll content, nutritional status, and signs of stress. In the analysis of stomata, stomatal density, stomatal size, and the degree of opening are automatically determined. Information regarding gas exchange and water loss can also be obtained. Trichome (leaf hair) analysis involves evaluating trichome count, density, and distribution through image analysis. Trichome number and distribution can be used to evaluate plant development and responses to certain environmental stresses **(Tsaftaris et al., 2016; Yang et al., 2020)**. In leaf vein network analysis, vein structure and vein density are examined. By examining the vascular structure and density, water and nutrient transport as well as developmental differences can be evaluated **(Yang et al., 2020; Maraveas, 2024)**.

Deep learning algorithms separate leaves from the background (segmentation), identify each leaf as a distinct object, automatically calculate leaf area, determine growth rates by comparing daily images, and track the same plant over time **(Ronneberger et al., 2015; He et al., 2017; Tsaftaris et al., 2016; Singh et al., 2021)**. Many systems developed in the literature automatically analyze rosette development, leaf size, leaf number, and the growth curve **(Fahlgren et al., 2015; Yang et al., 2020; Maraveas, 2024)**. For example, the APTES system can identify individual leaves and automatically perform detailed morphological measurements using an enhanced Cascade Mask R-CNN model (Zhai et al., 2025).

Root Analysis

Root analysis refers to phenotyping practices aimed at evaluating a plant's below-ground development and root architecture **(Fahlgren et al., 2015; Yang et al., 2020)**. Primary root length, lateral root number, lateral root length, root density, root growth rate, root branching pattern, root angle, and total root length are traits that can be measured using artificial intelligence **(Tsaftaris et al., 2016; Yang et al., 2020; Singh et al., 2021; Maraveas, 2024)**. Root analysis is an important process, as it indicates the plant's water uptake capacity, provides information on nutrient uptake, and enables the assessment of drought tolerance. It also reveals differences between genotypes. It also helps in understanding the plant's adaptation to environmental conditions. Computer vision and deep learning methods separate roots from the background, identify primary and lateral roots, track root growth day by day, and quantitatively analyze root architecture **(Ronneberger et al., 2015; Tsaftaris et al., 2016; Singh et al., 2021)**. In *A. thaliana* studies, AI-based platforms such as ChronoRoot can monitor root development as time series, calculate root growth rates, and automatically assess changes in root architecture. These systems are widely used, particularly in studies on drought and nutrient deficiency **(Gaggion et al., 2021)**.

Abiotic Stress Analysis

Abiotic stress analysis is the assessment of the responses of plants to environmental factors such as drought, salinity, heat, cold, and nutrient deficiency **(Yang et al., 2020)**. Stresses in plants—such as drought stress, salt stress, high-temperature stress, low-temperature stress, nutrient deficiencies, and oxidative stress—can be detected using artificial intelligence **(Singh et al., 2021; Maraveas, 2024)**. Symptoms such as changes in leaf color, wilting, leaf curling, leaf temperature, reduced growth rate, changes in the rosette area, slowed root development, and alterations in light reflectance properties can be analyzed by artificial intelligence **(Fahlgren et al., 2015)**. Plants under stress exhibit small changes that are difficult to detect with the naked eye. Artificial intelligence can identify these changes at an early stage, classify different stress levels, predict the severity of stress, and help the researcher make faster decisions (Yang et al., 2020; Maraveas, 2024).

Arabidopsis is one of the most frequently used model plants in stress studies, such as those concerning drought and salinity. AI-powered systems can distinguish stressed plants from healthy ones, identify signs of drought by analyzing leaf images, and classify stress levels using hyperspectral or RGB imagery **(Singh et al., 2021; Maraveas, 2024)**. These studies contribute to the development of plant varieties resistant to stress conditions for future agricultural production **(Yang et al., 2020; Maraveas, 2024)**. Artificial intelligence-enabled phenotyping applications in *A. thaliana* enable the automated analysis of leaves, roots, and environmental stress **(Fahlgren et al., 2015; Yang et al., 2020; Maraveas, 2024)**. With the help of computer vision and deep learning algorithms, plant growth, development, and responses to environmental changes can be evaluated with high accuracy, thereby enabling a more comprehensive examination of genotype-phenotype relationships **(Tsaftaris et al., 2016; Singh et al., 2021; Maraveas, 2024)**.

Current Software

Numerous software programs have been developed to enable the rapid and accurate analysis of images obtained in high-throughput phenotyping studies. These software programs automatically evaluate the morphological and physiological characteristics of plants using computer vision, image analysis, and deep learning methods. Some of the most frequently used software programs in *Arabidopsis thaliana* studies are APTES, ChronoRoot, and PlantCV **(Fahlgren et al., 2015;** Zhai et al., 2025**; Gaggion et al., 2021) (Table 2)**.

Table 2: Comparison of Software for Phenotyping

Software	Primary Aim	Key Feature
APTES	Leaf phenotyping	Individual recognition and segmentation of leaves
ChronoRoot	Root phenotyping	Monitoring root development over time
PlantCV	General phenotyping	An open-source platform capable of analyzing different types of images.

APTES

(*Arabidopsis* Phenotyping Platform Based on Deep Learning)

The purpose of using APTES is to automatically identify *Arabidopsis* rosette leaves and analyze their phenotypic traits **(**Zhai et al., 2025**) (Fig. 2)**. Its key feature is that it is based on deep learning. It uses the Mask R-CNN algorithm. It can identify individual leaves. It performs leaf segmentation. Calculates leaf area. Determines the number of leaves. Measures rosette size.

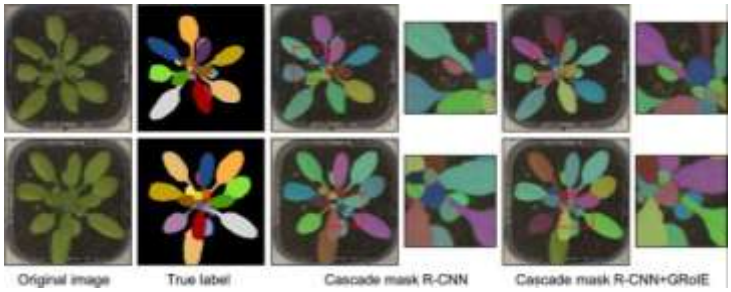

Fig. 2: Leaf instance segmentation results and phenotypic trait extraction in *A. thaliana* (Zhai et al., 2025), CC BY 4.0.

It can analyze different developmental stages. Its advantages are that it reduces the need for manual measurement, ensures high accuracy, can analyze many images in a short time, and is suitable for time-series studies. It yields successful results with *Arabidopsis* images. Areas of application include leaf phenotyping, mutant analysis, growth monitoring, and the investigation of genotype-phenotype relationships **(Yang et al., 2020;** Zhai et al., 2025**)**.

ChronoRoot

It is possible to automatically monitor the development of the Arabidopsis root system over time using ChronoRoot **(Gaggion et al., 2021) (Fig. 3)**. ChronoRoot is based on deep learning. It performs root segmentation. It identifies the primary root. Identifies lateral roots. Tracks daily root development. Analyzes root architecture. Generates time-series data. Its advantages include analyzing root development without the need for manual measurement, revealing dynamic growth changes, and processing large datasets. It can examine the root architecture in detail. It is used in root phenotyping, drought studies, nutrient element research, monitoring root development, and plant physiology research **(Gaggion et al., 2021; Yang et al., 2020)**.

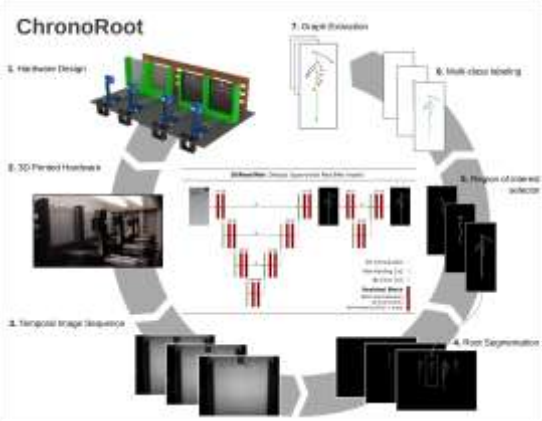

Fig. 3: Components of the ChronoRoot system and the root phenotyping process (Gaggion et al., 2021), CC BY 4.0.

PlantCV

The purpose of PlantCV is to process plant images and analyze phenotypic traits using open-source tools **(Gehan et al., 2017) (Fig. 4)**. It is open source. It is Python-based. It has a modular structure. It can analyze RGB images. It can work with hyperspectral images. It can evaluate thermal images. It can analyze fluorescence images. Customizable by the user. The characteristics it can analyze include leaf area, leaf count, plant height, plant width, color analysis, signs of chlorosis, signs of necrosis, biomass estimation, and plant segmentation (Singh et al., 2021). Its primary advantage is that it is free. It has a large user community. It can be used with various plant species. It can analyze large datasets. It is constantly being updated. Its areas of application include *Arabidopsis* research, plant breeding, agricultural phenotyping, stress physiology, and image analysis studies **(Gehan et al., 2017; Yang et al., 2020)**.

CONCLUSION AND FUTURE PERSPECTIVE

Conclusion

Arabidopsis thaliana is one of the most widely used model organisms in plant biology, thanks to its short life cycle, small and well-characterized genome, ease of genetic transformation, and extensive mutant collections. Due to these characteristics, it is also used as an important research model in the development and validation of AI-powered, high-throughput phenotyping systems. High-throughput phenotyping technologies enable the rapid and reliable analysis of large amounts of data obtained from imaging systems and sensors. However, the increase in the volume of this data has rendered traditional manual assessment methods inadequate, making the use of computer vision, image analysis, and deep learning-based artificial intelligence approaches essential. Thanks to software developed in recent years such as APTES, ChronoRoot, and PlantCV leaf development, root architecture, plant growth, and abiotic stress responses can be analyzed with high accuracy. These technologies not only accelerate the data analysis process but also contribute to conducting research that is more objective, reproducible, and highly accurate.

AI-powered phenotyping approaches:

- Enable the analysis of large volumes of image data in a short time.
- Reduce time loss associated with manual measurements.
- Minimize human-induced measurement variations.
- Allow for the monitoring of plant growth over time.
- Enable the automated assessment of leaves, roots, and other morphological structures.
- Contribute to the early detection of abiotic stress symptoms.
- Support a more detailed examination of genotype-phenotype relationships.
- Facilitate the identification of candidate genotypes in plant breeding programs.

Future Perspective

Rapid advancements in artificial intelligence technologies are significantly shaping the future of plant phenotyping research. In the coming years, phenotyping processes are expected to become increasingly automated using more advanced algorithms, more powerful imaging systems, and computers with higher processing capacities.

In particular,

- the combined use of multiple imaging techniques (RGB, hyperspectral, thermal, and 3D imaging),

- the integration of multiple data sources with artificial intelligence,
- the joint analysis of genomic, transcriptomic, and phenomics data,
- the development of open-source software,
- the widespread adoption of cloud-based analysis platforms, and
- the development of real-time phenotyping systems

will make significant contributions to the future advancement of this field.

Adapting methods developed on *Arabidopsis thaliana* following appropriate validation studies to economically important crops such as wheat, rice, maize, and tomatoes offer significant opportunities for sustainable agriculture, plant breeding, and food security.

AI-powered high-throughput phenotyping is regarded not merely as a technological innovation in plant research, but as a significant approach that transforms research processes. Methods developed using *Arabidopsis thaliana* enable a more detailed understanding of plant **development and the more effective analysis of phenotypic data. It is anticipated that, with the future advancement of AI algorithms and the widespread adoption of high-throughput phenotyping systems, these technologies will be utilized more effectively across a broad spectrum of applications ranging from basic plant biology to plant biotechnology and sustainable agriculture.**

THE ROLE OF SUPPLEMENTARY IRRİGATİON FOR FOOD PRODUCTİON İN A SEMİ-ARİD COUNTRY PALESTİNE

By:
Eng. Mohammed Yousef Sbeih
Irrigation Project Coordinator
P.O. Box 1664
Ramallah, West Bank
Palestine
Email: sbeih2005@yahoo.com

Keywords: Palestine, Irrigation, Economics, Supplementary, Irrigation, Food Production

Abstract: Palestine consists of the West Bank and the Gaza Strip. The proclaimed state of Palestine has a land area of 6,657km³.

Water is always considered as an essential factor of life and development in arid and semi-arid countries. In Palestine the total per capita water consumption is 139m³.

The total available water for Irrigation is 239 MCM which is responsible for irrigating only 330,000 dunums out of 2,314.000 dunums cultivated that can be irrigated if water is available i.e. 5% of the total cultivated land.

The average rainfall is 450mm and unfortunately there isn't any water harvesting structures i.e. dams, most of this rainwater flowing towards the Dead Sea or the Mediterranean Sea as waste. So harvesting this water in individual farmer land and using this water for supplementary irrigation to irrigate olive trees, almonds, grapes and cereals will be of a great impact on the Palestinian land for feed production. It should be noted that there are few farmers who practice supplementary irrigation for production of vegetables that are planted in summer as individual initiative. The quantity and quality of production that they have is extremely tangible.

Since most of the land in Palestine is planted by olive, grape, and cereals, supplementary irrigation should be introduced and practiced where the production of wheat via irrigation by treated wastewater was three times that under rain fed planting project implemented in a pilot project.

Reuse of treated wastewater for irrigation as supplementary irrigation will increase the irrigated area in Palestine and will replace the fresh water that can be used for domestic purposes.

The Need for Supplementary Irrigation in Palestine:

As it was mentioned before, Palestine is a semi-arid country, where the average rainfall is 450mm. The availability of water is questionable. Furthermore, the availability of water for agriculture is reducing in a tangible way due to the followings:

The normal increase in growth rate, the population of the country is increasing, so the demand for domestic water is also increasing. This will affect the availability of water for agriculture.

Since rainwater is the only source of water, the quantity of rainwater (rainfall) has been decreasing in the recent years.

There is a huge conflict on water issues at this stage between the Palestinians and the Israelis since Israel occupied Palestine. It should be mentioned here that during early negotiations in the peace process, four main issues have been delayed since 1992; they are Jerusalem, refugees, water and borders. Still after 8 years of negotiations, there hasn't been any significant movement on these issues. So the quantity of water that can be available for the Palestinians will probably not be increased.

The quality of ground water wells especially in Gaza and Jericho becomes saline and shortly it cannot be safely available for agriculture.

From the above, it seems that extra availability of water for additional irrigated area or even to sustain the irrigated area is not an easy task.

Total cultivated area in the West Bank is 2,100.00 dunums, but the irrigated area is 110,000 dunums. From the small experience (pilot project) for this field as well as other country experience i.e. Syria. It has been proven that the production of crops under supplementary irrigation is 3 times higher than under rain fed crop, in addition to the increase in the quality of the product. So if supplementary irrigation has been practiced we can easily increase the production of rained crops to three times or twice. This will play a major role in providing food for the people and even exports can take place and the net income of the country will be increased.

Background

It is foreseen that the world's food production has to be doubled in the next 25 years, and thus, the agriculture continues to be an important sector in the 21st century. Meanwhile, the agriculture sector remains the largest user of the water resources, and it is evident that there is a decline of agricultural water due to increasing demands from cities, industries, and hydropower utilities in the developing countries such as Asia. Much of the water has to come from irrigation water savings.

Population and economic growth in many developing countries of Asia have created serious problems, such as the shortage of food, the scarcity of water, and the deterioration of the environment.

Some of the irrigation and drainage projects have been seriously criticized due to their high-cost and low-efficiency for the construction and maintenance. The concept of maximum yield is now changing to optimum yield for creating an efficient irrigation schedule. The water saving is the most sustainable conservation, because it reduces the new construction needs to meet the increased water demand. The major issues of agricultural water are how to increase withdrawals about 15 – 20% by water saving, how to increase storages 10 – 15% by new irrigation facilities, and how to conserve the water quality of irrigation.

SUPPLEMENTAL IRRIGATION

Definition

ICARDA defines supplemental irrigation (SI) as; the addition of essentially rain fed crops of small amounts of water during times when rainfall fails to provide sufficient moisture for normal plant growth, in order to improve and stabilize yields. Accordingly, The concept of SI in areas having limited water resources is built on three bases:

First: water is applied to rain fed crops, that would normally produce some yield without irrigation;

Second: since precipitation is the principal source of moisture for rain fed crops, SI is only applied when precipitation fails to provide essential moisture for improved and stabilized production and;

Third: the amount and timing of SI are not meant to provide moisture stress-free conditions rather to provide minimum water during the critical stages of crop growth to ensure optimal instead of maximum yield.

The management of supplemental irrigation is seen as a reverse case of full or conventional irrigation (FI). In the latter the principal source of moisture is the fully controlled irrigation water, while the highly variable limited precipitation is only supplementary. Unlike FI the management of SI is dependent on the precipitation as a basic source of water for crops grown.

Water resources for supplemental irrigation are mainly surface, but shallow groundwater aquifers are being increasingly used lately. Non-conventional water resources are of a potential for the future, but an important one emerging is water harvesting. (Dwas 2001).

Improving Production with SI

Research results from ICARDA and other institutions in the dry areas as well as harvest from farmers showed substantial increases in crop yields in response to the application of relatively small amounts of supplemental irrigation. This increase covers cases with low as well as high rainfall. Average increases in wheat grain yield under low, medium and high annual rainfall in Tel Hadya reached about 400%, 150% and 30% using amounts of SI of about 180, 125 and 75mm respectively. Generally, optimal SI amounts range from 75mm to 250mm in areas with annual rainfall between 500 to 250 mm, respectively. Determining the optimal amount under various conditions will be discussed later (Oweis 2001).

When rainfall is low, more water is needed but the response is greater, but increases in yield are remarkable even when rainfall is as high as 500 mm. The response was found to be higher when rain distribution over the season is poor. However, in all rain fed areas of the region it was found that some time in the spring there is usually a period of stress, which threatens, yield levels. This soil moisture stress usually starts in March, April of May, if total annual rainfall received is low, average or high respectively (Oweis 2001).

In Syria average wheat yields under rain fed conditions are only 1.25 t/ha and this is one of the highest in the region. With SI the average grain yield was up to 3t/ha. In 1996 over 40% of rain fed areas were under SI and over half of the 4 mil tons national production was attributed to this practice. Supplemental irrigation does not only increase yield but also stabilizes farmer's production. The coefficient of variation in rain fed production in Syria was reduced from 100% to 10$ when SI was practices. This is of special socio-economic importance since it affects farmer's income (Oweis
2001).

INTRODUCTION

Historical Palestine is located between the Mediterranean Sea and the Jordan River, as well as to the Red Sea from the south. The present proposed Palestinian state consists of West Bank and Gaza Strip. The other part of Palestine is occupied by Israel in 1948. This study focuses on the West Bank and the Gaza Strip. The proclaimed state of Palestine has a land area of 6657 square kilometres (Kateeb 1993). Population senses has been taken place recently by the Bureau of Statistics early 1998. It is reported that the population of the West Bank is 1571571 and Gaza Strip is 963026 where the total population of the Palestinian people is 2534598 people.

Ground water is the main water source in the country. It is recharged by rainfall. Rainfall varies from 100mm in the south east to 800 mm in the north. The average rainfall is 550mm (Sbeih - 1995). Where the average rain fall in Jordan Valley is from 100 mm to 270 mm/year (Zaru - 1992), and in Gaza is 200 - 400 mm/year (Abu Safieh - 1991).

Not all the rainwater is available to the Palestinian due to Israeli Military orders. Water is abstracted from the ground water through 340 wells in the West Bank and 1781 wells in Gaza. In addition to that springs contribute a lot, where half of the irrigation water in the West Bank is due to springs.

The quality of the available water varies from almost rain water to Brackish water. In the Jordan Valley where it is the lowest point in the elevation in the world where temperature is very high in this area especially in summer. As example, the chloride content is reaching 68 mg/l and the SAR reaches 11.7 where the TDS reaches 5000PPM. Still the utilization of this saline

water is not as efficient and environmentally safe as it should be where further utilization of this water could play a major role in developing the area where still the irrigated area consists of not more than 6% of the cultivated area in the West Bank.

It should be mentioned that not only saline water does already exist and utilized unproperly, but it also seems to be that the additional water that can be allocated for irrigation is also saline water which is going to be from:

1. The Eastern aquifer to be used in Jordan Valley
2. From the treated waste water from different cities and villages in the West Bank

Water sources in Occupied Palestine

a) West Bank

Two main water sources are available for Palestinian in the occupied Palestine (West Bank and Gaza Strip) for agricultural, domestic and industrial use. These are rainfalls and ground water sources - Palestinians consume water mainly through ground water wells and springs (where rainfall is considered the main recharge). The total annual water springs discharge varies according to the rainfall. The total annual flow of the 113 fresh water springs in the West Bank ranges between 24 MCM (as in the year 1978/79) to 119.9 MCM (as in the year 199/92) and with an average of 52.9 M.C.M. as calculated from the annual flow in the past 24 years. Around 86% of the total annual flow of these 113 springs is within the eastern drainage (in/or toward the Jordan Valley), while the other 14% is within the western and south-west (Nusseibeh 1995) where the total estimated annual water discharge from ground wells is 60 M.C.M. (Awartani 1992). So that the total annual water available to Palestinian is 113 M.C.M. In addition to that there is another 2.5 M.C.M. is collected directly from the rainfall in cisterns in Palestinian houses. So that the total available water is 116 M.C.M./year, for more information see Table No. I.

b) Gaza Strip

Water situation in Gaza Strip is very critical. The Gaza Strip lies on top of two water strata. The upper is fresh water, the lower carries saline water. The annual consumption of water is at present in the vicinity of 100 M.C.M. These aquifers get replenishment of some 60% leaving a deficit of 40 M.C.M. of water (Shawwa 1991).

Even the Gaza water is lower in quality than West Bank, but due to the complication of the situation there and due to the geographic location where my work is more in the West Bank. This paper will address West Bank issues more clearly.

Basic land and water indicators for Israel and the Occupied Palestinian and other Arab territories

(1dunum = 1,000 m²)

	West Bank	Gaza Strip	Israel
Total area (dunums)	**5 573 000**	**360 000**	**20 000 000**
Population (1988)	**900 000**	**600 000**	**4 300 000**
Area of land cultivated (dunums)	**2 100 000**	**214 000**	**4 250 000**
Area of land irrigated (dunums)	**000**	**000**	**850 000**
Percent of total irrigated land	**5**	**56**	**44**
Percentage of total land cultivated	**38**	**59**	**21**
Annual water consumptoin for irrigation (million m³)	**95**	**80**	**1320**
Annual water consumption for households (million m³)	**27**	**21**	**325**
Annual water consumption for industry (million m³)	**3**	**2**	**125**
Total annual water consumption (million m³)	**125**	**103**	**1770**
Total per capita water consumption (m³)	**139**	**172**	**411**
Per capita water consumption per household (m³)	**30**	**35**	**75**
Per capita water consumption for industry (m³)	**3.3**	**3.3**	**29**
Per capita water consumption for irrigation (m³)	**106**	**133**	**307**

Irrigated areas in the occupied Palestine

In Palestine, being a semi arid country, we are confronted by a demographic growth, and agricultural development as well livestock and industrial development. Thus in essential growing water requirement makes the rational management of water resources supremely important in order for development to be lasting and for environment to be served.

On a global basis at least 60% of all water abstracted at present is used for agricultural production. In Palestine 70% of all water consumed is due to agriculture.

Here in Palestine, agriculture is considered to be one of the main national income. Agricultural production contributes 47.61% of the total national income in 1970.

The potential for irrigation to raise both agricultural productivity and the living standards of the rural poor has long been recognized. Irrigated agriculture occupies approximately 17% of the world's total available land but the production from this land comprises about 34 % of the world total.

In Palestine, irrigation is considered to be the spinal chord of plant production for the following reasons:

1. Palestine is considered as a semi arid region where some of the crops cannot be grown without irrigation (example, citrus).

2. In the Jordan Valley, which constitutes the main agricultural production for the country, irrigation is a must due to low rainfall and high temperature.

3. With irrigation the same plot of land can be planted up to three times per year while it cannot be planted more than two times with dry farming.

4. Different varieties and crops can be planted in any region due to the availability of water i.e. more flexibility of planting several crops at different regions in different times of the year.

5. **Job creation:** Since the labour requirement per irrigated durum is more than double that of job required per dry farming per one season. This has now become more vital due to continuos of closures of the West Bank and Gaza Strip where the number of labourers that are working in the Palestinian part that occupied in 1948 is sharply reduced.

6. Agricultural production is much higher for irrigated farming than for dry farming per dunum per season. As example average tomato production per dunum is as follows:

- Dry farming: 2-3 ton per dunum per season.
- Irrigated (open land) 6-8 ton per dunum per season
- Irrigated (greenhouse) 12-16 ton per dunum per season

7. Net income per dunum of dry farming does not exceed $150 while from irrigated area the net income can exceed $1500 per dunum

8. Especially in Palestine, where the horizontal expansion in agriculture by increasing the total cultivated area due to the Israeli occupation, and shortage of water. The vertical expansion could be the main parameter to play with. Irrigation will be the main element in this formula. So that providing extra water for irrigation to irrigate as much as possible of the cultivated area is a must. This implies that Palestinian should use any drop of water. Regardless the quality of that water practically and efficiently:
Table no. 2 shows the irrigated area in each district in Palestine where the total irrigated area in 1993-94 was 217,000 dunum (PSBS 1996).

Available area that is ready for irrigation

Where in Gaza Strip the irrigated area could be doubled or tripled in terms of topographical situation but due to the limitation of the water both quality and quantity it is very difficult to increase the irrigated area while in the West Bank the area that could be irrigated in terms of topographical conditions estimated to be 535 thousand dunums (Awartani 1991) as in table 3.

Table 1: Distribution of area that could be irrigated in the West Bank

Location	Dunum
Plains in Jenin and Tulkarem	**99,600**
High land	**277,40**
Eastern slopes	**64.6**
Jordan Valley	**93.5**
Total	**535.1**

Source (Awartani 1991)

Where in the study conducted by PWA in 1992 in order to develop a plan for the western Ghore the following locations could be the most suitable area to be ready for irrigation:

1. <u>Northern Ghore</u>

The areas suitable for irrigated agriculture in this region include:

18000 dunums in Ein Al Beida, Bardalla villages
5300 dunums in the Ghore
3500 dunums in the Ghore

But the Ghore and Zhor areas are mostly closed by the Israeli Military orders.

2. El-Bique Valley

This is a large flat area to the west of the hills of northern Ghore. This area includes about 18500 dunums of fertile smooth deep soil. The Palestinian farmers as rainfed excluding 5500 dunums where the two settlements their (Baquat and Roi) are occupying cultivate all this area.

3. Upper El Fara' valley area (Semi-Ghore)

In this area, there are 13100 dunums that are suitable for irrigation and can be easily irrigated as follows:

Sahl Tubas	3600 dunums
Sahel Tayassear	900 dunums
Sahel Tammun	1900 dunums
Sahel El Fara'	5000 dunums
El Nassarieh (additional)	1700 dunums

Where there are another 7000 dunums, which are already irrigated.

4. The middle and south Ghore

This region extends from approximately grid north 180 (northern of Marj Najeh) in the north to the Dead Sea in the south and from the Jordan River in the east to the feet of the west-bank mountains.

The total area that could be ready for irrigation in this area is 145500 dunums. In summary, the total area that can be used in irrigated agriculture in the western ghore will be:

Northern Ghore	26800 dunums
Biquia valley	18500 dunums
Semi-Ghore	201000 dunums
Southern Ghore	145500 dunums
Total	210900 dunums

Where about 44000 (PCBC 1991) dunums of this area is currently irrigated. So the total additional area that could be irrigated in the West Bank is (210900 - 44000 + (535,100 - 93,5000) = 608500 dunums.
It should be mentioned that the Jordan Valley produces more than 59% of the vegetables produced in the West Bank. It also produces 100% of the bananas produced in Palestine.

Palestinian Experience of Supplementary Irrigation

Still the term supplementary irrigation is not even used formally and officially in Palestine. Until this time there is not any plan of implementing any project of supplementary irrigation.

This is mainly due to the lack of qualified staff at the Ministry of Agriculture as well as to the lack of great interest to agriculture from M.O.A. due to the following reasons:

The lack of responsibility of the Palestinian Authority on most of the agricultural land due to the occupation.
The lack of finance and funding to development projects.

Nevertheless, there are individuals who attempt to use supplementary irrigation, an example of that are few farmers in Sinjel town in the Ramallah area.

Description of Agricultural area in Sinjel

This village is located just between Ramallah and Nablus cities, situated 20km to the north of Ramallah. The total agricultural area in the village excess 4000 dunums, out of these areas. About 1000 dunums are plain and flat.

This 1000 dunums is planted with vegetables in summer and cereals in winter. All of this area is rain fed, there are no source of water for irrigation since this area is located close to the village (houses), it is easy for the farmers to bring water by mobile tanks.

Usually the farmers in summer, bring some water and store them in a container (barrel) of 200 liter capacity each, since the ownership of land is between 3-5 dunums, the number of barrels used are 6-8.

In summer farmers used to plant vegetables, at the time of planting the seedlings, farmers used to irrigate the seedling by a bucket. Farmers used to mix the fertilizer water and irrigation at the time of planting the seedlings. Later on, after 20 days the second irrigation with fertilizer is applied. The third one and the last one are provided with fertilizer before flowering. The total amount of water applied per each plant is not more than 1 liter, for a dunum of 1000 plants, 1000 liter is applied 1 cubic meter of water applied for the whole season per one dunum. While for the irrigated area the minimum irrigation water requirement is 70m^3/dunum per the season.

In this village, Singel, and through my investigation, in the year 2000 I found 3 farmers who are using this approach technology, when I asked one of them what is the result that you will expect, he broadly replied:

The quality of agricultural product that I used to obtain for the last two years where I used to use supplementary irrigation is much better than the product of my neighbor in the same plot of land in the village, so the price per 1 kg. That I got is much higher also.

The total production is much higher than that of my neighbor, i.e. I got 4 tons each per dunum, my neighbor got 2 tons of squash per dunum.

The period of production that I have is much bigger than that of my neighbor has, this means that total income that I gained is much higher. I used the produce vegetables for 2 months, while my neighbor only one month, i.e. the harvesting period is much higher when supplementary irrigation used
I informed this farmer that I am working on an irrigation project coordinator for an NGO that provides funds for farmers. Since this farmer believes that he was happy from his production since he has only 3 dunums and all of his family working in this plot of land, he did not ask

what service that since that we offered, this totally indicated that he is happy, and he did not need any further assistance. At that time there was visiting irrigation professor from Canada. This professor told me that we should use him as a model to encourage people using appropriate technology.

Another example of using supplementary irrigation is found in Hebron where a farmer from Al Tamimi family, who has a grape field and luckily a pipe water pass through his field and used to get some water from this pipe and provide some water for his grape. In winter since the rainfall in Hebron is not exceeding 300mm, as well as in July.

It is well known in Hebron, that the quality of grape of that man is the best in Hebron, since Hebron is of the biggest producing city (country) in Palestine.

Since the municipality constructed a pilot treatment plant, it thought of planting crops using the treated effluent. This was funded by American Near East Refugee Aid (ANERA). Three crops were selected by the Agriculture Department to be planted for the first time in Palestine using treated wastewater:

Artichokes on 150m² - plantead on October 31, 1993.
Onion frozen production on 500m² - planted on November 6, 1993.
Wheat on 1000 m² - planted on November 22, 1993.

Drip irrigation as well as sprayers were used.
Several treatments were made as follows:

Irrigation with wastewater used, fertilization was used.
Same as above, but without application of fertilization.
Irrigation not used but fertilization was used.
No irrigation and no fertilization (dry land farming).

All the agricultural practices were used (pesticides, ploughing, seed control, etc..)
Table 13 shows the production of each kind of treatment. The impact of using treated wastewater appears clear.

Table 13: Results of El Bireh wastewater treatment pilot plant using treated wastewater.

Treatment	**Production of wheat (anber variety), all the plants, kg/dunum**
Irrigation with treated wastewater with Fertilizer	2520
Irrigation with treated wastewater without Fertilizer	20036
Without irrigation, with fertilizer	1600
Without irrigation, without fertilizer	572

Notes:

Time of planting was October 1993; all the crops received rainfall during the growing period.
Time of harvesting was June 2, 1994.

Production with irrigation with treated wastewater with fertilization was five times without irrigation and fertilization.
Production increased the soil when irrigated with treated wastewater where fertilization was applied on both cases (irrigated and non-irrigated).

Methodology of Practising Supplementary Irrigation In Palestine

Since the ownership of land is very small in size i.e. from 5-10 dunums, supplementary irrigation can be easily implemented for vegetables, trees and to cereals to some extent constructing of small poonds of 40-50 m³ capacity, i.e. this pond can be located on a 14-18 meter square area. This pond can be located on the lowest point in elevation of the individual land. This land serves two farmers if agreed upoon where it can be sited on the border of each farmer land.

Distributing of water to the plant can be done manually by lifting the water and distributing it to the plants by a bucket. Another way of distributing this wataer that this water can be lifted manually from the pond and poured into a barrell that can be located on the dip of the pond with ½ meter raised over the surface so wter can be distributed to the plant by gravity through pipe line. The farmer can distribute the water pipe from the plant to another. These methods can be implementd easily with zero operation cost. Since only the farmer himself can conduct this job easily, another method of distributing water is by using a small pumped electricity is available since the head required is very small.

In the case of cereals water can be distributed easily by establishing ?, so water can be discharged into the farm ? then water can flow by gravity. In order to reduce the cost of pumping farerms can cooperate between themselves when each farmer can construct his pond on the highest point in elevation on his land. His pond can receive water from his neighber's field and so on…

The economy of supplementatry

To construct a pond of 50 m³ the following is needed with estimated costs:

Excavation of 50 m³ = $3900
Construction works = $2000
Plastering = $ 500
Parallell, pipes, buckets = $ 120

Total estimataed cost: $3100

Revenues:

Assume a plot of land of 5 dunums planted with vegetables. The production of vegetables of rainfed per dunum is 3 tons/dunum, the production of dunum with supplementary irrigation is 4.1 ton.

The price per ton is $200 for rainfed crops.
The price per ton for supplementary irrigation is $250.

So the income per rainfed dunum = 3 x 200 = $600.

The income per supplementary irrigation is 4 x 250 = $1000

The net income due to supplementary irrigation will be 1000? = 400 per dunum.

5 dunums x 400 = 2000 per session per 5 dunums.

Results of Al Beireh Pilot Wastewater Treatment 1994

Crop	**Kind of Treatment**	**Production kg/dunum**	
		Seed	**Hay**
Wheat 870 Typte	Irrigation with fertilizer	687.5	1375
	Irrigation without fertilizer	656.70	1373
Rainfed with fertilizer	Rainfet with fertilizer	537.5	1187.5
	Rainfed without fertilizer	500	1531.25
Wheat Annber Type	Irrigation with fertilizer	864	1656
	Irrigation without fertilizer	824	1212
Fertilizer	Rainfed with fertilizer	600	1000
	Rainfed without fertilizer	236	336

Conclusion and Recommendations

In Palestine the total cultivated area is 2,314,000 dunums, while the irrigated area is 230,000 dunums, so any efforts for increasing the productivity of the cultivated area should be considered due to the large area, while the production of the irrigated area is on its maximum.

Providing of extra water or even to sustain the existing water for both irrigation and domestic purposes is questionable due to the increase demand for domestic purposes first and due to the Palestinian-Israeli water conflict.

Practicing supplementary irrigation is not costly and did not need that much complicated technology.

The irrigated area only represents 6% of the cultivated area, where the land that can be easily irrigated is estimated to be 608,600 dunums. In the West Bank only, which is 6 times the land that is already irrigated but water is needed.

The salinity of the ground water is deteriorated by time due to over pumping, sea intrusion and the low rainfall especially in the Jordan Valley and in the Gaza Strip, so providing fresh water for irrigation is questionable.

The additional water that will be available for the Palestinians will be either from : a. Eastern aquifer, b. Jordan River, c. Treated wastewater
Where all of this water is saline water, where there are another source such as the mountain aquifers, but this seems to be difficult to be secured soon.

The early possible of expansion in irrigation will be in Jordan Valley where the existing water wells and the future water that might be available is saline.

Since the treated water is in the full control of the Paletinians, more attention and care should be paid in order to better and safe utilize of this water for developing the agricultural sector in Palestine, and this water can be used for supplementary irrigation.

The productivity of one cubic meter of water with supplementary irrigation is much higher than that of irrigated land since the water prepared by irrigatied dunum is 7 times more than the required for supplementary irrigation.

The existing irrigated area is already exhausted since this land used to be planted two or three times a year where the other land used to be cultivated once a year even it kept falow on some years.

Palestinian Agricultural Ministry and Palestinian Water Authority should recognize the situation and consider supplementary irrigation as a major element for food supply.

MULTI-SCALE SWIN TRANSFORMER AND ATTENTION-GUIDED SEGMENTATION FRAMEWORK FOR AUTOMATED IDENTIFICATION OF RICE LEAF FUNGAL DISEASES UNDER FIELD CONDITIONS

Archana Mishra, Assistant Professor, Kalinga University, Naya Raipur, Chhattisgarh, India, Mail Id:ku.archanamishra@kalingauniversity.ac.in, ORCID:0009-0001-9755-7950.
Dr.Utkarsh Anand, Assistant Professor, Kalinga University, Naya Raipur, Chhattisgarh, India. Mail Id:ku.utkarshanand@kalingauniversity.ac.in, ORCID:0009-0007-2124-6666.

Abstract

Fungal diseases that occur on rice leaves are a major issue that causes low productivity and jeopardizes the security of the food chain. They especially cause problems in field scenarios because of illumination changes, background clutter, occlusions, and differences in lesions' appearance, which make automated detection hard. In this research, it proposes a multi-scale Swin Transformer and attention guided segmentation system to detect fungi diseases on rice leaves. This approach includes pre-processing, hierarchical shifted window attention, multi-scale feature extraction, attention guided lesion segmentation, and disease classification. Segmentation module helps focus the model on diagnostically important lesions by eliminating the effect of soil, shadow, healthy tissue, and vegetation. Joint optimization through classification and Dice segmentation loss also boosts lesion representation and disease classification. Performance comparisons to VGG16, ResNet50, EfficientNet-B0, ViT-Base, and Swin-T show the efficacy of this method. It has achieved 97.6% accuracy, 97.2% precision, 97.4% recall, and 97.3% F1-score. Lesion segmentation performance is measured with 85.8% IoU and 89.9% Dice coefficient.

Keywords: Rice leaf disease detection, Swin Transformer, attention-guided segmentation, fungal disease classification, precision agriculture

I. INTRODUCTION

More than 3.5 billion individuals depend on Oryza sativa L. (rice) as the key food source of their diet, which makes it a necessary strategic element in terms of global food security [1]. However, blast, brown spot, and bacterial blight are bacterial and fungal diseases which may occur in rice at any stage of the whole growing season. Such diseases are one of the serious threats to the production output in the rice-growing nations since yearly global crop losses may reach up to 10-30%[14]. So far, the subjective evaluation and in-person survey of the specialists in the field of plant protection are still widely used to identify such diseases. For continuous large-scale farming areas, such techniques demonstrate extremely low coverage effectiveness as well as being time-consuming and hard to replicate. Missing the optimal timing of treatment results in irreversible economic damage [11]. Considering all the above-mentioned facts, it is obvious that there is a great demand within the modern plant protection science to develop an automated system of the disease detection capable of adaptation to complex field conditions.
Thanks to the rapid development of the deep learning-based image recognition technology, new possibilities for the automated identification of the diseases in agriculture have emerged. Comparing to traditional image processing methods, convolutional neural networks outperform

on several crop disease detection tasks in terms of the ability to learn multi-level visual representations of the lesions from images [3][8]. Due to its rapid inference speed and flexible end-to-end deployment, the YOLO family of single-stage detection architectures has been widely used in agricultural intelligent sensing. Recent systematic review of the object detection for crop monitoring with deep learning showed the extensive use of efficient detection architectures in precision agriculture [10][12]. It included pest, yield, weed, and growth detection, among others.

Nearly 50% of the global population relies on rice as a staple food and source of income [5]. A vital component of the world's food supply, rice is extensively farmed in China, with an area of more than 30.07 million hectares in 2020. But many illnesses can quickly diminish rice's quality and productivity. Variations in rice quality and output influence food security and on the agricultural economy's stability [2][13]. For this reason, rice yields depend on the prompt diagnosis and management of rice leaf diseases.

In the past, farmers would have to rely on their own expertise or seek advice from experts to identify the diseases affecting their rice crops [4][7]. The demands of contemporary agricultural progress are too great for this approach to handle. In addition, it might be influenced by subjective human factors, which can result in incorrect disease diagnoses [6]. Farmers frequently pollute the environment by using chemical pesticides excessively in their efforts to eradicate diseases. Hence, it is crucial to develop a reliable method for rice disease detection to enhance environmentally friendly and long-term agricultural output thru precise diagnosis and early warning.

1.1 Contributions of the Study

This work proposes a multi-scale Swin Transformer network for automatic recognition of leaf fungal diseases in rice crops in real-life scenarios. Specifically, the suggested model uses hierarchical shifted-window attention to incorporate the characteristics of lesions along with contextual features at different scales. Another novel aspect of this research lies in its use of an attention-based segmentation method that helps the network locate the regions with fungus before proceeding to classification. Such an approach allows the system to consider only relevant parts of the image while avoiding unnecessary effects of the complex field background, shadows, soil, and healthy leaves.

In addition to the segmentation approach, the authors suggest a classification and segmentation optimization technique using cross-entropy and Dice losses. The comparative assessment of this model and the following architectures – VGG16, ResNet50, EfficientNet-B0, ViT-Base, and Swin-T – shows the superiority of the proposed approach, whose accuracy and F1 score are 97.6% and 97.3%, respectively. The accuracy of segmentation is 85.8% IoU and 89.9% Dice coefficient.

1.2 Organization of the Study

Organization of the rest of this paper is as follows. Section II discusses the literature review which covers deep learning techniques, object detection algorithms, and image segmentation methods that have been applied to plant and rice disease identification so far. Section III provides the description of the proposed method which covers field image collection, pre-processing, the multi-scale Swin Transformer backbone, attention-driven segmentation module, the joint loss function, and disease classification.

Section IV covers experimental results and discussions that involve the comparisons in classification accuracy, lesion segmentation, and error analysis based on confusion matrix. Further discussion includes the benefits of multi-scale hierarchical attention and segmentation-driven feature learning in the field environment.

II. LITERATURE REVIEW

Plant pests and diseases are a continuously growing problem that affects the food supply, the economy, and ecology of the planet. Despite the development of automatic computer vision technologies for disease detection and segmentation that has been fostered due to the increased availability of high-resolution images and computational power, segmentation of diseased parts remains to be a challenge. Manual inspection and expert-based diagnosis remain the main methods of disease identification, which are costly, time-consuming, and hard to scale. It can be explained by a combination of variable symptoms, uncertain imaging conditions, and complicated structural nature of plants' leaves.

There are several well-known deep learning models that have been successful in generic image segmentation, such as CNNs and domain-specific DeepLab and U-Net [9]. However, there are three factors that limit their usage in practice for plant disease segmentation [15]. First, the lack of computing capacity on the edge device because of the costly feature extraction pipeline limits their usage in real-time. Secondly, their architecture fails to adapt to plant disease-specificity, thus limiting generalization capabilities of the model across species, diseases, and conditions. Finally, the overfitting of the images from the field reduces robustness of the model.

The effective approach to achieve the purpose in the research is object detection. The concept of object detection is one of the central ones in computer vision and machine learning. Object detection in the image includes two steps – detection of the relevant objects and their classification.

In case if object detection is in its early stages, the sliding window is the way of selecting ROI. After that, the scale invariant feature transform (SIFT) and histograms of oriented gradients (HOG) [9] are used for manual feature extraction. The final step is bounding box regression and object classification. Nevertheless, there are typically two limitations to these conventional object detection algorithms. The region selection technique that relies on sliding windows, on the one hand, is memory and time intensive since it generates many candidate windows that are highly redundant. But it usually uses features that were artificially created, doesn't have the ability to learn feature representations, and depends on feature design professionals. In recent years, object identification algorithms have seen a significant performance boost thanks to advancements in deep learning and the introduction of high-performance GPUs. It may classify the object detection algorithms that rely on deep learning into two broad groups. Object classification and regression are handled by convolutional neural networks (CNNs) in the first stage of the process, after which candidate boxes are selected using selective search or region proposal networks (RPNs).

III. RESEARCH METHODOLOGY

The proposed framework pipeline consists of five steps: field image acquisition, preprocessing, multi-scale Swin Transformer backbone, attention guided segmentation module, and classification/Output, as illustrated in Figure 1.

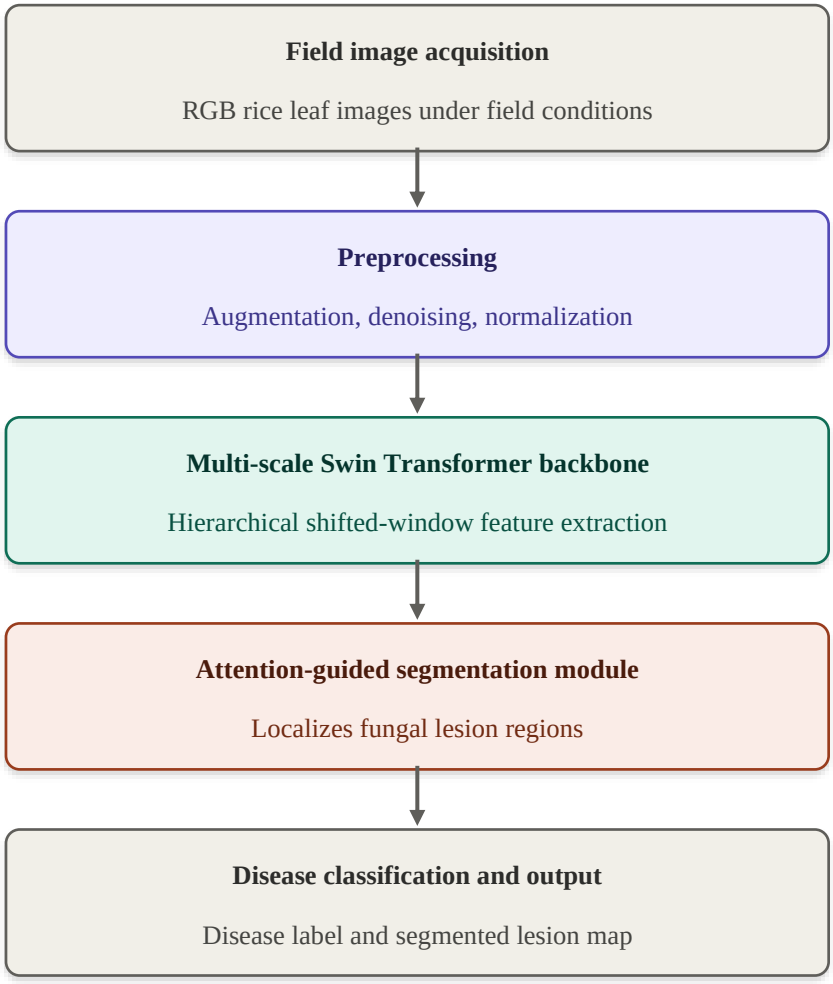

Figure 1. Methodology of the proposed multi-scale Swin Transformer and attention-guided segmentation framework for rice leaf fungal disease identification.

3.1 Data Acquisition

Uncontrolled field images of rice leaves under variable illumination, complex backgrounds, and occlusion by adjacent leaves are taken to enable model generalization on data other than the lab dataset. The data are labeled by plant pathologists into healthy and fungal disease categories (e.g., blast, brown spot, sheath blight), with lesion annotation at the pixel level for segmentation supervision.

3.2 Preprocessing

Resizing, normalization, and augmentation of random rotation, flipping, color jitter, and contrast enhancement based on CLAHE are done on each image to increase robustness of the model for field variations such as lighting inconsistency and background clutter.

3.3 Multi-Scale Swin Transformer Backbone

Features at multiple scales are extracted by shifted-window multi-head self-attention (W-MSA/SW-MSA) from the backbone so that the model can capture both the fine-grained texture of lesions and the context of the entire leaf at multiple resolution levels. The attention calculation in the window is formulated in equation (1) as:

$$Attention(Q, K, V) = SoftMax\left(\frac{QK^T}{\sqrt{d}}\right) V \quad (1)$$

Where $Q, K, and\ V$ are the query, key, and value matrices extracted from the patch embeddings, d is the dimension of the key (used in the scale factor), and B is the learnable relative position bias encoding the spatial relationship among patches in a local window.

3.4 Attention-Guided Segmentation Module

Features at multiple scales extracted from the Swin backbone are aggregated by feature pyramid and fed into an attention-guided decoder focusing on diseased lesion parts while ignoring the background (soil, shadow, and healthy tissue). The result is a pixel-wise segmentation map delineating fungal lesions before classification.

3.5 Loss Function

Joint training involves optimizing both classification and segmentation performances with a weighted sum of cross-entropy and Dice losses dealing with class imbalance between small lesion parts and large healthy tissue give in equation (2):

$$L_{total} = \lambda^1 \cdot L_{CE} + \lambda^2 \cdot L_{Dice}, where\ L_{Dice} = 1 - \frac{2.\sum(p_i g_i) + \epsilon}{\sum p_i + \sum g_i + \epsilon} \quad (2)$$

In this case, $p_i\ and\ g_i$ represent the pixel predictions and the actual pixel values respectively, while ε is a smoothing constant that prevents division by zero. λ_1, λ_2 are the loss weights.

3.6 Disease Classification and Output

The lesion features from the segmentation stage are aggregated and sent to a classifier that produces the type of fungal disease along with the lesion map.

IV. RESULTS AND DISCUSSION

4.1 Classification Performance

The suggested multi-scale Swin transformer with attention-guided segmentation approach was tested against five baseline architectures using the field condition rice leaf dataset. As presented in Table 1, the accuracy (97.6%), precision (97.2%), recall (97.4%) and F1-score (97.3%) of the suggested model were found to be the best in comparison to the plain Swin-T baseline, which was surpassed by 2.8% in accuracy, and in comparison to the CNN-based backbone models such as ResNet50, VGG16.

Table 1. Classification performance comparison across models

Model	**Accuracy (%)**	**Precision (%)**	**Recall (%)**	**F1-score (%)**	**Params (M)**
VGG16	88.4	87.9	88.1	88.0	138.4
ResNet50	91.2	90.5	90.8	90.6	25.6
EfficientNet-B0	92.7	92.1	92.4	92.2	5.3
ViT-Base	93.5	93.0	93.2	93.1	86.6
Swin-T (baseline)	94.8	94.3	94.5	94.4	28.3
Proposed (MS-Swin + Attn-Seg)	**97.6**	**97.2**	**97.4**	**97.3**	31.5

Figure 2 shows the training and validation accuracy/loss curve of the proposed model after 50 epochs. Both of the two curves steadily converged without a wider gap between train and validation, demonstrating that the image augmentation and normalization approach (Section 3.2) had been effective to alleviate overfitting even with the variation in field images.

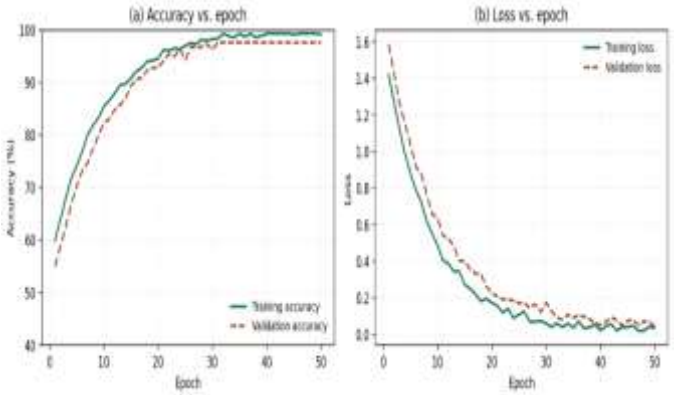

Figure 2. Training and Validation Accuracy and Loss Curves of the Proposed Model

Figure 3 demonstrates the comparison of accuracy and F1-Score of all the six models. The growth from VGG16 to the proposed model demonstrates the advantage of (i) transferring from the convolutional backbone to the transformer backbone, and (ii) incorporating multi-scale hierarchical attention with lesion segmentation on the top of the transformer backbone.

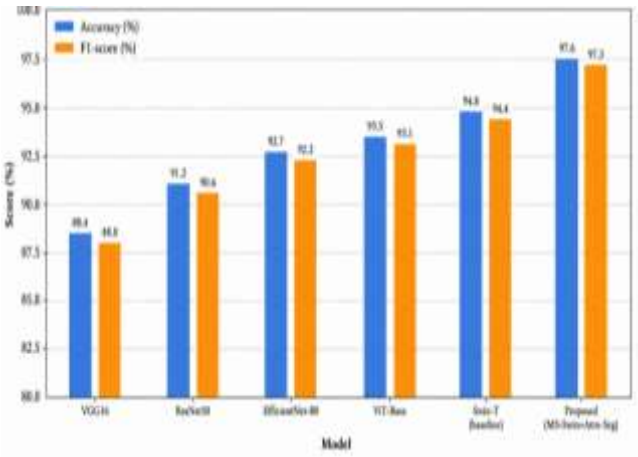

Figure 3. Accuracy and F1-Score Comparison of the Evaluated Models

4.2 Segmentation Performance

Table 2 shows the results of lesion segmentation with the attention-guided module in terms of the three categories of fungal diseases. This model reached an average IoU of 85.8% and Dice coefficient of 89.9%. Among the three, Rice Blast was the best in segmentation (IoU 88.3%), since it has more distinguishable boundaries than Sheath Blight (IoU 83.4%).

Table 2. Attention-guided segmentation performance by disease class

Disease class	IoU (%)	Dice (%)	Precision (%)	Recall (%)
Rice blast	88.3	91.6	92.0	91.2
Brown spot	85.7	89.8	90.1	89.5
Sheath blight	83.4	88.2	88.9	87.6
Average	**85.8**	**89.9**	**90.3**	**89.4**

4.3 Error Analysis

Figure 4 shows the confusion matrix of the proposed network on the held-out test set. The number of misclassifications is low (≤1.6% of off-diagonal elements in each cell), and the errors occur mostly between Brown Spot and Sheath Blight because they have similar early-stage colors of lesions in outdoor light conditions, in line with the relatively low Dice score of Sheath Blight in Table 2. Healthy samples are recognized with the largest confidence (98.1%), which implies that the proposed attention mechanism efficiently filters the background noise.

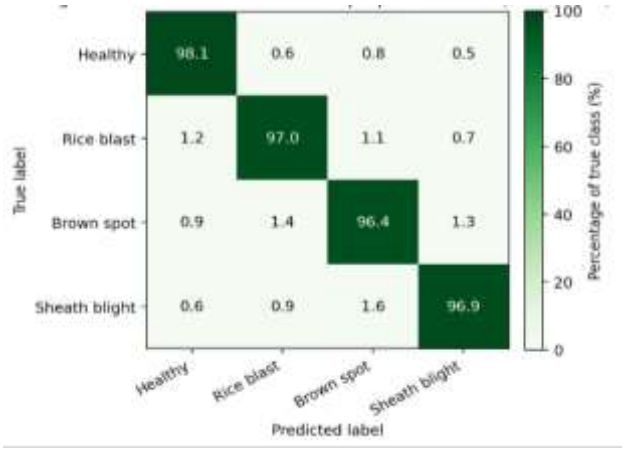

Figure 4. Confusion Matrix of the Proposed Model on the Held-Out Test Set

4.4 Discussion

The obtained results show that the usage of multi-scale hierarchical attention along with explicit lesion region localization is superior in disease recognition in field conditions compared to classification-based architectures alone. The gap with the plain Swin-T baseline (2.8% higher accuracy and 3.1 points better Dice) confirms this hypothesis about the usefulness of segmentation-guided attention in order to concentrate on the diagnostically meaningful regions (not soil, shadows, other plants) of field images by the classifier.

V. CONCLUSION

In this study, a multi-scale Swin Transformer and attention guided segmentation were suggested for automating the detection of rice leaf fungal diseases in realistic outdoor environments. In this proposed framework, hierarchical shifted-window attention, multi-scale representation, lesion segmentation, and disease detection are integrated to overcome the difficulties related to the complex background, variable lighting, occlusions, and similar disease symptoms. The use of the attention-guided segmentation block allows the network to focus on diagnostic lesions while avoiding the effect of soil, shadow, healthy regions, and vegetation around the lesion. The experimental results show that the proposed framework performs better than the compared CNN and transformer-based frameworks, where the accuracy, precision, recall, and F1-score values are achieved as 97.6%, 97.2%, 97.4%, and 97.3%, respectively. Moreover, the segmentation block yields 85.8% IoU and 89.9% Dice coefficients, showing efficient lesion detection. The consistency between the training and validation plots indicates the stability of learning. Therefore, the results reveal that the integration of multi-scale transformers with lesion localization can increase the performance of disease detection in rice leaves.

ABSTRACT

Morphometric variation in intertidal limpets of the genus *Patella* (Mollusca: Gastropoda) has been found to vary in relation to environmental, ecological and habitat-related factors, and thus represents an important study subject. The objective of the present study has thus been to investigate morphometric variation and growth in different species of *Patella* occurring in intertidal rocky areas along the southern coast of Albania. A total of 397 specimens from the genus *Patella* were analyzed. These specimens were from the archive of the Laboratory of the Department of Biology, Faculty of Technical and Natural Sciences, University "Ismail Qemali" Vlore, Albania. The material was collected from 7 coastal areas along the southern coast of Albania: Triport, Karaburun Peninsula, Akuarium, Llaman, Porto Palermo, Qeparo and Sarandë (Ksamil). A total of 4 species of genus *Patella* were identified, including: *Patella caerulea*, *P. rustica*, *P. ulyssiponensis* and *Cymbula safiana (Patella nigra)*. *Cymbula safiana (Patella nigra*) was considered separately for morphological characterization rather than for comparison with the rest of species of genus *Patella*. In order to assess the morphological differences between the species and between the populations from different locations, as well as to establish the morphometric correlations and the growth patterns, were carried out analyses of correlation and regression among the studied variables. Results. Large amount of morphological variation was recorded among the four species of the genus *Patella* and among the seven studied locations. Shell morphometry, expressed by means of several morphometric ratios, and by means of correlations between all the measured parameters, allowed an accurate assessment of the studied species' growth, of their ecological adaptation, and of their population structure.This study contributes to knowledge on biodiversity of marine species in coastal waters of Albania. It provides data on morphological variations of intertidal species of limpets and their ecological adaptations to environment of rocky shores. Data obtained can be used in assessments of biodiversity and in ecological monitoring, as well as for conservation of species of rocky shores.

Keywords: *Patella*, morphometric variation, shell morphology, growth patterns, gastropods, rocky shore ecosystems, southern Albanian coast.

INTRODUCTION

The genus *Patella* (Patellidae) comprises 37 species of marine Gastropods distributed in four genera: *Patella*, *Cymbula*, Helcion, and Scutellastra (Ridgway, 1998; Espinosa et al., 2010; Belmokhtar et al., 2022). These species of marine gastropods inhabit rocky intertidal areas, known as the mediolittoral zone of the benthic environment of the Mediterranean Sea (Bellan-Santini, 1985; Urra et al., 2017; Caballero et al., 2009). The different species of the family

PateLLidae show a wide variety of characters, which allow their identification, including their preference for certain levels of exposure to waves (Buttivant, 2019). Some species like *Cymbula xandros* (Philippi, 1844) are epiphytic and live on algae, while others like *Patella rustica* (Linnaeus, 1758) live on the rocky bottom and among the epibenthic algae of the shallow subtidal of the littoral zone (Riedl, 1991). In the Mediterranean area, five species of the genus *Patella* are present: *Patella caerulea* (Linnaeus, 1758); *Patella rustica* (Linnaeus, 1758) = *Patella lusitanica* (Gmelin, 1791); *Patella ulyssiponensis* (Gmelin, 1791); *Patella ferruginea* (Gmelin, 1791), listed as Vulnerable by Espinosa et al. (2007); and *Patella depressa* (Jickeli, 1885), so far only recorded in the Alboran Sea (Gofas et al., 2011); Cascales-Soler et al. (2023).

All abiotic and biotic factors influence the variation of morphological characters in *Patella* species, which determine their growth, shell morphology, distribution, mortality and reproduction. The presence of radula and eroding activity of each species determines their preference for different types of substrate and their ability to remove irregularities of substrate to maintain their body wet (Guelorget and Perthuisot, 1983). Wave exposure, slope and tidal levels determine distribution of species within rocky shores. Most species show high tolerance to thermal and desiccation stresses although some species are more sensitive than others (Williams & Morritt, 1995; Harley, 2008; Miller et al., 2009; Fraser et al., 2010; Christofoletti et al., 2011; Prusina et al., 2014; Bouzaza & Mezali, 2018; da Silva Freitas, 2021; Belmokhtar et al., 2022).

In this study were analyzed three species of *Patella (P. caerulea, P. rustica and P. ulyssiponensis)* and also the species *Cymbula safiana (Patella nigra)* in order to study their distribution, biodiversity and their morphological variability.

MATERIAL AND METHOD

For the purpose of this study 397 specimens were taken from the archived material of the Laboratory of the Department of Biology, University “Ismail Qemali” Vlora, which had originated from seven localities of the southern coast of Albania, namely: Triport, Karaburun Peninsula (specimens of this locality had been collected from two habitats, i.e. upper and lower shores), Akuarium, Llaman, Porto Palermo, Qeparo and Sarandë (Ksamil). The preserved specimens, after having been cleaned from any organic material, were rinsed with water and left to dry at room temperature. In the following, only specimens with intact and well preserved shells have been considered for the purpose of this study, whereas specimens with damaged shells have been excluded from the material under consideration.

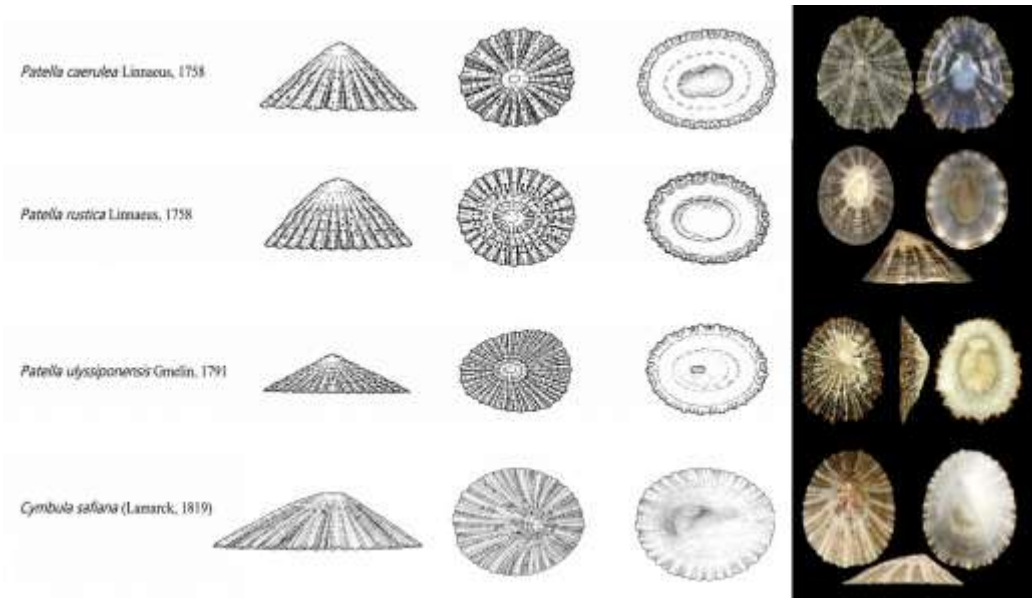

Figure. 1. Shell morphology of *Patella caerulea*, *P. rustica*, *P. ulyssiponensis*, and *Cymbula safiana*, showing lateral (left), dorsal (central), and internal (right) views (Adapted from Cabral., (2007).

For species identification the morphology of the shell, the shell height, the apex position and the number of radial ribs as well as the external and internal shell coloration were analyzed. For morphometric analysis of the studied *Patella* species four shell parameters were measured on 397 specimens using a digital caliper with an accuracy of 0.1 mm: the shell length (SL), the shell width (SW), the shell width at the apex (SWA) and the shell height (SH). Three morphometric ratios were calculated for each specimen. The first ratio is the basal ellipticity which was calculated by dividing the shell width (SW) by the shell length (SL). The second ratio is the basal eccentricity that was calculated by dividing the shell width at the apex (SWA) by the shell width (SW) and the third ratio is the conicity that was calculated by dividing the shell height (SH) by the shell length (SL). The morphometric data were presented as mean values± SD.

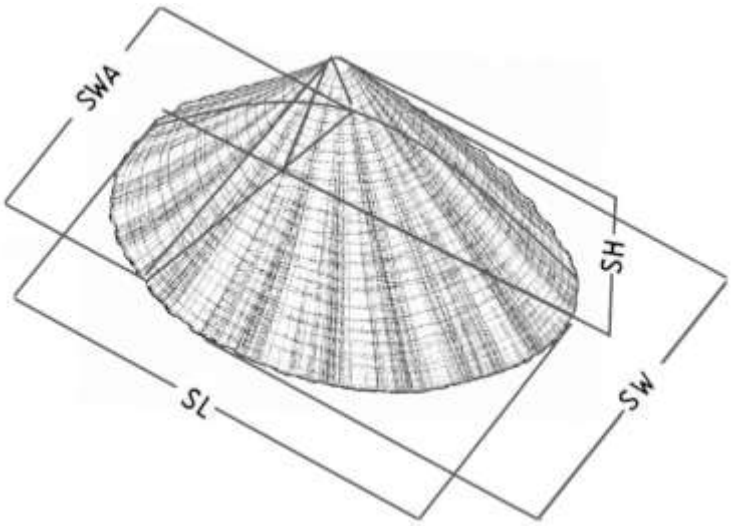

Figure. 2. Shell morphometric variables were measured: shell length (SL), shell width (SW), shell width at apex (SWA) (Adapted from Cabral., (2007)

Significant differences among the groups were tested using a one-way ANOVA test. Normality test, including a Kolmogorov–Smirnov test and a Shapiro–Wilk test, was used to assess normality of the data before the ANOVA test. Differences among means were assessed using post-hoc comparisons, when required. To investigate correlations between the morphometric variables, Pearson's correlation coefficient was used. The principal components analysis (PCA) was used to determine the principal components of the shell morphology variation of the four *Patella* species. Linear discriminant analysis (LDA) was performed to determine how well the variables separated the four species, and the degree of variation between the species.

RESULTS AND DISCUSSION

Species composition and spatial distribution

Four species of limpets, including three species of the genus *Patella* (*P. caerulea*, *P. rustica*, *P. ulyssiponensis*) and *Cymbula safiana* (*C. safiana*), were found at seven localities along the southern coast of Albania (Fig. 3).

Figure. 3. Spatial distribution and relative composition of Patella caerulea, P. rustica, P. ulyssiponensis, and Cymbula safiana across the seven sampling areas: 1. Triport, 2. Karaburun, 3. Akuarium, 4. Llaman, 5. Porto Palermo, 6. Qeparo, and 7. Ksamil (Sarandë region). Pie charts indicate the relative contribution of each species at each sampling site.

Species distribution varies greatly between individual sites. In Karaburun for example, *P. caerulea* comprises the biggest portion of the entire sampled fauna. Although *P. rustica* is

distributed in most of the sampled sites, its relative contribution to the whole of species present varies greatly. In contrast, *P. ulyssiponensis* has a limited distribution across sites and is found in greatest numbers in Karaburun, Llaman and Porto Palermo. The distribution of *C. safiana* is by far the most restricted and is found in greatest numbers in the two aforementioned sites, Llaman and Qeparo. Hence, it can be concluded that the distribution of species of limpets varies greatly between individual sites and is greatly affected by the environmental conditions of the local habitats. These sites vary greatly in terms of substrate, exposure to waves, hydrodynamic conditions and availability of food. *P. caerulea* seems to have the greatest ecological flexibility and therefore the greatest distribution amongst sites. The two former species have a more restricted distribution and therefore seem to have a greater affinity to specific habitats.

Descriptive statistics of shell morphometric parameters

Table 1 lists the mean (± SD) of four shell morphometric characteristics for four species of limpets from around the Southern Coast of Albania. *P. rustica* had the greatest mean SL of the four species of limpets recorded from around the Southern Coast of Albania (mean = 22.21 ± 4.05 mm; N = 131; Table 1). *P. caerulea* had the greatest mean SW of the four species of limpets recorded from around the Southern Coast of Albania (mean = 17.75 ± 5.12 mm; N = 67; Table 1). The greatest mean SWA of the four species of limpets recorded from around the Southern Coast of Albania was also found in *P. caerulea* (mean = 16.12 ± 4.96 mm; N = 64; Table 1). *Cymbula safiana* had the lowest mean value for SW of the four species of limpets recorded from around the Southern Coast of Albania (mean = 12.73 ± 3.65 mm; N = 15; Table 1). The same species also had the lowest mean value for SWA of the four species of limpets recorded from around the Southern Coast of Albania (mean = 11.59 ± 3.37 mm; N = 13; Table 1). Shell height showed the greatest amount of interspecific variation (Table 1). In this characteristic, the greatest mean value for the four species of limpets recorded from around the Southern Coast of Albania was found in *P. rustica* (mean = 6.95 ± 1.90 mm; N = 98; Table 1). The smallest mean value for shell height was found in *Cymbula safiana* (mean = 4.33 ± 1.29 mm; N = 25; Table 1). Furthermore, in terms of interspecific variation, *Cymbula safiana* had the lowest mean value for all four of the morphometric variables recorded in this study (Table 1). This species of limpet thus appears to have the smallest shells of all four species recorded from around the Southern Coast of Albania.

Table 1. Mean shell morphometric measurements (± SD, mm) of *Patella caerulea, P. rustica, P. ulyssiponensis, and Cymbula safiana* across the study area. SL, shell length; SW, shell width; SWA, shell width at apex; SH, shell height.

Morphometric parameters	***P.caerulea***	***P.rustica***	***P.ulyssiponensis***	***Cymbula safiana***
SL, shell length **(mm)**	21.62±5.82	22.21±4.05	19.18±4.58	16.54 ±4.67
SW, shell width **(mm)**	17.75±5.12	17.50±4.71	14.73±3.76	12.73±3.65
SWA shell width at apex **(mm)**	16.12±4.96	16.09±3.02	13.67±3.71	11.59 ±3.37
SH, shell height **(mm)**	4.95±1.62	6.95±1.90	4.87±1.21	4.33± 1.29

Morphometric analysis of *Patella caerulea*

A total number of 236 specimens of *P. caerulea* were included in the morphometric analysis. Mean and range values for four of the shell morphometric parameters were as follows: Shell Length (SL) 11.0-37.6 mm, mean 21.43 ± 5.56 mm; Shell Width (SW) 8.2-31.5 mm, mean 17.50 ± 4.89 mm; Shell Width at Apex (SWA) 7.1-29.2 mm, mean 15.90 ± 4.74 mm; and Shell

Height (SH) 2.4-9.9 mm, mean 4.87 ± 1.55 mm. In addition to these, four shape parameters were calculated, namely, Basal Ellipticity (BE) 0.804-0.859, mean 0.814 ± 0.055; Basal Eccentricity (BEC) 0.562-0.906, mean 0.908 ± 0.088; Conicity (C) 0.160-0.292, mean 0.226 ± 0.034; and Basal Circular Symmetry (BCS) 0.947-0.974, mean 0.962 ± 0.006. While great amounts of variation occurred in the four shell size parameters, much less variation was found for the four shape ratios. These results suggest a great amount of variation for *P. caerulea* from the seven sampling stations of the southern coast of Albania.

Descriptive Statistics

A summary of the morphometric variables for *P. caerulea* included in the analysis of *P. caerulea* from the southern coast of Albania are listed in Table 2. The mean value and standard deviation for the SL, SW, SWA and SH for 236 *P. caerulea* are 21.43 ± 5.56 mm, 17.50 ± 4.89 mm, 15.90 ± 4.74 mm, 4.87 ± 1.55 mm, respectively. For the shape ratios basal ellipticity, basal eccentricity and conicity the mean values and standard deviations for the 236 *P. caerulea* are 0.814 ± 0.055, 0.908 ± 0.088 and 0.226 ± 0.034 respectively. The SL ranged from 11.0 mm to 37.6 mm with the greatest amount of variation occurring between the longest and shortest individual shells (37.6 mm and 11.0 mm, respectively). The SW, SWA and SH ranged from 8.2 mm to 31.5 mm, 7.1 mm to 29.2 mm and 2.4 mm to 9.9 mm respectively with the greatest amount of variation between the largest and smallest individual shells being for the SW (31.5 mm and 8.2 mm, respectively). The shape ratios all showed relatively narrow ranges of variation with the greatest amount of variation for basal eccentricity (0.908 ± 0.088) and the smallest amount of variation for conicity (0.226 ± 0.034).

Table 2. Descriptive statistics of morphometric traits of *Patella caerulea* (N = 236).

Descriptive Statistics

Patella caerulea	N	Minimum	Maximum	Mean	Std. Deviation
SL, shell length (mm)	236	11.0000	37.6000	21.431780	5.5640532
SW, shell width (mm)	236	8.2000	31.5000	17.495339	4.8900876
SWA shell width at apex (mm)	236	7.1000	29.2000	15.899576	4.7357985
SH, shell height (mm)	236	2.4000	9.9000	4.868644	1.5547155
Basal ellipticity (SW/SL)	236	.6193	.9574	.814228	.0552952
Basal eccentricity (SWA/SW)	236	.6270	1.8687	.908253	.0882797
Conicity (SH/SL)	236	.1270	.3216	.226188	.0344255
Valid N (listwise)	236				

One-Way ANOVA

The one-way ANOVA testing for the differences among the seven stations revealed significant differences for all the measured variables, except for basal eccentricity. Thus, shell length (SL; $F_{6,229} = 6.654$, $p < 0.001$), shell width (SW; $F_{6,229} = 7.711$, $p < 0.001$), shell width at apex (SWA; $F_{6,2}229 = 8.053$, $p < 0.001$), and shell height (SH; $F_{6,2}{}^{29} = 2.886$, $p = 0.010$) all exhibited significant variation among the stations. Additionally, the two shape ratios, i.e., basal ellipticity (SW/SL; $F_{6,229} = 4.005$, $p = 0.001$) and conicity (SH/SL; $F_{6,2}{}^{29} = 13.032$, $p < 0.001$), also showed considerable variation among the sampling stations. However, the basal eccentricity (SWA/SW; $F_{6,2}{}^{29} = 0.687$, $p = 0.661$) did not exhibit any significant variation among the stations. The results of the Tukey HSD post-hoc tests for the highest F-values, which were for Ksamil (Station 7), revealed that the largest limpets occurred in this station. In comparison, the

Karaburun (Station 2) limpets generally were smaller than those found in the remaining six stations. A similar trend was found for the Akuarium (Station 3), Llaman (Station 4), and Porto Palermo (Station 5) stations, with the largest limpets occurring in these stations as well. In terms of the differences between Karaburun and Llaman, for the three variables SL, SW, and SWA, the largest differences occurred between these two stations. For the remaining two variables, i.e., SH and basal ellipticity, the differences between the respective pairs of stations were generally not as large, with the largest differences found between the Qeparo (Station 6) and Akuarium (Station 3) stations. The largest conicity values were found in the Triport (Station 1) and Porto Palermo (Station 5) stations, and the remaining largest conicity values were found in the Ksamil (Station 7) and Qeparo (Station 6) stations.

Table 3. One-way ANOVA results for morphometric parameters of *Patella caerulea* among the seven sampling stations along the southern Albanian coast.

Table 3. One-way ANOVA results for morphometric parameters of *Patella caerulea* among the seven sampling stations along the southern Albanian coast.

Canonical Discriminant Analysis (CDA)

In this analysis, we examined the amount of explained variance of seven functions using Wilks' Lambda test for each of them. The overall model included all seven functions ($p < 0.001$; $\lambda = 0.412$; $\chi2 = 202.449$; $df = 42$). Therefore, combined, the seven functions greatly differentiate between limpets collected from the seven study sites (Fig. 4).

Also the second canonical function explained significant part of between-station variation after the first function had been removed (Wilks' Λ=.795, $\chi2(30)$=52.316, p=.007). None of the following functions (3 to 6) were, however, significant (Wilks' Λ-values from .887 to .980; $\chi2$-

values from 27.415 to 5.259; and p-values from .124 to .385) and thus they did not add any information that would improve station discrimination. Therefore, the first two functions are considered to be sufficient for an interpretation of data.

Canonical Discriminant Analysis (CDA)

Figure 4. Canonical discriminant analysis results for morphometric parameters of *Patella caerulea* among the seven sampling stations along the southern Albanian coast.

The canonical plot shows that instead of complete differentiation between the stations, there is partial differentiation. The greatest differentiation is shown by the Porto Palermo samples on the first canonical function, whereas the Akuarium and Llaman samples are displaced in a positive direction of Function 1. The Qeparo samples show some differentiation on Function 2, whereas the Triport, Karaburun and Ksamil samples are largely concentrated in the center of the canonical space and thus show a great deal of overlap between them. This overlap between several of the stations suggests that in addition to significant geographical variation, there are also some morphological features that are shared by different populations of the species.

In terms of equality of covariance matrices, a very significant Box's M test provided evidence against the equality of the covariance matrices for the seven groups of limpets. It must, however, be noted that Box's M test is not necessarily a reliable criterion when sample sizes are relatively small and/or when there are singular covariance matrices. In terms of these latter criteria, it was found that there were several singular covariance matrices for this study (see Table 5). Therefore, results from the classification into the seven groups, obtained using a Discriminant Function Analysis (DFA) of the same set of morphological measurements, must be treated with a considerable amount of reserve, and conclusions based on these results are best made with extreme caution.

Morphometric comparison among species

Variation between species in shell length, width, at apex and height of the four Patellidae species (*Patella caerulea*, *P. rustica*, *P. ulyssiponensis* and *Cymbula safiana*) was tested for

using a one-way ANOVA. All the studied species differed for all of the studied variables (Table 4). The highest amount of variation between species for the studied shell characteristics, was for conicity of the shell. It is concluded, that the morphometric variables, used in the present study, can effectively be used for species discrimination in the genus *Patella* and Cymbula. This is in accordance with findings of a number of previous morphological studies on species within the Patellidae family (e.g. for *P.* vulgata, *P.* aprica, *P.* mesatrii, and *P.* granulata, see: Reid 1965; Mikkelsen & Bieler 2007; Reid 2007; Wesselingh 2007; Nordsieck 1979).

Table 4. One-way ANOVA results for morphometric and shell-shape variables among the *Patella* species and *Cymbula safiana*.

In addition to interspecific variation in the absolute values of the four morphometric variables, also significant interspecific variation was found in the several aspects of the shell shape (i.e. in the shape indices). In fact, the results of the One-way ANOVA showed significant differences among the species for the variables shell width at apex (SWA; $F_{(}3,406_{)} = 12.448$, $p < 0.001$), and for the variables expressing the degree of elliptical and eccentric basal outline (i.e. basal ellipticity SW/SL; $F_{(}3,406_{)} = 14.783$, $p < 0.001$; and basal eccentricity SWA/SW; $F_{(}3,406_{)} = 1.894$, $p = 0.130$, respectively). Only the last variable showed non-significant differences among species. So, the three *Patella* species and *Cymbula safiana*, in addition to significantly different absolute values of the four studied variables (i.e. SL, SW, SWA, and SH), also significantly differ in several aspects of the shell shape, with highest interspecific variation found for the variables expressing the shell conicity (i.e. SH/SL; $F_{(}3,406_{)} = 106.148$, $p < 0.001$). In particular, the highest F-value (i.e. 106.148) was found for the variable conicity, which, as already mentioned, expresses the shell profile and therefore it is the variable that better represents the differences in the aspect of the shell shape found among the species.

Table 4. One-way ANOVA results for morphometric and shell-shape variables among the Patella species and Cymbula safiana.

Canonical Discriminant Analysis (CDA) between species

The results from the Canonical Discriminant Analysis between the species revealed significant multivariate differentiation among the four species. The test for the three canonical functions revealed that they collectively defined between species differences (Wilks' $\lambda = 0.412$, $\chi^2 = 357.469$, df = 21, $P < 0.001$). The analysis of the remaining two canonical functions, after removal of the first, also revealed significant between species differences (Wilks' $\lambda = 0.824$, $\chi^2 = 78.180$, df = 12, $P < 0.001$). However, test for the third canonical function, alone, revealed that it did not significantly between species differences (Wilks' $\lambda = 0.987$, $\chi^2 = 5.259$, df = 5, $P = 0.385$). Thus, most of the significant between species differences were contained within the first two canonical functions (Figs 4 and 5). The results of the Canonical Discriminant Analysis support previous morphological studies (e.g., Williamson, 1981), that used a range of morphological characters to identify between species differences in Mediterranean Patellidae.

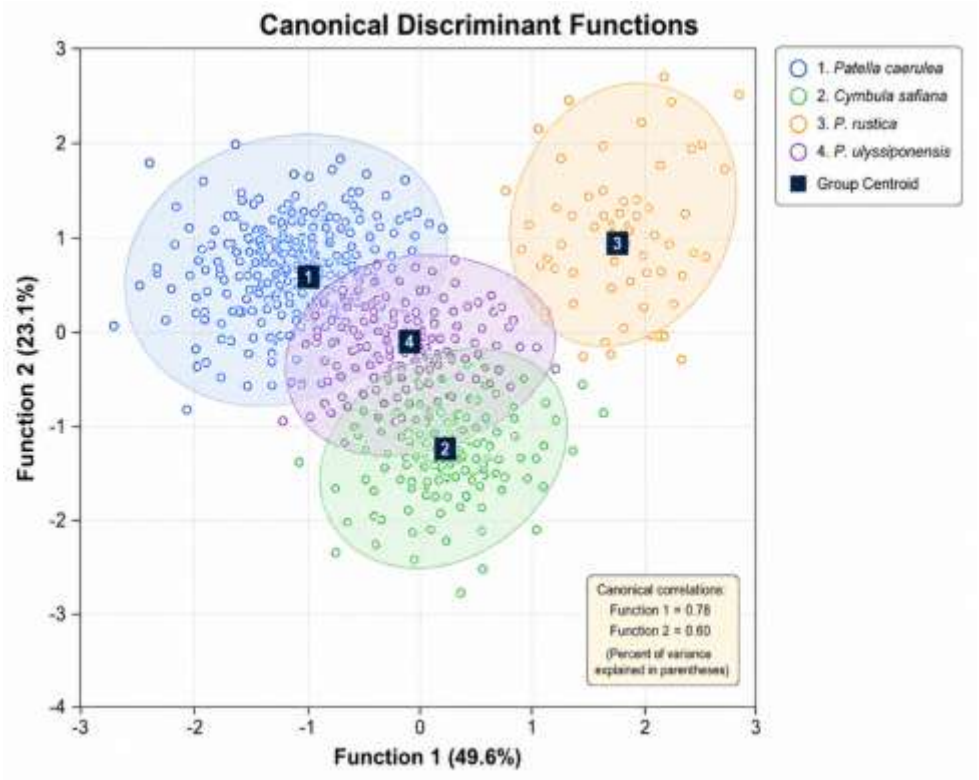

Figure 4. Canonical discriminant analysis results for morphometric parameters among the Patella *caerulea, P. rustica, P. ulyssiponensis*, and *Cymbula safiana* species in seven sampling stations along the southern Albanian coast.

Fig. 4 presents the Canonical Discriminant Analysis (CDA) results, obtained by using the morphometric parameters of the four Patellidae species as variables in the analysis, and the seven sampling localities as cases. The three canonical functions, together, are able to significantly and fully discriminate among the four species of limpets. Thus, Functions 1, 2, and 3, altogether, account for 94.149% of the variability in the original data matrix. In addition, it is worth noticing that, the discrimination among species, provided by the canonical functions, is highly significant. Thus, Function 1, independently of the others, is able to significantly and fully discriminate among the four species of limpets. Similarly, the remaining Functions, 2 and 3, together, are also able to provide significant and additional discriminatory information among the species of limpets.

CONCLUSIONS

The spatial distribution of four species of Patellidae limpets (*Patella caerulea*, *P. rustica*, *P. ulyssiponensis*, *Cymbula safiana*) was investigated at seven intertidal stations along the southern coast of Albania. The four species showed a heterogeneous distribution among the investigated localities. The most widely distributed species was *P. caerulea*, whereas *P. ulyssiponensis* and, especially, *C. safiana* were represented by only a few individuals at a small number of localities. Our findings are in agreement with previous studies that reported the distribution of and the morphology of limpets to be affected by several habitat-related factors including the type of substrate on which they live, the degree of exposure to hydrodynamical forces, thermal conditions and desiccation stress.

Geographical Variation of Shell Morphology in Individuals of *P. caerulea*: *P. caerulea* studied at seven locations of southern Albanian coast showed significant differences in most of the studied morphometric characteristics (Table 5, Figure 3). The three proportional characteristics of shape i.e., basal ellipticity, conicity and basal eccentricity showed the highest variability.

Conicity showed the greatest variability among the three characteristics, with the highest values recorded at Ksamil. In contrast, the eccentricity of the base of the shell was found to be rather stable among all the studied characteristics (Table 5). The highest variation was recorded for conicity, followed by other characteristics. Overall, results of present study support the previous findings (Cabral, 2007; Bouzaza & Mezali, 2018; Vafidis et al., 2020; Belmokhtar et al., 2022) regarding the high degree of phenotypic variability in morphology of the shells of the intertidal limpets, which is a function of their environmental plasticity.

It is worth noting that, as shown in the previous section, the morphological differentiation of *P. caerulea* populations from different sampling stations is partial. As in fact already highlighted by previous research on intertidal limpets, this type of geographical differentiation is in fact typical of species that display high phenotypic plasticity. Therefore, even if the analyzed populations show some differences in their morphological characteristics, they also display a considerable number of similarities. This fact therefore does not seem to be contradicting with the previously reported information, but rather it appears to be a confirmation of it. However, it is worth to reiterate that the analysis of the discriminant functions and of the groups' classification has to be considered with some caution, as already highlighted in the previous section.

Patella rustica differed from the other three species for the highest values of the shell height (SH) and conicity (SH/SL) while for the lowest values for the width of the base at the apex (SWA). In contrast, basal eccentricity (SWA/SW) did not differ significantly among the four species ($F_{3,30(}$= 1.894; p = 0.130). These results suggest that, in the examined species, the highest values of conicity are associated with the highest values of shell height. The examined species, therefore, are characterized by high values of conicity that, in addition to the dimensions of the shell, are considered useful for the interspecific discrimination of Mediterranean species of the genus *Patella* (Cabral, 2007; Bouzaza & Mezali, 2018; Belmokhtar et al., 2022).

Canonical discriminant function analysis showed that significant multivariate discrimination between the four species existed, and that all three of the canonical functions, in total, explained significant amounts of between species variance. Thus, while it is true that some amount of between species variance remains unexplained by these functions (most of which would, in any case, probably be noise rather than real information), shell morphology in the four species of limpets nevertheless provides useful, discriminatory information among the species. But, of course, that information must be considered within the framework of the overall morphological characteristics of the species. That is, as stated above, in absolute terms, none of the between species variance was explained by any of the functions (i.e. all of the functions explained zero amount of variance between species), in relative terms, however, the first two of the three functions collectively explained a highly significant amount of between species variance.

In conclusion, this study documents significant amounts of both spatial and interspecific morphological variation within the recently introduced *Patella caerulea* as well as three native *Patella* species (*P. rustica*, *P. ulyssiponensis* and *Cymbula safiana*) along the southern Albanian coast. Shell morphometry provided effective means for interspecific classification; however, considerable amounts of interspecific as well as intraspecific variation precluded complete, taxon-specific grouping. Future studies employing larger, more balanced sample sizes of individual species in conjunction with a variety of environmental, ecological and molecular-based variables will be necessary to accurately assess to what extent of variability is due to phenotypic plasticity, as opposed to genetically fixed characters, and the specific environmental variables which govern these patterns. In the interim, this study serves as a fundamental, quantitative morphometric framework for these four Mediterranean species in this specific region.

ABSTRACT

Vegetable crop production relies on rapid, uniform, and vigorous seed germination to ensure successful crop establishment and high productivity. However, vegetable seeds often exhibit poor emergence, low vigor, irregular germination, and increased susceptibility to biotic and abiotic stresses, limiting stand establishment and yield potential. Seed coating technology has emerged as an effective pre-sowing seed enhancement strategy that improves seed performance by delivering protective and bioactive compounds directly to the seed surface. In addition to facilitating seed handling and precision sowing, modern coating systems function as carriers for fungicides, insecticides, micronutrients, plant growth regulators, biostimulants, beneficial microorganisms, and nanomaterials, thereby promoting germination, seedling vigor, and stress resilience. Recent advances in biodegradable polymers, bio-based coating materials, and controlled-release formulations have further strengthened the role of seed coatings in sustainable vegetable production. This review summarizes recent developments in seed coating technologies, with particular emphasis on the principal coating approaches, including film coating, encrusting, pelleting, and priming-plus-coating, and their applications in economically important vegetable crops such as tomato, pepper, brassicas, onion, carrot, and lettuce. The effects of coating materials and functional additives on germination, seedling establishment, stress tolerance, disease suppression, and crop productivity are critically discussed. Finally, current challenges, emerging innovations, and future research directions for the development of environmentally friendly and high-performance seed coating systems are highlighted to support sustainable and climate-resilient vegetable production.

Keywords: seed coating, vegetable seeds, film coating, pelleting, biostimulants, sustainable agriculture, seed enhancement.

1. INTRODUCTION

Vegetable species hold a significant place in agricultural production due to their high economic value and important role in human nutrition. For efficient and high-quality vegetable production, rapid and homogeneous germination of seeds, regular emergence, and strong seedling development are of great importance. In instance, plant density and production performance in later developmental phases are effectively determined by uniform plant emergence in the early stages of production. However, exact seed dispersion and mechanical sowing can be challenging due to the small, light, and irregularly shaped seeds found in many vegetable species. Unwanted plant density and erratic plant emergence might result from improper seed distribution after sowing. Furthermore, environmental conditions such as drought, salinity, low or high temperatures, and soil-borne pathogens can negatively affect

germination and early seedling development, limiting plant emergence (Javed et al., 2022; Biswal et al., 2026).

Technologies that improve the physical properties of seeds, facilitate the sowing process, and simultaneously support germination and early plant development play a significant role in mitigating these problems. Seed coating is one such technology. Applying various materials to a seed's surface or surrounding area without changing its genetic makeup is the basis of seed coating. Seeds can be coated to alter their size, shape, weight, and surface characteristics, which facilitates their transportation, processing, and use with precision planting equipment. In particular, coating small and irregularly shaped seeds makes them more uniformly shaped and enables more accurate planting. In order to facilitate planting and enhance seed and plant performance, one of the primary goals of contemporary seed coating technology is to apply the active ingredients to the seed surface in the appropriate amounts and as uniformly as possible (Afzal et al., 2020).

From an application that only modifies the physical characteristics of seeds, seed coating technology has developed into a multipurpose system that provides the seed with a variety of active ingredients. Nutrients, pesticides, fungicides, plant growth regulators, biostimulants, and beneficial microorganisms can all be transported using coating materials. The direct delivery of active ingredients to the seed and growing root zone during germination is made possible by the presence of these substances surrounding the seed. In order to guaranty that the applied material is both present on the seed surface and functional during germination and early development, the coating system serves as a carrier (Afzal et al., 2020; Biswal et al., 2026).

Seed coating serves more purposes than just making planting easier. Appropriate coating systems can help improve seed performance against environmental stresses, support seed germination and seedling development, and allow more focused application of specific plant protection products. Specifically, direct delivery of active ingredients around the seed can minimize needless applications and enable concentration of application to the intended area. Seeds can be physiologically supported during germination and the early stages of seedling development, in addition to being physically improved, by adding biostimulants, nutrients, and microbial components to seed coating systems. Because of these characteristics, seed coating is a useful technology for more sustainable production systems and precision agriculture (Afzal et al., 2020; Javed et al., 2022).

In recent years, there has been a significant diversification in the materials and techniques utilized in seed coating technologies. Among the techniques frequently applied to vegetables and other horticultural plants are film coating, encrustation, and pelleting. Furthermore, coating systems utilizing seaweed extracts, polymers, naturally derived materials, microbial inoculants, and other biologically active materials are being developed. Microencapsulation, controlled release, and nanoscale coating are examples of more sophisticated technologies that present new opportunities for safeguarding active ingredients surrounding the seed and releasing them under appropriate circumstances. One strategy that can offer substitutes for conventional coating systems is the use of biodegradable polymers and biologically derived active substances in sustainable horticultural production (Gong et al., 2025; Biswal et al., 2026).

The characteristics of the coating material, the thickness of the coating, the kind and concentration of the active ingredient, the physical and physiological characteristics of the seed, and environmental factors can all affect how effective seed coating technologies are. By restricting the seed's access to water and oxygen, an excessively thick or inappropriate coating layer can postpone germination. In contrast, a suitable coating system developed taking into account seed characteristics and growing conditions can improve seed sowing performance while supporting germination, emergence, and early seedling development. Therefore, the

coating material and application method should be evaluated according to the characteristics of each vegetable species (Afzal et al., 2020; Javed et al., 2022).

The main objectives of seed coating are:
• To facilitate seed processing and sowing;
• To deliver active substances directly to the spermosphere;
• To improve germination and seedling establishment;
• To reduce pesticide use through targeted application of active substances;
• To support precision agriculture and sustainable crop production.

These advancements in seed coating technologies have the potential to combine seed protection and early development support with precision planting in the same application, especially in vegetable varieties with small and irregularly shaped seeds. Today, research focuses not only on improving the physical properties of seeds but also on developing new and sustainable coating systems for the efficient delivery of nutrients, biostimulants, and biological agents, supporting germination and seedling development, and using resources more efficiently (Afzal et al., 2020; Biswal et al., 2026).

2. MAJOR SEED COATING TECHNOLOGIES

Seed coating technologies are evaluated under different methods depending on the amount of material applied, the properties of the coating layer, and the physical changes it creates on the seed. The main approaches commonly used in vegetable seeds are film coating, encrustation, and pelleting, and the combined application of seed priming and coating stands out as an important approach to improving seed performance. These methods offer different advantages in terms of improving the sowingability and homogeneous emergence of seeds, efficient transport of active components, and supporting germination and early seedling development (Biswal et al., 2026).

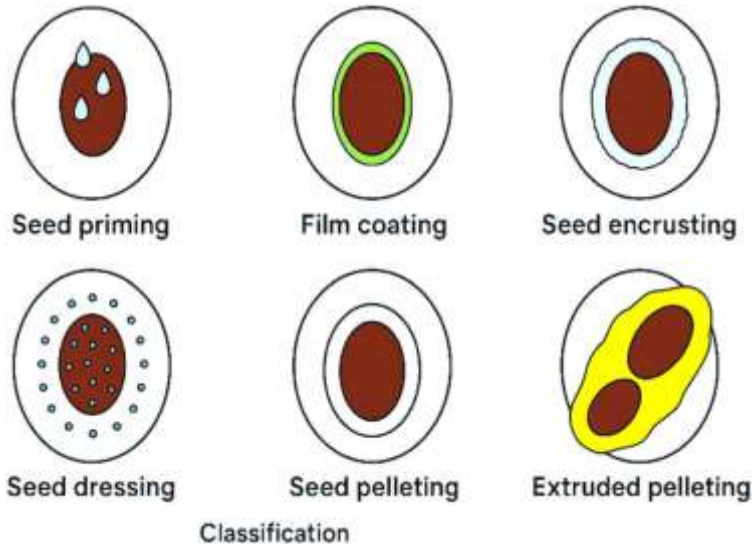

Fig. 2 Classification of seed coating technologies (Biswal et al., 2026).

2.1 FILM COATING

Film coating is a technology based on applying a thin and homogeneous layer of coating material to the seed surface, usually in an amount not exceeding 5% of the seed weight (Pedrini et al., 2017). Coating materials mostly consist of polymers, pigments, plasticizers, and colorants; polymer-based binders ensure the dissolution or **homogeneous distribution of**

active components within the coating (Taylor and Harman, 1990; Qiu et al., 2005). Rotary coating systems are the most commonly used equipment in commercial applications, while fluidized bed systems are used more limitedly. One of the important advantages of film coating is that it allows the application of different active components to the seed without significantly altering its size and shape. Therefore, it can be used in the delivery of plant growth regulators, nutrients, biostimulants, and plant protection products. For example, it has been reported that applying a film coating containing 0.0075% uniconazole to Brassica napus L. seeds can reduce the negative effects of flood stress and increase antioxidant enzyme activities (Willenborg et al., 2004). However, it has been noted that the application did not have a significant effect on germination. Similarly, it has been reported that germination performance improved in canola seeds coated with a polymer film under low temperature and humidity stress conditions (Pedrini et al., 2018). These findings suggest that film coating can be used in delivering active ingredients to the seed and supporting early plant development under stress conditions.

2.2 PELLETING

Pelletizing is the application of a thick coating layer in the form of aggregates or pellets around the seed. This method is particularly preferred for processing small or irregularly shaped seeds (Taylor et al., 2001; Pedrini et al., 2020). Pelletizing is a technique that provides a greater weight increase by applying liquids and inert materials (such as diatomaceous earth, talc, and bentonite) to the seed surface; therefore, it is considered a continuation of the mini-pelletizing process (Afzal et al., 2020). This process can also be performed using a rotary drum or rotary pan. However, pelletizing generally transforms the seed morphology into a larger, spherical shape that is difficult to distinguish from the original seed shape (Halmer, 2000). Pelletizing contributes to the improvement of planting with mechanical planting equipment by increasing the weight percentage by 500-5000%. It facilitates planting for garden plants with small seeds or irregular seed shapes, including lettuce and tomatoes (Kangsopa et al., 2018; Javed et al., 2022). Newly pelleted seeds should be dried before packaging and storage.

2.3 ENCRUSTING

Encrustation is a seed coating method that involves applying liquid and solid particulate materials to the seed, completely coating it while preserving its original shape (Taylor, 2020). Encrusted seeds can also be called mini pellets or, in some cases, coated seeds. The main equipment used in obtaining encrusted seeds is a rotary coater and a coating pan. Due to the high amount of water used during encrustation, the coated seeds must be dried to their original moisture content before packaging and storage. The increase in seed weight after encrustation can vary between 8% and 500% (Afzal et al., 2020).

Encrusted seeds have been reported to improve seedling emergence. Encrusted fescue seeds before storage showed significantly higher germination rates compared to seeds encrusted after storage or those without any treatment (Olivera et al., 2017). However, the thickness of the coating layer or the amount of coating on the seed can affect the germination rate, and encrusted seeds are reported to germinate in a longer time compared to film-coated seeds (Gorim and Asch, 2012). The amount of binder used during encrustation can also alter the mechanical properties of the coating, such as integrity, compressive strength, and dispersal time after wetting (Qiu et al., 2020).

2.4 PRIMING COMBINED WITH COATING

The strategy of combining the physiological preparation of the seed for germination with the protective and transport qualities of the coating is known as "combined seed priming and coating." Before going through the coating process, seeds are dried to the proper moisture content after carefully absorbing water to start metabolic processes during priming. This application can promote more uniform seedling emergence and hasten the germination process of seeds. The combined application of priming and coating has the potential to enhance the performance of seeds and seedlings in the early developmental stage, particularly in challenging environmental conditions like low temperatures, drought, and salinity (Pedrini et al., 2017; Afzal et al., 2020).

In addition to enhancing the seed's physical characteristics, the coating procedure that comes after priming enables the introduction of active ingredients into the seed environment, including nutrients, biostimulants, plant growth regulators, and biological agents. Therefore, the protection and regulated transport of active substances offered by coating support the physiological benefits of priming. According to reports, this method has a lot of potential, especially when it comes to strong seedling development, quick and uniform emergence, and improved seed performance under stressful circumstances (Pedrini et al., 2017; Afzal et al., 2020; Qiu et al., 2020). Priming, however, may have an impact on the seeds' storage qualities. Since the storage life of primed seeds may be reduced, ensuring appropriate drying and controlled storage conditions after application is crucial. Therefore, in systems where priming and coating are used together, priming conditions, drying level, coating material properties, and storage conditions should be evaluated as a whole (Gorim and Asch, 2017; Pedrini et al., 2017).

3. MATERIALS USED IN SEED COATING

Seed coating materials determine the physical properties of the coating as well as ensuring the efficient and homogeneous transport of active ingredients to the seed surface. The materials used generally include polymers and binders, fillers and active ingredients, as well as biostimulants, nutrients, plant protection products, and beneficial microorganisms. The selection of the coating material should be made considering the properties of the component to be applied, the target dose, the coating method, and the physical properties of the seed. A suitable combination of materials and equipment is important to ensure homogeneous adhesion of the coating to the seed surface while preventing mechanical damage to the seeds (Zhang et al., 2022; Biswal et al., 2026).

3.1 POLYMERS AND BINDERS

Polymers and binders contribute to the formation of a homogeneous coating layer and the maintenance of coating stability by ensuring the adhesion of coating materials to the seed surface. They also support the retention of coating components on the seed surface, the regulation of water uptake, and the transport of active substances to the seed. Binders include biologically derived substances like starch, cellulose derivatives, alginate, chitosan, proteins, and natural gums, as well as synthetic polymers like polyvinyl alcohol (PVA) and polyacrylates. Biodegradable polymers are becoming more and more popular, especially when it comes to lowering environmental effects and creating sustainable farming methods (Ryu et al., 2006; Kimmelshue et al., 2019; Sohail et al., 2022; Biswal et al., 2026).

3.2 FILLERS

Fillers are frequently used inert bulking materials that allow seeds to be physically altered, especially during the encrustation and pelleting processes (Zhang et al., 2022). They can be made from a single substance or by combining several different substances. Fillers influence seed size, shape, and planting accuracy by adding to the volume and structural characteristics of the seed coating. Additionally, they may aid in the regulated release of active components (Afzal et al., 2020).

3.3 ACTIVE INGREDIENTS

The functional elements of seed coating systems that have a direct impact on seed and seedling performance are called active ingredients. These components are primarily used to protect seeds from biotic stressors or to enhance plant performance during germination, seedling emergence, early development, and stress situations. Plant protection products, plant nutrients, biostimulants, plant growth regulators, and beneficial microorganisms are the primary active ingredients found in seed coatings (Afzal et al., 2020).

Insecticides, nematicides, fungicides, and other protective agents are used to shield seeds from pests and diseases, particularly during germination and seedling emergence. However, choosing the right dose and formulation is crucial because high doses of some protective agents can have a detrimental effect on germination and seedling development (Rocha et al., 2019). Nutrients, on the other hand, can support early nutrient utilization by ensuring the delivery of microelements such as nitrogen (N), phosphorus (P), potassium (K), boron (B), copper (Cu), manganese (Mn), molybdenum (Mo), and zinc (Zn) to the seed environment. It has been reported that these applications can have positive effects on germination, plant development, and yield (Sohail et al., 2022).

Biostimulants and plant growth regulators are also increasingly used in seed coating systems. The application of plant growth regulators such as salicylic acid, gibberellic acid, and abscisic acid, as well as various biostimulants, via coating can contribute to supporting germination and early seedling development and increasing stress tolerance. In particular, direct delivery of the active ingredient to the seed environment during the early development stage is a significant advantage that can increase the effectiveness of the application (Amirkhani et al.; 2016; Afzal et al., 2020; Chen et al., 2024).

Beneficial microorganisms also constitute an important group of active ingredients. Microorganisms such as plant growth promoting bacteria (PGPB/PGPR), Trichoderma species and arbuscular mycorrhizal fungi can be applied to the seed surface via seed coating. These microorganisms can support root colonization, nutrient uptake and plant development; It can also increase plant resilience under some biotic and abiotic stress conditions (Maity et al., 2018; Rocha et al., 2019). In particular, direct application of biological agents to the seed strengthens the biological function of the coating technology by ensuring the presence of active microorganisms in the seed and root zone in the early period.

As a result, the type of active ingredient, its dose, distribution within the coating and release characteristics are the main factors that determine the success of the seed coating application. Homogeneous delivery of active ingredients to the seed in a suitable coating matrix; It can support germination, seedling development and stress tolerance while reducing unnecessary input use. Therefore, the choice of active ingredient should be evaluated not only based on the targeted biological effect, but also on the seed type, coating method and growing conditions (Afzal et al., 2020; Sohail et al., 2022).

4. APPLICATIONS OF SEED COATING IN VEGETABLE CROPS

4.1 IMPROVED SOWING QUALITY

To achieve uniform plant emergence and suitable plant density in vegetable cultivation, even and controlled seed distribution during sowing is essential. Individual dosing and placement at suitable intervals in precision sowing machines can be difficult when dealing with small and irregularly shaped seeds, especially those of lettuce, carrots, onions, and celery. By improving the uniformity of the seeds' size and shape, seed coating applications can help achieve more accurate seed separation and placement during mechanical sowing (Taylor et al., 1990; Pedrini et al., 2017). Research using a variety of seed coating applications has shown how these benefits affect different kinds of vegetables. For vegetable varieties with tiny, irregularly shaped seeds, pelletizing stands out as a crucial application in enhancing precision sowing performance. Pelleting lettuce (Lactuca sativa L.) seeds enhances their physical characteristics, making it simpler to separate and place them at the right intervals in precision seeding machines. This helps direct seeding systems better control plant density (Hill, 1999; Halmer, 2008). Similarly, due to the small, light, and irregular structure of carrot (*Daucus carota* L.) seeds, pelleting allows these seeds to acquire physical and mechanical properties more suitable for mechanical seeding. Hacıyusufoğlu and Akbaş (2019) reported that pelleting changed the size, shape, and weight characteristics of carrot seeds, and that this change is important for seeding. A similar advantage is seen in onion (*Allium cepa* L.) seeds. Karayel et al. (2020) compared the performance of naked and pelleted onion seeds in a vacuum precision seeding machine and revealed that a more suitable seed distribution was obtained in pelleted seeds. Also, Yogeesha et al. (2017) reported that pelleting onion seeds facilitated seed handling and created a more uniform seed structure. In contrast, film coating can be a more suitable option in situations where a significant change in seed size is undesirable. For example, in economically valuable vegetable species such as tomatoes (*Solanum lycopersicum* L.), film coating allows the application of coating materials without significantly altering the initial size of the seed and contributes to maintaining the existing seed calibration in precision planting systems (Halmer, 2008). These studies show that the seed size and shape of the vegetable species and the planting system used should be evaluated together when choosing the coating method. While film coating enables the application of coating materials without appreciably changing the seed size, pelleting allows the seeds to acquire more uniform physical characteristics, particularly in small and irregularly shaped seeds. Therefore, depending on the features of the vegetable species and the specifications of the precision planting systems, various coating techniques may offer varying benefits.

4.2 CROP PROTECTION

During the early stages of germination and seedling development, seeds are extremely vulnerable to diseases, especially those brought on by soil-borne pathogens. Particularly in vegetable cultivation, pathogens like Pythium, Rhizoctonia, and Fusarium can adversely affect germination and seedling emergence, resulting in large losses. Fungicides and other protective active ingredients can be directly applied to the seed environment using seed coating technologies, providing targeted protection during the plant's most vulnerable early developmental stage (Taylor and Harman, 1990; Halmer, 2008). Compared to large-field applications, concentrating active ingredients around the seed environment allows for direct application to the target area and the use of fewer protective agents. Numerous studies have shown how this method can be applied to vegetable species. Fungicide-containing coatings are applied to tomato (Solanum lycopersicum L.) seeds, especially to suppress Fusarium, Rhizoctonia, and Pythium species that cause dumping-off diseases. During germination, protective elements on the seed surface can create a protective environment that lowers the

likelihood that young root and stem tissues will come into contact with pathogens (Taylor and Harman, 1990). Similarly, soil-borne diseases that affect Brassica group vegetables (cabbage, broccoli, cauliflower, and kale) in their early stages of development are managed through seed treatments. According to Taylor et al. (1998), using fungicides in conjunction with seed guaranties that the active ingredients are delivered straight to the seed area and that targeted application can minimize needless pesticide use. Coating applications are also used in onion (*Allium cepa* L.) seeds to prevent potential fungal diseases, particularly during germination and seedling development. Fungicides applied to seeds by encrustation and film coating guaranty the presence of protective elements surrounding the seed and their efficacy during the early stages of development (Halmer, 2008). As a result, it can help prevent diseases that might arise during the seed and early seedling stages.

A novel strategy for managing disease is the application of biological agents in seed coatings, in addition to chemical fungicides. In particular, species of Bacillus, Pseudomonas, and Trichoderma can prevent the spread of disease in a number of ways, including by competing with pathogens, generating antagonistic compounds, and boosting the plant's defense mechanisms (Nigro et al., 2014). Beneficial microorganisms can be present in the seed and root zone from the start of germination by coating the seed surface with these microorganisms. Biological seed applications have substantial potential for lowering chemical inputs and creating more sustainable disease management systems, according to Pedrini et al. (2020). In conclusion, coating vegetable seeds with chemical and biological protective components can help suppress soil-borne pathogens, particularly during germination and seedling emergence. However, the type and dosage of the active ingredient used, along with the target pathogen, vegetable species, and coating formulation, may all affect how well the application works.

4.3 ENHANCED GERMINATION AND STAND ESTABLISHMENT

Applications of seed coatings can enhance the sowing qualities of seeds as well as promote early seedling development and faster, more uniform germination. Particularly in challenging environmental circumstances, germination and seedling emergence can be supported by the appropriate microenvironment produced by the coating materials surrounding the seed and the active ingredients in the formulation (Halmer, 2008; Pedrini et al., 2017). Research on vegetable species also demonstrates that this effect can change based on the species and application technique. For instance, it has been noted that under low temperature and humidity stress conditions, canola seeds coated with polymer film perform better during germination (Taylor et al., 1998). Similarly, it has been found that applying encrustation to onion seeds can boost the germination rate, vigor index, root length, and shoot length; additionally, applying a coating that contains thiram specifically promotes the development of seedlings. These findings demonstrate that seed coating technologies can effectively promote germination and guaranty stronger seedling formation when utilized with suitable formulations.

4.4 NUTRIENT AND BIOSTIMULANT DELIVERY

Through the direct application of nutrients and biostimulants to the seed environment made possible by seed coating technologies, these elements can be used more effectively during germination and the early stages of seedling development. Specifically, the incorporation of microelements and components that promote plant growth into coating formulations guaranties that nutrients are situated near the seed and young root zone, which enhances the efficiency of nutrient utilization (Pedrini et al., 2017). Additionally, by allowing the controlled release of nutrients to the seed environment, new generation formulations like hydrogel coatings based on alginate can support nutrient supply during early development (Skrzypczak et al., 2021).

Similarly, it has been reported that seed coatings can support root development, seedling growth, and nutrient uptake in vegetable production by transporting microorganisms, microelements, and biologically active components. As a result, seed coating is regarded as a carrier system that transports nutrients and biostimulants to the intended area rather than just an application that physically modifies the seed surface.

4.5 BIOLOGICAL SEED COATINGS

In order to ensure that beneficial microorganisms are present around the seed during germination and the early stages of seedling development, biological seed coatings are a sustainable application method. When incorporated into seed coating formulations, microorganisms like Bacillus, Pseudomonas, and Trichoderma, in particular, can support colonization in the root zone and suppress soil-borne pathogens (Nigro et al., 2014; Pedrini et al., 2017). In vegetable cultivation, these types of biological coatings are reported to be used not only for disease suppression but also for supporting root development and plant growth. However, the ability of the coating material to maintain the viability of the microorganisms and ensure their proper adhesion to the seed is a crucial factor for the success of the application. Therefore, biological seed coatings are being considered as an alternative or complementary approach to chemical seed treatments in more sustainable vegetable production systems.

4.6 IDENTIFICATION AND TRACEABILITY

In addition to their physical and biological functions, seed coatings can also be used to identify and trace seeds. Coating materials can be given different colors and visual features, especially in order to easily distinguish different varieties, seed lots and application types. Colored coatings can facilitate rapid identification of seeds during processing and storage stages, while also reducing the risk of mixing or misuse of different applications (Halmer, 2008; Pedrini et al., 2020). In addition, associating the coating color or appearance with a specific seed lot or application can contribute to supporting quality control in production and distribution processes. For this reason, seed coating technologies are considered not only as an application that improves planting and seed performance, but also as a practical tool to support the identification, quality control and traceability of seeds throughout the production chain.

5. EMERGING SEED COATING TECHNOLOGIES

More controlled, targeted, and effective delivery of active ingredients to the seed is the focus of recent developments in seed coating technologies, which go beyond conventional coating applications. Specifically, next-generation coating systems with nutrients, nanomaterials, and beneficial microorganisms present substantial chances to improve seed performance, increase stress tolerance, and improve resource utilization efficiency (Afzal et al., 2020). As a result of these advancements, seed coating is becoming a multifunctional delivery and seed enhancement technology rather than just a physical coating application.

5.1. MICROBIAL SEED COATINGS

The use of microorganisms that promote plant growth, particularly growth-promoting bacteria (PGPB), rhizobacteria, and beneficial fungi, in seed coatings holds significant potential for supporting nutrient uptake and plant growth, and suppressing soil-borne diseases and pathogens (Ma, 2019; Rocha et al., 2019). Applying beneficial microorganisms via seed coating allows for their direct delivery to the seed zone, enabling the use of lower inoculum amounts and offering an effective inoculation method (Scott, 1990; Taylor and Harman, 1990; Cho et al., 2000). The use of suitable carrier materials contributes to the adhesion of microorganisms to the seed surface and their protection against external environmental conditions, thus supporting their viability within the coating (Deaker et al., 2004; Tufail et al., 2018; Głodowska et al., 2017). Indeed, while it has been reported that biotic stress is reduced and emergence and early plant development are supported in seeds coated with microorganisms that promote plant growth (Głodowska et al., 2017), pelleting sesame seeds with the E681 strain has been found to reduce the incidence of seedling damping-off disease (Ryu et al., 2006). With these characteristics, microbial seed coatings are considered a new generation approach that supports seed performance and early plant development, contributes to biological disease management, and has potential for sustainable production systems.

5.2. NANO-SEED COATINGS

An emerging strategy that makes it possible to precisely and carefully deliver nutrients, growth regulators, and other biologically active substances to seeds is the integration of nanotechnology into seed coating systems. By facilitating the adhesion of coating components to the seed surface and the controlled release of active substances, the high surface area and distinctive physicochemical characteristics of nanoscale materials can enhance germination and seedling development (Singh et al., 2024). In particular, the use of ZnO, Si, and other nanomaterials can have beneficial effects on root development, water and nutrient uptake, and the encapsulation of nutrients and biostimulants within nanocarriers supports the metabolic activity of the seed (Okan, 2020; Al Jabri et al., 2022; Singh et al., 2024). Additionally, by holding water inside the coating and releasing it to the seed gradually, nano-coatings can help maintain the water status of seeds during drought conditions. For instance, controlled water release has been reported to be possible with graphene oxide and hydrogel-based nanomaterials (Silva et al., 2025). Furthermore, according to Singh et al. (2024), nano-coating systems may enhance seed performance and seedling resilience in the face of abiotic stressors like heat, salinity, and drought. These characteristics set nano-seed coatings apart as a cutting-edge seed coating technology that seeks to enhance germination, early seedling development, and stress tolerance by facilitating the precise and regulated delivery of active ingredients.

5.3. NUTRIENT-ENHANCED COATINGS

The availability of sufficient nutrients during the early stages of plant development is crucial for healthy germination and seedling growth. Coating seeds with appropriate amounts of macro and especially microelements allows nutrients to be directly deposited around the seed, reducing nutrient losses and increasing nutrient use efficiency (Scott, 1989; Farooq et al., 2012). The use of microelements such as Zn, B, Fe, Mn, Cu, Mg, and Mo in seed coatings has shown positive results on germination, emergence, plant development, and yield in various plant species (Afzal et al., 2020). However, since direct contact of high amounts of macroelement coatings with the seed can cause phytotoxicity and negatively affect germination and seedling development, it is recommended to create a protective starting or boundary layer between the nutrient-containing layer and the seed (Scott, 1989). Reducing nutrient losses through seed coating can also contribute to lower production costs compared to traditional soil applications

(Farooq et al., 2012). Furthermore, it has been reported that maize seeds coated with slow-release N-P-K exhibit improved emergence and yield characteristics compared to conventional fertilizer application (Dong et al., 2016). Therefore, nutrient-enriched coatings are considered an effective seed coating approach that supports early plant development and has the potential to reduce nutrient losses and fertilization costs.

6. CHALLENGES

Although seed coating technologies offer significant advantages, the success of the application depends on the proper optimization of the coating formulation and coating thickness. Inappropriate coating properties or excessive coating thickness can negatively affect germination and seedling development by limiting the seed's water and oxygen uptake (Javed et al., 2022). Furthermore, the use of polymers, nutrients, pesticides, and biological agents within the same coating system makes maintaining compatibility and biological efficacy between these components a crucial technical requirement (Afzal et al., 2020). In systems where priming and coating are applied together, the potential decrease in seed storage performance necessitates ensuring appropriate storage conditions after application. In addition, dust-off generated during coating or during planting and transport poses a significant problem in terms of the dispersal of active ingredients into the environment; therefore, the coating must adhere strongly to the seed surface and be resistant to abrasion (Langlet et al., 2024). The persistence of non-biodegradable synthetic polymers in the environment and the formation of microplastics are becoming increasingly important for the sustainability of seed coating technologies (Sohail et al., 2022; Langlet et al., 2024). Therefore, future research should focus on achieving a suitable balance between coating efficacy and germination, storability, compatibility of active ingredients, and environmental safety.

7. FUTURE PERSPECTIVES

In the future, environmentally friendly, precise, and product- and environmental condition-specific coating systems are expected to come to the forefront in the development of seed coating technologies. Increasing the use of biodegradable and biologically derived polymers constitutes an important research area in terms of reducing the environmental impact of synthetic coating materials (Sohail et al., 2022; Langlet et al., 2024). In addition, the more effective incorporation of microbial inoculants and plant biostimulants into coating systems offers new opportunities for improving the resistance of seeds to biotic and abiotic stresses (Afzal et al., 2020). The development of smart coatings that can release active substances in a controlled manner in response to environmental signals such as humidity, temperature, or pathogen presence can contribute to the widespread adoption of precise and needs-based applications in the future. Additionally, faster determination of appropriate coating compositions for various vegetable types and production conditions can be made possible through the use of artificial intelligence and data-driven approaches in coating formulation design. Developing coating formulations tailored to crop and environmental conditions holds great promise for enhancing seed performance and the resilience of production systems in production areas facing stresses like drought, salinity, and high temperatures. Additionally, tracking seed variety, applied coating, and batch information throughout the production chain can be facilitated by the development of digital systems that allow the traceability of coated seeds.

CONCLUSION

By combining developments in materials science, biotechnology, and precision agriculture, seed coating technologies have developed into a sophisticated platform for seed development. In addition to improving mechanical planting performance, targeted germination, seedling emergence, plant protection, and nutrient delivery, modern coating systems also allow for a decrease in chemical inputs. The sustainability and resource efficiency of vegetable production systems are anticipated to be further improved by emerging technologies like biodegradable polymers, microbial inoculants, nanotechnology, environmentally responsive smart coatings, and AI-powered formulation designs. In order to meet the increasing demand for high-quality, long-lasting, and ecologically friendly vegetable production, coating formulations must be continuously developed and optimized for various vegetable types and production conditions.

ABSTRACT

Sustainable development has seen significant growth in recent years in agriculture, particularly in the food industry sector. As a part of this initiative, the food industry has focused on the valorization and recycling of industrial waste from food production in order to reduce costs and protect the environment. The most common example is the use of dairy effluents, such as dairy wastewater. Our study focused on the use of dairy wastewater, specifically first rinse water (excluding CIP system water), in the formulation of gluten-free and low-fat cookies. In this type of formulation, the purpose of dairy wastewater was to replace fat. First, a sample of this dairy wastewater, obtained from processed cheese production, was sampled and its quality was tested. The quality control included standard physicochemical, nutritional, and microbiological analyses. The physicochemical analysis involved measuring pH, Dornic acidity, density, conductivity, and freezing point; the nutritional analysis consisted of dry matter content, ash content, butyric acid content, protein content, and lactose content; the microbiological analysis encompassed the enumeration of *E. coli*, *Enterococci*, and *sulfite-reducing Clostridium*. Second, the cookies made with dairy wastewater were prepared using two gluten-free flours: oat and quinoa. After baking the cookies, a sensory evaluation by a panel of 30 tasters was conducted. The questionnaire of the sensory test determined the evaluation of the parameters of appearance, shape, taste, persistence, mouthfeel, smell and texture. Therefore, a total of 30 samples of dairy wastewater were analyzed. These samples were found to be relatively acidic, with a pH of approximately 6 and an acidity assessed at 53.33°D. The fat content was high, compared to the protein content, estimated at approximately 8.5% and 1.7% respectively. The tasters unanimously approved of the use of dairy wastewater in the preparation of the reduced-fat, gluten-free cookies.

Keywords: Sustainable development, Dairy wastewater, Valorization, Recycling dairy effluent Cookies.

INTRODUCTION

Sustainability is a global concept, driven by several factors, including environmental pollution. The concept of sustainability emerged in the agricultural sector to support farmers and entrepreneurs by offering potential solutions to their problems. Today, sustainable development also aims to address the challenges faced by manufacturers in the agri-food sector. The most common example of this is the dairy sector, known for its high daily production and significant organic waste output [1,2].

Dairy effluents vary depending on the type of production [3], ranging from whey to rinsing, washing, and disinfection water [4]. These effluents are rich in nutrients (proteins, fats, sugars, etc.) [5] as well as bacteria [6] that contaminate soils and groundwater. This dairy wastewater contamination has thus become a global problem [2], sparking the need for treatment and/or recycling. Nevertheless, most of the solutions have been limited to treating this dairy wastewater for the production of biomass, biopolymers, biofertilizers, and primarily energy [4]. Nowadays, research is moving towards new food solutions, which are increasingly focused on the reuse of nutrients from dairy wastewater in the formulation of other food products**,** such as the production of confectionery based on lactose from dairy wastewater [4].
Following this approach, this study aims to reuse the dairy wastewater from rinsing processed cheese in the production of gluten-free cookies. This dairy wastewater, a by-product of fermented food, will likely bring lightness and tenderness to the finished product. Furthermore, the dairy wastewater is incorporated through basic heat treatment and simple filtration, without resorting to complex processes such as extraction and concentration, thus minimizing production costs.

MATERIEL AND METHODS

This research was conducted from February 2025 to June 2025, where 30 samples of dairy wastewater were collected in sterile vials and subjected to analytical characterization tests (Figure 1). The dairy wastewater studied came from the first rinse of the pipes and tanks of the processed cheese production line and was free of any chemicals indicated by the clean-in-place process to ensure its safety for reuse in food. The dairy wastewater was filtered twice and treated at a high temperature (140°C for 2–3 seconds).

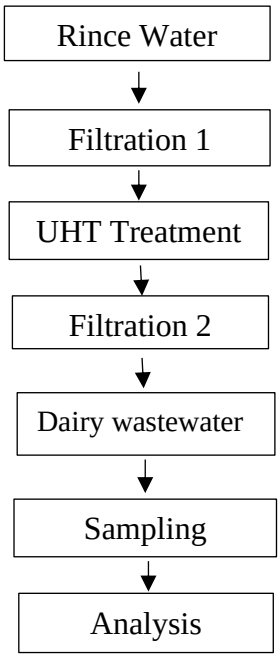

Figure 1: Dairy wastewater diagram process methodology

These samples first underwent microbiological analysis to ensure the safety of this water type. The parameters analyzed included the detection of fecal contaminants related to dairy, such as *E. coli* (ISO 9308-1:2014), *Enterococci* (ISO 7899-2:2000), and *sulfite-reducing Clostridium* (ISO 15213:2023). However, physicochemical and nutritional parameters, including density, conductivity, freezing point, ash content, protein content, and lactose content were measured directly using an Ultrasonic Portable Milkanalyser (Milkotronic Ltd-Bulgaria). Therefore, pH was measured using a pH meter; acidity was determined via an acid-base titration with sodium hydroxide (N/9) and phenolphthalein as a color indicator. The total dry extract was determined with a desiccator at 120°C until evaporation of water and the butyric content was quantified by the conventional Van Gulik Method (ISO 3433: 2008).

Following the quality control of the dairy wastewater samples, they were incorporated into quinoa and oat-based cookies. It is important to note that in this study, the dairy wastewater replaced the usual fat, which is butter. The cookie recipe included, in the following order of ingredients: dairy wastewater, sugar, salt, egg, flour, baking powder, chocolate chips, and dried fruit (Figure 2). The dough was then refrigerated for approximately one hour to make it pliable. The cookie dough was baked at approximately 180°C for 15 minutes, then cooled and packaged in boxes. Finally, the prepared cookies were analyzed by a panel of 30 untrained tasters; the coded samples were placed on plates with a glass of water. The tasting sheet allowed for the evaluation of appearance, shape, taste, persistence, mouthfeel, smell, crunchiness, sandy texture, tenderness, softness, moisture and friability on a hedonic scale of 1 to 9.

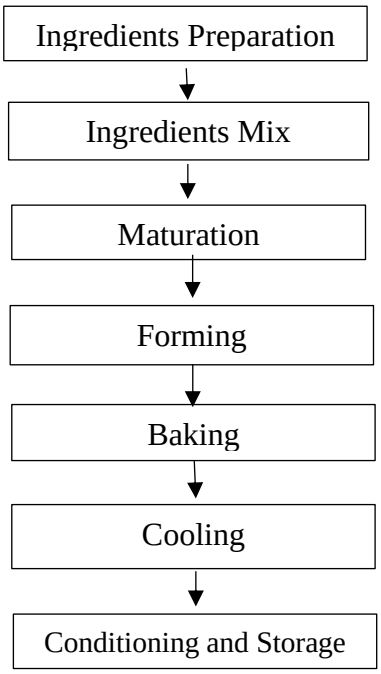

Figure 2: Diagram of cookies process

RESULTS AND DISCUSSION

After the recovery of dairy wastewater from cheese production, it appeared as a solid state. Its texture was similar to that of creamy butter or a spread (Figure 3). Microbiological analyses revealed that the dairy wastewater was free of fecal contamination.

Figure 3: Dairy wastewater aspect

Regarding the physicochemical parameters, the results showed interesting and exploitable properties (Table 1). The pH was relatively more acidic than milk (6.09 vs. 6.4) and more alkaline than cheese (5.8). Our results were similar to those of [7], where the pH of the dairy wastewater was measured at 6.07. As for acidity, it is relatively high, measured at 53.33°D, compared to that of milk, which is normalized to 18°D. However, it was observed that the acidity of the dairy wastewater varied depending on the processed cheese production and the amount of water used for rinsing (recipe and residues), ranging between 50°D and 60°D. Our results confirm the hypothesis put forward by [8] that the properties of the dairy wastewater depend on both the type of product and the process. The conductivity value fluctuated at 4.89 mS cm−1, corresponding to the quantity of electrolytes (minerals). This value was almost identical to that of [7], which was 4.75 mS cm−1.

Table 1: Physicochemical characterization of dairy wastewater

Parameters	**pH**	**Acidity**	**Density**	**Conductivity**	**Frozen Point**
Dairy wastewater	6.09±0.25	53.33±5.77	14.72±1.87	4.89±0.81	-0.326±0.03

Similarly, in terms of nutritional properties, dairy wastewater exhibited a relatively rich nutrient composition (Table 2). Its total dry extract (TDE) proved quite interesting, approaching that of milk. Dairy wastewater showed a high mineral content (which explains the conductivity results) and a high fat content of 1.046% and 8.5%, respectively. However, dairy wastewater was low in protein and lactose content with 1.74% and 2.62%, respectively.

Table 2: Nutritional characterization of dairy wastewater

Parameters	**TDE**	**Ash**	**BAC**	**PC**	**Lac**
Dairy wastewater	13.35±8.87	1.046±0.71	8.5±0.5	1.74±0.29	2.62±0.43

TDE: Total dry extract; BAC: Butyric acid content; PC: Protein content; Lac: Lactose

After baking, the cookies were cooled and arranged on plates (Figure 4). These cookies were presented to an untrained panel of 30 consumers, who were given tasting notes. The results of the sensory analysis are shown in Figure 5.

Figure 4: Oat and quinoa cookies presentation

The scores were satisfactory, ranging from 6 to 7.5 for most attributes, including appearance, shape, taste, persistence, mouthfeel, smell, tenderness, softness, moisture, and friability. Only the crunchiness and sandy texture received scores below 4. This perception confirmed that the dairy wastewater, which is rich in fat, contributed to the cookies' tenderness and soft texture rather than the crunchy or sandy effect. These results are close to the original cookie recipe, as crunchiness is more associated to the puff pastry and the sandy texture to the shortbread biscuit.

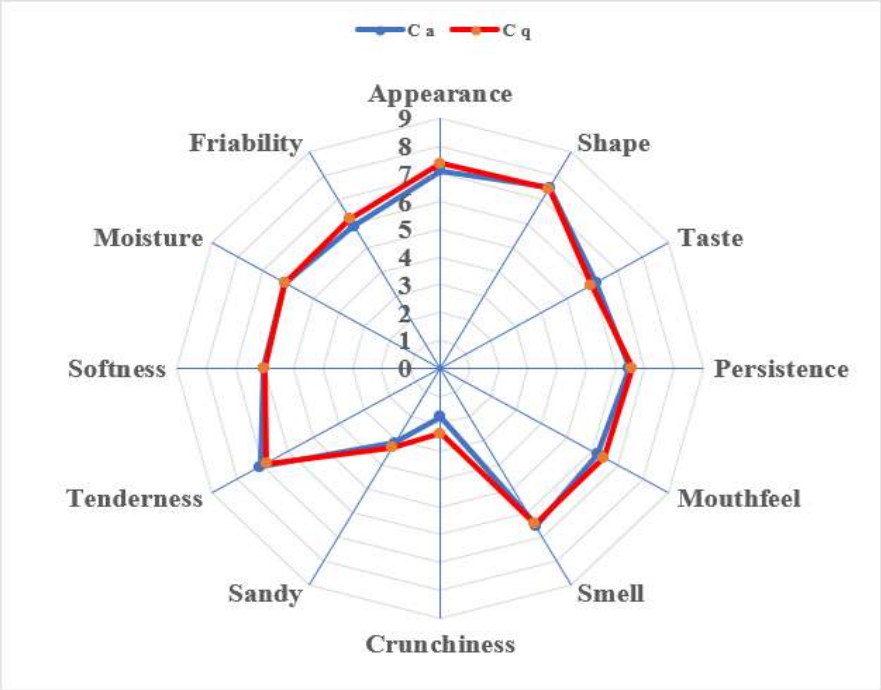

Figure 5: Sensory perception of the panelists
Ca: Oat cookies; Cq: Quinoa cookies

Regarding the use of gluten-free flours, it was observed that the shape, texture, aroma, and soft, moist feel were nearly identical for both cookies. However, the appearance, mouthfeel, and

crumbly texture (friability) were more appreciated in the quinoa flour cookies. Conversely, the oat flour cookies received higher marks for taste parameters, specifically sweetness and tenderness. Ultimately, the quinoa flour cookies were rated higher than the oat flour cookies.

CONCLUSION

This study demonstrated that dairy effluents, such as dairy wastewater, can be recycled into food products other than dairy. Dairy wastewater proved to be a good alternative for reducing production costs and preserving the environment. Dairy wastewater is a by-product composed of nutrients that can be used to enrich the production of other food products such as cookies. Dairy wastewater helped guarantee the quality of gluten-free cookies, while ensuring their sensory acceptability.

ABSTRACT

As demonstrated by several studies, livestock farming practices are synonymous with yield and quality for farmers. They influence the quality of animal products as well as the zootechnical parameters of the animals themselves. However, dairy cattle are not exempted from this equation; where farming practices play a limiting role in mastering the quality of milk and dairy products. For this purpose, a study was conducted in this context on three farms in the wilaya of Mostaganem; it is a Mediterranean region located in the northwest of Algeria. These farms were characterized by raising only one breed of imported cows, belonging to the French breed 'the Montbéliarde'. Therefore, the experimental approach was structured around two axes; the first axis included a prospecting (survey) and the second axis an analytical part. First, the survey was carried out using a questionnaire that primarily gathered information on farming practices. Second, the sampling process consisted of six 250ml samples collected from each farm. They were collected in sterile vials after the morning mixed milking from several Montbéliarde cows. Then, the samples underwent physicochemical analysis and lactic acid bacteria enumeration to link the effects of farming practices to milk quality. The physicochemical analysis performed, by using a lactoscan, allowed for the determination of pH, density, conductivity, ash, protein content, fat content, and lactose content. The enumeration of lactic acid bacteria was carried out on MRS medium incubated at 30°C for 24 hours. A total of 18 milk samples were analyzed and showed a minimal fat content and a moderate protein content estimated at approximately 3%. The lactic acid bacteria count was approximately 260 x 10^6 UFC.

Keywords: Farming practices, Quality, Dairy cattle, Montbéliarde, Questionnaire.

INTRODUCTION

The Montbéliarde is the most common dairy breed in France after the Holstein [1]. However, the Montbéliarde is also considered as a dual-purpose breed, producing both milk and meat [2]. It is generally considered as a robust [3] and highly productive breed. In northern Cameroon, production reaches approximately 9.1 kg per day per cow [4]. This breed is also known for its high-quality of hard cheeses, such as Gruyère and Emmental [5][6].

Nevertheless, milk production depends on both internal breed-related factors and external factors [7]. The most studied limiting factors are external factors that are not genetically linked to the animal. Breeding practices have been the subject of several studies and have shown a significant effect on milk production. Therefore, this study aims to investigate the effect of

breeding practices implemented in the wilaya of Mostaganem on the quality of the imported Montbéliarde breed.

MATERIAL AND METHODES

This research was conducted in May 2023 in the wilaya of Mostaganem, a coastal city bordering the Mediterranean Sea to the north. It is characterized by a humid climate, mild temperatures, and average rainfall of approximately 90 mm.

This research focused on three farms raising Montbéliarde cows; the Montbéliarde is a mountain dairy breed imported from France. The aim of this study was to investigate the impact of farming practices implemented in the Mostaganem province on the milk quality of Montbéliarde cows. The farms ranged in size from 4,500 hectares to 8,600 hectares, a factor that directly influences cow behavior and milk production. A questionnaire was distributed to the farmers to gather as much information as possible about their farming practices. This questionnaire consisted of two parts: the first concerned the farmers' personal information, and the second covered the farming practices employed.

Subsequently, milk sampling was carried out in the morning, with six 250 ml samples collected from each farm. This sampling included mixed milk to randomize the samples and exclude internal factors affecting the cows (age and stage of lactation). These samples were collected in sterile containers to prevent and avoid contamination. The samples underwent physicochemical analysis using an Ultrasonic Portable Milkanalyser (Milkotronic Ltd-Bulgaria) to measure pH, density, conductivity, protein content, butyric acid content, lactose content, dry matter content degreased, and ash content (Figure 1).

Figure 1: Milkotronic Ltd-Bulgaria

Lactic acid bacteria counts were performed on MRS medium at 30°C for 24 hours. Decimal dilutions up to 10^{-9}, depending on the bacterial load, were prepared (Figure 2). Then each 1 ml dilution was inoculated using the pour-plate technique on MRS medium (Figure 2).

Figure 2: Enumeration of lactic acid bacteria

RESULTS AND DISCUSSION

The questionnaire results showed a similarity between farm 2 and farm 3 (Table 1). Only the breeder from farm 1 refused to disclose information about their farm; this explains the absence of results for farm 1. The results are identical for both farms (farm 2 and 3) regarding the farmer's level of education (primary), the breeding method (natural), the housing method (free-range), the water trough and its distribution method (collective/restricted), and the quantity of forage distributed per herd per day (4 kg).
Regarding the other parameters, milk production was found to be higher on farm 2 than on farm 3 (10L vs. 9L). It was also noted that the diet was richer at farm 2 than at farm 3, with diversified meals including forage, concentrate, hay, straw, and pasture. Conversely, farm 3 relied more heavily on concentrate (9 kg per herd per day) than on green forage, as clearly indicated by the pasture area, which was estimated at 3 hectares for farm 3 compared to 4 hectares for farm 2.

Table 1: Characteristics of Montbéliarde farms in Mostaganem

Parameters	**Farm 2**	**Farm 3**
Breeder institution	Primary	Primary
Milk production	10L	9L
Grazing area	4 Hectares	3 Hectares
Feeding	Forage, concentrate, pasture, hay and straw	Forage, concentrate and pasture
Forage ration/herd/day	4Kg	4Kg
Concentrate	Seeds and oilseed cakes	Not mentioned
Concentrate ratio/herd/day	4Kg	9Kg
Hay	Grasses and legumes	Not mentioned
Straw	Maize, sorghum and barley	Not mentioned
Unlimited water	No	No
Watering trough	Collective	Collective
Milking	Automatic and manual	Manual
Stalling	Free	Free
Reproduction	Naturel	Naturel

As for the physicochemical results shown in Table 2, they appeared to be within normal limits, with a pH between 6.4 and 6.8 and a density of 28 to 34 or 35. However, the pH of the milk

from farm 1 was high (7), suggesting that the cows were probably at the end of lactation or had an early infection.

Table 2: Physicochemical parameters of Montbéliarde milk from the 3 studied farms

Parameters	**pH**	**D**	**C**
Farms			
Farme1	7±0.15	33.2±0.11	5.02±0.07
Farm 2	6.57±0.0068	33.04±0.16	5.18±0.036
Farm 3	6.56±0.0087	33.13±0.16	5.1±0.017

D: Density; C: Conductivity

The results of the nutritional quality assessment of Montbéliarde milk are presented in Table 3. The fat content was higher in the milk from cows on farms 2 and 3, and rather low in the milk from cows on farm 1 (2.46% vs. 1.83%). According to the questionnaire results, on farms 2 and 3, the breeders fed their cows with concentrate, hence the higher fat content (2.44% on farm 2 and 2.48% on farm 3). The 1.83% fat content for the milk from farm 1 suggests that the cows were either not fed concentrate or received at least 4 kg/herd/day. Regarding protein content, the levels were higher in the milk from farms 2 and 3 than from farm 1 (3.04% vs. 3.03% vs. 2.95%, respectively). Our results are lower than those of [8], where the milk from Montbéliarde cows contained 3.58% fat and 3.18% protein. Their cows' diet was based primarily on corn and wheat bran. Similarly, for [9], the fat content of Montbéliarde milk was estimated at 3.8% and the protein at 3.3%, which is higher than our results. Their cows' diet was based on grazing in the summer and corn silage or haylage in the winter. The SNF was assessed at 8.68%, which represented a smaller quantity compared to our results estimated on average at 9.79%.
It is clear that feed and feed ratio influenced the composition of Montbéliarde milk. Lactose content was fairly similar for all the milk samples, around 4.4%, as lactose levels are generally stable in milk. Ash content was also stable and similar for all the milk samples.

Table 3: Nutritional parameters of Montbéliarde milk from the 3 studied farms

Parameters	**F**	**P**	**L**	**SNF**	**Ash**
Farms					
Farm 1	1.83±0.02	2.95±0.003	4.34±0.04	9.62±0.03	0.61±0.0001
Farm 2	2.44±0.03	3.04±0.008	4.53±0.005	9.89±0.03	0.65±0.0001
Farm 3	2.48±0.001	3.03±0.0001	4.53±0.002	9.86±0.042	0.63±0.0157

F: Fat; P: Protein; L: Lactose; SNF: Solid Non-Fat

The results obtained from the lactic acid bacteria count (Table 4) showed an increased count for the milk from farms 2 and 3 (222 x 10^6 CFU and 228 x 10^6 CFU, respectively). In contrast, the milk from farm 1 showed a lower count (144 x 10^6 CFU). Lactic acid bacteria represent the original flora of the milk; that is, they are naturally present and do not represent a source of contamination. Therefore, by comparing the quality parameter results with the lactic acid bacteria count, it can be observed that the lactic acid bacteria count was higher in the milk with a higher nutrient content, namely the milk from farms 2 and 3. By contrast, the count was lower in the milk from farm 1, where the nutrient content is lower. This suggests that the lactic acid

bacteria load increased with the amount of nutrients in the milk., which is likely linked to the quantity and type of feed ingested by the Montbéliarde cow.

Table 4: Lactic Acid Flora

Parametres	**LAB**
Farmes	
Farm 1	144.10^6
Farm 2	222.10^6
Farm 3	228.10^6

LAB: Lactic Acid Bacteria

CONCLUSION

This study suggests that the Montbéliarde cow breed adapts easily to different climates. Originally from a rather cold climate, it has successfully adapted to warm temperate and humid climates, where its milk production is estimated at 9 liters to 10 liters per day. However, this production is linked to the farming practices employed. A well-balanced diet with a good ratio of feed and protein ensures good milk quality; a high quantity of concentrate increases the fat content. On the contrary, a high quantity of forage increases the protein content.
Farming practices also influence the load of lactic acid bacteria. An increase in nutrients leads to an increase in the quantity of lactic acid bacteria in the milk. It is important to know that lactic acid bacteria are a good indicator of milk quality, especially for milk intended for processing, specifically milk that will undergo fermentation. This process allows for the natural production of raw fermented products such as Lben (fermented milk), Raib (fermented milk), and more refined fermented products with enhanced flavors, such as yogurt and cheeses. This represents a good alternative for artisanal and/or traditional industries that prefer to rely on natural, practical, and inexpensive processes.

TAXONOMIC REVISION OF THE FAMILY LILIACEAE IN THE FLORA OF ALBANIA

Saliaj O[1]., Gjeta E.[1], Mullaj A.[2]

[1]Research Center of Flora and Fauna, Faculty of Natural Sciences, University of Tirana, Albania

[2]Center for Scientific Research, Projects and Innovation, University College of Business, Tirana, Albania

ABSTRACT

The family Liliaceae has historically represented one of the most broadly circumscribed groups within monocotyledonous plants in the Albanian flora. In *Flora e Shqipërisë* (*Flora of Albania*, Vol. 4), the family was treated in a traditional taxonomic sense and included 25 genera characterized by considerable morphological diversity. However, advances in molecular phylogenetics and the development of modern classification systems during recent decades have substantially redefined the circumscription of Liliaceae, resulting in the transfer of numerous genera to several distinct families. The present study provides a critical taxonomic revision of Liliaceae in Albania through a comparative analysis between the traditional treatment presented in *Flora of Albania* and contemporary international taxonomic databases, including *Euro+Med PlantBase* and the *Plants of the World Online* (POWO) database of the Royal Botanic Gardens, Kew. Additional information was obtained from the *Distribution Atlas of Vascular Plants in Albania*, the *Checklist of Albanian Flora*, and other relevant botanical and taxonomic literature. The results demonstrate that, of the 25 genera traditionally included within Liliaceae, only five genera are currently accepted as members of the family: *Erythronium*, *Fritillaria*, *Gagea*, *Lilium*, and *Tulipa*. Most of the remaining genera have been reassigned to families such as Asparagaceae, Amaryllidaceae, Asphodelaceae, Colchicaceae, Melanthiaceae, Smilacaceae, and Nartheciaceae. The revised Albanian Liliaceae flora includes taxa of considerable floristic, phytogeographical, and conservation importance, including endemic and subendemic species such as *Tulipa albanica*, *Tulipa kosovarica*, *Fritillaria ionica*, and *Lilium chalcedonicum*. This study highlights the importance of integrating modern phylogenetic concepts into national floristic treatments and contributes to the taxonomic standardization and updated interpretation of the Albanian vascular flora.

Keywords: Albania; Balkan flora; floristic revision; Liliaceae; nomenclature; plant taxonomy

INTRODUCTION

The flora of Albania has been the subject of extensive botanical research over many decades. *Flora e Shqipërisë* (*Flora of Albania)* represents the most comprehensive and important contribution to the study of the country's vascular plants. It documents 3,235 species and 689 subspecies, grouped into 165 families and 300 genera. The work was published in four volumes (I, 1988; II, 1992; III, 1996; IV, 2000) by the Institute of Biological Research of the Academy of Sciences of Albania. The compilation of this flora was primarily based on material preserved in the National Herbarium, comprising more than 150,000 specimens, and also incorporated

numerous contributions from Albanian and international botanists who conducted field expeditions throughout the country.

Liliaceae family is of considerable botanical and ecological importance, comprising many species with wide distribution in temperate regions of the Northern Hemisphere. Globally, it includes taxa of significant horticultural, medicinal, and ornamental value, while in the Balkan Peninsula it is represented by several native species adapted to diverse habitats ranging from lowland ecosystems to alpine zones. In the context of Balkan flora, *Liliaceae* contributes to regional plant diversity and serves as an important group for biogeographical and evolutionary studies, particularly due to its complex taxonomic history and recent revisions based on molecular data (Euro+Med PlantBase; Plants of the World Online).

The family *Liliaceae*, as treated in *Flora e Shqipërisë* (Vol. 4), included 25 genera. However, according to updated taxonomic revisions based on modern phylogenetic systems and international databases such as the Euro+Med PlantBase and Plants of the World Online, the circumscription of this family has been significantly reduced. These revisions reflect major advances in plant systematics, resulting in a redefinition of generic boundaries and the reassignment of many taxa formerly included in *Liliaceae* to other families.

This study aims to reassess the Liliaceae taxa reported in Albania based on *Flora e Shqipërisë* and update their nomenclature in accordance with international databases.

MATERIALS AND METHODS

The study was based on a critical revision of the family Liliaceae in Albania through the comparison of traditional floristic sources with contemporary taxonomic databases and recent literature. Initially, volume 4 of *Flora e Shqipërisë* (*Flora of Albania*; Vangjeli et al., 2000) was systematically examined in order to compile the taxa traditionally included within Liliaceae in the Albanian flora.

Subsequently, the recorded taxa were revised and updated according to current taxonomic concepts using major international plant databases, including Euro+Med PlantBase and the Plants of the World Online (POWO) database of the Royal Botanic Gardens, Kew. Nomenclatural updates and taxonomic standardization were primarily based on Euro+Med PlantBase. Additional information was obtained from the *Distribution Atlas of Vascular Plants in Albania* (Barina, 2017), the *Checklist of Albanian Flora* (Barina et al., 2018), and other relevant published studies.

All collected data were critically evaluated and organized in order to identify taxonomic and nomenclatural changes and to provide an updated overview of the family Liliaceae in Albania according to contemporary classification systems.

RESULTS AND DISCUSSIONS

Following a critical revision of the family *Liliaceae* in *Flora e Shqipërisë* (Flora of Albania, Vol. 4; Vangjeli et al., 2000), it was found that the family was originally represented by 25 genera. However, according to updated taxonomic treatments based on Euro+Med PlantBase and the Plants of the World Online (POWO) database, only five genera are currently retained within *Liliaceae*: *Tulipa* L., *Lilium* Tourn. ex L., *Gagea* Salisb., *Fritillaria* Tourn. ex L., and *Erythronium* L.

The remaining genera have been redistributed into several families, most notably *Asparagaceae*, reflecting significant advances in phylogenetic understanding and modern

taxonomic restructuring of monocotyledons. The full list of taxa and their updated classification is presented in Table 1.

Tab 1: Updated classification of *Liliaceae* genera in Albania

Genus	**Family in *Flora e Shqipërisë***	**Updated Family**
Allium L.	Liliaceae Juss.	Amaryllidaceae J. St.-Hil.
Aloe L.	Liliaceae Juss.	Asphodelaceae Juss.
Anthericum L.	Liliaceae Juss.	Asparagaceae Juss.
Asparagus L.	Liliaceae Juss.	Asparagaceae Juss.
Asphodeline Rchb.	Liliaceae Juss.	Asphodelaceae Juss.
Asphodelus L.	Liliaceae Juss.	Asphodelaceae Juss.
Bellevalia Lapeyr.	Liliaceae Juss.	Asparagaceae Juss.
Colchicum L.	Liliaceae Juss.	Colchicaceae DC.
Convallaria L.	Liliaceae Juss.	Asparagaceae Juss.
Hyacinthus L.	Liliaceae Juss.	Asparagaceae Juss.
Muscari Mill.	Liliaceae Juss.	Asparagaceae Juss.
Narthecium Huds.	Liliaceae Juss.	Nartheciaceae Bjurzon
Ornithogalum L.	Liliaceae Juss.	Asparagaceae Juss.
Paris L.	Liliaceae Juss.	Melanthiaceae Batsch
Polygonatum Mill.	Liliaceae Juss.	Asparagaceae Juss.
Ruscus L.	Liliaceae Juss.	Asparagaceae Juss.
Scilla L.	Liliaceae Juss.	Asparagaceae Juss.
Smilax L.	Liliaceae Juss.	Smilacaceae Vent.
Urginea Steinh.	Liliaceae Juss.	Asparagaceae Juss.
Veratrum L.	Liliaceae Juss.	Melanthiaceae Batsch

For the five genera currently retained within *Liliaceae family (Tulipa* L., *Lilium* Tourn. ex L., *Gagea* Salisb., *Fritillaria* Tourn. ex L., and *Erythronium* L.), a reassessment was conducted based on updated taxonomic databases and other references described in the methodology. The corresponding data are presented in Table 2.

Tab 2: Representation of updated Liliaceae taxa in the National Herbarium of Albania

Genus	Taxon	Status in Albania
Erythronium L.	*Erythronium dens-canis* L.	Native
Fritillaria L.	*Fritillaria gussichiae* (Degen & Dörfl.) Rix	Native
	Fritillaria ionica Halácsy	Subendemic (Albania and Greece)
	Fritillaria ionica Halácsy subsp. *ionica*	Subendemic (Albania and Greece)
	Fritillaria ionica subsp. *thessala* (Boiss.) Kamari	Native
	Fritillaria macedonica Bornm.	Native
	Fritillaria messanensis Raf.	Native
	Fritillaria messanensis Raf. subsp. *messanensis*	Presence doubtful
	Fritillaria messanensis subsp. *gracilis* (Ebel) Rix	Native
	Fritillaria messanensis subsp. *neglecta* (Parl.) Nyman	Native
	Fritillaria montana W. D. J. Koch	Native
	Fritillaria pontica Wahlenb.	Native
Gagea Salisb.	*Gagea amblyopetala* Boiss. & Heldr	Native
	Gagea bohemica (Zauschn.) Schult. & Schult.f.	Native
	Gagea fragifera (Vill.) Ehr. Bayer & G. López	Native
	Gagea lutea (L.) Ker Gawl.	Native
	Gagea minima (L.) Ker Gawl.	Native
	Gagea pratensis (Pers.) Dumort.	Native
	Gagea pusilla (F. W. Schmidt) Sweet	Native
	Gagea villosa (M.Bieb.) Sweet	Native
Lilium L.	*Lilium albanicum* Griseb.	Native
	Lilium candidum L.	Native
	Lilium chalcedonicum L.	Subendemic (Albania and Greece)
	Lilium martagon L.	Native
	Lilium carniolicum Bernh. W. D. J. Koch	Native
	Lilium lancifolium Thunb.	Cultivated
Tulipa L.	*Tulipa albanica* Kit Tan & Shuka	Endemic
