WELCOME NOTES

You are welcome to our VI. AGBIOL Conference that is organized by Trakya University. The aim of our conference is to present scientific subjects of a broad interest to the scientific community, by providing an opportunity to present their work as oral or poster presentations that can be of great value for global science arena. Our goal was to bring three communities, namely science, research and private investment together in a friendly environment of Edirne, Turkey in order to share their interests and ideas and to get benefit from the interaction with each other.

In September 2018, we organized the first AGBIOL Conference with more than 700 scientists and researchers from all over the world with over 800 scientific papers. Due to COVID-19 situation, II. AGBIOL 2020 has organized fully on-line event which was one of the biggest online conferences in recent years in the world with 499 papers and 1133 authors with 333 oral and 166 e-poster presentations from 55 countries. Due to COVID-19 situation, AGBIOL 2021 was organized online again. AGBIOL 2022 conference was organized with a worldwide participation from 44 countries over 522 papers contributed by over 1300 authors. AGBIOL 2023 was organized with a record and worldwide participation from 33 countries 833 papers contributed by over 2000 authors with 522 oral and 311 poster presentations.

There is a worldwide participation from 55 countries 835 papers contributed by about 2000 authors with 522 oral and 311 poster presentations in AGBIOL 2024.

The AGBIOL 2024 is normal participation as well as with online participation in Trakya University Balkan Congress Center in Edirne, Turkey on 18-20 September, 2024. The program included oral talks by invited prominent scientists and oral and e poster presentations by participants in selected topics from the submitted abstracts focusing on Agriculture, Biology and Life Sciences topics.

With care for our nature and environment, we aim the green congress, meaning that as little as possible papers will be used. Abstract book is published in electronic book and is distributed to the participants by e mail for online participants. All the e-posters are prepared in electronic form and then submit to via the conference e mail and exhibited in electronical poster boards as well as in online e poster hall in our web page during the conference.

The participants with paid conference fee accesssed all the normal and virtual presentation talks in each session, as well as to visit the virtual poster hall via preliminary provided. The abstracts were published in the Conference Abstract and Proceedings Book. Participants might send us their full papers, which based on their preferences are published either in our Conference Abstract and Proceedings Book or in selected International Indexed Scientific Journals.

Conference Topics:

Agriculture, Forestry, Life Sciences, Agricultural Engineering, Aquaculture and Biosystems, Animal Science, Biomedical science, Biochemistry and Molecular Biology, Biology, Bioengineering, Biomaterials, Biomechanics, Biophysics, Bioscience, Biotechnology, Botany, Chemistry, Chemical Engineering, Earth Sciences, Environmental Science, Food Science, Genetics and Human Genetics, Medical Science, Machinery, Pharmaceutical Sciences, Physics, Soil Science.

We would like to thank all of you for joining this conference and we would like to give also special thanks to our sponsors and collaborators for giving us a big support to organize this event.

Prof Dr Yalcin KAYA
Head of the Organizing Committee

ABSTRACT

In addition to being low in calories, mushrooms are important natural sources of essential fatty acids, protein, vitamins and minerals, which, taken together, make them an important part of a healthy diet. Used as a nutritious food, many mushroom species are specially collected and used in cooking in many parts of the world. *Hohenbuehelia petaloides* (Bull.) Schulzer (*Pleuroteceae*) is an edible tree mushroom that is naturally distributed in Türkiye. While apoptosis is a programmed cell death, necrosis and autophagy occur when cells are under stress. One of the effective measures for tumor suppression is to reconstruct the signal transduction system of tumor cell apoptosis and induce cancer cell apoptosis. This study aimed to determine whether *H. petaloides* hexane extract (IC_{50}= 93.95± 0.02 µg/mL) induces apoptotic cell death in HT-29 and to determine the amount of cells in the division phase. 300 g dried mushrooms were extracted with hexane then apoptosis and cell cycle analysis were investigated in HT-29 by flow cytometry using ModFit LT according to Yilmazer 2011 method. According to the flow cytometry analysis performed to determine the amount of cells in the division phase, it was determined that the hexane extract of *H. petaloides* induced apoptosis in HT-29 in 24 hours ($2xIC_{50}$ = 42.5%) in parallel with the increase in concentration. Cell cycle analysis, it was found that the number of cells in the G1 phase (IC_{50} concentration 4.42% and 2x IC_{50} concentration 16.76%) increased and the number of cells in the S and G2 phases (IC_{50} concentration 5.41%, and 2x IC_{50} concentration 16.85%) decreased in HT-29 cells at 24 hours as the doses of hexane extract increased compared to the control. In conclusion, *H. petaloides* hexane extract at 2x IC_{50} concentration induces Q2 stage apoptosis in HT-29, leading to the arrest of HT-29 at G1 stage of the cell cycle.

Keywords: *Hohenbuehelia petaloides*, colon cancer cell line, HT-29, apoptosis, cell cycle

INTRODUCTION

While apoptosis is a programmed cell death, necrosis and autophagy occur when cells are under stress. When the apoptosis mechanism is inhibited, excess cells cannot be eliminated by cell death and malignant tumour cells are produced. Therefore, one of the effective measures to suppress tumour is to reconstruct the signal transduction system of tumour cell apoptosis and induce cancer cell apoptosis (Liu et al., 2022). The first application is to analyse the cell cycle by determining the amount of DNA in the cell. The amount of DNA in the cell can be stained with various dyes and the binding of dyes is related to the amount of DNA in the cell. Therefore, flow cytometry can be used to determine the number of cells in each division phase. Diploid cells are in the G0 /G1 phase, while the DNA content of cells in the S (synthesis) phase is between diploid and tetraploid cells. Cells in G2 and Mitosis are observed as tetraploid since they carry DNA in the amount of 4n (Anev and Muranlı 2016). Cells in S+G2+M phase are defined as S Phase Fraction (SPF) and high SPF is an indicator of high proliferation rate (Martinez et al., 1990). Fragmented DNA can be seen in the sub-G1 phase. In the histogram obtained, it is seen to the left of this peak separately from the G0-G1 peak (Kanev and Muranlı., 2016).

Mushrooms are important natural sources of healthy nutrition due to their low calorie content, essential fatty acids, protein, vitamins and minerals. Used as a nutritious food, many mushroom species are specially collected and used in many parts of the world (Duru and Çayan 2015; Park et al., 2024). *Hohenbuehelia petaloides* (Bull.) Schulzer is a member of the *Pleuroteceae* family and is an edible tree mushroom naturally distributed in Türkiye (Sesli et al., 2020). In HT-29, hexane extract showed no toxicity at 24 and 48 hours (IC $_{50}$>200 µg/mL) and showed cytotoxic activity at 72 hours with IC_{50}= 93.95± 0.02 µg/mL (Korkmaz et al., 2024). So that ın this study, flow cytometry analysis was performed to determine whether *H. petaloides* hexane extract (IC_{50}= 93.95± 0.02 µg/mL), which showed cytotoxic effect in HT-29 cell line, induced apoptotic cell death.

MATERIAL AND METHOD

1. Mushroom Material

The edible species *Hohenbuehelia petaloides* (Bull.) Schulzer was freshly collected from *Dichondra pepens* L. and woody tree remains in a mixed forest of *Pinus brutia* L., *Pinus pinea* L. and *Phoenix theophrasti* Greuter trees in Datça Turkey. The fungarium material was deposited in the Natural Products Laboratory of Muğla Sıtkı Koçman University under the code CK010.

2. Mushroom Extract

300 g of dried mushrooms were extracted with hexane under room conditions (24 h x 3 times) system in the solvent system. Solvents were removed in a rotary evaporator.

3. Investigation of Apoptosis By Flow Cytometry

In this study, flow cytometry analysis was performed to determine whether *H. petaloides* hexane extract (IC_{50}= 93.95± 0.02 µg/mL) induced apoptotic cell death in HT-29 cell line (Korkmaz et. al., 2024). The eBioscience™ Annexin V-FITC Apoptosis Detection Kit (Thermo Fisher Scientific, 88–8007-72) was used to determine apoptosis by flow cytometry (Alper and Guneş 2020). HT-29 cells were seeded in 6-well plates at 5×10^5 cells/well. Cells were treated with concentrations of $2xIC_{50}$, IC_{50} and $IC_{50/2}$ values of *H. petaloides* hexane extract. Apoptotis effects of HT-29 cells were analyzed by flow cytometry (BD FASCanto A, BD Biosciences, BD FACSDiva software v6.13). Apoptotic, late apoptotic, viable and necrotic cells were quantitatively determined by flow cytometry.

4. Cell Cycle Analysis by Flow Cytometry

Concentrations of *H. petaloides* hexane extract (IC_{50}= 135.45±0.06 µg/mL) at $2xIC_{50}$, IC_{50} and $IC_{50/2}$ were applied for 24h. Samples were stored at − 20 °C for at least 24 h, then centrifuged at 12,000 rpm for 10 min, and the pellets were washed in cold 5-mL PBS. Cell pellets were then dissolved in PBS containing 0.1% Triton-X. Twenty-microliters of RNase A (200 µg/mL) was added to each pellet and incubated at 37 °C for 30 min. After incubation at room temperature for 15 min, readings were completed using the ModFitLT 30 program related to flow cytometry. According to method Yılmazer 2011, readings were completed using the ModFitLT 30 program related to flow cytometry.

RESULTS AND DISCUSSION

In this study, flow cytometry analysis was performed to determine whether *H. petaloides* hexane extract (IC_{50}= 93.95± 0.02 µg/mL), which showed cytotoxic effect in HT-29 cell line, induced apoptotic cell death. Apoptosis percentages and necrosis were determined by calculating FITC-labelled Annexin V binding and the amount of PI binding to DNA. In addition, cell cycle analysis was performed with flow cytometer to determine the amount of cells in which division phase of the cells. According to in vitro findings, *Pleurotus flabellatus* lectin (IC_{50} ranges of 67 µg/mL) significantly reduced apoptosis induction in HT-29 cell line (Murugesan et al., 2023).

Sherr (1999) reported that the mammalian cell cycle is divided into 4 separate phases: G1, S, G2, and M phases. During G1 phase, cells respond to extracellular signals by either advancing toward another division or withdrawing from the cell cycle into a resting state (G0). Ethanol extract of *Inonotus obliquus* (Chaga mushroom) was reported to cause G1 cell cycle arrest in HT-29 human colon cancer cells (Lee et al., 2015). In the other study the anticancer property of lentinan on colon and gastric cancer cell lines through inhibition of the G2/M phase in the cell cycle has been reported (Park et al., 2024).

In this study according to the results of flow cytometry analysis when analysed Table 1, performed to determine the amount of cells in the division phase, it was determined that the hexane extract of *H. petaloides* induced apoptosis in HT-29 in 24 hours (2xIC_{50} = 42.5%) in parallel with the increase in concentration (Figure1). When analysed cell cycle analysis, it was found that the number of cells in the G1 phase (IC_{50} concentration 4.42% and 2x IC_{50} concentration 16.76%) increased and the number of cells in the S and G2 phases (IC_{50} concentration 5.41%, and 2x IC_{50} concentration 16.85%) decreased in HT-29 cells at 24 hours as the doses of hexane extract increased compared to the control (Figure 2-5). In conclusion, *H. petaloides* hexane extract at 2x IC_{50} concentration induces Q2 stage apoptosis in HT-29, leading to the arrest of HT-29 at G1 stage of the cell cycle.

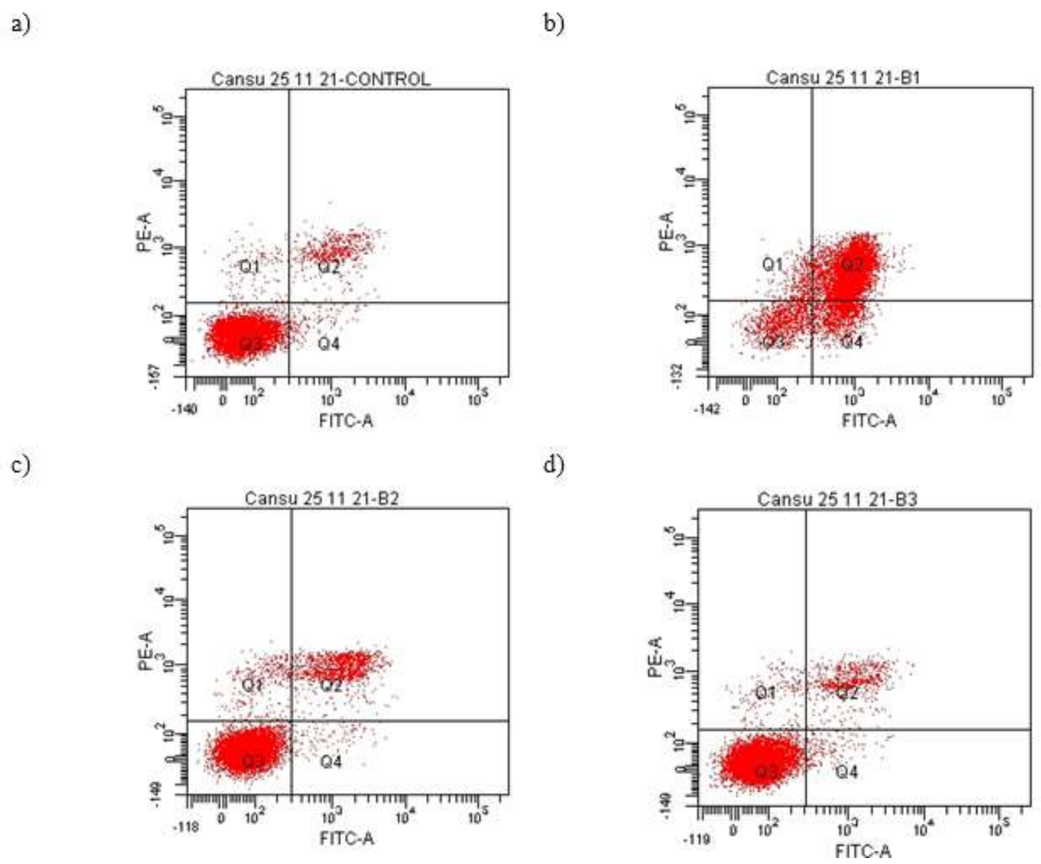

Figure 1. Flow cytometric analysis of HT-29 cells exposed to *H. petaloides* hexane extract concentrations for 24 hours a) control b) 2x IC_{50}: B1 c) IC_{50}: B2 ve d) IC $_{50}$ ½: B3

Table 1. HT-29 cell cycle by ModFit LT programme according to the concentration of *H. petaloides* hexane extract at 2x IC_{50} value

	HT-29 population (%)				
İnkübation time / Extract		Viable Cell (Q3)	Early Apoptosis (Q4)	Late Apoptosis (Q2)	Necrosis (Q1)
24 h / Hexane	**2xIC50**	42.6	7.1	**42.5**	7.8
	IC_{50}	90.4	2.3	6.5	0.8
	IC_{50} 1/2	86	4.7	8.3	1.0
24 h / -	Control	86.9	2.5	10.3	0.3

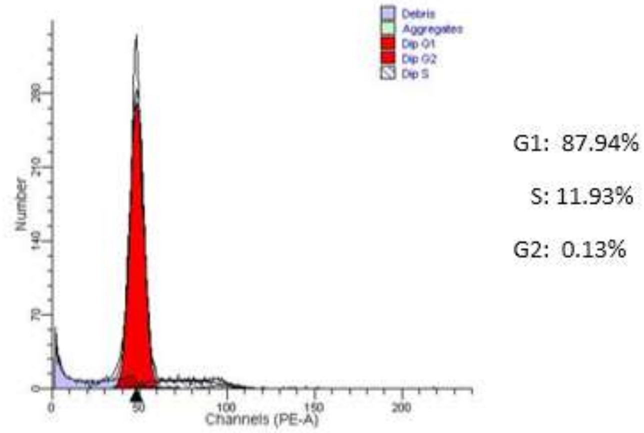

Figure 2. HT-29 cell cycle by ModFit LT programme according to the concentration of *H. petaloides* hexane extract at 2x IC_{50} value

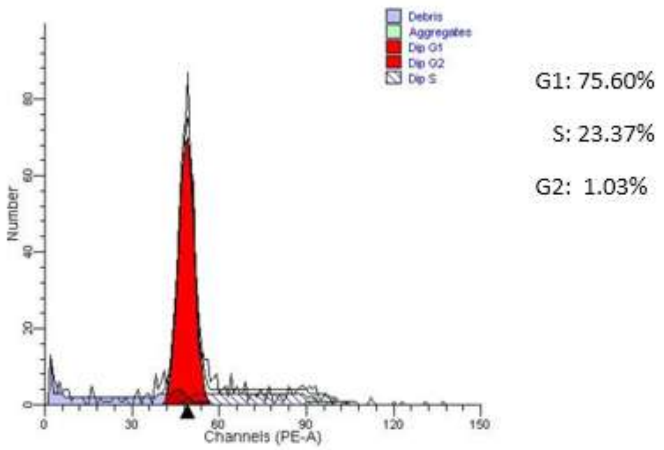

Figure 3. HT-29 cell cycle with ModFit LT programme according to the concentration of *H. petaloides* hexane extract at IC_{50} value

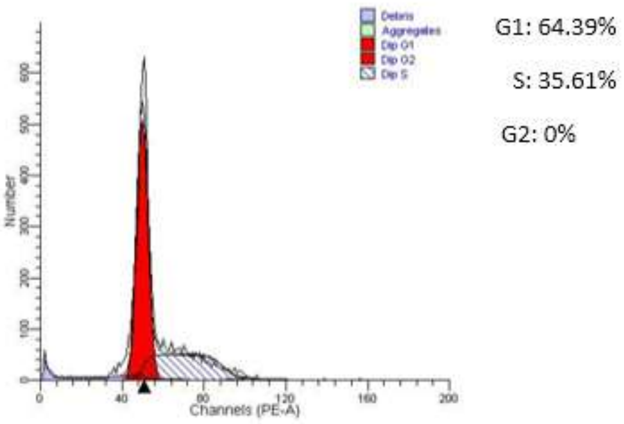

Figure 4. HT-29 cell cycle by ModFit LT programme according to the concentration of *H. petaloides* hexane extract at IC_{50} ½ value

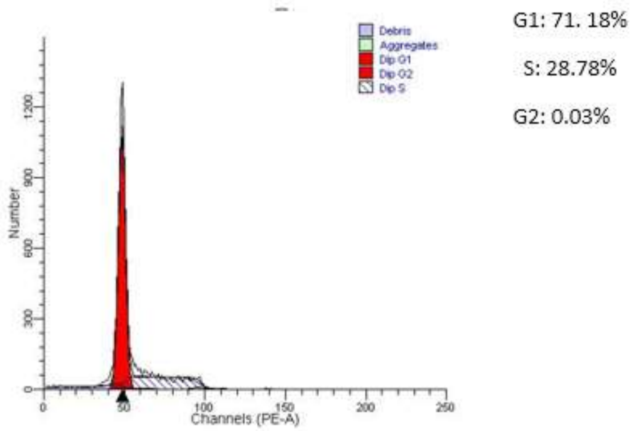

Figure 5. Cell cycle of HT-29 control group with ModFit LT programme

CONCLUSIONS

In conclusion, it was determined that the hexane extract of *H. petaloides* induced apoptosis in HT-29 in 24 hours ($2xIC_{50}$ = 42.5%) in parallel with the increase in concentration. *H. petaloides* hexane extract at 2x IC_{50} concentration induces Q2 stage apoptosis in HT-29, leading to the arrest of HT-29 at G1 stage of the cell cycle. These results shed light on the future for its further use in in vivo and in vitro cancer studies.

ACKNOWLEDGEMENT

This study was supported by Muğla Sıtkı Koçman University Scientific Research Projects Unit (BAP) with the project number 21/129/02/1/4. The authors would like to thank "YÖK 100/2000 Natural and Herbal Products/ Cosmetic" programs for providing PhD scholarship to Cansu Korkmaz. We would also like to thank TUBITAK (BIDEB 2211-A) and BIDEB 2250 projects for their support to Cansu Korkmaz.

DETERMINATION OF GENETIC DIVERSITY IN SOME MELON VARIETIES USING PEROXIDASE GENE MARKERS

*Seher TOPRAK, Ömer Faruk COŞKUN**

[1]*Hatay Mustafa Kemal University, Faculty of Agriculture, Department of Horticulture, Hatay, Türkiye*

ABSTRACT

Melon is one of the most important summer vegetables produced widely in the world. Many local melon genotyp and commercial varieties are used in cultivation in the world. The success of melon breeding is based on the existence of sources with high genetic diversity, the characteristics of the genetic material and the creation of combinations with the desired characteristics. Genetic characterization of plant material is the most important step of this process. In this study, 14 specific peroxidase gene (POX) primers were used to determine peroxidase gene polymorphism (POGP) in 12 melon genotyp. In the study, 244 of the 259 bands obtained from 14 POX primers were found to be polymorphic. The average polymorphism was 94.4% and the number of bands varied between 13 and 26. The similarity coefficient range of the genotyp varies between 0.30 and 0.90. The genotyp that are genetically closest to each other are number 2 genotyp and number 3 genotyp, while the most distant genotyp are genotyp 1 and 10. The findings obtained from the current study show that there is genetic variation among the melon genotyp examined. The obtained data will enable the melon genotyp with genetic differences to be used more effectively in future breeding programs.

Keywords: *Cucumis melo*, genetic characterization, melon, POGP, POX, UPGMA

INTRODUCTION

Melon is an important cucurbit vegetable that can be produced intensively in tropical and subtropical plants. The origin of melon is probably from Northeast Africa (Swamy, 2017). Melon, which has become an important product in the global market, provides a delicious addition to the cuisines of many countries (Maietti et al., 2012; Manchali et al., 2021). Melon products can cover more than 1 million hectares of land in the world and provide a yield of 28.6 million tons (FAOSTAT, 2022). China ranks first with approximately 14 million tons, and Türkiye ranks second with 1.6 million tons. Melon (*Cucumis melo* L., 2n = 2x = 24), belonging to the Cucurbitaceae family, has a small diploid genome size of 450 Mb (Garcia-Mas et al., 2012). Melon, which has a wide variety and genotypes in the world, shows high levels of features in morphological, characteristic and biochemical properties (Pitrat, 2016).

Changing consumer demands increase the necessity of carrying out new breeding studies in melon. Characterization studies have an important place in a development program of variety. Characterization studies using morphological and biochemical markers are not sufficient due to the effects of the environment. For this reason, the importance of analyzing genomic variation is increasing. DNA sequence differences can be revealed in determining genetic similarities and differences. Marker techniques based on PCR techniques have been used for molecular characterization purposes (Zhang et al., 2016; Karaman et al., 2018; Aslan et al., 2021; Coşkun, 2022). Peroxidase isoenzymes are found in different ratios in many plants. Peroxidases play a role in biotic and abiotic stress conditions in plants (Passardi et al., 2005; Gulsen et al., 2010). Peroxidase gene-based markers (POX) have been used successfully for genetic characterization in some plant species (Gulsen et al., 2010; Uzun et al., 2014).

Genotyping and genetic diversity determination studies can be carried out reliably and rapidly using markers. High-performance genotypes with desired characteristics can be detected in early generations thanks to molecular markers. When the literature is examined, it is seen that genetic characterization studies conducted on melon are insufficient. This study aims to determine the genetic diversity of some melon genotypes using POX markers.

MATERIALS AND METHODS

This study was carried out in the greenhouse and genetic laboratory of the Department of Horticulture, Faculty of Agriculture, Hatay Mustafa Kemal University. The melon genotypes previously collected from producers and listed below were used as genetic material.

DNA isolation from young melon leaf samples was performed by the CTAP technique. The operating conditions of the PCR device were optimized as follows. A total volume of 15 µl contained 1.5 µl 10X PCR buffer, 1.33 mM primer, 200 µM each dNTP (dATP, dGTP, dCTP and dTTP), 2.5 mM MgCl2, 1 unit of taq DNA polymerase enzyme, 20 ng DNA and 4.3 µl ddH2O. DNA. Cycling parameters included one cycle of 3 min at 94 ◦C, 34 cycles of 1 min at 94 ◦C, 1 min at 40–53 ◦C, 2 min at 72 ◦C, and for final extension one cycle of 5 min at 72 ◦C. 14 pairs of ISSR primers were used in the studies. The resulting mixture was loaded onto a 2% agarose gel and run for 4 hours under 115 V electric current. After the electrophoresis process, the gels were taken to the gel imaging unit and the gel images were recorded on the computer under UV. Each of the bands displayed on the agarose gel was recorded as ‘’1’’, ‘’0’’ or ‘’9’’, with 1 indicating the presence of the band, 0 indicating the absence of the band, and 9 indicating bands that could not be evaluated. The total number of bands, the number of polymorphic bands, and the polymorphism rates were determined for each primer combination. The obtained data were analyzed in the NTSYS (Numerical Taxonomy Multivariate Analysis System, NTSYS-pc version 2.1, Exeter Software, Setauket, N.Y.,) USA computer package program. Similarity indices were calculated according to the Dice method and dendrograms were created according to the UPGMA (Unweighted Pair-Group Method With Arithmetic Average) method.

RESULTS AND DISCUSSION

DNA data were obtained in melon genotypes using fourteen pairs of POX markers. In total, 14 pairs of POX primers were used for genetic characterization in 12 melon genotypes. A total of 259 bands and an average of 18.5 bands per primer were obtained. A total of 244 polymorphic bands and an average of 17.43 per primer were determined. The total number of bands per primer varied between 13-26 and the highest number of bands were obtained from the POX-5 primer (26 bands). The number of polymorphic bands in the primers varied between 14-24 and the highest number of polymorphic bands were obtained from the POX-12 primer (24). The polymorphism rate varied between 83.3-100% and the average was calculated as 94.4%. The band range was determined between 110-1640 in all primers.

In this study, it can be evaluated that POX-2, POX-7, POX-8, POX-11, and POX-14 primers are more effective in terms of polymorphism rate in melon genotypes investigated. A 100% polymorphism rate was obtained from these primers. According to the Dice similarity index, similarity coefficient values between genotypes were determined between 0.3007-0.9630. The most distant genotypes are genotype number 1 (genotype taken from Şanlıurfa province) and genotype number 10 (genotype taken from Hatay province) with a similarity coefficient of 0.3007. The closest genotypes are genotypes number 2 and 3 (genotypes taken from Diyarbakır province) with a similarity coefficient of 0.9630.

Table 2. Primer name, primer sequence, numbers of bands, and percentage of polymorphism detected by POX.

In the UPGMA dendrogram, similarity rates vary between 0.46 and 0.96. In the dendrogram, it is seen that genotypes numbered 1 and 5 are clustered separately from the others. Among the remaining genotypes, genotypes numbered 10 and 4 are clustered separately, respectively. It is seen that the remaining 8 genotypes are gathered in a similar cluster. It is possible to state that these genotypes are separated into 3 subclusters. Genotypes numbered 2 and 3 form the first subcluster, genotypes numbered 6, 7, 8 and 9 form the second subcluster and genotypes numbered 11 and 12 form the third cluster. The genotypes clustered closest to each other in the dendrogram are genotypes numbered 2 and 3, as in the Dice similarity index (Figure 1).

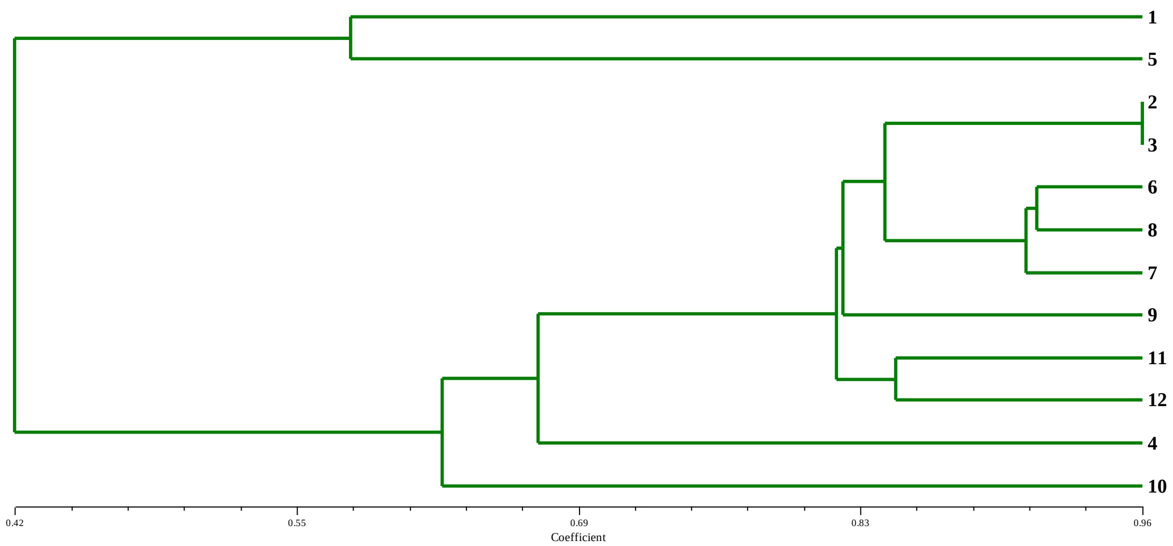

Figure 1. Dendrogram obtained from UPGMA (Unweighted Pair-Group Method with Arithmetic mean) cluster analysis using the Dice coefficient.

Molecular markers are used to direct the genetic potential of plants following breeding purposes. Molecular markers are used in selection, genetic characterization (Toprak et al., 2023), relationship mapping studies (Coskun, 2023a), and genotoxicity studies (2023b). Scorable bands were obtained in all peroxidase gene polymorphism (POGP) primers used in this study. A total of 259 bands were obtained in 12 melon genotypes used with POGP primers.

It was observed that 244 (94.4%) of the 259 bands were polymorphic. Peroxidase gene polymorphism (POGP) bands observed in the investigated melon genotypes showed polymorphism between 83.3% and 100%.

In some previous studies, genetic characterization was determined in melon genotypes. For this purpose, RAPD primers (Nhi et al., 2010), ISSR primers (Guliyev et al. 2018), AFLP primers (Garcia-Mas et al. 2000), SSR primers (Danin-Poleg et al. 2001) were used. In a study, genetic diversity determination study was carried out using 13 SSR markers in melon genotypes and an average of 5.31 alleles per locus was obtained (Solmaz et al., 2016). Yıldız et al. (2011) examined the polymorphism percentage in 63 melon genotypes using different molecular markers and reported that genetic similarities within the group varied between 0.46 and 0.96. In this study, genetic similarity coefficients were determined with POX primers with a wider range (0.3007-0.9630). Chen et al. (2010) determined 265 polymorphic bands in 61 melon genotypes using SRAP primer combinations. Kohpayegani and Behbahani (2008) determined 87% polymorphism in Iranian melon genotypes with 15 SSR markers. In this study, a 94.4% polymorphism rate was obtained using POX primers. In another study, the ISSR marker technique was used in melon genotypes. The polymorphism rate obtained from ISSR primers was 36.3%. Similarity coefficients between genotypes also varied between 0.90 and 0.99 (Coskun and Bozdağ, 2024). When compared with other polymorphism determination studies on melon, it can be said that peroxidase gene polymorphism (POGP) markers are more effective in determining polymorphism in this plant species.

Türkiye is one of the most important countries in the world in terms of plant genetic resources. However, genetic resources are in danger of extinction due to significant changes in ecology, increased monoculture cultivation, irregular construction and human mobility. The protection of these resources is essential to ensure future plant production. For this purpose, it is very important to identify our rich genetic resources. In this study, the genetic characterization of some melon genotypes was determined using the POX marker technique and important data were obtained for breeding studies.

ABSTRACT

Tomato (*Solanum lycopersicum*) is among the most produced and consumed annual vegetables worldwide. The rich nutritional content of tomato makes it a foodstuff that attracts consumers' attention. Tomato, which is an important foodstuff in terms of both health and economy, is used as a model organism in studies. In this study, 14 specific peroxidase gene (POX) primers were used to determine peroxidase gene polymorphism (POGP) in 12 tomato genotyp. In the study, 127 of the 192 bands obtained from 14 POX primers were found to be polymorphic. The average polymorphism rate was 65.9% and the number of bands varied between 9 and 18. The similarity coefficient range of the genotyp varied between 0.74 and 0.97. According to the UPGMA dendogram, the closest genotyp are determined as the number 7 genotyp and number 8 genotyp, while the most distant genotyp are the number 3 genotyp and number 5 genotyp. The findings obtained from the current study show that there is genetic variation among the domates genotyp examined. The obtained data will enable the domates genotyp with genetic differences to be used more effectively for future breeding programs.

Keywords: Molecular characterization, POX, POGP, *Solanum lycopersicum*, Tomato

INTRODUCTIONS

Tomato (*S. lycopersicum* L.) is one of the most cultivated vegetable species in the world. According to FAO data, tomato production in 2021 had a production capacity of over 189 million tons (FAO, 2024). Tomato fruits are an important source of minerals and vitamins for human nutrition (Tieman et al., 2017). Although tomato production is increasing worldwide, difficulties such as improving quality, tolerance and resistance may arise (Hochholdinger and Baldauf, 2018). To meet the consumption requirement, it is necessary to develop yield, high-quality, disease-resistant tomato varieties (Hickey et al., 2019). Hybrid varieties mostly provide tomato cultivation in the world. Parental characters are of great importance in terms of hybrid variety breeding. Heterosis power mainly depends on the genetic structure and heterogeneity of the parents (Liu et al., 2021). The way to identify different parental characters is to have a good genetic resource pool. In modern cultivated tomatoes, genetic narrowing has increased due to breeding studies (Blanca et al., 2015). Therefore, the characterization of local tomato genotypes may be important for breeding studies. Tomato landraces are intermediate products of the breeding process (Mavromatis et al., 2013).

Determining the genetic structures of plant genotypes is important in plant breeding and new variety development studies. Unlike morphological and biochemical markers, the fact that molecular markers are not affected by environmental conditions is important for obtaining the correct answer. Many marker techniques have been used in genetic characterization studies in vegetables (Karaman et al., 2017; Morilipinar et al., 2021; Coskun, 2023). Genetic characterization studies have been conducted in tomato with PCR-based marker techniques before (Tam et al., 2005; Benor et al., 2008; Aguilera et al., 2011; Ibrahım and Erdinç, 2020). Peroxidase enzymes are important in the stress response of plants. Higher diversity can be found in peroxidase gene sequences among plant genotypes (Zhang et al., 2001). POGP markers have been used to determine genetic diversity in some plant species (Ceylan et al., 2014).

Although tomato is one of the most preferred plant species in genetic studies, the discrimination power of POX primers in tomato is not known sufficiently. Studies conducted to determine molecular diversity of POPG markers in tomato genotypes are not sufficient. The aim of this study is to determine the genetic diversity of 12 different local tomato genotypes using POGP markers.

MATERIALS AND METHODS

Twelve tomato genotypes collected from Hatay and its surroundings were used as material (Table 1). DNA was isolated from young tomato leaves according to the CTAB protocol (Doyle and Doyle, 1987). DNA quantity and quality were determined by agarose gel method. 14 pairs of POPG primers were used in this study (Table 2).

The reaction mixture (15 ml) contained 30 pmol of each primer pairs, 200 mM of each of dNTPs, 2.5 mM of MgCl2 as a final concentration, 1 unit of Taq polymerase and 25 ng of template DNA. PCR amplification included a denaturing stage at 94 ˚C for 2 minutes, followed by 34 cycles denaturing step at 94 ˚C for 1 minutes, an annealing step at a temperature according the melting temperature of each primer for 2 min and an extension step at 72 ˚C for 2 minute, one cycle of 5 min at 72 C. PCR products were separated on 2 % agarose gel at 110 V for 5 h, stained with Ethidium Bromide and visualized and 1, 0 and 9 data were obtained. Clustering analyzes were performed using NTSYS (Numerical Taxonomy Multivariate Analysis System, NTSYS-pc version 2.1, Exeter Software, Setauket, N.Y., USA) package program (Rohlf, 2000).

Similarity indexes between individuals were calculated according to the DICE method (Dice, 1945). UPGMA (Unweighted Pair Group Method with Arithmetic Mean) dendrogram based on DICE similarity matrix.

RESULTS AND DISCUSSION

In this study, the effectiveness of some POPG markers in local tomato genotypes was determined and genetic characterization study was carried out. In the study carried out with fourteen pairs of POPG primers, a total of 192 bands were obtained and 127 of them were found polymorphic. The polymorphism rate varied between 26.7% and 100% and the average was determined as 65.9% (Table 2).

Table 2. Polymorphism and Band Information Obtained from POX primers

Primer Name	Primer Sequences (5’--3’)	Number of Polymorphic Band	Number of Total Band	Polymorphism Rate (%)

Total		127	192	
Mean		9.07	13.71	65.9

The number of polymorphic bands varied between 3 and 13 and the average was determined as 9.07. The total number of bands varied between 9 and 18 and the average was determined as 13.71. The highest total number of bands was obtained from POX10 primer (18), the lowest total number of bands was obtained from POX8 and POX3 primers (9). The lowest number of polymorphic bands was obtained from POX8 primer (3), and the highest number of polymorphic bands was obtained from POX2, POX4, POX9, POX12 and POX14 primers (13). While the lowest polymorphism rate was determined in POX6, the highest polymorphism rate was obtained from POX4 and POX11 primers with 100% (Table 2).

The similarity coefficients determined according to the DICE similarity index using the NTSYS program were determined between 0.74 and 0.94. The closest genotypes to each other are genotypes 7 and 8 with a similarity coefficient of 0.97. Also, genotypes 7 and 9 are the closest to each other with a similarity coefficient of 0.97. The farthest genotypes to each other are genotypes 5 and 6 with a similarity coefficient of 0.74.

Table 3. Similarity coefficient values among tomato genotypes according to dice similarity index

	1	2	3	4	5	6	7	8	9	10	11	12
1	1.0											
2	0.93	1.0										
3	0.87	0.91	1.0									
4	0.91	0.93	0.88	1.0								
5	0.77	0.81	0.76	0.76	1.0							
6	0.85	0.88	0.80	0.88	0.74	1.0						
7	0.92	0.94	0.87	0.91	0.83	0.90	1.0					
8	0.90	0.92	0.86	0.90	0.81	0.89	0.97	1.0

10	0.89	0.90	0.82	0.90	0.75	0.88	0.92	0.91	0.93	1.0		
11	0.91	0.92	0.83	0.87	0.80	0.84	0.92	0.92	0.93	0.90	1.0	
12	0.91	0.91	0.83	0.91	0.77	0.88	0.92	0.92	0.92	0.94	0.93	1.0

In the UPGMA dendrogram made according to the DICE similarity index, 3 main clusters were formed. The first cluster included genotypes 1, 2 and 4; the second cluster included genotypes 7, 8, 9, 10, 11 and 12. Genotypes 6, 3 and 5 were clustered further away from these genotypes, respectively. In the clustering analyses, it was determined that genotype number 5 was separated from the others with a similarity rate of 0.78.

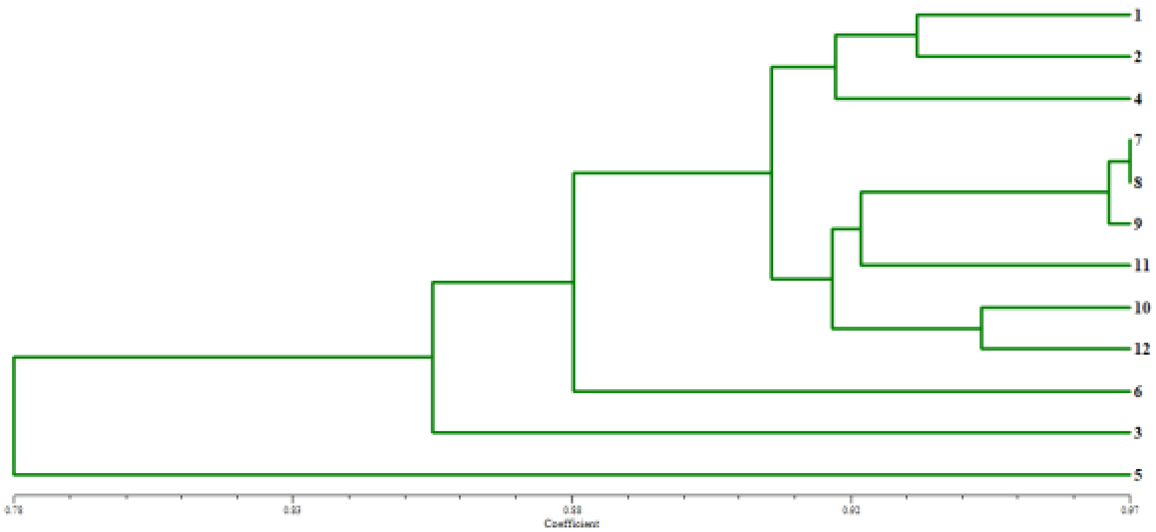

Figure 1. Dendrogram obtained by using the similarity indices obtained from POPG data in the SHAN module.

Many molecular studies have been conducted on tomatoes in the world and in Türkiye, and tomatoes have been used as a model plant. Tomatoes are grown locally in many cities in Türkiye. After long-term cultivation, the number of local populations has increased. Determining the characteristics of genetic resources is important for the preservation of genetic resources and their use in breeding. Hatay is an important city where local tomato genotypes are found. Studies determining the genetic differences of tomato genotypes collected from this city are few. Determining the genetic structure of Hatay tomato genotypes is important for breeding studies. The genetic diversity study in Hatay tomato genotypes was previously determined using the ISSR marker technique (Coskun and xxxx., 2024). With this study, the effectiveness of POX primers was determined for the first time in this material.

Villand et al. (1998) determined the genetic structure among 96 genotypes by obtaining 98 polymorphic RAPD markers from 41 RAPD primers. Benor et al. (2008) detected a total of 150 alleles using 35 different SSR polymorphic markers to determine the genetic diversity of 39 tomato lines. Kwon et al. (2009) obtained 132 polymorphic bands with 33 SSR markers in 63 different commercial tomato cultivars. Kaushal et al. (2017) detected 22 SSR alleles using twenty different SSR markers. Castellana et al. (2020) obtained 60 alleles using SSR markers in 121 tomato genotypes. In his study, Öztürk (2022) conducted a genetic characterization study using the ISSR technique on 24 tomato genotypes and determined the average polymorphism rate as 80%. In this study, an average polymorphism rate of 65.9% was detected with POX primers. In a study, the genetic similarity coefficient between tomato genotypes was determined between 0.56 and 0.95 using the ISSR marker technique (Terzopoulos and Bebeli, 2008). In the study conducted by Al-Shaal et al. (2021), the average genetic similarity coefficient in tomato genotypes was determined as 0.79 using ISSR markers. In this study, the genetic similarity coefficient was determined between 0.74 and 0.94.

When the literature was examined, it was determined that the use of SSR markers from PCR techniques in tomatoes has increased in recent years and that they can distinguish polymorphism. In this study, it was determined that genetic diversity can be distinguished with POX primers in tomatoes. In this study, the polymorphism rate was found to be similarly high. Local tomato genotypes are grown in many locations in Türkiye. It is important to characterize tomato genotypes with marker techniques. Different marker techniques may be more advantageous in genetic characterization. As a result of this study, it can be concluded that there is genetic diversity among tomato genotypes and that the POPG marker technique can be used due to its ability to show polymorphism. The results of this study provide important information to improve the characteristics of new varieties in tomato breeding programs.

GROWTH, MORTALITY AND YIELD OF OHRID TROUT STOCK IN LAKE OHRID

Valbona KOLANECI[1], Marsida BLLACA[1]

Agricultural University of Tirana, Faculty of Agriculture and Environment Department of Aquaculture and Fisheries, Tirana, Albania

Corresponding author e-mail: vkolaneci@ubt.edu.al

ABSTRACT

The fish fauna of Lake Ohrid stands out as one of Europe's most diverse and abundant. This ancient lake harbors seventeen native fish species, among them the endemic Ohrid trout (*Salmo letnica*) and belushka/belvica (*Salmo ohridanus*). In 2022, inland waters fishery production in Albania totaled 3,388 tons, with Lake Ohrid contributing an estimated 155.5 tons. Of this, 93 tons were Ohrid trout catch. While the Lake's production may seem modest compared to Albania's total fishery production of 17,799 tons (including marine, inland waters, and aquaculture) for the same year, it is of significant local importance. The fishery constitutes the primary source of income for many families in the fishing villages along the Albanian part of Ohrid lakeshore. Despite the control measures implemented over the past decade to manage the exploitable fish stocks of Lake Ohrid, the lake's fish populations have faced various stressors, including pollution, habitat degradation, and invasive species, in addition to overfishing. Furthermore, the Ohrid trout is being exploited without sufficient knowledge of its stock status. The IUCN Red List of Threatened Species lists the Ohrid trout as Data Deficient. This study aims to provide an initial assessment of the condition and productivity of the Ohrid trout stock in Lake Ohrid. Growth parameters were calculated using length at age analysis of fish collected by the local small-scale fishery, while the total mortality rate was estimated through length-converted catch curve analysis. Stock production was predicted using the model developed by Beverton and Holt and adapted for FiSAT II (2005). The growth of the Ohrid trout population was expressed using the total length-based function L_t=68.0*(1-$e^{-0.21*(t+0.01)}$). The total mortality rate was estimated at M=0.76 yr^{-1} and the exploitation rate at E=0.51 yr^{-1}. The model's predicted production indicates that the Ohrid trout stock is currently exploited at maximum sustainable yield. Maintaining the same exploitation rate while increasing the length at first capture to 32 or 35 cm would increase the stock's relative yield per recruit (Y'/R) by 0.035. Implementing the national fishery regulation on minimum size at first catch for Ohrid trout would not only ensure sustainable productivity but also support population growth.

Keywords: Ohrid trout, growth, mortality, stock.

INTRODUCTION

Lake Ohrid, located on the border between Albania and North Macedonia, is a significant freshwater lake renowned for its natural values, large number of habitats, rich biodiversity and its indisputable cultural and historical assets. The Lake is home is home to indigenous species, including its trout species (*Salmo letnica* and *Salmo ohridanus*) which are key components of its unique aquatic ecosystem and making it a critical site for trout fisheries in the region (Spirkovski & Talevski 2002, Spirkovski et al., 2017; Bllaca & Kolaneci, 2023). Trout fishery is an important economic activity for the communities around Lake Ohrid, offering a significant source of income and sustaining the livelihoods of many families, especially those residing in the fishermen villages along the lakeshore.

In 2022, inland waters fishery production in Albania totaled 3,388 tons, with Lake Ohrid contributing an estimated 155.5 tons (INSTAT, 2023). Of this, 93 tons were Ohrid trout (Bllaca & Kolaneci, 2023). While the Lake's production may seem modest compared to Albania's total fishery production of 17,799 tons (including marine, inland waters, and aquaculture) for the same year (INSTAT, 2023), it is of significant local importance. The fishery constitutes the primary source of income for many families in the fishing villages along the Albanian part of Ohrid lakeshore. The fishery activities within the Albanian border of Lake Ohrid are typically family-operated. There are 220 boats, with engines ranging from 3.5 to 15 horsepower, holding fishing permits. The primary fishing gear used includes nets (ranging from 500 to 1000 meters in length, with mesh sizes from 26-32 mm to 45-90 mm) and hook lines (50 meters in length with up to 150 hooks) (Bllaca & Kolaneci, 2023). To support the Ohrid trout fishery, the Lake is regularly stocked with fingerlings. This supplementation aims to maintain or increase trout populations, counteracting the impacts of fishing and natural mortality (Spirkovski et al., 2017, INSTAT, 2023). However, there is no monitoring in place to ensure that the stocking and fishing practices do not exceed the lake's ecological capacity.

Despite the implementation of control measures over the past decade to manage the exploitable fish stocks in Lake Ohrid, the lake's fish populations are facing various stressors. These include pollution, habitat degradation, invasive species, and overfishing (Kostoski et al., 2010; Spirkovski et al., 2017; Schöffmann & Marić, 2023). These studies emphasizes that the population structure and health of Ohrid Trout are crucial indicators of the lake's overall ecological status. Moreover, the exploitation of Ohrid trout in Lake Ohrid occurs without adequate knowledge of the stock's status. The IUCN Red List of Threatened Species classifies the Ohrid trout as "Data Deficient" (Crivelli, 2006), highlighting the urgent need for uptodate and reliable data on stock structure, abundance and dynamic in order to assess and manage the population effectively. This study aims to provide an initial assessment of the condition and yield of the Ohrid trout stock in Lake Ohrid.

MATERIAL AND METHOD

Fish samples collected from local small-scale fishery on the main landing sites of fishing boats along the Albanian part of Lake Ohrid shore (Figure 1a). Ohrid trout were fished within the Albanian border of the Lake area, using seine fishing of 1000 m length and 45 mm mesh size and hook lines with up to 150 hooks. The sampling, adapted after Spare & Venema (1992), took place in four subsequent days in June 2023. The total length (TL) data were composed together as a single time collection Taking in consideration the short period of sampling, the fish growth within sampling period was not taken in consideration. The total length (TL) of 89 sampled individuals was measured up to 0.1 cm and grouped into 1 cm length classes. for each length class, the average age was calculated through and the age were estimated by scale reading (Figure 1b). The estimation of growth parameters of Ohrid trout population was performed based on length at age analysis (direct search using nonlinear method of least squares) that involve a direct search of the values of K, L_∞ and t_0, that best fit a curve through the length at age data (Gayanilo et al., 2005). The analysis of pseudo cohorts was performed to obtain the growth function of the population.

Figure 1. (a) Primary landing sites of fishing boats, where fish samples were collected (Google Maps 2023); (b) Measurement of Ohrid trout lengths.

Total mortality (Z) for Ohrid trout population was estimated through length-converted catch curve (Pauly 1984; 1990). Natural mortality (M) was estimated according to Pauly's empirical formula $\ln M=-0.0152-0.279*\ln L_\infty+0.6543*\ln K+0.463*\ln T$ (Pauly, 1980) for the average annual temperature of Lake Ohrid of $T=13.7^0C$. Fishing mortality (F) was estimated as $F=Z-M$, while the exploitation rate (E) as $E=F/Z$.

Prediction of the stock production as relative yield per recruit (Y'/R) was evaluated after the model developed by Beverton and Holt (1966) and adapted for FiSAT II (Gayanilo et al., 2005). The calculations were done using the knife edge method and the values of the ratio L_c/L_∞ and M/K. The biological target reference values of exploitation were compared with the current exploitation rate and utilized to assess the status of the Ohrid trout stock in Lake Ohrid.

RESULTS AND DISCUSSION

The sample of Ohrid trout consisted of 89 individuals, with total lengths (TL) ranging from 25.0 to 51.7 cm. The most common age groups among the sampled fish were 3 and 4 years, corresponding to mean total lengths of 31.86 cm and 38.71 cm, respectively. The growth parameters for Ohrid trout were estimated as follows: asymptotic length (L_∞) of 68.0 cm (TL), growth coefficient (K) of 0.21 yr^{-1}, and age at length zero (t_0) of -0.01yr. The growth of the Ohrid trout population was described using the following total length-based function: $L_t=68.0*(1-e^{-0.21*(t+0.01)})$ (Figure 2). According to Kottelat & Freyhof (2007), the maximum standard length (SL) for Ohrid trout in Lake Ohrid can reach up to 60 cm. Additionally, a maximum total length of 76.0 cm has been reported for introduced Ohrid trout in some lakes and reservoirs in Colorado, Minnesota, Montana, Tennessee, and Wyoming, USA (Crawford, 1993).

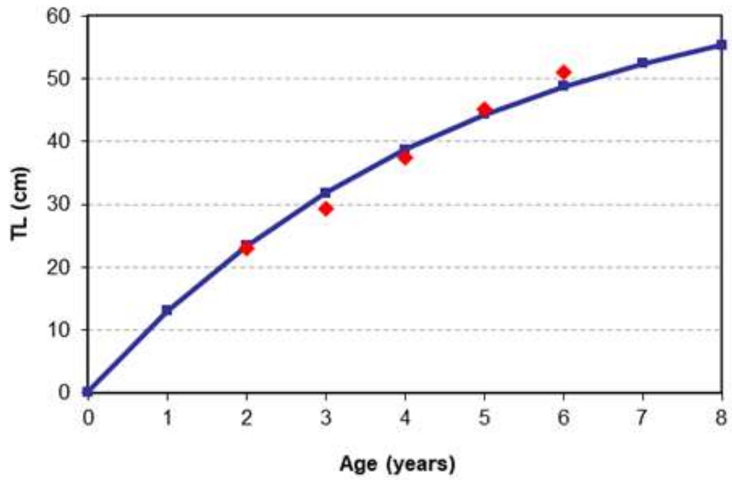

Figure 2. Von Bertalanffy growth curve for Ohrid trout population (red dots: observed values, blue dots: calculated values).

The total mortality rate (Z) for the Ohrid trout population was calculated to be 0.76 yr^{-1}. Natural mortality (M) and fishing mortality (F) were estimated at 0.37 yr^{-1} and 0.39 yr^{-1}, respectively. The exploitation rate (E), which represents the proportion of the total mortality rate attributable to fishing, was estimated at E=0.51 yr^{-1}. For decades, Lake Ohrid has been stocked with Ohrid trout fingerlings by the respective fishery authorities of Albania and North Macedonia. Although not empirically tested, it is likely that this additional recruitment compensates for the higher fishing mortality rate, helping to maintain the population size and structure.

The Relative Yield per Recruit Analysis (Y'/R) for the Ohrid trout stock in Lake Ohrid is presented in Figure 3. With a current stock exploitation rate of E=0.51 yr^{-1} and parameter values of M=0.37 yr^{-1}, K=0.21 yr^{-1}, L_∞=68.0 cm and L_c=20.4 cm, the relative yield per recruit of the current stock is Y'/R=0.027 (indicated by the red star on the isobars in Figure 3a). A simulation was conducted to examine the effect of increasing the length at first capture (L_c) on relative yield (Figure 3b). The model indicates that increasing L_c to 32 or 35 cm, while maintaining the current exploitation rate of E=0.51 yr^{-1}, would result in a relative yield per recruit of Y'/R=0.035 (represented by the red star on the isobars in Figure 3b). Additionally, along with increasing L_c, reducing the exploitation rate below E=0.51 yr^{-1} would not only sustain the stock's productivity but also support its growth.

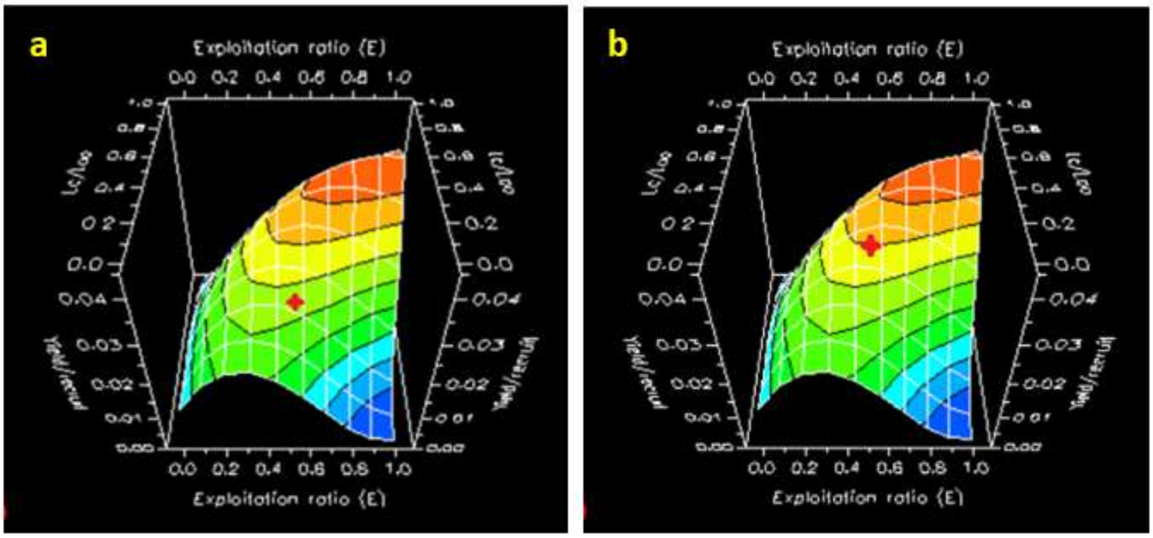

Figure 3. Relative Yield per Recruit Analysis (Knife-edge Selection) for the Ohrid trout stock as a function of the exploitation rate (E) and the ratio of length at first capture to asymptotic length (L_c/L_∞) (a) Y'/R of the stock (indicated by the red star on the isobars) for E=0.51 yr^{-1} and L_c=20.4 cm. (b) Y'/R of the stock (indicated by the red star on the isobars) for E=0.51 yr^{-1} and L_c=32.0 cm.

It should be noted that the low calculated value of L_c results from fishing trout below the minimum allowable size, which is also evident in the sample. If the regulation (MoARD, 2022) enforcing a minimum allowable size of 32 cm for the species had been strictly applied, as simulated in Figure 3b, the stock's production under the current level of exploitation would have been higher.

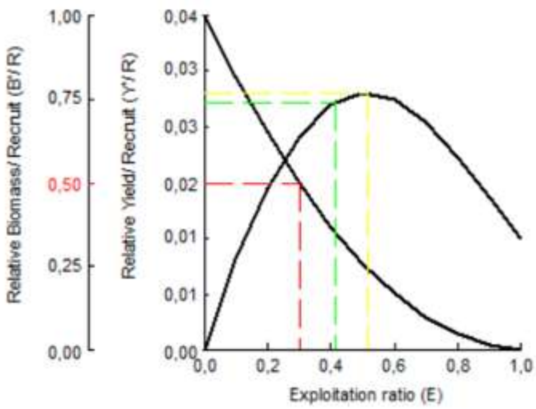

Figure 3. Production prediction as Y´/R and B´/R, as function of exploitation rate (E) for Ohrid trout stock.

The rate of exploitation rate that is currently applied to the trout reserve (E=0.51 yr-1) is almost equal to the rate of exploitation that ensures the maximum sustainable yield per recruit to the trout stock (E_{max}=0.515 yr^{-1}) (indicated by the yellow line in Figure 4). If a more conservative approach is adopted, the exploitation rate should be reduced to the E_{10} level of 0.413 yr^{-1}. This reduction ensures that the stock remains well within safe limits, avoiding overfishing (indicated by the green line in Figure 4). The long-term conservation objective for the stock can be reached with the reduction of exploitation rate at E_{50}=0.300 yr^{-1}. In long term it would provide a biomass level equal to the half of the initial population biomass (indicated by the red line in Figure 4).

It should be noted that data on the population dynamics and stock levels of the Ohrid trout over the past decades are lacking, making it impossible to predict trends in population abundance. The stocking of the lake with trout fingerlings (approximately 1.6 million fingerlings were stocked by the Albanian Fishery Authority in 2022, INSTAT, 2023) is not supported by reliable data on the current stock status or the impact the stocking has on the population. The information provided in this paper are limited and represents only an initial step in a broader study aimed at evaluating the dynamics of the populations and the status of native trout stocks in Lake Ohrid.

CONCLUSIONS

High fishing mortality rate of Ohrid trout stock while the exploitation rate actually applied is at the level of Maximum Sustainable Yield (MSY) might be consequence of yearly supplementing the stock with fingerlings. In such a scenario, careful management and monitoring are crucial to ensure that the combined impacts of fishing and natural mortality do not surpass the stock's recruitment capacity. To evaluate whether natural recruitment combined with supplemental stocking is sufficient to sustain the population and yield at MSY despite high fishing mortality, the future studies should include the recruitment analysis of the stock. For the Ohrid trout stock, it is recommended to operate with an exploitation rate below the E_{max} level. This precautionary measure takes into account the limited area of the species' distribution, as well as uncertainties and variability in stock dynamics. It is advisable for the Ohrid trout stock to maintain an exploitation rate below the E_{max} level. This precautionary approach considers the species' limited distribution area, slow growth rate and the uncertainties and variability in stock dynamics.

HEALTH EFFECTS AND USES OF CHERRY LAUREL: A REVIEW

Tuğba ER[1]

[1]*Giresun Hazelnut Research Institute, Department of Food Technology, Türkiye*

Corresponding author e-mail: tugbaer2003@hotmail.com

ABSTRACT

Cherry laurel is an important fruit species that grows naturally in the Black Sea region of Turkiye. It attracts attention for its nutritional value and diverse uses, offering numerous health benefits due to its high antioxidant capacity and rich phenolic compounds. As a healthy food source, it is rich in vitamins, minerals, and dietary fibers and is widely utilized in traditional medicine. Its blood sugar-lowering, anti-inflammatory, and antioxidant properties make it an effective option for treating various health problems. Cherry laurel is used in products such as jam, marmalade, vinegar, liqueur, and compote, and is also valued in the landscaping and cosmetics sectors. The oil extracted from its seeds is used in the cosmetic industry. Studies on the bioactive compounds and positive health effects of cherry laurel indicate that this fruit is an attractive option for the functional foods and food supplements industries. In summary, increasing the recognition of cherry laurel and expanding its usage areas will both contribute to the fruit's genetic diversity in our country and provide significant benefits for public health. More research and promotional activities are required to fully evaluate the potential of cherry laurel.

Keywords: Taflan, traditional medicine, diabetes, *Prunus laurocerasus* L.

INTRODUCTION

Turkiye is one of the world's important fruit gene centers due to its geographical location and ecological conditions. Consequently, the country is the homeland of many fruit species and holds a significant place in fruit-growing culture. The Black Sea region of Türkiye, rich in natural resources and plant diversity, is particularly notable for its favorable ecological conditions. Among the various fruit types found in this region, cherry laurel stands out for its contribution to the fruit genetic diversity.

Cherry laurel (*Prunus laurocerasus L.*), belonging to the Rosaceae family, thrives in humid and temperate climates, preferring slightly acidic soils rich in organic matter. It grows naturally in the Black Sea region (*Laurocerasus officinalis Roem.*, syn: *Prunus laurocerasus L.*) and serves both as a fruit-bearing and ornamental plant. This evergreen tree or shrub, which retains its leaves year-round, can reach heights of 5-15 meters. The leaves are oval or elliptical, dark green, shiny, and have a hard structure with slightly toothed edges. In spring, the cherry laurel blooms with fragrant white or cream-colored flowers arranged in clusters (Table 1).

Table 1. Cherry laurel blooms (Damla ÇİL, 2023)

The fruit of the cherry laurel, approximately 6-25 mm in length, undergoes color changes as it ripens from green to red, purple, yellow, white, and finally dark, almost black, depending on the variety (Table 2). Fruit ripening begins in June and can extend until the end of August, depending on the genotype. The taste of the fruits ranges from sweet to astringent and bitter (Er, 2013).

Table 2. The fruit of the cherry laurel (Tuğba ER, 2024)

In Turkiye, cherry laurel is known by various names including taflan, Georgian cherry, laz grape, laz cherry, tanal, and tçkoo, with "taflan" being the most common (Anonymous, 2024). Recognizing the nutritional importance of cherry laurel, numerous studies have been conducted to cultivate and disseminate it (Karadeniz and Kalkisim, 1996; Sulusoglu, 2011; İslam and Deligöz, 2012).

The aim of this review is to enhance the recognition of cherry laurel fruit, which contributes significantly to the fruit genetic diversity of Turkiye. Despite its growth in many countries, its usage has not developed beyond local consumption or production. This review seeks to highlight its biochemical contents, areas of use, and health benefits.

BIOCHEMICAL CONTENT OF CHERRY LAUREL

The nutritional composition of cherry laurel includes a variety of macro and micronutrients that enhance its health value. This fruit contains high amounts of water, protein, and carbohydrates. It is also rich in pectin, an important dietary fiber. Additionally, cherry laurel is abundant in phenolic compounds (including flavonoids such as anthocyanin, flavonols, tannin, and lignin), vitamins (A, C, D), and minerals (K, Mg, Ca, P) (Karahalil et al., 2011; Kalyoncu et al., 2013). Studies on the nutritional content of cherry laurel have revealed its high antioxidant capacity, attributed to the rich phenolic compounds it contains (Ayaz, 2001; Var and Ayaz, 2004; Yazıcı et al., 2011; Ozturk et al., 2019; Celik et al., 2020).

The nutritional composition of cherry laurel fruit is influenced by several factors, including the place where it is grown, soil characteristics, season, and the maturity of the fruit. There are also numerous species of cherry laurel, leading to considerable variability in fruit content. For this reason, nutritional content information was taken from the National Food Composition database and is presented in Table 1.

The most abundant mineral in cherry laurel is potassium. In addition to potassium, other important minerals found in cherry laurel include calcium, magnesium, and phosphorus. The fruit also contains natural sugars, primarily fructose and glucose, which vary depending on the fruit's development and ripening process (Ayaz, 2001). The sweet and slightly sour taste of cherry laurel is due to these sugars combined with the fruit's natural acidity.

Cherry laurel's high antioxidant capacity is attributed to its rich phenolic compounds, particularly vanillic acid, known for its anti-inflammatory effects (Ayaz, 2001; Var and Ayaz, 2004; Yazıcı et al., 2011; Ozturk et al., 2019; Celik et al., 2020). The fruit's nutritional composition makes it a healthy snack and a nutritious addition to the diet. With its high vitamin and mineral content, strong antioxidant properties, and low-fat content, cherry laurel can be consumed as part of a balanced diet.

USES OF CHERRY LAUREL

Cherry laurel has a range of uses in both traditional and modern applications. The fruit, with its slightly bitter taste, is consumed fresh and is used in making jam and marmalade, enhancing these products with its rich aroma and taste. It is also added to compotes to impart flavor and scent.

In the Black Sea region, cherry laurel is grown both naturally and partly through cultivation. Locally, it is consumed fresh and used in forms such as jam, molasses, and salting. Liqueur is also made from its fruits, and in recent years, the fruit has been consumed dried. In the Eastern Black Sea Region, cherry laurel leaves are brewed as tea, serving as a cough suppressant and antispasmodic for nervous disorders (FAE, 2024). The fruits are also considered diet-friendly due to their easy digestibility and ability to induce a feeling of fullness (Çalışır et al., 2002).

Studies on the use of cherry laurel in food products have generally yielded positive results. However, there has not been a significant increase in its use within the food industry. Increased research on its industrial applications is likely to boost its commercial value (Vahapoğlu et al., 2018).

Beyond its culinary uses, cherry laurel is valued as an ornamental plant in landscaping due to its evergreen nature. Its glossy leaves are used in making wreaths, floral arrangements, fish displays, and even as fodder for small ruminants. Additionally, the leaves are used to obtain aqua laurocerasi or laurocerasin for the pharmaceutical industry (Anonymous, 2024). The oil extracted from the seeds is utilized in the cosmetic industry. Consequently, cherry laurel has also become an attractive fruit for the functional foods and food supplements industries.

EFFECTS ON HEALTH

Cherry laurel is traditionally used in Türkiye to treat various health problems. The fruit and different parts of the plant have been utilized for their analgesic, antispasmodic, sedative, and blood sugar-lowering effects (Kolaylı et al., 2003). In the Eastern Black Sea Region, it is particularly valued for its ability to lower blood sugar levels. Additionally, it has been noted for its anti-inflammatory effects without causing gastric lesions (Erdemoglu et al., 2003).

Traditionally, cherry laurel fruits and seeds are recommended for treating digestive and respiratory diseases, bronchitis, eczema, and hemorrhoids (Çolak et al., 2005; Kolaylı et al., 2003). The high antioxidant content of the fruit helps reduce oxidative stress caused by free radicals in the body, thereby preventing cell damage. Polyphenols and flavonoids in the fruit may also protect heart health and prevent cardiovascular diseases.

Cherry laurel contains various glycosides, including cyanogenic glycosides such as amygdalin and prunasin. These compounds can release cyanide when hydrolyzed, offering potential health benefits but requiring caution due to toxicity risks. Like the fruit, cherry laurel leaves are used in traditional Turkish medicine to treat asthma, cough, and dyspepsia (Yeşilada et al., 1999).

Interest in cherry laurel has increased in recent years due to its high antioxidant and bioactive compound content. Studies suggest it may be effective in treating and preventing various diseases, including diabetes, cancer, cardiovascular, chronic, and neurodegenerative diseases (Karataş and Uçar, 2018).

CONCLUSION

Cherry laurel, abundant in our country, particularly in the Black Sea Region, stands out not only for its high water, protein, and carbohydrate content but also for its richness in phenolic compounds, vitamins, and minerals. This nutritional profile grants it a robust antioxidant capacity, making it a valuable asset for health. Traditional medicine has long recognized its analgesic, antispasmodic, and sedative properties, alongside documented benefits in lowering blood sugar and reducing inflammation.

Beyond its fresh consumption, cherry laurel is processed into diverse culinary delights such as jams, marmalades, vinegars, liqueurs, and dried fruits. It also finds use in landscaping as an ornamental plant. Recent biochemical research underscores its potential to enhance both commercial and industrial value. Encouraging findings suggest it could play a pivotal role in preventing and treating chronic ailments, including diabetes, cancer, cardiovascular diseases, and neurological disorders.

Increasing awareness and expanding applications of cherry laurel promise to elevate its economic significance and public health impact. Future strides in scientific inquiry and industrial innovation are poised to unveil its full potential, enabling broader consumption and furthering its beneficial contributions to society.

ABSTRACT

Parkinson's disease (PD) is a neurodegenerative disease characterized by dopaminergic neuron loss in the substantia nigra. The incidence of the disease, which has symptoms such as bradykinesia, rigidity, and tremor, increases with age. Although the mechanism of the disease, which affects millions of people, is not fully understood, it is reported that protein aggregation due to α-synuclein misfolding, neuroinflammation, and many gene mutations, including LRRK2, contribute to the development of PD. Chrysin is a flavone compound found in high amounts in honey, propolis, and various plants, and its anti-inflammatory and neuroprotective effects have been shown in various studies. In the *in silico* study, the binding scores of neuroprotective chrysin with Parkinson's disease-specific (α-synuclein, LRRK2, MAO-B) and neuroinflammation-related (mTOR, MAPK, JNK3, iNOS, nNOS) proteins were recorded and the interaction levels were evaluated. The 3D models of the target proteins selected for molecular docking studies were obtained from the RCSB Protein Data Bank with the ID numbers α-synuclein (1XQ8), LRRK2 (5OPB), MAO-B (1GOS), mTOR (2FAP), MAPK (5UOJ), JNK3 (2O0U), iNOS (3HR4) and nNOS (5VV0). The 3D structures of the ligand tests were obtained from DrugBank and NCBI PubChem databases and their structural minimizations were performed with USCF Chimera ver. 1.17.1. After the receptors and ligands were prepared with AutoDockTools 1.5.7, binding scores were recorded. In the obtained findings, it was shown *in silico* that chrysin interacts with α-synuclein, LRRK2, MAO-B, mTOR, MAP JNK3, iNOS and nNOS receptor proteins. The *in silico* findings obtained for chrysin, which targets protein aggregation through the interaction with α-synuclein and LRRK2, neuroinflammation through the interaction with mTOR, MAPK, JNK3, iNOS and nNOS, and the dopaminergic system through the interaction with MAO-B, demonstrate the potential effect of the target compound in Parkinson's disease and shed light on new studies to be conducted for the treatment of the disease.

Keywords: Chrysin, Molecular Docking, Neuroinflammation, Parkinson’s Disease

INTRODUCTION

Parkinson's disease (PD) is the second most common neurodegenerative disease worldwide, characterized by loss of dopaminergic neurons in the substantia nigra and misfolding of α-synuclein. The prevalence of the disease is expected to reach 12 million by 2040 with increasing age (Dorsey et al., 2018). Symptoms include bradykinesia, rigidity, tremor, postural instability, constipation, dementia, and sleep disorders, and current treatments for PD are only symptomatic. The pathogenesis of PD, which is associated with many mechanisms including oxidative stress, neuroinflammation and autophagy, has not been fully elucidated. In addition, the symptomatic nature of current PD treatment negatively affects the quality of life of patients. This situation increases the need for new treatment approaches for PD and causes researchers to focus on neuroprotective compounds (Jankovic et al., 2008; Cabreira et al., 2019; Angelopoulou et al., 2020).

Neuroinflammation, which aggravates neurodegeneration in the pathogenesis of PD, is induced by various factors. These factors include pathogens, prions, toxins, α-synuclein aggregates, and proinflammatory cytokines that cause activation of microglia expressed in the central nervous system (CNS) (Araújo et al., 2020). Activated microglia are closely associated with α-synuclein aggregation as well as an increase in proinflammatory cytokines. This results in an exacerbation of neuroinflammation (Li et al., 2021). α-synuclein, which has an important role in neuroinflammation, is a water-soluble protein in its normal form. α-synuclein aggregates are formed as a result of misfolding of α-synuclein. α-synuclein aggregates, which are used as biomarkers in the diagnosis of PD, have also been detected at high levels in the cerebsrospinal fluid (CSF) of Parkinson's patients. These aggregates induce neuroinflammation through various mechanisms, thereby exacerbating neurodegeneration (Liu et al., 2022). Leucine-rich repeat kinase 2 (LRRK2), which is associated with α-synuclein overexpression and increased neuroinflammation, plays a role in various pathways and cellular signals, including autophagy, in the pathogenesis of PD. It is known that LRRK2 mutations constitute the most common causes of familial and sporadic PD, and LRRK2 inhibition is used as a treatment strategy (Rosenbusch et al., 2016; Di Maio et al., 2018; Liu et al., 2022). In addition to LRRK2, inhibition of the mechanistic target of rapamycin (mTOR), which is associated with α-synuclein aggregation, has also been reported to have neuroprotective effects. mTOR, which regulates synaptic plasticity, neuronal development and survival, has also been closely associated with microglia activation, which aggravates neuroinflammation with protein aggregation (Lan et al., 2017; Dhapola et al., 2021). Many stress factors that activate microglia, especially proinflammatory cytokines, also induce mitogen-activated protein kinase (MAPK). MAPK, which regulates many physiological processes such as cellular stress response and cell death and intracellular signaling, also mediates pathways related to neuroinflammation, apoptosis and oxidative stress (Jayaraj et al., 2019; Ratih et al., 2023). However, it is known that c-Jun N-terminal kinase-3 (JNK3), which is also in the MAPK family, is intensely expressed in the CNS and plays a role in the pathogenesis of PD. In this context, MAPK and JNK3 are considered an important therapeutic target for PD in alleviating neuroinflammation (Bohush et al., 2018).

Oxidative stress, which plays an intricate role with neuroinflammation in PD, is known to be one of the important factors leading to neurodegeneration. Inducible nitric oxide synthase (iNOS), which increases oxidative stress levels, causes dopaminergic neuron death together with increased nitric oxide (NO) levels. In an *in vitro* PD model induced with 6-hydroxidopamine (6-OHDA), chrysin has been shown to reduce oxidative stress caused by iNOS (Zhang et al., 2015). In addition to iNOS, neuronal nitric oxide synthase (nNOS) also has an effect on increasing NO levels. NO demonstrates its neurodegenerative effect by altering axo-dendritic function, disrupting synaptic signaling, vesicular traffic, and dopamine homeostasis (Stykel et al., 2022). The decrease in dopamine activity along with the disruption of homeostasis worsens PD symptoms and increases degeneration. Monoamine oxidase-B (MAO-B), which metabolizes dopamine in striatal glial cells, also catalyzes the oxidation of various neurotransmitters. The decreased dopamine levels in PD are increased through MAO-B inhibition, and MAO-B inhibitors are used for PD treatment (Regensburger et al., 2023). In addition to dopaminergic activity, it has been reported that MAO-B is also closely associated with PD-specific α-synuclein and that the increase in MAO-B expression due to age triggers neurodegeneration through free radical damage (Kang et al., 2018). In this context, alleviating neuroinflammation and oxidative stress that worsen PD symptoms, increasing dopaminergic activity, and autophagy regulation are strategic approaches in PD treatment. However, determining the bioactivities and mechanisms of action of components obtained from natural products with low toxicity will enable the synthesis of these components or their new derivatives with increased activity and their use in the prophylaxis of neurodegenerative diseases.

Chrysin (5,7-dihydroxyflavone or 5,7-dihydroxy-2-phenyl-4H-chromen-4-one) is a bioactive flavonoid found in many plants such as *Oroxylum indicum*, *Passiflora incarnata* and *Passiflora caerulea*, mushrooms, honey and propolis (Figure 1). Chrysin, which has been shown to cross the blood-brain barrier, has been reported to have anticancer, antidiabetic, anti-inflammatory, hepatoprotective, cardioprotective, antioxidant, antiepileptic and neuroprotective effects. Chrysin is known to exhibit its neuroprotective effects by reducing various proinflammatory cytokine levels and oxidative stress (Naz et al., 2019; Angelopoulou et al., 2020).

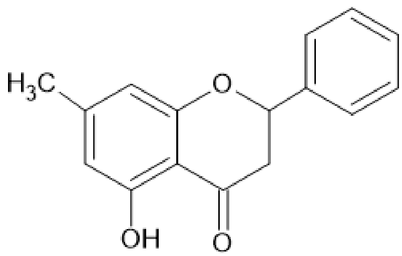

Figure 1. The structure of chrysin (Created by ACD/ChemSketch)

When the data in the literature is evaluated, chrysin’s neuroprotective effects has been shown in limited number of studies in PD, however the exact mechanism has not yet been clearly elucidated. In this study, for the first time, the binding scores of chrysin with PD-specific (α-synuclein, LRRK2, MAO-B) and neuroinflammation-related receptors (mTOR, MAPK, JNK3, iNOS, nNOS) that play a role in PD pathogenesis were determined using the molecular docking analysis method and the aim was to elucidate the mechanism of chrysin in PD.

MATERIAL AND METHOD

The 3D structure of chrysin used as a ligand for molecular docking analyses was downloaded from the online Drugbank database with the code DB15581. (DrugBank, https://go.drugbank.com/ accessed on 25 April 2024). Minimization of the ligand chrysin was performed with USCF Chimera ver. Implemented with 1.17.1 software and prepared for molecular docking analysis with the AutoDockTools-1.5.7 program. Experimentally elucidated structures of target receptors known to be associated with PD were obtained from the RCSB Protein Data Bank with the ID numbers α-synuclein (1XQ8), LRRK2 (5OPB), MAO-B (1GOS), mTOR (2FAP), MAPK (5UOJ), JNK3 (2O0U), iNOS (3HR4) and nNOS (5VV0).

(PDB, www.rcsb.org accessed on 25 April 2024). After preparing the receptors with AutoDockTools-1.5.7, the binding score of each receptor with chrysin was recorded (Garcia et al., 2023).

RESULTS AND DISCUSSION

Chrysin is a polyphenolic compound with many activities such as antioxidant, anti-inflammatory, neuroprotective and anticancer. It has been reported that chrysin plays a neuroprotective role in neurodegenerative diseases such as Alzheimer's disease (AD), epilepsy and PD, and the mechanisms through which it performs these effects are still a subject of research (Mishra et al., 2021). Findings obtained from molecular docking analyses showed that chrysin has significant binding affinity with PD-specific (α-synuclein, LRRK2, MAO-B) and neuroinflammation-related receptors (mTOR, MAPK, JNK3, iNOS, nNOS) that play a role in PD pathogenesis. Chrysin binding scores and interactions are visualized in Figure 2-9 and summarized in Table 1.

As a result of the findings obtained from *in silico* analyses, we determined the binding affinity of chrysin with PD-specific α-synuclein (-6.4 kcal/mol). It has been shown that chrysin reduces α-synuclein aggregation and dopamine degeneration in a 6-OHDA-induced PD model (Muhammed et al., 2022). It has been stated that chrysin, which has been shown to protect dopaminergic activity by reducing dopamine depletion in alleviating degeneration, can provide a significant improvement in dopamine levels in the hippocampus and prefrontal cortex regions of the brain (Mishra et al., 2021). Our *in silico* findings also showed that chrysin exhibits a strong interaction with MAO-B, which plays a role in dopamine homeostasis. At the same time, MAO-B inhibitors, which have been shown to delay the formation of α-synuclein aggregation, have been evaluated as an effective treatment strategy in preserving dopaminergic activity (Tan et al., 2022). In addition to dopaminergic activity, LRRK2, which is characterized by PD, leads to oxidative damage and disruptions in the autophagy pathway. It has been determined that LRRK2 inhibition alleviates neuroinflammation together with microglial activation, and LRRK2 inhibition has gained importance in PD treatment (Ilieva et al., 2024). LRRK2 also bound to chrysin with a high binding score (-9.3 kcal/mol) in *in silico* analyses. This demonstrates the potential of chrysin to exhibit its neuroprotective effect through LRRK2 inhibition. mTOR, which is known to mediate microglia activation, also induces iNOS via inflammatory pathways (Dhapola et al., 2021). In a study, an *in vivo* PD model was induced with 6-OHDA and neuroprotective effect was obtained by inhibiting nNOS, which is known to increase NO levels, as well as iNOS (Tiwari et al., 2022). In *in silico* analyses, the high binding affinity of chrysin to mTOR (-8.6 kcal/mol), iNOS (-9.9 kcal/mol) and nNOS (-9.6 kcal/mol), which are associated with neuroinflammation, makes these receptors a target for chrysin's effects in PD. In addition, it has been reported that chrysin plays a neuroprotective role in the alleviation of neuroinflammation by modulating JNK expression and directly reducing the amount of proinflammatory cytokines (Mishra et al., 2021). The high binding affinity of chrysin with JNK3 (-8.4 kcal/mol) and its superfamily MAPK (-7.5 kcal/mol) reveals the potential effect of chrysin in the mechanism of response to cellular stress.

CONCLUSIONS

Our findings from *in silico* analyses have shown that chrysin has the potential to affect PD by interacting with α-synuclein, LRRK2, MAO-B, mTOR, MAPK, JNK3, iNOS and nNOS. However, extended preclinical studies are needed due to unpredictable physiological processes.

ABSTRACT

Microalgae production has garnered significant attention across various industries due to its diverse applications and potential benefits. This study explores the current status and potential applications of microalgae production, focusing on its role in biodiesel production, cosmetics, thalassotherapy, bioremediation, and feed materials. The high lipid content of certain microalgae species makes them a promising source for sustainable biofuels, while their utilization in cosmetics and thalassotherapy underscores the value of microalgae-derived compounds in high-value products. Microalgae are also being explored for bioremediation purposes, particularly in treating textile wastewater, showcasing their versatility in environmental applications. Genetic engineering strategies are being developed to enhance biofuel production by increasing lipid accumulation in microalgae strains.

Keywords: Microalgae, feed, food, biofuel, treatment, waste

INTRODUCTION

Microalgae production has gained significant attention due to its diverse applications and potential benefits across various industries, including renewable energy, biopharmaceuticals, and nutraceuticals. The potential of microalgae production extends to biofuels, feed, food products, and other valuable compounds. Researchers have highlighted the rich energy content, rapid growth rate, cost-effective cultivation methods, and environmental benefits of microalgae, positioning them as a promising feedstock for biofuel generation. The current status of microalgae production is characterized by ongoing research and technological advancements aimed at maximizing the efficiency and scalability of microalgae cultivation. One prominent application of microalgae lies in biodiesel production, where the high lipid content of certain microalgae species presents a promising source for sustainable biofuels (Wu et al., 2012). Beyond biofuels, microalgae are being explored for bioremediation purposes, particularly in treating textile wastewater, showcasing the versatility of microalgae in environmental applications (Andrade & Andrade, 2018). The potential of microalgae extends to genetic engineering for enhanced biofuel production, with metabolic engineering strategies being developed to increase lipid accumulation in microalgae strains (Banerjee et al., 2016). Moreover, the biotechnological applications of microalgae have expanded to include the production of cosmetics, health products, fertilizers, feeds, and food, emphasizing the versatility of microalgae biomass in various industries (Ugya & Meguellati, 2022). Additionally, the utilization of microalgae in cosmetics and thalassotherapy has gained traction, highlighting the value of microalgae-derived compounds in high-value products (Mourelle et al., 2017).

The biotechnological potential of native microalgae from diverse ecosystems, such as the Peruvian Amazon, underscores the growing relevance of microalgae biotechnology in harnessing unique strains for specific applications (Cobos et al., 2020). Furthermore, the incorporation of microalgae into innovative food products and the extraction of valuable compounds like phytosterols for functional food and pharmaceutical applications highlight the growing interest in utilizing microalgae for health and nutrition purposes (Caporgno & Mathys, 2018; Luo et al., 2015). The development of low-cost and high-volume open microalgae biofuel production technologies signifies progress towards commercial-scale microalgae biofuel production, addressing the need for sustainable and renewable energy sources (Moheimani et al., 2013). Additionally, the genetic manipulation of microalgae for bioproducts and enhancing microalgae traits demonstrate the continuous advancements in biotechnology for optimizing microalgae-based applications (Vázquez-Villegas et al., 2018; Shin et al., 2016).

In conclusion, the current status and potential applications of microalgae production encompass a wide range of industries, from biofuels and cosmetics to bioremediation and feed products. The ongoing research and technological innovations in microalgae cultivation and genetic engineering are paving the way for a sustainable and versatile bio-based economy with microalgae at its forefront.

CURENT STATUS OF MICROALGAE PRODUCTION

Potential Applications

Food and feed material

Microalgae production is recognized for its potential as a sustainable and versatile source of food and feed materials, offering a wide array of nutritional and functional benefits.

Microalgae have historically been consumed by humans for their nutritional value and medicinal properties (Sathasivam et al., 2019).

Studies have demonstrated the feasibility of large-scale cultivation of microalgae for feed purposes, particularly in livestock and poultry production (Saadaoui et al., 2021). In the realm of food production, microalgae present a sustainable alternative as feed material for monogastric animals, providing a viable option to supplement or replace traditional feedstuffs like corn and soybean (Chaves et al., 2021). The nutritional composition of microalgae, which includes proteins, polyunsaturated fatty acids, antioxidants, and phytosterols, positions them as promising sources for food and feed applications (Sui & Vlaeminck, 2020). Additionally, the bioactive lipids found in microalgae have applications not only in aquaculture feed but also in the food and pharmaceutical industries, showcasing the versatility of microalgae-derived compounds (Luo et al., 2015).

Microalgae play a crucial role in aquaculture by serving as essential sources of polyunsaturated fatty acids for aquatic species (Soto-Sánchez et al., 2023). Their high nutritional value makes them suitable food sources for larval bivalves, shrimps, and fish, emphasizing their significance in aquaculture feed formulations (Ma, 2023). Furthermore, the industrial utilization of microalgae biomass includes the production of feeds, underscoring their importance in the food chain (Ugya & Meguellati, 2022). The nutritional composition and functional properties of microalgae proteins have been well-established, positioning them as a simple and effective protein source for food and feed applications (Hashim et al., 2023). Commercially, microalgae are already integrated into various food products, demonstrating their potential as versatile ingredients with nutritional benefits (Igual et al., 2021). The expanding industrial applications of microalgae encompass food, nutraceuticals, pharmaceuticals, animal feed, cosmetics, and biofertilizers, showcasing the diverse opportunities presented by these microorganisms (Udayan et al., 2021).

Microalgae production holds vast promise as food and feed material, providing sustainable and nutrient-rich alternatives for various industries. The nutritional value, bioactive compounds, and functional properties of microalgae make them valuable resources for addressing food scarcity, ensuring adequate nutrition, and promoting sustainable living practices.

Pharmaceutical and cosmetic industries

The pharmaceutical sector is increasingly exploring the therapeutic potential of microalgae-derived compounds, such as antioxidants, anti-inflammatory agents, antimicrobials, and anticancer agents, highlighting their pivotal role in biomedical applications (Khavari et al. 2021). These bioactive metabolites from microalgae hold significant promise for developing novel pharmaceutical products due to their diverse pharmacological activities (Kaur et al., 2023). In the cosmetic industry, microalgae have gained attention for their cosmetic and cosmeceutical applications, with compounds like astaxanthin being utilized as pigments in cosmetics and as active ingredients in skincare products (Villaró et al., 2021). The bioactive compounds present in microalgae, including pigments, vitamins, and minerals, offer a natural and sustainable source for formulating cosmetic products, catering to the increasing consumer demand for natural and eco-friendly alternatives (Dussably et al., 2022). Moreover, marine microalgae and cyanobacteria have been identified for their potential use in cosmetics and thalassotherapy, underscoring their significance in the cosmetic industry (Mourelle et al., 2017). The pharmaceutical and cosmetic industries are increasingly turning to microalgae as a valuable resource for developing high-value products. Microalgae's ability to produce a wide range of bioactive compounds, such as carotenoids, phytosterols, and fatty acids, positions them as versatile sources for pharmaceutical and cosmetic applications (Balasubramaniam et al., 2021). The bioactive metabolites synthesized by microalgae have demonstrated antioxidant, anti-inflammatory, and anti-microbial properties, making them attractive candidates for pharmaceutical formulations and cosmetic products (Morais et al., 2015). Furthermore, the sustainable production of microalgae biomass offers a cost-effective and environmentally friendly approach to sourcing bioactive compounds for pharmaceuticals and cosmetics (Jeevanandam et al., 2020). The potential of microalgae in producing value-added lipids, proteins, and other bioactive molecules presents opportunities for developing innovative pharmaceutical and cosmetic formulations (Conde et al., 2021). The bioprospecting of microalgae for biopharmaceutical applications underscores the growing interest in harnessing the therapeutic potentials of microalgae in the pharmaceutical industry (Saeed et al., 2021). In conclusion, microalgae production holds immense promise for the pharmaceutical and cosmetic industries, offering a sustainable and bioactive-rich source for developing a wide range of products. The diverse bioactive compounds synthesized by microalgae present opportunities for formulating novel pharmaceutical drugs, nutraceuticals, and cosmetic products, catering to the evolving needs of these industries.

Biodiesel production

Microalgae production has attracted significant interest as a sustainable and efficient feedstock for biodiesel production, offering a promising solution to the global energy demand

and environmental concerns. The potential applications of microalgae in biodiesel production have been extensively studied, highlighting their viability as a renewable energy source (Ajala et al. 2022). Microalgae possess characteristics that make them ideal for sustainable biodiesel production, including high lipid content and the ability to be genetically optimized for enhanced lipid accumulation (Mohamed et al., 2022).

The utilization of microalgae for biodiesel production involves various advanced technologies and influencing parameters that contribute to maximizing the efficiency of lipid extraction and conversion processes (Cao et al., 2013). The unique properties of microalgae, such as their ability to effectively remove nutrients and heavy metals from wastewater, further enhance their appeal as a biodiesel feedstock (Cobos et al., 2020). Additionally, the direct conversion of lipids within microalgae cells into biodiesel through in situ transesterification has emerged as an effective and simplified approach in biodiesel production (Hidalgo et al., 2015).

The potential of microalgae for biodiesel production extends to their high lipid content, which allows for the generation of saturated and monounsaturated fatty acids ideal for biodiesel synthesis (Mohmmed et al., 2022). The sustainable production of biodiesel from microalgae offers advantages over traditional plant crops, as microalgae can accumulate significant quantities of triglycerides and free fatty acids, making them a valuable resource for biofuel production (Andrade & Andrade, 2018). Furthermore, the joint production of biodiesel and bioethanol from microalgae biomass presents a cost-effective and efficient approach to biofuel production (Sendzikiene & Makareviciene, 2022). The biodiesel potential of microalgae is further underscored by their ability to grow in the presence of sunlight and carbon dioxide, making them excellent sources of biofuels after processing (Ma et al., 2014). The differential fatty acid profiles of microalgae grown with organic materials highlight the versatility of microalgae in biodiesel production and wastewater treatment applications. The integration of oleaginous microalgae cultivation with wastewater treatment is considered a low-cost and sustainable approach for producing algae-based biodiesel.

Biomethane and biogas production

Microalgae production has emerged as a promising avenue for biomethane and biogas production, offering sustainable solutions for renewable energy generation and waste management. The potential applications of microalgae in biomethane and biogas production have been extensively explored, showcasing their versatility as a renewable energy feedstock (Poggio et al. 2023). Microalgae possess unique characteristics that make them ideal for biomethane and biogas production, including their ability to capture CO_2 and convert it into valuable methane gas (Prandini et al., 2016). The integration of microalgae-based wastewater treatment with biogas purification accelerates nutrient removal while producing valuable biomass and biomethane, highlighting the dual benefits of microalgae in waste management and energy production (Ahmad et al., 2014). Furthermore, co-digestion of microalgae with organic waste streams, such as palm oil mill effluent, has been shown to enhance biogas and biomethane production rates, demonstrating the potential of microalgae in optimizing anaerobic digestion processes (Córdova et al., 2018).

The advantages of using microalgae as a substrate for biogas and biomethane production stem from their high productivity, ability to capture CO_2, and convert organic matter into biofuels efficiently (Jensen & Skovsgaard, 2017). The upgrading of raw biogas to biomethane involves removing excess CO2 to produce a higher quality fuel suitable for various applications, such as transportation and heat generation (Machado, 2023). The scalability of anaerobic digestion of microalgae biomass within water resource recovery facilities further emphasizes the potential of microalgae in large-scale biomethane production (Milbrandt et al., 2016). Photosynthetic biogas upgrading has enabled the production of biomethane while concurrently treating digestate in constructed wetlands to obtain biofertilizers, showcasing the integrated approach of utilizing microalgae for energy and environmental benefits (Díez-Montero et al., 2020). The techno-economic analysis of biogas production from microalgae through anaerobic digestion highlights the feasibility and sustainability of biomethane production from this renewable feedstock (Murano et al., 2021). Moreover, modeling studies on hydrogen sulfide removal under biomethane production underscore the importance of optimizing biogas purification processes for efficient biomethane generation (Chernysh et al., 2021).

Bioremediation of air and wastewater

Microalgae have been recognized as a versatile and sustainable solution for bioremediation of air and wastewater, offering a promising approach to environmental cleanup and resource recovery. Extensive research has demonstrated the ability of microalgae to efficiently remove pollutants and contaminants from various environmental matrices (Jalilian et al. 2020; Uguz et al., 2022). Microalgae are well-known for their capacity to thrive in wastewater environments and effectively remediate pollutants, making them valuable assets in the pursuit of cleaner ecosystems and sustainable resource management.

The utilization of microalgae for bioremediation of wastewater presents a win-win paradigm, where the bioremediation capacity of microalgae is harnessed to treat wastewaters, thereby promoting the development of the microalgae industry and offering alternatives to conventional wastewater treatment processes (Delrue et al., 2016). Microalgae-based bioremediation processes have been shown to be cost-effective, energy-efficient, and highly effective in reducing pollutant levels compared to traditional wastewater treatment methods (Singh et al., 2022). The ability of microalgae to assimilate organic nutrients from wastewater for growth while simultaneously reducing pollutant content underscores their dual role in bioremediation and biomass generation (Chew & Show, 2022). Studies have demonstrated that microalgae can effectively remove contaminants from wastewater, leading to a reduction in biological oxygen demand and nutrient levels, thereby contributing to cleaner water sources and sustainable environmental practices (Rawat et al., 2011). The bioremediation potential of microalgae extends to the treatment of various types of wastewaters, including industrial effluents and urban waste, highlighting their versatility in addressing pollution challenges (Mutanda et al., 2020). The integration of microalgae-based bioremediation processes with biofuel production further enhances the sustainability and efficiency of wastewater treatment, offering a holistic approach to environmental stewardship (Renuka et al., 2014). Moreover, the application of microalgae in bioremediation of air and wastewater is not only effective in pollutant reduction but also contributes to biomass production, which can be utilized for various purposes, including biofuel production and nutrient recycling (Miazek et al., 2015). The ability of microalgae to thrive in contaminated environments and remove pollutants, such as heavy metals and organic compounds, underscores their potential as eco-friendly bioremediation agents (Li et al., 2018). The integration of microalgae with other remediation technologies, such as sulfate-reducing bacteria, in continuous treatment systems further enhances the efficiency and effectiveness of bioremediation processes. In conclusion, microalgae offer a sustainable and effective solution for bioremediation of air and wastewater, providing a dual benefit of environmental cleanup and biomass generation. The diverse applications and promising results of microalgae-based bioremediation processes highlight the potential of microalgae in promoting environmental sustainability and resource recovery.

CONCLUSIONS

Microalgae production is at the forefront of a sustainable bio-based economy, with applications in various industries. High lipid content in some microalgae species makes them a promising source for sustainable biofuels, addressing energy demands and environmental concerns. Their bioactive metabolites are increasingly used in pharmaceuticals and cosmetics. Microalgae biomass production provides a cost-effective and eco-friendly source of bioactive compounds for these industries. On the other hand, microalgae offer nutrient-rich alternatives for livestock, poultry, aquaculture feed, and food products, addressing food scarcity and promoting sustainability. Additionally, microalgae serve as feedstock for biomethane and biogas, offering renewable energy solutions and waste management. Integrating microalgae-based wastewater treatment with biogas purification accelerates nutrient removal and biomass production, showcasing dual benefits. Their application in bioremediation of air and wastewater offers sustainable solutions for environmental cleanup, contributing to cleaner ecosystems. In summary, microalgae-based technologies hold significant potential for environmental sustainability, resource recovery, and developing a bio-based economy that addresses energy demand, pollution, and resource management challenges.

ABSTRACT

The study was conducted in the Harran Plain (HP), which has high agricultural potential. No severe natural factors limit agricultural activities in the study area. This study aims to determine the uses that cause the loss of agricultural lands in the Harran Plain and to determine the distribution and percentage ratios of these areas within the plain. Among these uses, settlements (CS; Current Settlements and HHS; Historical Harran Structures) and the region used as a Military Border Zone (MBZ) were considered. It has been determined that the non-agricultural area of the study area, which has a surface area of 157,252 ha, is 6474.04 ha due to CS, HHS, and MBZ. This amount means that approximately 4.11% of the Harran Plain is taken out of agriculture by the people. These lands, which were taken out of agriculture, were formed not because of misuse but because of basic needs. Moreover, lands outside agriculture caused by road networks formed over time in the study area are not included in this value. However, another data revealed in the interpretation of the satellite image is that the excessive and unplanned road network also reduces the usage areas of agricultural lands in the plain. The results show that remote sensing methods using up-to-date satellite imagery play an important role in revealing the distribution, amount, and causes of lands taken out of agricultural use in areas where intensive agricultural activities are applied.

Keywords: Remote sensing, non-agricultural mapping, land use, Harran Plain.

INTRODUCTION

38% of Turkey's surface area consists of lands with a slope of 0-12% and 62% consists of lands with a slope of 12-30%+. Only 13% of the 38% consists of flat/near-flat lands (0-2%) (Topçu, 2012). In places where the topography has such a distribution, the importance of arable and flat areas increases. The study area is a very fertile plan and is in this 13% valuable flat/near-flat area. Agricultural lands in the study area are no longer used for agricultural purposes because of human-induced misuse and unplanned use. Therefore, there is a loss of agricultural areas in the Harran Plain. It is possible to encounter the same problem in different geographies.

The researchers found that change detection analysis in Mansoura and Talkha during 25 years shows that the built-up area has increased from 28 to 255 km2 by more than 30% and agricultural land has reduced by 33% (Hegazy and Kaloop, 2015). The image characteristics on the satellite data of the Harran Plain and Mansoura and Talkha are very similar in terms of land use, shape, and area size. In a study conducted in Sivas province, they found that the city developed in the northeast, south, and southwest directions (Karakuş et al., 2015). Many lands are facing different problems like soil erosion, water logging, groundwater depletion, heavy runoff, and productivity losses. (Barah, 2010; Zolekar and Bhagat, 2014). Urban sprawl is one of the main problems that threaten the limited highly fertile land in the Nile Delta of Egypt

(Shalaby, 2012; Shalaby et al., 2012). In a study conducted between 1992 and 2009, it was determined that the total available agricultural areas decreased by 43.5% compared with the total area, whereas urban use increased to 202.5% within the same period and area (Afifi et al., 2013). In a study conducted in the Nile Delta, while the rate of loss of agricultural lands to urban use was high between 1984 and 1992, urban development was directed to lands that were not suitable for agriculture between 1992 and 2006 (Shalaby, 2012). In a study in Nigeria, the researchers found that the percentage changes in arable lands, bare surface lands, settlements, forests, and water bodies were 11.24%, -5.86%, 28.36%, -33.87%, and 0.13%, respectively (Balogun et al., 2011). Several studies have shown that unplanned changes in land use due to urbanization have become a major problem (Zhao et al., 2004; Nanda, 2005). In a study conducted between 1987 and 2001 on the northwestern coast of Egypt, a serious land cover change occurred because of agricultural and tourism development projects, vegetation deteriorated in a part of the study area, and water accumulation areas emerged (Shalaby and Tateishi, 2007).

Remote sensing and GIS approaches were used to identify land use and land cover change between 2002 and 2022 in the Mymensingh region of Bangladesh, which is a rapidly developing and growing region. Researchers found that over a 20-year period, the biggest change was in construction land use, resulting from the expansion of the Bhaluka town area by 217.1% (6.56 km2) (Seyam et al., 2023). Similarly, another important finding found in another studies are that the growth rate of urbanization and population growth are among the main factors that cause cultivated areas to become non-agricultural (Ding et al., 2022; Abebe et al., 2023).

In this study, we aimed to determine the current land uses that caused the loss of agricultural lands in the Harran Plain using remote sensing and to determine the percentages by mapping the distribution of these areas within the plain.

MATERIAL AND METHOD

The study area is a very fertile plain in the southeastern Anatolia Region of Turkey (Figure 1). It is located between the coordinates $37^{o}11^{'}59^{''}$ N, $38^{o}47^{'}58^{''}$ E and $36^{o}39^{'}54^{''}$ N, $36^{o}11^{'}59^{''}$ E and is adjacent to Syria. The geological formation of the study area is a graben plain. HP has plenty of settlements (mostly small) in 157.252 ha. Apart from these residential areas, there is a historical site in the middle of the plain where the old Harran houses are located. The study area has a bowl-shaped slope in the west-east direction and a slight slope toward the Syrian border in the North-South direction (Figure 2). Therefore, the Harran Plain has very fertile soils.

Google Earth satellite imagery was used to identify land uses in the study area. The resolution of the image is highly suitable for this interpretation. QGIS 3.16.2 was used for digitizing and GIS processes (geo-referencing, labeling, mapping, etc). Necessary proportional calculations were performed using Microsoft Excel.

Figure 1. Location map of the study area (Harran Plain).

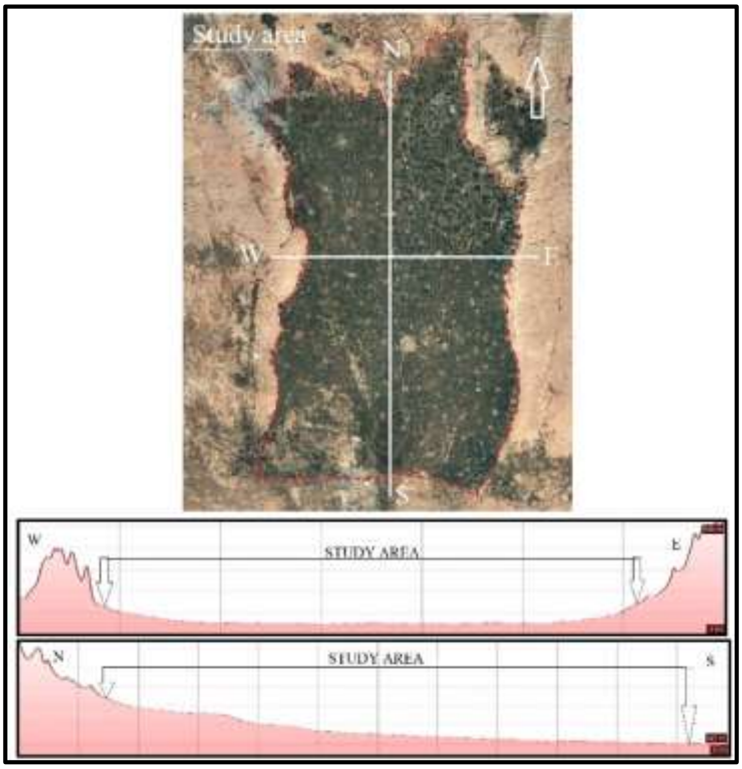

Figure 2. On top; directions of cross sections (North-South, and East-West) on the satellite image (Google Earth) and below; its cross-section profiles of the study area.

Methodology; five basic stages were applied in this study. The study area was identified in the first stage. The Harran Plain (HP) was selected as the study area. The second stage includes downloading satellite imagery of the study area and its geo-referencing process. The coordinates required for the control points to be used in the geographic correction of the satellite image were obtained from Google Earth satellite data. The third stage is the interpretation of the satellite imagery. Roads, irrigation cannels, HHS, CS, and MBZ were defined as a result of image interpretation. Digitization of identified land use types is the fourth stage of this study.

The borders of the study area, historical settlements, residential areas, and mined fields were digitized. We focused on these uses in the agricultural fields of HP. The data obtained according to the results of the research findings were also evaluated in the fifth stage, which constitutes the last stage of the study. The workflow of the applied methodology is shown in Figure 3.

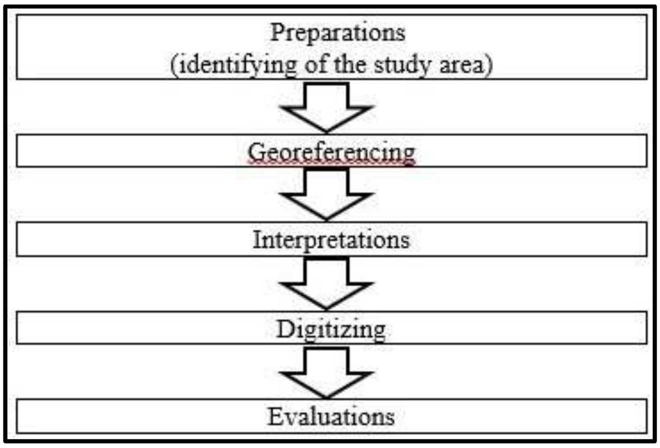

Figure 3. Workflow of the applied methodology in the study.

RESULTS AND DISCUSSION

The study area is approximately 155,252 ha. It is mostly used for agricultural activities. However, some agricultural areas have irregular shapes and some small sizes because of traditional reasons. There are too many roads between agricultural fields and settlements. While it is desired that the agricultural lands be adjacent to the road at least at one border, this situation is also seen in the second and even third borders in the study area. This is a factor that causes the loss of agricultural lands in the HP. These positions of the roads were not evaluated in this study.

In the image interpretation, it was determined that the main land use types in the study area were CS (5518.17 ha), HHS (69 ha), and MBZ (886.87 ha), with the exception of roads. These land use types are shown in Figure 4. The spread of CS, HHS, and MBZ in the study area was 3.51, 0.04, and 0.56%, respectively (Figure 5). In other words, 6,474.04 ha of the study area (4.11 %) has been excluded from agricultural use because of the defined uses.

A closer look at the area where the HHS is located reveals that this historic settlement is surrounded by CS (Figure 6). This close location also increases the risk of damage to the HHS tissue.

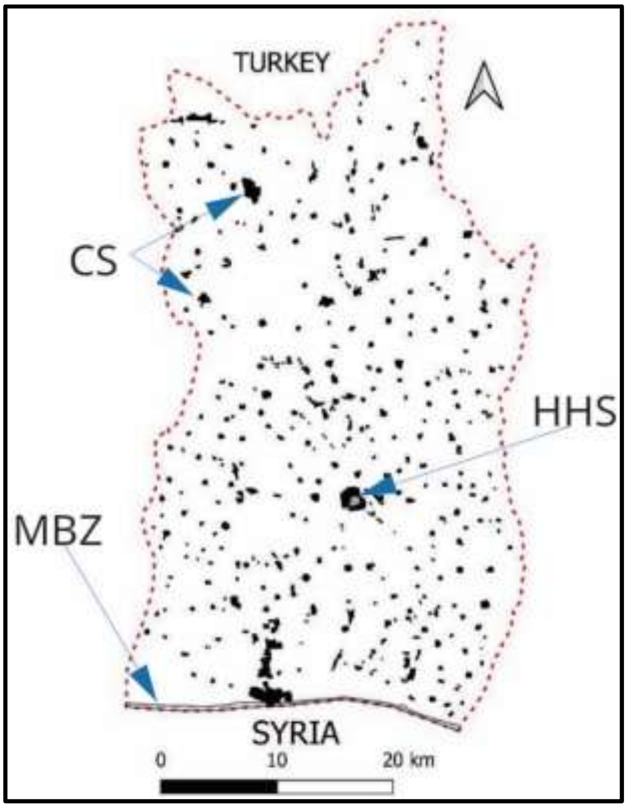

Figure 4. Distributions of CS (all of the black pieces), HHS, and MBZ in the study area.

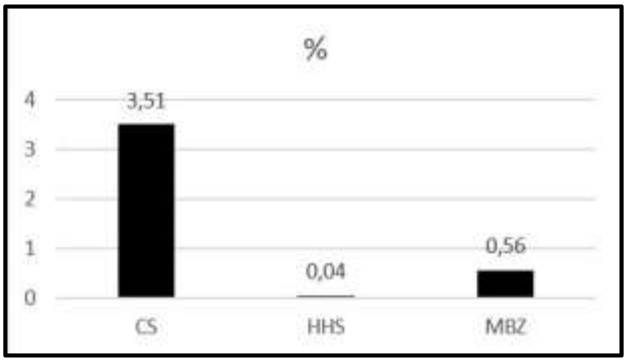

Figure 5. Distribution rates of land use (CS; Current Settlement, HHS; Historical Harran Settlement, MBZ; Military Border Zone) causing loss of agricultural area within the study area.

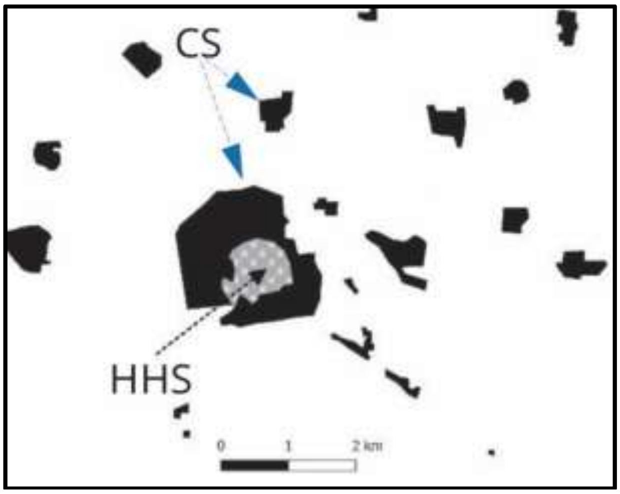

Figure 6. Black areas show CS, gray area shows HHS in the study area (a more detailed view).

It has been determined that a significant amount of agricultural land has been lost in a way that cannot be recycled because of unplanned and incorrect land use in the study area. Considering the road network used for transportation in the Harran Plain, the loss of agricultural lands has increased.

CONCLUSIONS

In a previous study, land uses were successfully determined, and the findings were mapped using remote sensing methods. In the other conducted research, it was observed that agricultural lands decreased over a 25-year period (decreased by 33%), and this reduction was attributed to the expansion of residential areas (increased by 30%). In a study conducted between 1992 and 2009 (19-years period), it was determined that the total available agricultural areas decreased by 43.5% compared with the total area, while urban use increased to 202.5% within the same period and area. In previous studies, positive/negative changes in agricultural and residential areas over the years have been assessed. However, in this study, the current distributions of land use types causing the loss of agricultural areas have been evaluated. In both cases, the factors leading to the loss of agricultural areas exhibited similarities.

In conclusion, the results of this research demonstrated that the study area has three main reasons for the loss of agricultural area. These are settlements (CS and HHS), military zones, and road networks in the Harran Plain. It is predicted that the irregularity of the settlements is caused by culture, and the military zone is due to the geopolitical position. The road network also exhibits a distribution that is dependent on the spread of settlements within the study area. In other words, the arrangement of settlements and the pattern of the road network are directly proportional to each other. If we make a comparison; considering that a soccer field is approximately 0.71 ha, there is a loss of land suitable for agricultural use in the size of approximately 9021 soccer fields in the study area.

The factors that cause loss of agricultural land are not the same in different environments and cultures; these factors may vary. MBZ, which is an important factor in our study, may not be important in another agricultural area. The effect of road networks on the loss of agricultural land increases in direct proportion to the irregularity and density of settlements. Complex road network characteristics are also the result of irregular settlements. The next step in the future should be the assessment of the unplanned road network and the changes in the loss of agricultural areas in Harran Plain from the past to the present.

Furthermore, this study has the potential for further investigations, particularly in assessing the impact of unplanned road networks on agricultural land loss. As technology continues to advance, these methods offer a pathway for creating informed land management strategies that balance the demands of urbanization with the preservation of vital agricultural areas. Overall, this study contributes to a broader understanding of landscape changes, offering insights that can inform sustainable land use planning and resource management practices.

ABSTRACT

The present study aimed to investigate the total phenolic and total flavonoid amounts of two distinct endemic species, namely Astragalus tokatensis Fischer and Verbascum myrianthum Boiss. A review of the literature revealed no studies on the bioactive compounds of these two plants. Consequently, methanol and hexane extracts of the flowers and leaves of the two plants were obtained. The flavonoid and phenolic amounts of the extracts obtained in different solvents were determined and compared with one another. The findings demonstrated that both Astragalus tokatensis Fischer. and Verbascum myrianthum Boiss. possess flavonoid and phenolic active compounds. The findings indicate that the total phenolic substance measurements were higher in the methanolic extracts of Verbascum myrianthum and Astragalus tokatensis plants than in the ethanolic extracts. In the case of the Astragalus tokatensis plant, the total flavonoid content was found to be similar in both the methanolic and ethanolic extracts.

Keywords: *Astragalus tokatensis Fischer*, *Verbascum myrianthum* Boiss., flavonoids, and phenolics.

INTRODUCTION

Phenolic compounds are defined as compounds containing one or more hydroxyl groups directly attached to the aromatic ring (Vermerris et. Al 2006). Phenolic substances are of great importance for both the plants themselves and for humans when plants are consumed. Phenolic substances are known to possess a multitude of properties, including antioxidant properties. Antioxidant substances are capable of suppressing the formation of free radicals. Consequently, a significant number of studies have concentrated on the antioxidant properties of phenolic substances. Research has demonstrated that antioxidant substances have a beneficial impact on degenerative diseases, cardiovascular diseases and, in particular, cancer (Murkovic et al). Consequently, the determination of the total amount of phenolic substances in plants has become a crucial area of interest.

Flavonoids are currently employed in a multitude of fields, particularly in the pharmaceutical, medical, and cosmetic sectors. Flavonoids, which are found in diverse plant parts, are regarded as significant natural products due to their polyphenolic structures (Panche et. Al 2016).

The determination of phenolic matter was modified and developed by Folin and Ciocalteu in 1927 and has since become the most widely used method for the determination of total phenolic matter. Despite this, there are still hundreds of plants whose total phenolic matter content has not been determined, despite the fact that the determination of phenolic matter can be performed for approximately a century.

Flavonoids are a subclass of phenolic substances. They are found in a variety of vegetables and fruits. The most well-known flavonoids are quercetin and rutin. Studies have demonstrated that flavonoids possess antioxidant properties, whereby they neutralise free radicals. Subsequent studies have revealed that flavonoids have beneficial effects in the treatment of certain diseases, including inflammation, viral infections and cancer (Duangjai et al 2018).

Currently, there are numerous products on the market that claim to be antioxidant-effective. Recently, there has been a notable surge in demand for such antioxidant-containing products. However, due to concerns about the synthetic nature of these products, there has been a shift towards natural alternatives.

The aim of our study was to determine the total phenolic and total flavonoid content in the leaves, buds and flowers of two plant species: Astragalus tokatensis Fischer and Verbascum myrianthum Boiss.

The genus Verbascum is a member of the family Scrophulariaceae, which comprises 360 species distributed worldwide. The species in this genus are typically found in the temperate climates of the northern hemisphere, occupying dry, rocky, and open habitats (Heywood, 1979; Juan et al., 1997). In Turkey, Verbascum is known by the vernacular names ‘mullein’ and ‘king's candlestick’, and 185 of the 233 species are endemic (Davis, 1978; Davis et al., 1988; Güner et al., 2000). Verbascum myrianthum Boiss. is a biennial or perennial species, reaching a height of 60-100 cm. It is characterised by a dense greyish pubescence, which transitions to white pubescence, and an early deciduous habit. The plant becomes glabrous at maturity above. The stem is broadly angular and typically branched from the base. The basal leaves are oblong-angular-lanceolate, measuring 15-20 x 4-6 cm. They are coarsely and bluntly notched, or more often with mid-carved lobes. The margin has carved lobes that are notched or with shallowly lobed segments below. The petiole is 3-5 cm long and the upper petiole is short and subentire. The inflorescence is markedly branched and broadly paniculate, comprising one to four loose flower clusters. The bract (or flower petal) is acutely to ribbony in shape. The peduncle measures 7 mm, and the bracts are narrow and small. The calyx measures 3-6 mm and comprises lobes that are ribbed or ribbed oblong, with blunt tips. The corolla is yellow in colour, with a diameter of 12-16 mm, and is characterised by the presence of transparent glands and external hairs. The plant bears five stamens and spikelets that are reniform in shape. The phyllaries are coated in whitish-yellow hairs, and there are two spikelets that are hairless above. The capsule is elliptic ovate, measuring 4-5 x 3-4 mm, and is characterised by a hairy texture (Davis, 1978; Seçmen et al., 2018). Verbascum species have a long history of use in traditional medicine in their regions of origin and remain in use today. Verbascum species belonging to the Scrophulariaceae family have been employed for centuries in the treatment of various internal and external infections. The majority of communities in Europe, Asia, Africa and North America have also documented the utilisation of the leaves and flowers of Verbascum species, which contain a range of active constituents, for a variety of purposes (Meurer-Grimes et al., 1999).

The Fabaceae is one of the largest families of flowering plants, representing the third largest angiospermae family in the world in terms of number of species. It is surpassed in this regard only by the Asteraceae (Compositae) and Orchidaceae, with nearly 770 genera and more than 19,500 species. In economic terms, it is the second largest family after Poaceae (LPWG, 2017). A total of 69 genera and 958 species have been identified within our country (Seçmen et al., 2018). Astragalus tokatensis Fischer is an endemic species of dwarf cushion-forming shrub, measuring approximately 10 cm in height. The leaves are characterised by the presence of hairs and spines on the petioles. The leaves are 4–6 cm long, oblique, and flattened towards the base. The leaflets are 10-14 mm in length, ovate in shape, mucronate, and simple white tomentellous, with five to six parts. The leaflets, or stipules, are located at the base of the petiole and measure approximately 8 mm. They are ovate to obtuse in shape and sparsely hairy when young, but become glabrous with age. The flowers are sessile, occurring in numbers of three to five in the axils of the leaves. The inflorescence is ovate in shape and approximately 3.5 cm in diameter, comprising 50 or more flowers. The bracts, which are scalelike leaves, are approximately 9 mm long, lanceolate, navicular, and pubescent towards the apex. The bracts measure 6-7 mm and exhibit hairiness towards the apex, while the lower surface is glabrous. The calyx is 10-13 mm in length and is densely hairy, with lobes that are more or less divided at the base. The colour of the corolla is unknown; the standard is 18-20 mm. The flower has a diameter of 7 mm. It is found in steppe habitats at an altitude of approximately 1300 m. These findings were reported by Davis (1978), Davis et al. (1988), and Güner et al. (2000).

MATERIAL AND METHOD

The total phenolic and total flavonoid contents were determined in plants of the species *Verbascum myrianthum* (1) and *Astragalus tokatensis* (2). The plants were subjected to a 15-day drying process in a shaded environment, after which they were separated and subjected to a second drying process in an oven maintained at 40°C. The moisture content of the plants was then determined.

Sample preparation: In total phenolic and flavonoid process, the plants were ground after drying and subjected to both ethanolic and methanolic extraction experiments. In these experiments, the solvent was applied at a ratio of 1:15, and the extraction process was conducted in an ultrasonic bath for six hours. The separated plants were assigned distinct codes.

***Astragalus tokatensis* (ethanolic extract)**	2E		

Total Phenolic Substance Determination Method

The total phenolic content was determined using the Folin-Ciocalteu reagent (FCR) method. A Shimadzu UV 1800 Spectrophotometer was utilized for the analysis, with gallic acid (GA) employed as the reference standard. The results were expressed as gallic acid equivalents (GAE). The Folin reagent was prepared at a concentration of 0.5 N. To quantify the phenolic content in terms of mg GA per gram of sample, a stock solution of gallic acid was prepared and subsequently diluted to produce a series of standard solutions. These standards were derived from a 1000 ppm GA stock solution and included concentrations of 500, 250, 125, 62.5, 31.25, and 15.625 ppm. A 10% sodium carbonate (Na_2CO_3) solution was used as the colorimetric indicator. Upon preparation of these solutions, the pipetting process commenced. Total phenolic matter concentration was found by reading the results at 760 nm wavelength.

Determination of Total Flavonoid Substance

Total flavonoid content is determined by $AlCl_3$ colourimetric method. Based on quercetin (QE) standard, it is analysed according to quercetin equivalence. Total flavanoid content was determined by using Shimadzu UV 1800 Spectrophotometer. The absorbance was made by photometric method at 415 nm. For the standard, 1000 ppm stock quercetin (QE) standard was prepared, and 6 different standards were obtained by serial dilution as 250; 125; 62.5; 31.25; 15.625 ppm. 2% $AlCl_3$ was prepared as reagent. Pipetting was performed by adding 2% $AlCl_3$, water, sample in certain ratios to the balconies prepared for pure water, standard and sample. It was kept in the dark for 60 minutes. Total flavonoid matter concentration was found by reading the results at 415 nm wavelength.

RESULTS AND DISCUSSION

In our study, the plants were subjected to a 15-day period of drying in a shaded environment, followed by a second drying process in a 40°C oven. Subsequent to the process of dehydration, measurements of moisture content were conducted. The seeds of Verbascum myrianthum exhibited a moisture content of 8.45%, the flowers displayed 8.72%, and the leaves demonstrated 9.25% moisture content. In contrast, the leaves of Astragalus tokatensis exhibited a moisture content of 7.41%. Subsequently, the harvested plants were diluted in a 1:15 ratio with a solvent. The solvent employed was a methanol-ethanol mixture, and the sample was subjected to an ultrasonic-assisted extraction process for a period of six hours. The total phenolic and flavonoid content assays were conducted in sequential steps, following the prescribed methodology. The Shimadzu UV 1800 spectrophotometer was employed to obtain the appropriate absorbance values.

The results of the determination of total phenolic matter in the leaf parts of the Verbascum myrianthum plant yielded the following values: 255,623 mg GA/L in the methanolic extract (1MY) and 143,582 mg GA/L in the ethanolic extract (1EY). In the determination of total flavonoid content, the methanolic extract exhibited a value of 198,666 mg QE/L, while the ethanolic extract demonstrated a value of 138,582 mg QE/L.
The total phenolic content in the bud parts of the Verbascum myrianthum plant was recorded as 820,547 mg GA/L in the methanolic extract (1MT) and 546,773 mg GA/L in the ethanolic extract (1ET). Upon subjecting the same methanolic and ethanolic extracts to total flavonoid determination, the methanolic extract yielded 197,271 mg QE/L, while the ethanolic extract yielded 179,416 mg QE/L.

In the ethanolic extracts of the yellow flowered (1MC) parts of the same plant, the measurement of total phenolic matter was read as 338.963 mg GA/L, while the total flavanoid amount was read as 144.03 mg QE/L.

The application of the total phenolic matter determination process to the methanolic extract of Astragalus tokatensis yielded a concentration of 415,415 mg GA/L, whereas the ethanolic extract resulted in a concentration of 247,404 mg GA/L. With regard to total flavonoid matter, the methanolic extract exhibited a concentration of 246,543 mg QE/L, while the ethanolic extract demonstrated a concentration of 255,567 mg QE/L.

The findings revealed that the total phenolic substance measurements were higher in the methanolic extracts of *Verbascum myrianthum* and *Astragalus tokatensis* plants than in the ethanolic extracts. In *Astragalus tokatensis*, the total flavonoid content was found to be similar in both methanolic and ethanolic extracts.

Table 2. Total phenolic matter and total flavonoid matter amounts

Numune	**Concentration mg GA/L Total Phenolic Substance**	**Concentration mg QE/L Total Flavanoid Substance**
1MY	255,623	198,666
1MT	820,547	197,271
1MC	338,963	144,03
1EY	143,582	138,582
1ET	546,773	178,416
2M	415,415	246,543
2E	247,404	255,567

CONCLUSIONS

Endemic plants are defined as plant species that are unique to a particular geographical region and do not occur naturally outside that region. These species are typically plants that have adapted to specific ecological conditions and are unable to survive in other regions. An understanding of the ways in which endemic species adapt to specific geographical and climatic conditions is crucial for the study of adaptation mechanisms. These studies yield valuable insights into the genetic diversity of species and the evolutionary processes that shape them. A significant number of endemic plants are utilized in traditional medicinal practices and are also of value for the development of new pharmaceutical agents in modern medicine. The conduct of experimental studies enables the investigation of the pharmacological effects and the medicinal potential of these plants. Phenolic substances and flavonoids have been demonstrated to possess robust antioxidant properties. These compounds serve to safeguard cells against oxidative stress by neutralizing free radicals. The quantification of these compounds in endemic plants is a crucial aspect in the evaluation of the antioxidant capacity and potential health benefits associated with the plant.

EFFECTS OF BIOSOL BIOFERTILIZER ON THE PRODUCTIVITY AND CHANGE OF HERBAGE IN NATURAL PASTURES IN STRANDZHA MOUNTAIN.

Dimitrinka Krusheva

Experimental Station of Agriculture, 8300, Sredets, Bulgaria
Corresponding author e-mail: kasidi4@abv.bg

ANNOTATION

This article presents the results of a study on the impact of BIOSOL biofertilizer on the productivity and change of the herbage in natural pastures in Strandzha Mountain. Fertilization is the key factor for boosting the productivity and quality of biomass. For sustainable productivity and quality of biomass from grass associations, the most sensible approach is the application of appropriate biological fertilizers. Observations were made on 4 natural grasslands, fertilized with BIOSOL in the area near the state border in South-Eastern Bulgaria (Strandzha Mountain), during the period 2022-2024. The study results provide evidence that fertilization with BIOSOL biofertilizer on natural pastures in the region of Strandzha leads to increase in the yield of green mass by 7-8%. After fertilization, there are changes in the height of the plants in the pasture; the content of crude protein in the dry mass also increased. Botanical composition and herbage density were not affected by fertilization with BIOSOL.

Key words: Strandzha, natural pastures, productivity, biofertilizer

INTRODUCTION

Natural pastures are of quite significant economic and ecological importance, they are the main source of grass protein-rich fodder. The use of natural pastures is the traditional way of feeding animals in the Strandzha Mountain area. One of the main priorities today is the full utilization of the available natural resources, while at the same time emphasizing their preservation. In order to thrive in the future, natural ecosystems require conservation, restoration and proper management *(Godwin et al., 1998; Sutherland et all., 1995).* Integral part of these ecosystems are natural meadows and pastures which are the main source of ecologically clean fodder *(Stoeva et al., 2005).*

Natural pastures in Bulgaria produce 700-1200 kg/ha of hay *(Pavlov, 2007).* Fertilization is the key factor for boosting the productivity and quality of biomass.Studies in Bulgaria show that fertilizing with mineral fertilizers has a strong impact by increasing yields of green fodder and improving the quality of composition of existing natural pastures. (*Boikov. S., 1986; Owen, O., 1981; Totev and Valkov, 1988; Totev, T., 1984; Yakimova, Ya., et al., 1977).*

Conducted studies prove that fertilizing with mineral (nitrogen, phosphorus and potassium) fertilizers on a natural pasture in the Strandzha region leads to an increase in the yield of green mass up to 5.8 times, (*Stoeva, K., V. Vateva, 2007).* For the conditions of the Sakar region, with complete mineral fertilization of a dry field pasture on highly eroded leached cinnamon-forest soil, the yield from the pasture increased 5-8 times *(Dzhingov , Al. et al., 1994).*

Fertilization of eroded terrains has a twofold benefit. On the one hand, the application of fertilizers improves the nutritional status of the soil, creating more favourable conditions for the development of vegetation therein. On the other hand, the introduction of fertilizers improves the water-physical characteristics of the soil which on its part affects the intensity of washing out of the soil. *(Myanushev, E., et al., 2005).*

A study conducted in the period 2005-2008 at the Agricultural Experimental Station – town of Sredets (*Stoeva K. et al., 2010)* demonstrates that on average for the period, the yields of green mass from a perennial grass mixture varied between 2258.1 and 2624.8 kg/daa, and of dry mass - from 778.8 to 861.8 kg/daa when fertilizing with different types and rates of manure.

Most of the territories of Strandzha are characterized as low-mountainous, hilly areas. The hilly areas of Strandzha are formed by dry xerophytic meadows. (*Yancheva, Hr. 2006)* and accordingly *(Stoeva, K et al., 2005),* the pastures in Strandzha are chiefly composed of Bermuda grass / perennial ryegrass (*Cynodon dactylon L. / Lolium perennial L.*). Most of the soils have a humus content of less than 2% and high acidity. The area is one of the driest in Bulgaria. Precipitation is insufficient and as a result of the drought in spring and summer, the grass vegetation ceases its growth and dries up (*Stoeva, K. et al., 2002).* A significant fraction of the pastures also suffer from water erosion, I and II degree.

All this necessitates the combination of appropriate agrotechnical and meliorational measures to improve the general condition in terms of the productivity, quality and botanical composition of the grassland. For sustainable productivity and good quality of the biomass from grass associations, the most reasonable approach is the use of suitable biological fertilizers.

The goal of the study presented herein was to determine the impact of biofertilizer BIOSOL on the productivity and the change of the herbage of natural pastures in the Strandzha Mountains.

MATERIALS AND METHODS

The study was conducted on 4 natural grasslands in the border area of South-Eastern Bulgaria (Strandzha Mountain)

They have been so selected so as to cover the most typical and used natural grasslands in the foothills of the region.

Plot 1 (variant 1) – 240 m altitude, with slope 8°, east exposure.
Plot 2 (variant 2) - 350 m altitude, with slope 6°, south exposure.
Plot 3 (variant 3) - 380 m altitude, with slope 12°, northwest exposure.
Plot 4 (variant 4) - 280 m altitude, with slope 4°, southeast exposure.

Respectively, tests have been carried out on these four plots to monitor the impact of biofertilizer BIOSOL in a dose of 30 kg/da. Fertilization was done manually at the beginning of March and after the first swath. Mowing was done manually during hay maturity phase.

During the period of the study hereof, the following parameters were tracked down: yield of green mass by weighing the mowed fresh mass from the plots; botanical composition of the herbage – it was determined by weight and the percentage of cereals, legumes and miscellaneous grasses was determined; the density of the grass - expressed in pieces/m^2; the grass height - the measurement was made before mowing; chemical composition of the dry matter on the average of the four variants - the percentage content of crude protein, crude fats, crude fiber, minerals and nitrogen-free extract; climatic characteristics and their impact on the productivity of natural pasture grasses.

RESULTS AND DISCUSSION

Meteorological conditions and especially rainfall are the dynamic factors that have a strong influence on the formation of the productivity of natural grasslands.

The meteorological conditions during the three years of the study (2022-2024) differed significantly from each other. Major differences between meteorological conditions were also reported as compared to the standard values for the region.

Regarding rain precipitation (Figure 1), during the vegetative phase, the highest amount of rainfall was measured in 2022 - 595.9 mm, and the least precipitation was marked in 2024 – 439.2mm. In 2023 the reported value of the rainfall in said period was 446.3 mm. Above data reveals that 2023 and 2024 had precipitation below the average value for the region, while precipitation in 2022 was above the average norm for the region - 528.9 mm. Uneven distribution of rainfall during the observed vegetative phase was also noticed.

In terms of temperature (Figure 2), all three years were warm, the average monthly temperatures being significantly higher than the average values for the multi-year period. The table reveals that the average temperatures during the vegetative phase are higher than the average temperature of the region for the multi-year period, that is 9.7°C. More precisely, in 2022 average temperature was 10.12°C, in 2023 - 11.12°C and in 2024 - 12.34°C.

In Figure 3, the botanical composition of the natural grasslands in Strandzha is showcased. The percentage ratio between cereal, leguminous and miscellaneous grasses is given. It can be seen that the pastures have higher content of cereal components - between 31.5% - 47.5% and miscellaneous grasses - between 29.3% - 60.6 %, the increase being due to the lower fraction of leguminous species - between 7.0% - 23.2%. No changes in the botanical composition were observed in the fertilized variants.

The density of the herbage, averaged over the three years (Figure 4) is expressed in pcs/m^2. The number of plants per m^2 in the control plot is smallest in Plot 1 - 1120 pcs/m^2, and largest in Plot 3 - 1420 pcs/m^2. On average for the period, there was no significant difference in the density of the herbage for the fertilized variants.

Plant height averages over the three years of the study is shown in Table 1. The data indicates that before the first cut, the height of the cereal species in the control plot is in the order of 61.2 - 80.5 cm, and of the leguminous species -between 36.8 and 40.0 cm. Before the second cutting, the height of the cereal species is from 36.5 cm to 42.1 cm and from 16.5 cm to 28.5 cm for the leguminous species. The difference in the height of the fertilized variants of the cereal grass compared to the control plot is less than 1 cm. More significant increase in height compared to the control plot was observed in leguminous grasses - from 1.5 cm to 3.2 cm.

The chemical composition of the dry matter on the average for the variants for the three years of the study is shown in Table 2. It shows that in the control plot, the average crude protein content is 6.90%, and crude fiber is 28.90%. Fertilization with biofertilizer BIOSOL leads to an increase in crude protein content up to 8.10% and decrease in the crude fiber to 25.30%. The content of crude fats, minerals and nitrogen-free extracts also increases in the fertilized variants compared to the control plot.

The data on the impact of fertilization with biofertilizer BIOSOL on the yield of green mass by year and on average for the three-year period (2022-2024) are presented in Table 3.

The table clearly demonstrates that 2023 has the highest yields in the control variants, this can be explained by the large amount of precipitation in the spring from March to June (307.6 mm) as well as due to the high temperatures in the winter months and temperatures in the spring close to the average for the region, which led to a rapid growth of the grasses.

The results reveal that the highest yield of green mass on average for the two swaths was recorded in the variant 3 grassland. The control plots values were respectively: for 2022 – 770 kg/da, for 2023 - 775 kg/da. and for 2024 – 765 kg/da. In the fertilized variants these were respectively: 845 kg/da, 827.5kg/d and 820 kg/da, which is most probably due to the higher content of leguminous and cereal grasses and the higher altitude of the pasture.

Variant 1 has the lowest productivity, in all three years with between 460 kg/da and 479 kg/da in the control plot while fertilized variants produced from 482.5 kg/da to 517.5 kg/da green mass.

On average for the three-year period, the amount of yielded green mass in the variants fertilized with biofertilizer BIOSOL increased by 7.0-8.0% compared to the control plots.

Definitely better results were observed on the pastures fertilized with biofertilizer BIOSOL although the weather conditions during the three years of the study differed significantly from each other in terms of both average monthly air temperatures as well as monthly precipitation totals.

CONCLUSIONS

The study of the three-year period allows us to draw the following conclusions:

Fertilization with BIOSOL on natural pastures in the Strandzha region leads to an increase in the yield of green mass by 7.0-8.0%.

After fertilization, there are changes in the height of the grass plants; the content of crude protein in the dry mass is also elevated.

Botanical composition and herbage density were not affected by BIOSOL fertilization.

Fertilization with biofertilizer BIOSOL has a positive effect on the grass characteristics in the natural pastures in the Strandzha Mountain region.

ABSTRACT

Leaf senescence represents the final phase of development, culminating in cell death. While leaf senescence poses challenges in the post-harvest lifespan of horticultural plants and the yield of agricultural plants, it plays a crucial role in facilitating the re-mobilization of nutrients within plants. Various factors can influence the regulation of leaf senescence. The natural senescence of the leaf starts and progresses according to a regular schedule. During senescence, morphological and physiological events occur along with intracellular changes. Despite this, these processes have not been thoroughly explored across many species. The snapdragon (*Antirrhinum majus* L) flower serves as a valuable model system that has been extensively studied in terms of genetic traits, flower development, and cellular death. However, the senescence of its leaves has not been investigated. This study delved into the morphological attributes of senescing snapdragon leaves and revealed significant alterations in various indicators as senescence progressed. The results indicated that many indicators changed significantly with the onset and progression of senescence. Notably, there were significant decreases in fresh and dry weight, photosynthetic pigment levels, total soluble protein content, and chloroplast numbers per cell. Conversely, ion leakage and the incidence of dead cells increased with the progression of senescence. Trypan blue staining elucidated that cell death initiation occurred at the leaf tip, progressing to encompass all cells within the leaf blade during the later stages of senescence.

Keywords: Chlorophyll, Chloroplast, Ion leakage, Soluble protein, Trypan blue

INTRODUCTION

Leaf senescence, the final stage of leaf development, is associated with a wide range of morphological, physiological, biochemical, cellular, and molecular changes. Leaf senescence includes changes in leaf color, chlorophyll degradation, breakdown of macromolecules, changes in the intracellular organelles, recycling of nutrients, and the activation of senescence-associated genes (SAGs), and it mainly starts with changes in developmental age (Guo, 2019).

The initial indications of leaf senescence become apparent through changes in leaf color (Zhao et al., 2018). Following a period of rapid expansion and achieving full maturity, a leaf initiates the senescence process, influenced by either the leaf's age or developmental stage or by environmental factors. Typically, the first signs of senescence involve the yellowing of the leaf tip, which gradually spreads inward towards the leaf blade. Eventually, the entire leaf blade takes on hues of yellow, orange, or purple, and the leaf dries up and shrinks, ultimately leading to cell death (Lim et al., 2007; Woo et al., 2018; Zhao et al., 2018).

Senescence is inevitable in all organisms. However, it can be delayed. The delay in senescence can be important in agricultural and horticultural crops in terms of yield and shelf life of crops. It can also impact carbon and nitrogen consumption in plants (Liang et al., 2014). Studies have indicated that senescence syndrome can be evaluated with morphological and physiological changes such as pigment content, nutrient content, ion leakage, and organelle structure. Age-related senescence is different in plant species. At different levels, leaf senescence has been investigated in a few model plants such as *Arabidopsis thaliana* (Buchanan-Wollaston et al., 2005). Therefore, an accurate description of leaf senescence using quantitative methods is very important in other plant species.

For many years, snapdragon (*Antirrhinum majus* L.) has been used as a model system for genetic studies and flower development (Lian et al., 2020; Rabiza-Świder et al., 2020). Recently, its petals have been considered in the evaluation of the programmed cell death (Roghayeh Nabipour Sanjbod et al., 2023a, 2023b). However, there is still no information about the senescence of its leaves. In this study, age-related senescence in snapdragon leaves will be investigated through some basic methods.

MATERIAL AND METHOD

This experiment was conducted at the University of Mohaghegh Ardabili, Ardabil, Iran in 2021 to investigate the leaf senescence of snapdragon. The F_1 seeds of snapdragon (*Antirrhinum majus* cv. Legend White) were purchased from the Takii seed company. The seeds were germinated in Petri dishes (20 °C, LED light, 3000 lux intensity) and sown in plastic pots (length = 18 cm and height = 15 cm) after the selection of coeval germinated seeds. The mixture of pot soil was vermicompost and complete organic fertilizers (3:1). The snapdragon plants were transferred to a greenhouse with standard conditions (15-18 °C, natural daylight) and were grown in December. The irrigation of pots was once every 2 days. Leaf longevity was divided into ten time points and the sampling of leaves was performed at these stages (days 18, 32, 46, 60, 74, 88, 102, 116, 130, 144). The first leaf was analyzed at each time point.

The measurement of fresh and dry weight was performed with a digital Micro Balance (Semi-Micro Analytical Balances GR-200, A&D Company, JAPAN). The samples were dried in an oven (60 °C, 48 h).

For investigation of electrolyte leakage, the leaf segments (squares of 1 × 1 cm) were immersed in deionized water (10 mL) and then placed in a water bath (25 °C, 30 min). After the measurement of initial conductivity (using conductivity meter, WTW InoLab Cond 720 Conductivity Meter, Carl Stuart Limited Company, UK), the samples were incubated in a water bath of 96 °C for 15 min. Then, the total conductivity was calculated and expressed as the percentage of the initial conductivity versus the total conductivity.

The content of chlorophyll and carotenoid was evaluated with the Lichtenthaler method (Lichtenthaler and Buschmann, 2005; Lichtenthaler and Wellburn, 1983). The pigment absorption was determined at three wavelengths (470, 645, and 662 nm) using a spectrophotometer (SP-UV 200, Spectrum Instruments Limited, Australia). The concentration of pigments was calculated using the following equation.

$$C_a\ (\mu g/ml) = 11.24 \times A_{661.6} - 2.04 \times A_{644.8}$$

$$C_b\ (\mu g/ml) = 20.13 \times A_{644.8} - 4.19 \times A_{661.2}$$

$$C_{(x+c)}\ (\mu g/ml) = \frac{(1000 \times A_{470} - 1.90 C_a - 63.14 C_b)}{214}$$

The leaf samples were fixed in 3.5% (v/v) glutaraldehyde for 1 h in the dark for chloroplast number per cell area. The samples were washed with Na2EDTA buffer (0.1 M, pH=9) and kept in this buffer. The samples were then placed in a shaker water bath (60 °) for 2.5 h and stored at 4 °C. The pictures of leaf samples were taken by light microscopy. Image J software was applied for quantification of chloroplast count (Evans et al., 2010).

For soluble protein, the leaf tissue (100 mg) was homogenized in phosphate buffer (pH=7) and centrifuged at 10000 rpm (10 min) at 4 °C. The supernatant (100 µL) was separated and mixed with Coomassie solution (5 mL). After vortexing, absorbance was read at 595 nm. BSA standard curve was applied for the calculation of total soluble protein (Roghayeh. Nabipour Sanjbod et al., 2023).

Dead cells of snapdragon leaf were detected with trypan blue staining. For this purpose, the excised leaves were placed in trypan blue staining solution at 96 °C for 1 min. The samples were left at room temperature for 1-24 h. The staining solution was removed and the samples were immersed in chloral hydrate solution for 2–4 h. After that, the chloral hydrate solution was removed and the samples were placed in 70% glycerol. The staining of leaves was recorded by taking pictures (Guo, 2019).

This experiment was conducted as a completely randomized design (CRD) with five replications and analyzed using SPSS software (version 16; SPSS Inc, USA). The means were evaluated with Duncan's multiple-range tests at 5% probability.

RESULTS AND DISCUSSION

The results of this study showed that with increasing age of the plant, fresh and dry weight increased and reached the maximum value on day 60, then with the onset and progression of senescence, a severe decrease in these parameters was observed, which was visually associated with leaf desiccation (Figure 1A and 1B). Interestingly, the leaves had the highest ion leakage on day 18 in electrolyte leakage. Gradually, with increasing age, ion leakage decreased. On the 88th day, an increase in electrolyte leakage was observed, which coincided with the progress of senescence and the beginning of cell death. After that, ion leakage decreased in the stage of leaf shriveling and desiccation (days 116, 130, and 144) (Figure 1C). The highest content of photosynthetic pigments was observed on the 46th day. After that, the content of chlorophyll a, chlorophyll b, and total carotenoids gradually decreased. (Figure 1D, 1E and 1F) The examination of the total soluble protein content showed that with increasing age and reaching day 88, this parameter increased with a gentle slope, and then with the onset of cell death, cell proteins were broken down and their content significantly decreased (Figure 1G). The highest number of chloroplasts per cell was recorded on the 46th day and their number decreased in the following days (Figure 1H). Trypan blue staining showed that the number of dead cells increased with increasing age. Furthermore, the death of the cells started from the tips and margins of the leaves and gradually the whole leaf cells experienced death (Figure 2).

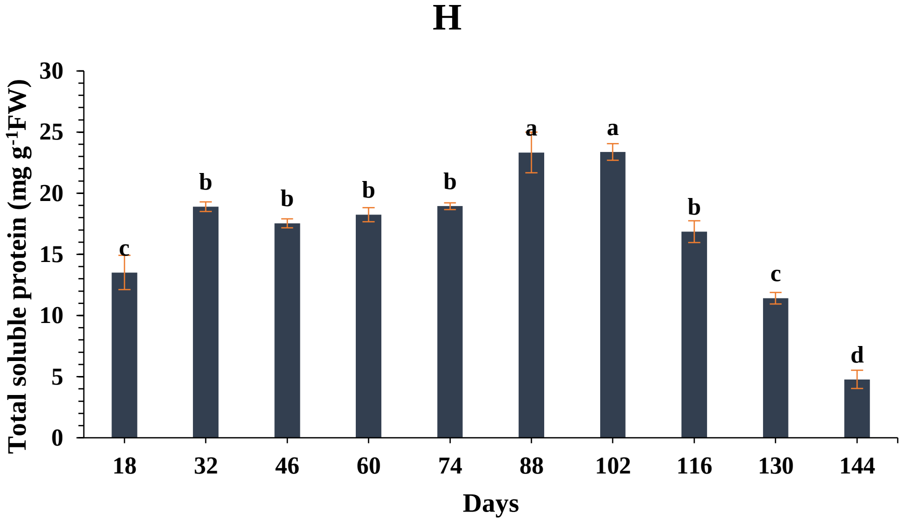

Figure 1. Phenotypic characteristics of snapdragon leaves during senescence. (A): fresh weight, (B): dry weight, (C): electrolyte leakage, (D): chlorophyll a content, (E): chlorophyll b content, (F): carotenoids content, (G): chloroplast number, (H): total soluble protein. Different letters indicate significant differences at p≤ 0.05 (Duncan's test). Error bars represent ±SD, n=5.

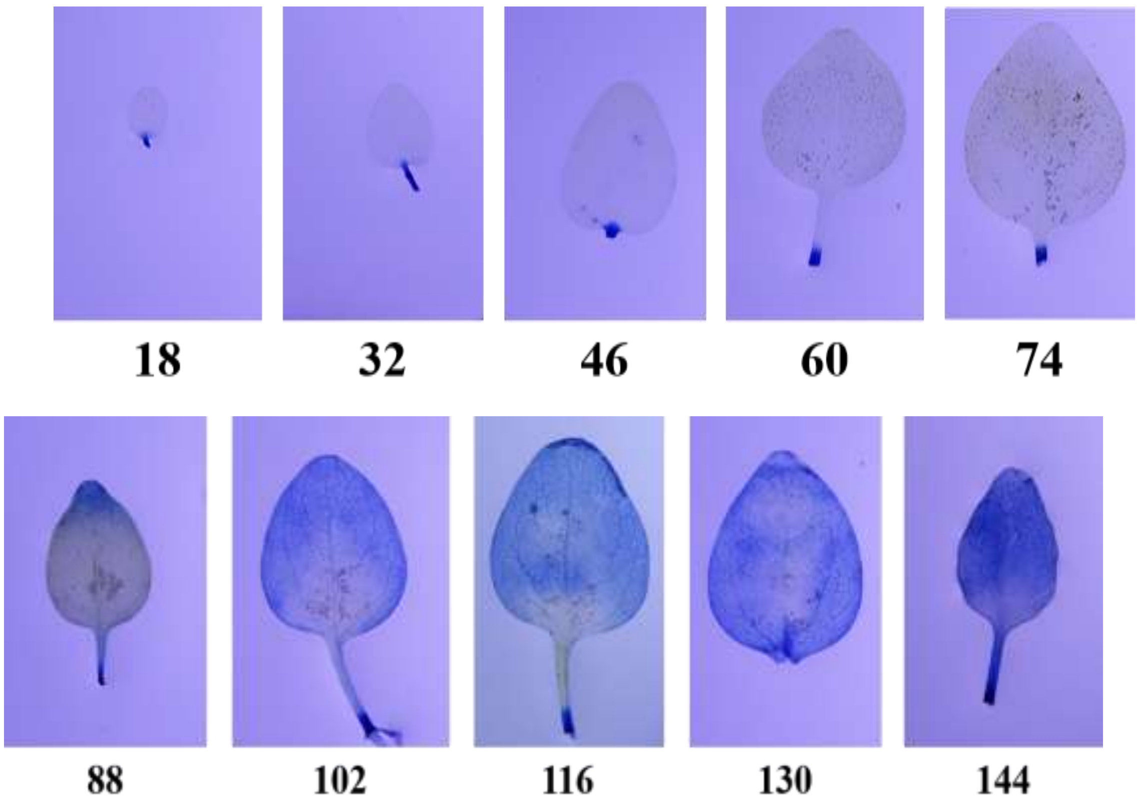

Figure 1. Progression of cell death in snapdragon leaves.

Leaves, as specialized organs for photosynthesis, require considerable energy and nutrients for production; following a productive period, leaves enter senescence where nutrients are redistributed to younger leaves, seeds, or stored for future growth, resembling a recycling program at the organismal level (Quirino et al., 2000).

The senescence of leaves can be discerned through alterations in their appearance. The initial visible indications of leaf senescence involve changes in leaf color. Following growth and maturation, a leaf enters the senescence phase. In typical circumstances, the initial signs of senescence with the yellowing of the leaf tip, progressing gradually towards the leaf blade, eventually resulting in the entire blade, followed by leaf desiccation and shrinkage, culminating in cell death (Guo, 2019) as observed with trypan blue staining.

Chloroplasts are among the primary organelles targeted for degradation at the onset of senescence. Similar to our findings, the loss of chlorophyll is a noticeable occurrence during senescence and is frequently used as a biomarker for the start of senescence. On the other hand, numerous other breakdown processes such as protein, lipid, and nucleic acid degradation also happen (Zhao et al., 2018).

Protein degradation represents a crucial process during leaf senescence, playing a pivotal role in nitrogen recycling. Studies at the transcriptomic level have revealed a significant upregulation of genes related to proteolytic activities (Breeze et al., 2011). Predominantly, serine proteases and CysProt enzymes are prominently associated with leaf senescence, although aspartic, threonine, and metalloproteases have also been identified (Diaz-Mendoza et al., 2016). Plant protease activities have been identified in various cellular compartments such as nuclei, chloroplasts, cytosol, ER, vacuoles, mitochondria, apoplast, cell wall, and specialized vesicles (Diaz-Mendoza et al., 2016). The chloroplast stands as the primary reservoir of mobilizable proteins within the cell, with Rubisco and the chlorophyll-binding light-harvesting proteins of PSII (LHCIIs) being the major proteins (Hörtensteiner and Feller, 2002). Chloroplast proteins account for up to 80% of the total leaf nitrogen and serve as a key nitrogen source during mobilization from senescing leaves. Throughout senescence, chloroplast proteins are believed to undergo degradation through coordinated actions of chloroplast proteases, senescence-associated vacuoles (SAVs), and the ubiquitin/26S proteasome pathway (Diaz-Mendoza et al., 2016).

CONCLUSIONS

The findings revealed that several markers experienced significant alterations as senescence began and developed. Noteworthy was the considerable reduction in both fresh and dry weight, levels of photosynthetic pigments, total soluble protein content, and the number of chloroplasts per cell. In contrast, there was an increase in ion leakage and the prevalence of dead cells as senescence progressed. Analysis with trypan blue staining showed that the initiation of cell death occurred at the tip of the leaf, extending to encompass all cells in the leaf blade in the advanced stages of senescence.

ABSTRACT

Snapdragon (*Antirrhinum majus* L.) flower has unique inflorescence, attractive colors, and shapes, and is known as a cut flower in the world flower market, however, it is considered a sensitive flower to ethylene. Ethylene hormone plays an important role in the senescence of ethylene-sensitive flowers, especially snapdragon flowers, and causes the stem bending of cut flowers. This complication greatly reduces the ornamental value of snapdragon flowers and causes economic damage to producers and consumers. This study investigated different levels of ethylene hormone (0, 1, 10, and 100 µl. L^{-1}) on some growth characteristics and postharvest vase life of snapdragon flowers. The first visible response of snapdragon cut flowers to ethylene treatment was florets dropping whereas the flowers were turgid. The florets dropping was observed in all three levels of ethylene and indicated a significant difference with the control treatment. Ethylene also caused a disturbance in water absorption. Consequently, the relative water content, fresh weight, protein content, and vase life decreased. The curvature angle was also maximum at 100 µl. L^{-1} ethylene.

Keywords: *Antirrhinum majus* L, Curvature angle, Fresh weight, Post-harvest, Senescence

INTRODUCTION

The Snapdragon plant, scientifically known as *Antirrhinum majus* L., is a well-liked decorative plant appreciated for its attractive and aromatic blooms. In the United States, the sales revenue from freshly-cut snapdragons amounted to $12.18 million in 2015, positioning it among the top ten fresh-cut flowers. Challenges arise in the postharvest stage due to the plant's vulnerability to ethylene, which triggers florets' abscission and wilting. This sensitivity contributes to issues like limited vase life, incomplete flower opening, suppression of pigmentation, and stem curvature, impacting snapdragons' overall production and market performance (Kato et al., 2022; Xiang et al., 2020).

Snapdragon petals undergo abscission upon ethylene exposure, suggesting the sensitivity of snapdragon flowers to ethylene. Ethylene is recognized for its pivotal regulatory functions across diverse plant species. The biological activity of ethylene is evident even at very low concentrations ranging from 0.01 to 1.0 parts per million (ppm) (Heffron and Korban, 2022; Kato et al., 2022).

The longevity of cut snapdragon flowers is typically dictated by stem bending, as flowers with bent stems are unsuitable for commercial use. Regrettably, stem bending frequently manifests in snapdragon cut flowers within a brief period of vase life, making it a significant postharvest challenge (Naing et al., 2021). Research using ethylene and ethylene-action inhibitors like silver thiosulfate (STS) and 1-methylcyclopropene (1-MCP) has aimed to determine the involvement of ethylene as a positive regulator in snapdragon stem-bending. However, results varied, with some studies showing no significant impact on bending with STS or 1-MCP, while others reported a blocking effect, suggesting further research is needed to clarify ethylene's role in this mechanism (Çelikel et al., 2010; Naing et al., 2021; Woltering, 2016).

In the present study, we treated snapdragon cut flowers with ethylene and investigated the influence of ethylene on various vase-life characteristics of snapdragon, such as curvature angle and florets abscission.

MATERIAL AND METHOD

Snapdragon F_1 (*Antirrhinum majus* 'Legend White') seeds were germinated in Petri dishes under controlled conditions and placed in a greenhouse with regulated temperature and natural light. The plants were watered every other day until they reached the flowering stage, at which point they were moved to a growth chamber for ethylene treatment. Snapdragon flowers were trimmed to 40 cm and then treated with ethylene at 1, 10, and 100 µl l-1 for 48 h at 22 °C (each treatment with 10 repetitions). The treatment was performed in 38.8 × 39.0 × 38.8 cm glass chambers. The KOH solution (1 M) was placed inside the chamber to reduce CO_2 concentration (Chamani et al., 2005).

The cut stems were weighed on day 0 (before treatment), day 1 (1 day after treatment), day 3 (3 days after treatment), day 5 (5 days after treatment), day 7 (7 days after treatment), day 9 (9 days after treatment), and day 11 (11 days after treatment). The water absorption was also recorded at these time points. The floret's abscission was counted on day 1.

Vase life was determined by recording the number of days from treatment initiation (day 0) until 50% of the flowers in the spike began wilting or drying, indicating the end of their commercial viability. Soluble protein content in the petals was measured using the Bradford assay method to quantify the total protein content (Bradford, 1976) on day 1. Stem curvature in snapdragon cut flowers was measured using a protractor and stated in degrees on day 11. A straight stem was defined 0°.

Statistical analysis of the data was conducted using SPSS V16 software, with significance levels determined through Duncan's multiple range test at a 5% probability.

RESULTS AND DISCUSSION

Gradually, the weight of the shoot in the control increased with a gentle slope and decreased after 5 days. On the other hand, ethylene treatment (1, 10, and 100 µl. L^{-1}) caused a significant decrease in shoot weight 1 day after the treatment. With increasing ethylene concentration, weight loss occurred at a faster rate (Figure 2A). According to the changes in shoot weight, water absorption also revealed a significant increase in the control. Concentrations of 10 µl. L^{-1} and 100 µl. L^{-1} prevented water absorption in flower stems and as a result, the weight of the shoots decreased (Figure 2B). The treatment of cut snapdragon flowers with ethylene (10>100>1 µl. L^{-1}) caused the florets to drop severely. The lowest drop of florets was observed in the control (Figure 2C). As a result, the vase life of untreated flowers was recorded up to 8 days (Figure 2D). Ethylene also caused a significant decrease in total soluble protein content, which indicated the rapid degradation of proteins under ethylene treatment (Figure 2E). Furthermore, the degree of stem curvature observed in E10 and E100 treatments was significantly higher than those of the E1 and control treatments at 11 days after treatment (Figure 2F).

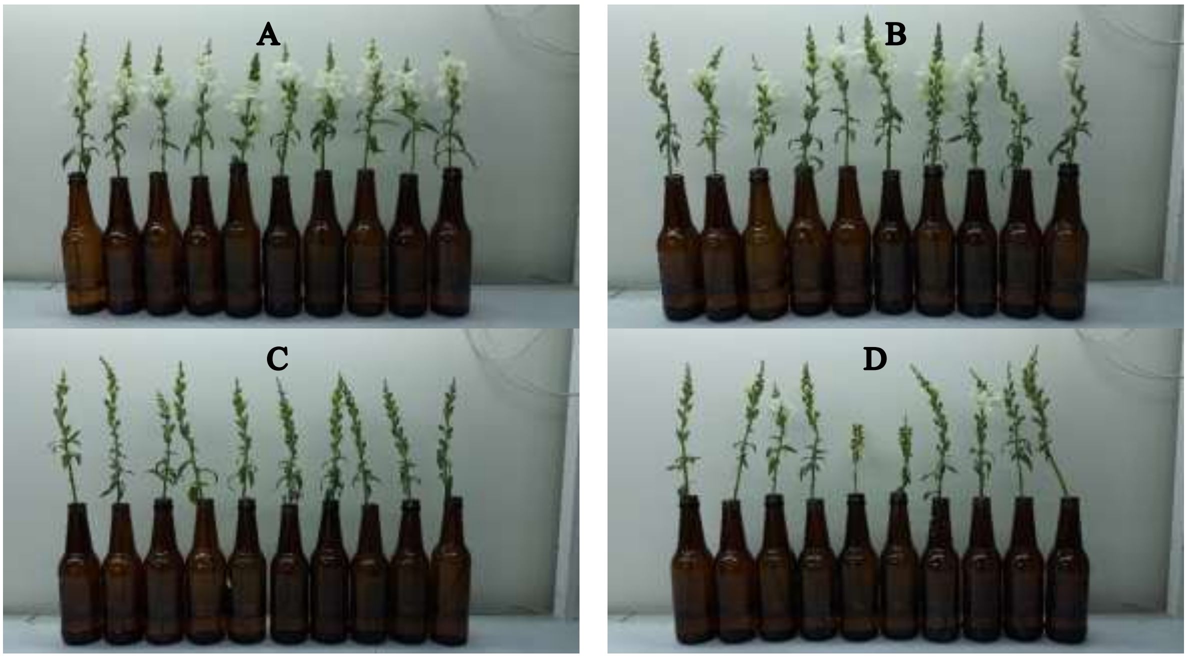

Figure 1. Comparison of the effects of different concentrations of ethylene on postharvest quality of snapdragon cut flowers. (A): control (0 µl. L^{-1}), (B): E1 (1 µl. L^{-1}), (C): E10 (10 µl. L^{-1}), (D): E100 (100 µl. L^{-1}). The photos were taken at day 5.

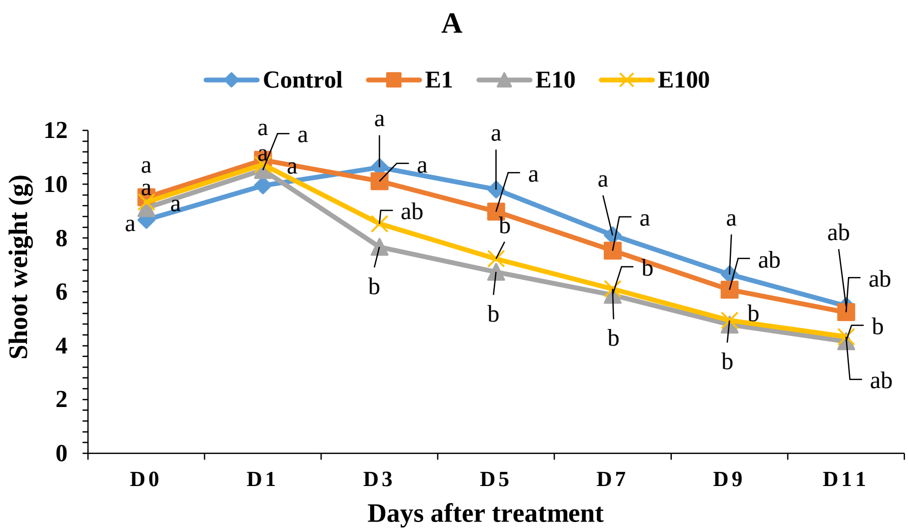

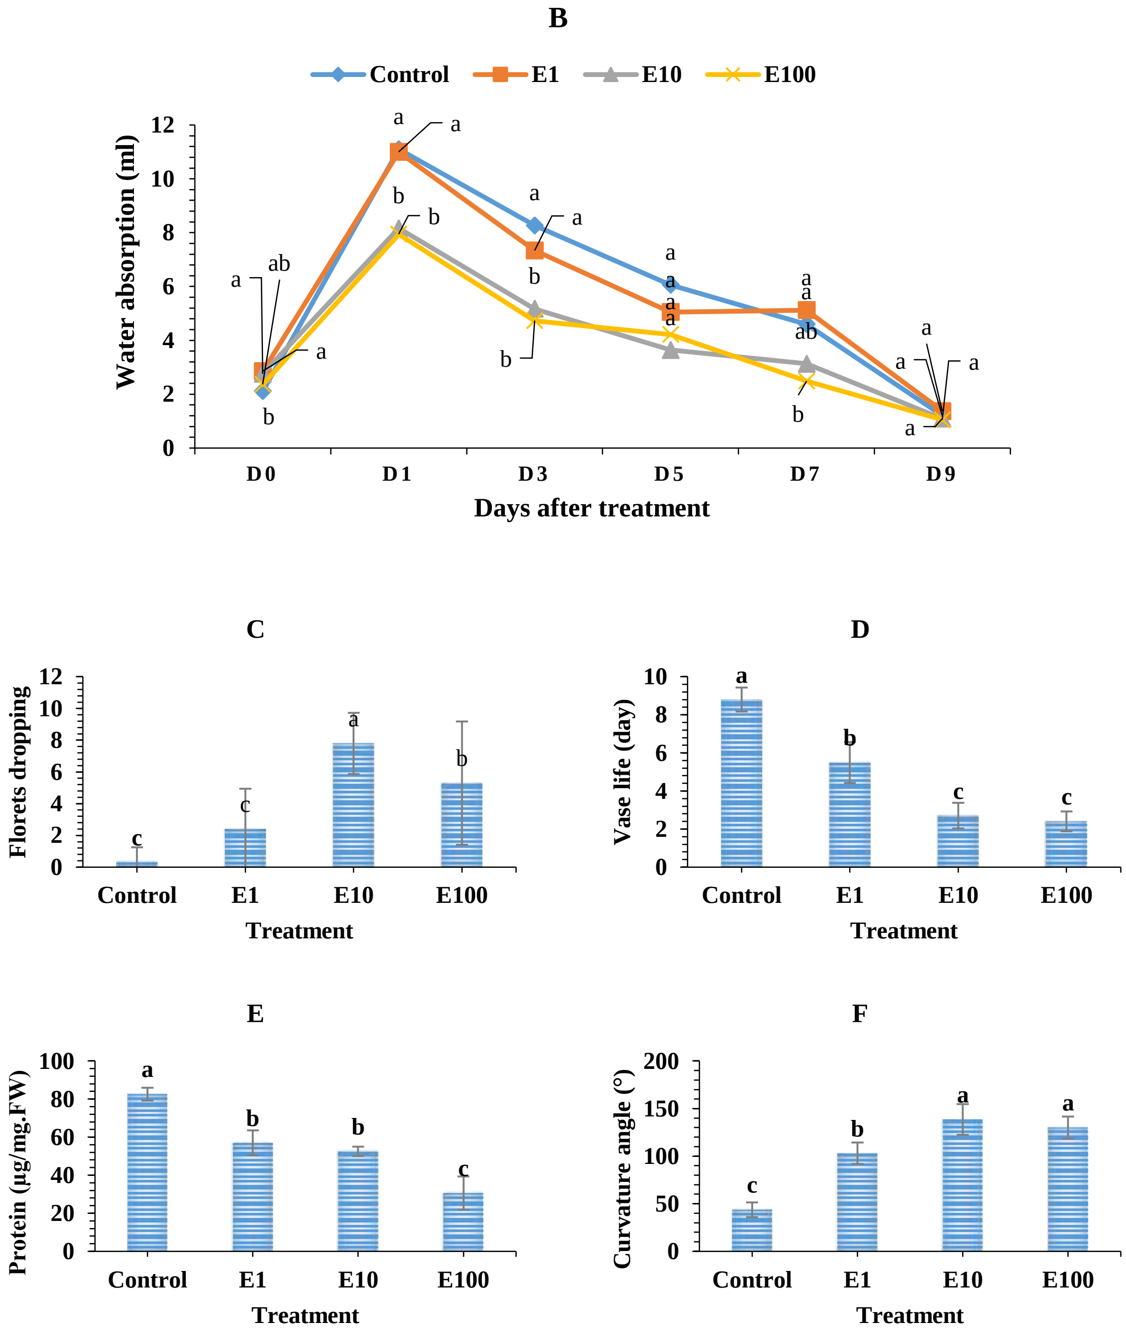

Figure 2. Some post-harvest characteristics of cut snapdragon flowers under ethylene treatment (0 µl. L^{-1}, Control; 1 µl. L^{-1}, E1; 10 µl. L^{-1}, E10; 100 µl. L^{-1}, E100). (A): shoot weight, (B): water absorption, (C): florets dropping, (D): vase life, (E): total soluble protein, (F): curvature angle. Different letters indicate significant differences at $p \leq 0.05$ (Duncan's test). Error bars represent ±SD, n=10.

In this study, we investigated the effect of different concentrations of ethylene on some characteristics of snapdragon flower post-harvest. This study indicated that increasing the concentration of ethylene can strongly increase the angle of curvature and bending of the stem. This incident was accompanied by a decrease in the weight of the stem, a decrease in water absorption, severe dropping of florets, and a lack of soluble protein, which ultimately led to the loss of the useful vase life of the cut flower.

Ethylene can stimulate many degenerative processes in cut flowers (Lukaszewska, 1985). In the present study, different concentrations of ethylene decreased total protein content. Proteins, as vital cellular components, are severely sensitive to adverse environmental conditions. The decrease in total protein is attributed to the involvement of ethylene in the expression of genes related to aging, activation of plant proteases, and proteolytic degradation (Chamani et al., 2007; Eason et al., 2002; Jones et al., 2005).

Many studies have been done on the effect of ethylene regulation on stem bending. However, the results are contradictory and it is not yet clear whether ethylene stimulates stem bending or not (Naing et al., 2021). In a study, the treatment of cut tulip stems with ethephon (ethylene-releasing compound) caused a delay in stem bending (Van Doorn et al., 2011). On the other hand, in some species such as Calendula officinalis and gerbera, ethylene inhibiting compounds have reduced the rate of stem bending, which depends on the structural nature of the stems of different species (Hemati et al., 2019; Lone et al., 2021; Naing et al., 2021).

CONCLUSIONS

This study revealed that the initial observable reaction of snapdragon cut flowers to ethylene exposure was the dropping of florets (in the turgid condition). This phenomenon was evident across all levels of ethylene, highlighting a notable contrast with the control group. Furthermore, ethylene led to a disruption in water uptake, resulting in reductions in relative water content, fresh weight, protein levels, and vase longevity. The highest curvature angle was recorded at an ethylene concentration of 100 µl. L^{-1} and had a significant difference with control.

ABSTRACT

Boxwood (*Buxus* spp.) is used as a forest tree and ornamental plant. It is distributed all over the world with 105 different species except Antarctica and is evaluated as a raw material source in various areas. However, boxwood (*Buxus* spp.), which provides both ecological and economic contributions, is unfortunately under the threat of an invasive pest, *Cydalima perspectalis* (boxwood moth). *C. perspectalis* has rapidly increased its presence in our country every year. The damage caused by the drying up of boxwoods by pests leads to serious economic and ecological losses. Therefore, developing methods to control this pest and taking early measures is of critical importance. In this study, it was aimed to implement a map application consisting of *C. perspectalis* information in boxwood locations in order to perform early detection of *C. perspectalis* in Turkiye and to take the necessary precautions. In this direction, field studies were carried out and coordinate information of boxwood locations in Turkiye was obtained. At the same time, the presence of *C. perspectalis* on boxwoods was confirmed with field studies. After the field studies, a data set was created with coordinate, date, altitude and *C. perspectalis* presence/absence information. The created data set was transferred to the Google Earth Engine (GEE) platform and visualized. In addition to the data set, an NDVI vegetation index graph was created using Sentinel-2A satellite images belonging to the date of the field studies. An application was developed with the codes written on the GEE platform and the date, altitude, *C. perspectalis* presence/absence and NDVI (Normalized Difference Vegetation Index) graph information of the clicked boxwood locations were shown on the panel. This study provides the first preliminary view of the presence of *C. perspectalis* in the same locations and dates in future periods.

Keywords: *Cydalima perspectalis*, Google Earth Engine, Boxwood

INTRODUCTION

Boxwood species naturally distribute in Turkiye. These plants, which are generally found in natural populations in forested areas, are also widely used as landscape plants in parks and gardens (Sarı and Çelikel 2019).

However, despite its widespread use and distribution, boxwood is facing the danger of extinction in our country, as well as all over the world, due to reasons such as harmful insects, diseases, and climate change. In particular, the invasive boxwood moth (*Cydalima perspectalis*) threatens this plant (Billen 2007, Van der Straten and Muus 2010).

Studies have shown that *C. perspectalis* produces 2, 3, 5 generations per year and that this situation varies according to climate and geographical conditions (Chen, 2005; Öztürk et al., 2016; Toper Kaygın and Taşdeler 2019; Yıldız 2021). When the ecological and morphological characteristics of *C. perspectalis* are examined, it is observed that it spreads very quickly due to its ability to feed on different hosts, its high flight speed ability and its ability to produce multiple generations (Matosevic, 2013).

A number of precautions need to be taken to prevent spread, control pests and ensure early detection.

Reviewing the literature on this subject, it is seen that the method of pest control is mostly biological control (Gugea and Vîrteiu 2017; Plant et al., 2019; Salioğlu 2020).

Recently, it has been observed that Geographic Information Systems (GIS) and remote sensing (RS) techniques and technologies, which have been widely used in pest control, early detection, monitoring, mapping, analysis and interpretation of damage caused by pests, are not used sufficiently either in the world or in Turkiye.

For these reasons, the aim of this study was to develop a map application consisting of *C. perspectalis* information in boxwood locations in order to enable early detection of the boxwood moth (*C. perspectalis*) in Turkiye and to take the necessary precautions.

For this purpose, cloud-based Google Earth Engine (GEE) platform and NDVI (Normalized Difference Vegetation Index) vegetation index, which are among UA and GIS technologies, were used.

MATERIAL AND METHOD

Turkiye was chosen as the study area due to its rich vegetation, suitable topography, climate and most importantly, its occupation by *C.perspectalis*. Coordinate information was obtained from 45 locations where boxwood is found in locations of Turkiye through field studies (Figure 1).

Figure 1. Study area and boxwood locations

During the field studies, the presence of *C. perspectalis* on the boxwoods was simultaneously observed and recorded along with the field dates and altitude. A database was created for the study in line with this information. The created database is given in Table 1.

Table 1. Database created through field studies

The database prepared via Excell was converted to be suitable for working on the GEE platform. The converted database was loaded onto the platform with the steps “Assets-> New-> CSV file (.csv)”. Coding was done in accordance with the purpose of the study using the coding panel provided by GEE to the users (Figure 2). With the coding, the locations were marked on the map, NDVI time series graphs were produced with Sentinel-2A satellite data with a resolution of 10 m based on the months of September, October, November, February, May, June, July and August, when the pest of the locations reproduced in Turkiye, and also the date, altitude, *C. perspectalis* presence/absence information and NDVI graphs were shown on the panel for each clicked location. Thanks to this coding, the panel changes for each clicked location and the necessary information for that location is shown.

Figure 2. Coding panel

RESULTS AND DISCUSSION

As a result of the study, an application was developed that provides preliminary views and information to users by visualizing the database generated and created through field studies on the GEE platform (Figure 3).

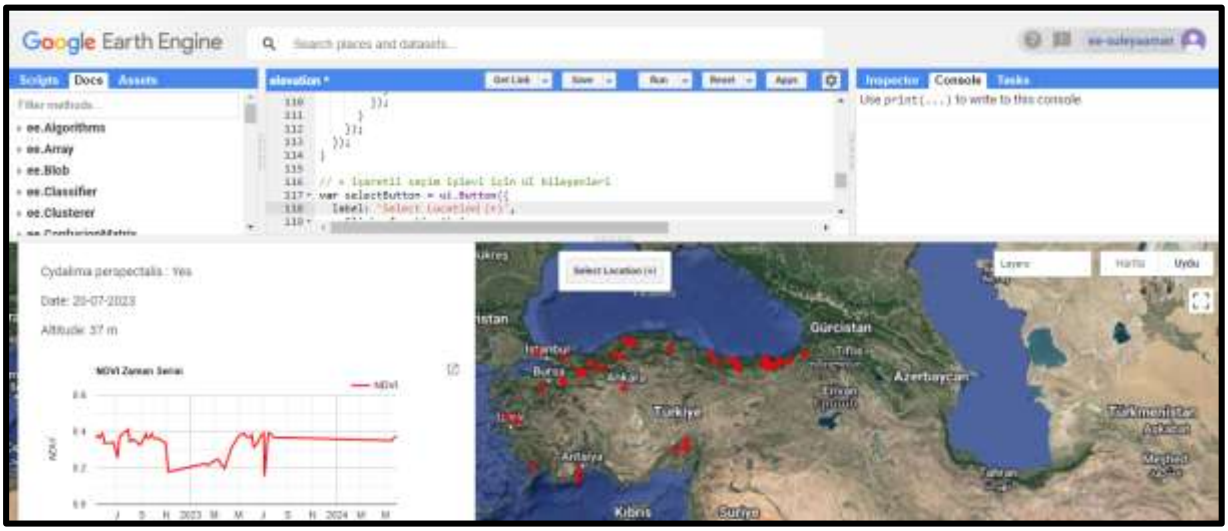

Figure 3. Application developed on Google Earth Engine platform

Sample representations of some of the results obtained with the application are given in Figure 4.

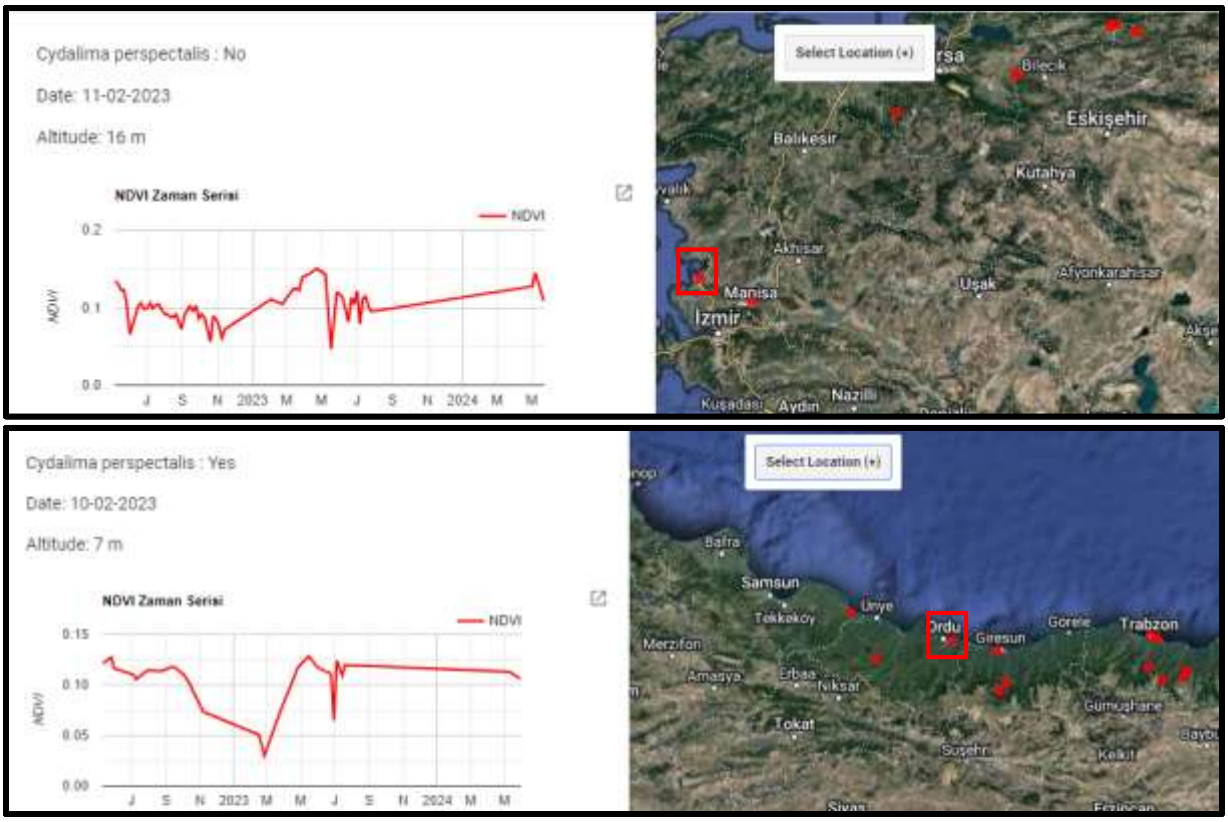

Figure 4. Some sample demonstrations of application results

With the application, it was aimed to monitor the damage caused by the pest with NDVI time series graphs. The use of plant indices such as NDVI in the detection of pests is an approach that facilitates the monitoring of the pest and the determination of the damage it causes. NDVI is a vegetation index that takes a value between -1 and +1, which expresses plant vitality. In this context, while the NDVI value of healthy plants approaches +1, it approaches -1 in cases where there are no signs of life or the vegetation is not alive. When the results of the NDVI time series graphs obtained in this context are examined in detail, it is observed that although the NDVI values do not fall into minus for all months, they vary between 0.1 and 0.3 and make irregular fluctuations. The reason for this situation is that boxwood, which is usually in the form of a bush, cannot be clearly separated from different plant species nearby. Another reason is that the highest resolution satellite data offered for free use has a maximum resolution of 10 m. Increasing the resolution of the satellite data used will provide a high-level solution to this situation. Another reason is that NDVI time series graphics cover a very long time and that events such as rain, snow, clouds, fog, etc. experienced during this time period cannot be completely eliminated even though masking is applied, which is why sufficient elimination cannot be made in the images. For these reasons, it has been concluded that NDVI results should be improved with different techniques.

The application, which works smoothly and beautifully, has been implemented for 45 locations. Increasing the number of locations will increase the efficiency of the study and will be a useful approach to create a complete *C.perspectalis* and boxwood distribution map of Turkiye.

When the altitude criteria and dates were evaluated, *C. perspectalis* was observed at 5 m in July and 1238 m in August, but not at 32 m and 1056 m in February. This shows that altitude is not the only criterion for the presence of *C. perspectalis*, and that criteria such as temperature, precipitation, humidity, etc. in the current month are also important.

CONCLUSIONS

During the application, some limitations were encountered due to reasons such as the inadequacy of current technologies and the physiological structure of plant species. Despite this, the application developed with this study works perfectly and flawlessly.

This study provided the first preliminary view of the presence of *Cydalima perspectalis* in the same locations and dates in the future periods and made it possible to detect and combat the pest early. Since this study has no example in the world or in Turkiye, it has a great place in terms of being a hope and an example for future studies.

It is aimed to carry the study further with the improvement of current technologies and the contributions of researchers. In this direction, it is expected that university-public cooperation will increase and the database will be kept up to date.

ACKNOWLEDGMENT

The study was financially supported as a research project by the Scientific and Technological Research Council of Turkiye (221O401).

ABUNDANCE AND BIOMETRIC CHARACTERISTICS OF Rhopılema nomadica (GALIL, SPANIER & FERGUSON, 1990) PASSING FROM GULF OF ANTALYA TOWARDS THE WEST

ABSTRACT

Rhopilema. Nomadica (Galil, Spanier & Ferguson, 1990) was initially observed in the Mediterranean Sea in the 1970s near the shores of Israel. It is classified as a Lessepsian jellyfish species. From the early 1980s onwards, these jellyfish have begun to gather in significant numbers near the shores of Israel, resulting in negative impacts on fisheries, tourism, the environment, thermal power plants, and human health. *R. nomadica* was not only found along the shores of Israel, but its presence also expanded to the coasts of Egypt, Palestine, Lebanon, Syria, Turkey, Greece, and Italy due to prevailing winds and current systems. The first detection on the Turkish coastline was on the eastern shores of the Göksu River between 1980 and 1982. *R. nomadica*, known for its crowd populations along the coasts of Israel, Lebanon, Syria, and the Gulf of Iskenderun, is shifting westward from the Gulf of Antalya coast between March and May. This movement is attributed to factors like global warming, eutrophication, overfishing, and a decline in its predators. Some of these jellyfish also enter the shallows of the gulf and cause concerns. In 2024, the first migration passings in the Gulf of Antalya started in late January and were completed in late April. The population density in the Gulf increased by 1 individual per 10 m^2 between March and April. In two samplings carried out between February and April, a total of 44 individuals were taken and transported to the research laboratory of Akdeniz University Fisheries Faculty. The average weight of the *R. nomadica* species migrating through Antalya Bay was 3780.11±304.85g, with a mantle diameter (mean±SE) of 37.25±1.40cm.

Keywords: *Rhopilema nomadica*, Biometric Characetistics, Abundance

INTRODUCTION

Rhopilema nomadica Galil Spanier & Ferguson, 1990, a Lessepsian jellyfish, was first recorded in the Mediterranean in the 1970s off the coast of Israel (Galil et al. 1990). It is reported that this planktotrophic jellyfish regularly forms significant swarms along the Levantine coast, depleting plankton resources in this ultra-oligotrophic part of the Mediterranean, and causing damage to tourism, fisheries and coastal facilities (Galil 2007). *R. nomadica* is considered one of the “100 Worst Invasive Species” in Europe. Its rapid proliferation and spread in the Eastern Mediterranean, reaching high densities, confirms this view (Deidun et al 2011).

On the Mediterranean coast of Türkiye, *R. nomadica* was first recorded in 1995 off the coast of Mersin (Kideys and Gücü 1995) and subsequently in İskenderun Bay (Avsar et al. 1996). Since then, large jellyfish aggregations have been observed at certain locations along the Mediterranean coast of Türkiye, particularly during the summer months. It has been reported that the high densities of *R. nomadica* on the eastern Mediterranean coast of Türkiye may be due to the high productivity and pollution of the sea in this region (Kideys and Gücü 1995). These researchers reported that in August 1995, many swimmers on the coast of Mersin had to undergo medical treatment due to contact with jellyfish. They also reported a decrease in the local fishermen's catches with gillnet fishing in that region and that jellyfish caught in their nets were a major problem. In addition, fish farms in İskenderun also experienced difficulties when they wanted to collect fish from cages due to the mass jellyfish population.

Figure 1. The presumed distribution route of *Rhopilema nomadica* in the Mediterranean to date (Deidun et al 2011).

The enormous distribution of *Rhopilema nomadica* in the eastern Mediterranean basin is promoted by its unique life cycle, which includes polyp asexual reproduction and resting periods through podocyst formation, and polydisc strobilation, which results in the release of multiple ephyrae from each polyp. *R. nomadica*, which is extremely abundant in the eastern Mediterranean basin, is drifted westward each year by currents and winds, following the path shown in Figure 1. Some of these jellyfish, which also migrate from the open sea of the Gulf of Antalya, are causing concerns by entering the gulf. The jellyfish, which started migrating in the Gulf of Antalya in January 2024, completed this migration in late April.

Due to the warmer winter and long northern winds, an extreme density of jellyfish was observed in the gulf this year. This study aimed to determine the average stock density, weight, and mantle diameter of jellyfish in the Gulf of Antalya.

MATERIAL AND METHOD

This research was carried out in the Falez region (36°52'16.51"N; 30°39'44.33"E), Konyaaltı beach (36°51'41.83"N; 30°38'33.02"E), Kemer (36°35'23.07"N; 30°35'30.92"E), and Üçadalar (36°27'24.18"N; 30°33'3.43"E) of the Gulf of Antalya. During the research, jellyfish samples were taken by scuba diving with a covered bucket. A total of 44 individuals were taken in 2 samplings carried out between February and April and transported to the Akdeniz University Fisheries Faculty Research Laboratory. The weight of the transported jellyfish was measured with a scale and their mantle diameters were measured with a meter. The stock density was calculated as the number of individuals falling into the designated areas on the sea surface.

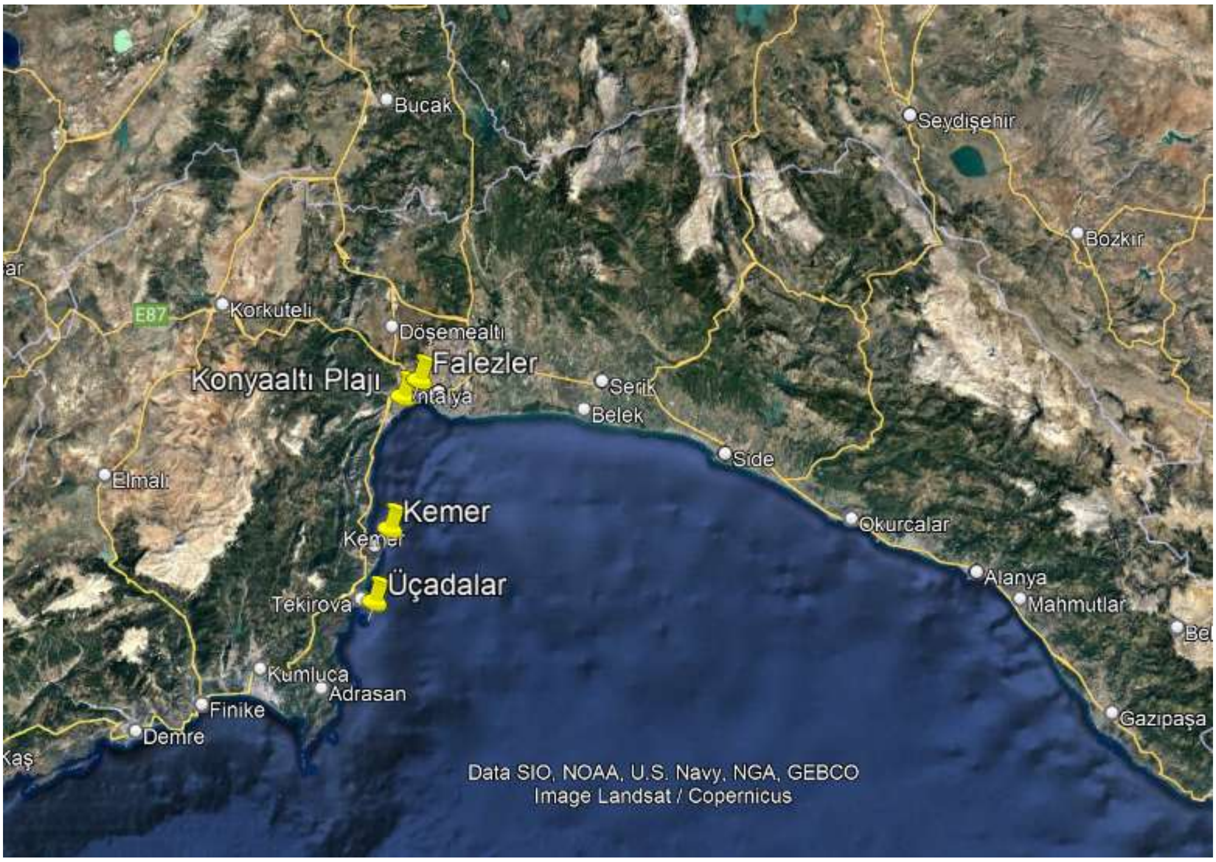

Figure 2. Stations taken jellyfish from the Gulf of Antalya

RESULTS AND DISCUSSION

Many researchers have reported that *R. nomadica*, which forms large populations in the Eastern Mediterranean, is carried westward by currents (Deidun et al. 2011; Edelist et al. 2020). In the Gulf of Antalya, this transition began in January 2024 and was completed by the end of April. The population density in the gulf reached 1 individual/10 m2 between March and April. It is thought that the reasons for this density are a warm winter season in 2023-2024 and long and strong northern winds. This density of jellyfish in Antalya, a tourist city, causes great concern. During this period when an increase in jellyfish was observed, tourism professionals constantly called our faculty and asked when the transition would be completed.

In our study, a total of 44 jellyfish were taken in 2 samplings carried out between February and April and transported to Akdeniz University, Faculty of Fisheries Research Laboratory. *R. nomadica* migrating from the Gulf of Antalya was found to have an average mass of 3780.11±304.85 g and a mantle diameter of 37.25±1.40 cm (mean±SE). Considering these values and the fact that small individuals were not detected in the gulf, it is shown that these jellyfish are individuals that reproduce in the eastern Mediterranean. Many researchers have also stated that this species reproduces in the eastern Mediterranean and is drifted westward by currents and winds (Deidun et al 2011; Zeidler et al. 2018; Edelist et al. 2020). The recent settlement and rapid spread of *R. nomadica* poses a serious threat to the ecosystem and human health (Galil, 2012; Angel et al., 2016). *R. nomadica* has become an important medusa in the eastern Mediterranean today.

CONCLUSIONS

As a result, *R. nomadica* proliferated on the coasts of Israel, Lebanon, Syria, and the Gulf of Iskenderun, poses a major problem for human health, tourism, ecology, and fishing, and is also a threat to tourism in the Gulf of Antalya and Türkiye, causing concerns. It is necessary to monitor this jellyfish, take measures to prevent its proliferation, and work to use this species for the benefit of humanity.

ABSTRACT

Rhopilema nomadica is considered one of the most dangerous invasive species in the Mediterranean. This species negatively affects the Mediterranean ecosystem, fishing, industrial facilities, tourism, and human activities in coastal waters. It has been determined that some juvenile fish are hiding under the umbrellas of these medusas drifting westward from the coast of Antalya during the winter and spring months. Thirty-three juvenile fish were detected on the *R. nomadica* sample having a bell diameter of 33 cm and weight of 6550 g in April. In identifying the species, it was determined that these juveniles belonged to *Alepes djedab*a. The average length and weight of these juveniles were determined as 44.54 mm and 1.38 grams, respectively. The smallest juvenile was found to be 23 mm in length and 0.14 g in weight, and the largest juvenile was 74 mm in length and 4.89 g in weight. According to these results, it can be said that in the Mediterranean ecosystem, *R. nomadica* contributes to the population increase of this fish by providing shelter to the juveniles of *A. djedaba*, which is also a Red Sea migrant.

Keywords: R*hopilema nomadica, jellyfish, Alepes djadaba, shelter*

INTRODUCTION

Seven Indo-Pacific jellyfish were spotted on the Mediterranean coast of Israel in 1977, and this species was identified as *Rhopilema nomadica* (Galil et al., 1990). The species of *R. nomadica* is a native to species of the Western Indian Ocean. This jellyfish is distributed along the coasts of Pakistan, Mozambique, and the Red Sea. (Tahera and Kazmi, 2015; Zeidler et al. 2018). *R. nomadica*, which is very abundant in Israel, Lebanon, Syria, and the Gulf of Iskenderun, drifts westward from the open waters of the Gulf of Antalya between March and May with the main currents of the Mediterranean. A portion of these jellyfish also enter the Gulf of Antalya and pose concerns for human health.

The blooming event of the invasive *R. nomadica* in the eastern Mediterranean is reported to be caused by many factors such as global warming, pollution, eutrophication, overfishing, and increasing water temperature (El Regal and Temraz, 2016). This species, which forms overpopulations on the coasts of Egypt, Israel, Lebanon, and Syria, has expanded its distribution towards the western Mediterranean and reached Italy, Malta, and Tunisia (Douek et al., 2024).

It is reported that these jellyfish swarms have an oligotrophic effect on marine resources, as well as negative effects on fishing, aquaculture, industrial facilities, tourism, and human activities in coastal waters (Galil, 2007; Balistreri et al., 2017). *R. nomadica* is venomous, and the active toxic substances found in jellyfish nematocysts cause painful stings in humans, characterized by systematic symptoms that include erythematous rashes, itching, and burning sensations, as well as fever, fatigue, and myalgias (Gusman et al., 1997; Balistreri et al., 2017).

It is stated that some species of juvenile fish accompany jellyfish and shelter under their tentacles and bells (Çeviker et al., 2011; Gulşahin and Tarkan, 2011; Artuz and Tuncer, 2016).

In a study conducted by Panikar and Parasad (1952) in India, *Caranx spp*. species were observed around *Rhopilema hispidum* and was reported that juvenile fish took shelter under jellyfish bells when disturbed. Some studies, conducted in the Mediterranean, been reported that juveniles of *Alepes djedaba*, a Carangid species were seen around and under *R. nomadica*. However, no information was found about the numbers, heights, and weights of these juveniles.

This study aimed to determine the number, length, and weight of *Alepes djedaba* found under the umbrella of *R. nomadica.*

MATERIAL AND METHODS

Another research was conducted (6 April 2022) in the Gulf of Antalya (Konyaaltı Beach), where individuals of *R. nomadica* were sampled during scuba diving. The *R. nomadica* sample, taken with a lidded bucket via scuba diving from the sea at Konyaaltı beach, was transferred in seawater to the Akdeniz University Faculty of Fisheries Laboratory. During laboratory studies (measurement of weight, umbrella diameter), many juvenile fish were detected using jellyfish umbrellas as shelter. Then, the species identification of juveniles was applied, and abundance, length, and weight were measured (Figure 1, 2). In the species identification made, it was determined.

A
B

Figure 1. *R. nomadica* (A) and *A. djedaba* (B) juveniles collected from Konyaaltı beach.

RESULTS AND DISCUSSION

In this research, juvenile fish using the invasive jellyfish *R. nomadica* bell as a shelter were identified as *Alepes djeddaba*. This fish, like *R. nomadica*, is a Lessepsian species and was later included in the Mediterranean ecosystem (Golani, 1998). This fish caught with purse seines, trawls, gill nets, and fishing rods along the Turkish coast is sold in markets and consumed by consumers. In another study, we conducted on hyperiids found on *R. nomadica* in Antalya Bay, *R. nomadica* was carefully taken into a bucket by scuba diving and the lid of the bucket was closed underwater (Yılmaz and Gokoglu, 2024) (Figure 1 (A).

Some studies showed that juvenile scads (*A. djedaba*) use jellyfish umbrellas as shelter. Ohtsuka et al. (2010) identified 43 *A. djedaba* in the umbrella of *Rhopilema hispidum* with a 26 cm diameter. In previous studies on *R. nomadica,* there is no record regarding the number, length, and weight of the scad juveniles that used the jellyfish umbrella as a shelter in the Mediterranean (Gunsahin and Tarkan, 2011; Artüz and Tuncer, 2016).

In this study, the number of juveniles using the umbrella of *R. nomadica* with 33 cm diameter and 6550 g weight was found to be 33. The average length and weight of these juveniles were determined as 44.54 mm and 1.38 g, respectively. The smallest juvenile was found to be 23 mm in length and weigh 0.14 g, and the largest juvenile was 74 mm in length and 4.89 g in weight (Figure 1).

Panikar and Parasad (1952) detected 56 juvenile *Caranx calla* with lengths ranging from 8.5 mm to 18.5 mm under the umbrella of the medusa in June 1950. In this study, the smallest juvenile was found to be 23 mm and weigh 0.14 g. When this study is compared with Panikar and Parasad's study, it is seen that the juvenile fish detected are larger. *R. nomadica*, drifting westward (towards Rhodes) with currents from Iskenderun Bay, passes through the open waters of Antalya Gulf in winter and spring. During this transition, some of these jellyfish enter the gulf and cause concerns in tourists swimming in the sea. However, this transition is completed towards the summer months. During this drift, the smaller *A. djedaba* juveniles grow until they reach the Gulf of Antalya.

In conclusion, jellyfish (*R. nomadica*), which are expanded into the Mediterranean by currents, may also contribute to the distribution of this fish species (*A. djedaba*) in the Mediterranean. Since *A. djedaba*, the fish we identified in this research, will spend the critical period of its life under the jellyfish umbrella, an increase in its population can be expected.

SEAFOOD FRAUD: ITS ASPECTS ON TRADE, MARKETING AND FOOD SAFETY

Nalan GÖKOĞLU[1]

ABSTRACT

Intentional manipulation of the structure of foods for economic gain is called food fraud. In addition to causing economic losses for food businesses, food fraud also causes losses to the image of countries in exporting products and poses a risk to consumer safety. Because the species have similar appearances, seafood products are susceptible to counterfeiting. Mislabeling, species substitution, species adulteration, overglazing of frozen products, short weighting, and undeclared additives are the main food fraud examples in seafood. There is a need to combat food fraud effectively. For this, national food programs should be strengthened, new regulations should be developed, and intergovernmental cooperation should be increased.

Keywords: Fraud, Seafood, Food safety, Economic loss

INTRODUCTION

Food fraud is generally defined as illegal deception for economic gain using food (Spink and Moyer, 2011; Spink et al., 2014; Spink et al., 2016; Wu et al., 2017, Spink et al., 2019). Food fraud is a phenomenon that can occur at all stages of the supply chain and on an international scale. Concerns, awareness, and dangers about food fraud are increasing. According to FAO (2021), food fraud is any suspected intentional action committed when a food business operator intentionally decides to deceive customers about the quality and/or content of the food they are purchasing to gain an economic advantage. Within the definitions for food fraud, the motivation or driving factor for economic gain is generally agreed (Robson et al., 2021). Food fraud has been conducted since antiquity. It was similar to those occurring in modern times, the scale then was limited and covered a small geographic area. Because modern food supply chains have been lengthened, complicated, and accelerated, the risk of food fraud has broadened to include entire global populations (Spink and Moyer, 2011). Food fraud is an issue affecting all food supply chains and therefore the entire food industry, customers, and consumers. Food supply chains are increasingly vulnerable due to globalization and lengthening of supply chains (Lotta & Bogue, 2015; Trivedi et al., 2016). Food fraud is committed in different ways. These include unauthorized production, mislabeling, misbranding, and intellectual property rights fraud. Adding sugar to honey is an example of this. Food fraud is multifaceted and complex. FAO (2021) has reported that food fraud cases reduce consumers' trust and cause them to view even safe products with suspicion. The same report also states that the success of food fraud may increase the likelihood that fraudsters will take greater risks on food, which in turn may pose a threat to the security and integrity of food supply chains. There are records of fraud for many foods, including cereals, dairy products, fruits and juices, meat and seafood, nuts, spices, organic foods, and honey (Manning, 2016). Despite technological advances that enable the detection of food fraud and consumers' sensitivity to food safety, it is stated that approximately 10% of the food on supermarket shelves in the USA is subject to fraud. Nowadays, food fraud is also quite common in Europe (Meerza et al., 2019).

FOOD FRAUD AND FOOD SAFETY

Food fraud could pose a food safety risk. With globalization, the fact that the food supply is long, complex, and often difficult to trace, insufficient traceability increases food fraud and, as a result, creates potential safety and health risks. Food safety risks in food fraud are generally unintentional and not intended to harm human health. It includes several common chemicals or pathogens that are generally known to pose public health hazards (WHO, 2016; Spink et al., 2017). Food adulteration poses a significant public health risk associated with food safety issues in the food market. Most food items on the market contain varying degrees of additives. These substances include chemicals, products that are not original ingredients of foods, low-quality products, and physical or inert substances (Gizaw, 2019).

ECONOMIC IMPACTS OF FOOD FRAUD

Food fraud can also result in severe economic consequences and can damage national reputations in the global food market. Food fraud is estimated to cost the global food industry $40 billion annually and $10 to $15 billion per person. The economic loss of a food scam may include costs of product recall or withdrawal, incident investigation, liabilities, lost sales, and share price decline. Current costs for companies include conducting a food fraud vulnerability assessment plan. A single food fraud scandal can cause long-term industry-wide losses, destroy valuable brands, close export markets, and damage trust in public institutions. Significant investment is required to obtain effective strategies for supply chain risk. (Galvin-King et al., 2018).

TRADE AND MARKETING ASPECTS OF FOOD FRAUD

The presence of many buyers and sellers in supply chains also increases the opportunities for fraud in the markets. Fraud can occur, especially when supplied from countries with weak or inadequately enforced local regulations or poorly structured legal systems. Failure to develop food fraud prevention strategies, wide supply chains, and difficulties in detecting fraud increase the risk of fraud in international trade. Food fraud can increase costs in trade. Because as food fraud increases, it increases the need for border inspections and testing and the costs of food safety. This increases the costs for both the buyer and the seller. Detecting and preventing food fraud is costly. The measures manufacturers take to demonstrate product authenticity, increase supply chain security, and demonstrate compliance with product and process standards are costly (Ehmke et al., 2019).

SEAFOOD FRAUD

Seafood fraud encompasses any illegal activity that misrepresents the fish you purchase, including mislabeling or substituting one species for another. Seafood is highly susceptible to fraud due to factors such as the similar appearance of many species, increasing global trade, and varying quality, supply, and demand (Silva et al., 2021). However, without distinct morphological indicators, it can be hard to visually determine whether a seafood product has been fraudulently labeled. Among food commodities, seafood has been identified as a commodity particularly vulnerable to misrepresentation. For example, the European Parliament identified fish and fish products as the second highest category of foods at risk for fraud (Kroetz et al., 2020). Each type of seafood fraud confers economic gain on the fraudster, either by selling a lower-quality product at a higher price or by avoiding costs. The extent of fraud in the seafood sector is difficult to ascertain because much fraudulent activity likely goes undetected. However, several studies in multiple countries have uncovered high rates of mislabeled seafood species. Given the significant seafood market share associated with popular seafood products, even low rates of some mislabeled products may result in consumers purchasing significant quantities of fraudulent seafood.

TYPES OF FRAUD IN SEAFOOD

The most common type of fish fraud involves intentional mislabeling and species substitution. To a lesser extent, fraud occurs when fish is overglazed or overbreaded, leading to deceiving consumers regarding the nature of fishery products. Undeclared use of water-binding agents is also a fraudulent practice that leads to increasing the weight of products and selling additional water substituted for fish.

Mislabeling

Mislabeling and species substitution have an important place among the most common frauds in seafood. This means that the consumer buys a different species instead of the one listed on the label. (Acutis et al., 2019). Seafood mislabeling has dire consequences, including compromising sustainable fisheries and undermining conservation efforts. Mislabeling can also create health risks for consumers. In recent years, the increase in seafood mislabeling fraud has increased concerns about the identity and safety of these products. (Kroetz et al., 2020).

Species substitution

Species substitution occurs when low-value or less-desirable fish species are swapped for more expensive varieties, for example, the fraudulent marketing of farmed salmon as wild-capture species. For instance, the substitution of whiting for haddock, coley for cod, dab for plaice or sole, and bigeye tuna for yellowfin tuna are just a few examples. The flesh of many fish species is similar in appearance, taste, and texture. It can be difficult to identify or differentiate species once these have been processed or prepared for consumption and presented with flavoring in sauces or batter. Species substitution can also occur where a higher-value species is marketed as a lower-value species to avoid taxation. It can also occur to conceal the geographical origin or to hide an illegally harvested protected species or a species from a protected area.

Species adulteration

Species adulteration is different from species substitution. In species adulteration, undeclared species are partially added to a named product. For example, a lower-value species is added to the declared species to add weight.

Overglazing of frozen products

Glazing seafood is a common practice used in the industry that not only aids in reducing product weight loss by dehydration but also prevents freezer burn by surrounding the product in a thin layer of ice. Although there is no exact standard, 5-10% is considered sufficient for most frozen seafood products. By over-glazing, the weight of the products is artificially increased, and consumers receive less product than expected while paying for extra ice.

In a study, it was determined that 7 of 111 frozen fish fillets collected from markets were over-glazed (>10% glazed) and 10 were short-weight (Peterson et al., 2021). In another study, Country of Origin Labeling (COOL) compliance, species authentication, acceptable market names, net weights, and percent glaze of shrimps were examined and as a result, 26% of the samples contained more than 20% glaze and 37% were found to have short weights 0and 37% were found to have species labeling errors (Rivers et al., 2024).

Short weighting

Less known, but far more common, is short-weighting. This is when processors misrepresent the weight of a seafood product through practices such as overglazing, soaking, and breading.

Processors will often add a layer of ice or a preservative to keep a seafood product fresh, a normal and legal practice. However, when a processor uses excess ice (overglazing) or additives (soaking) and includes that weight with the net weight of the seafood, that's fraud. Consumers should pay for the weight of the seafood alone. Short-weighting charges consumers more for less seafood.

Undeclared food additives

Sometimes salt or other chemical additives may be used to reduce the fish content of the product. Additives are added to the products by dipping and injection methods. This kind of methods are used to increase the water retention capacity of fish muscle and produce products with low fish content. Gel injection is performed to increase the weight of the shrimp and provide an attractive appearance. Since the injected products may be harmful to health, they may pose a risk to human health. For example, phosphates used to improve some properties of seafood can characterize economic fraud when used incorrectly or excessively (Gonçalves and Ribeiro, 2008).

CHALLENGES IN DETECTING AND PREVENTING FOOD FRAUD

1- One of the challenges is detecting the unexpected.
2- The issue of food fraud and its place in marketing is not fully understood and there is a need for a legal definition on this issue.
3- It may be difficult or impossible for consumers to detect food fraud at supermarkets or market stalls. Unless the product poses an immediate health hazard, consumers may not necessarily know, even after consuming the product that they were victims of food fraud.
4- All substances used to add food cannot be easily detected through food safety and quality tests.
5- Species identification of fish and seafood products is difficult because the morphological features that can usually be identified have been removed during processing steps such as cooking, smoking, salting, and canning.
6- Species substitution and mislabeling are difficult to detect when fish morphological features such as heads, tails, and fins are removed and fish are processed into fillets, ready-to-eat breaded or battered products, or highly processed in pre-prepared fish meals (FAO, 2018).

CONCLUSIONS

Fish traceability is key to combating fish fraud, enforcing food safety regulations, and ensuring high standards of sustainable fisheries management. Traceability is also critical for ensuring the quality of fish products and minimizing health risks for consumers. Close collaboration between all these different government agencies is essential for an effective response. There is a need to strengthen official national food control programs by developing new regulations to combat fish fraud; enhancing enforcement activities prohibiting landings and market access for products from illegal, unreported, and unregulated fishing; introducing monitoring and surveillance programs for assessing the degree of compliance with fish labeling regulations; and upgrading laboratory detection methods based on DNA barcoding (FAO, 2018).

PREVENTION OF MELANOSIS IN SHRIMP WITH THE COMBINATION OF ANTIMELANOTIC AGENTS AND VACUUM PACKAGING

ABSTRACT

Rich protein and low-fat content make shrimp a valuable food. Shrimps have a short shelf life due to microbial spoilage and melanosis. Melanosis is an enzymatic phenomenon in shrimps that reduces their quality and market value. For melanosis, which develops quickly, the necessary prevention method should be applied immediately after catching it. Various techniques and mechanisms have been developed to prevent enzyme activity. The most common and most effective method is the use of sulfites. However, the fact that sulfite causes allergic reactions has led researchers to develop new methods. This study investigated the effects of using grape seed extract and sodium metabisulfite combined with vacuum packaging on melanosis formation in shrimp (Aristaeomorpha foliacea). The shrimps, which were obtained from the fishermen immediately after being caught, were treated with grape seed extract and sodium metabisulfite, and packaged with and without vacuum. Packaged shrimps were stored at 4°C. Melanosis development and color values (L*, a*, b*) were measured during storage at daily intervals. Grape seed and sodium metabisulfite applications were effective in delaying melanosis. Additionally, vacuum packaging showed a synergistic effect with antimelanotic agents in preventing melanosis. Compared to the control group, the most effective application was the sulfite vacuum combination, followed by the grape seed vacuum combination.

Keywords: Shrimp, Melanosis, Prevention, Grape seed, Antimelanotic

INTRODUCTION

Shrimps have an important place in human nutrition. In addition to being rich in protein, shrimp meat is low in calories due to its low fat content. Shrimps, which are caught all over the world, have a significant export potential. A significant portion of the caught shrimp is offered to the market fresh and unprocessed. However, shrimp are perishable, and their shelf life is extremely limited. Its structure suitable for microbial development accelerates the deterioration process. Shrimps have a short shelf life and are extremely perishable due to microbial spoilage and melanosis (Gokoglu 2004; Martinez-Alvarez *et al.* 2005 a; Benner *et al.* 1994). Darkening called "melanosis" or "Black Spot", which begins immediately after catching and occurs enzymatically, is one of the factors limiting shelf life. During melanosis, phenols are oxidized to quinones by the polyphenol oxidase enzyme. This mechanism is followed by non-enzymatic polymerization of quinones, and this event causes the formation of high molecular weight and dark or black pigments (Montero *et al*. 2001; Arias *et al*. 2007). Blackening occurs shortly after fishing and is a very important problem in the shrimp industry. Melanosis develops very quickly in shrimps stored in the cold without being treated with any preservatives and can significantly change their market value within 24 hours (Rotllant *et al*., 2002). Although it is not harmful to consumer health, it negatively affects the acceptability and reduces the market value of the product (Montero *et al*., 2001).

Developing methods to preserve the quality of this valuable food product for a longer period or improving existing methods are among the main expectations of the relevant sector.

Various techniques and mechanisms have been developed for many years for this undesirable enzyme activity. These techniques attempt to eliminate one or more of the essential components (oxygen, enzyme, copper, or substrate) from the reaction (Gokoglu and Yerlikaya 2008). Physical methods and preservatives are used for enzymatic and non-enzymatic browning (Hardisson et al. 2002). Sulfites are the most effective and multi-purpose agent in controlling enzymatic browning in shrimp. The use of sulfites is gradually decreasing because it is known that sulfites cause some health problems such as asthma and allergic reactions (Gokoglu and Yerlikaya 2008; Villamiel 2006). Grape seed has strong antioxidative activity. Its antioxidative activity is related to its ability of radical scavenging, metal chelating, and synergism with other antioxidants.

In this study, it was aimed to investigate the effects of natural antioxidant source grape seed extract and vacuum packaging on preventing shrimp browning. To determine the effect of grape seed extract, it was compared with sodium metabisulfite, which is widely used to prevent melanosis.

MATERIAL AND METHODS

Giant red shrimp (*Aristaeomorpha foliacea*) was used as material in the study. Freshly caught shrimps were transported to the laboratory with ice in Styrofoam boxes without any protective chemical application. Commercial grape seed extract (5%) and sodium metabisulfite (1.25%) solutions were prepared with distilled water. In the laboratory, shrimps were divided into three groups (GS = Grape seed extract treated group; S = Sodium metabisulfite treated group; C = Without treatment group (Control). Shrimps were dipped in grape seed extract and sodium metabisulfite solutions for 1 minute. These groups were placed in polyethylene bags and then packed with and without vacuum. The packages were stored in the refrigerator at 4°C. During storage, color measurements were made in the samples and the development of melanosis was examined.

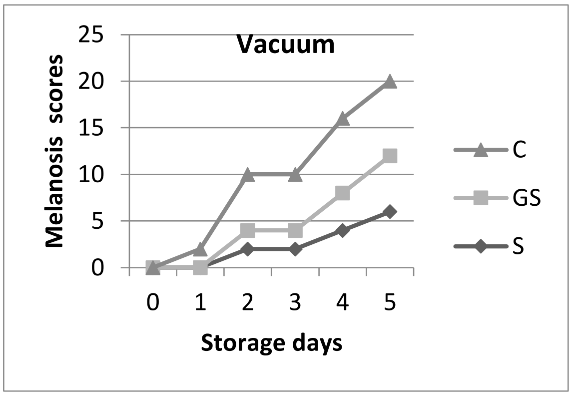
A chromometer instrument (CR 200 Konica Minolta, Osaka, Japan) was used for color measurement. Color was measured in 3 different areas on the shrimp shells and the results were given as average values. L*(brightness), a*(redness), and b*(yellowness) values were measured in the samples. Melanosis was assessed as sensory, and the scale developed by Otwell and Marshall (1986) was used for this purpose (Table 1).

Table 1. Scale for melanosis evaluation (Otwell & Marshall 1986).

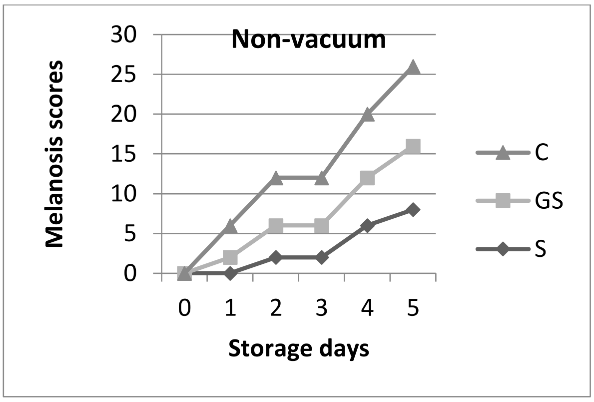
Melanosis scores	Description
0	Absent
2	Slight, noticeable on some shrimp
4	Slight, noticeable on most shrimp
6	Moderate, noticeable on most shrimp
8	Heavy, noticeable on most shrimp
10	Heavy, totally unacceptable

RESULTS AND DISCUSSION

It was determined that the application groups had significant ($p<0.01$) effects on melanosis scores. The highest scores were detected in untreated control samples. The lowest scores were determined in shrimp samples treated with sodium metabisulfite (Figure 1). Storage time had significant ($p<0.01$) effects on melanosis. Melanosis scores, which were initially "0", were determined as 6, 6, and 8 in vacuum-packaged S, GS, and C samples, respectively, at the end of the 5-day storage period, while they were determined as 8, 8, and 10 in non-vacuum samples. While the highest melanosis scores were determined in the control group at the end of the storage period, no difference was observed between the scores of sulfites and grape seed-treated samples. Sulfite is considered the best practice in preventing browning in shrimp. Metabisulfite has been reported to reduce quinones to phenols, react with quinones to give colorless compounds, or act as an irreversible PPO inhibitor, and therefore more effective in preventing melanosis (Lambrecth 1995; Ricquebourg *et al.* 1996). Bisulfites show competitive inhibition by binding sulfhydryl groups of the active part of the enzyme polyphenol oxidase. Bisulfide inhibition depends on the reaction of the sulfides with the quinones and results in the formation of irreversibly inhibited sulfoquinone forms of polyphenol oxidase (Kim *et al*. 2000). Grape seed extracts are rich in polyphenolic compounds. They are also used as food additives due to their antioxidant activity. It has also been reported by other researchers that grape seed extract inhibits melanosis (Gokoglu and Yerlikaya 2008; Sun et al. 2014).



(a)



(b)

Figure 1. Melanosis scores of vacuum (a) and non-vacuum (b) packaged application groups

In our study, it has been shown that grape seed extract can be used as an alternative to sulfite. Additionally, the extra effect of vacuum packaging in preventing melanosis has also been determined. When the color measurement analysis results were evaluated, the highest ($p<0.05$) brightness (L*) values were obtained with sulfite application. No difference was observed in the L* value between grape seed extract and control samples. While L* values increased in the first 3 days of storage, they showed a significant ($p<0.05$) decrease in the following days (Table 2). Vacuum packaging had no significant effect on L* values. Grape seed extract and sulfite applications significantly affected the a* value (redness). The highest a* value was determined in samples treated with grape seed extract. There was no significant difference between the sulfite-treated group and the control group. A significant ($p<0.01$) increase in a* values was detected with storage. Vacuum packaging also had a significant ($p<0.01$) effect on the a* value. Higher * values were obtained in vacuum-packaged samples. Effects of sulfite and grape seed extract applications on the b* values of shrimps were not significant. While a significant decrease was observed in b* values at the beginning of storage, a decrease was determined in the following days of storage. A significant ($p<0.01$) effect of packaging on b* values was observed (Table 2). Higher b* values were found in vacuum-packaged samples than in non-vacuum samples.

Table 2. Duncan Multiple Comparison Test results for color (L*, a*, b*) values[1,2,3]

Factors	L*	a*	b*
Applications

[1] Each number represents the mean ± standard deviation.
[2] S= Sodium metabisulfite.; GS= Grape seed extract.; C= Control
[3]Means within the same factor and the same column with different letters (a, b, c, d) are different at $p < 0.01$ and $p < 0.05$ levels.

CONCLUSIONS

Sodium metabisulfite and grape seed extract applications were effective in preventing the darkening phenomenon called melanosis in shrimps. Since sulfite applications cause allergic reactions in humans, it has been determined that grape seed extract, a natural herbal extract, can be used as an alternative. In addition to these applications, vacuum packaging also showed a synergistic effect with antimelanotic agents in preventing melanosis. Any application that will prevent or delay the darkening phenomenon called melanosis in shrimp, which is a product of high economic value, will prevent both product losses and economic losses in the shrimp industry.

ABSTRACT

Antibiotics are chemical substances that have specific actions for microorganisms and have been commonly used for many years in different fields such as medicine, veterinary medicine, aquaculture, and agriculture. The presence of residual antibiotics in the environment can act as a microbial inhibitor, leading to adverse effects on the life activities of animals and plants in the ecosystem. As a result of the limited absorption capability of antibiotics through animal intestines, the excessive release of veterinary antibiotics to the environment has become an urgent concern to meet, particularly in countries with extensive animal husbandry. Furthermore, environmental residual antibiotics can pose a potential direct or indirect threat to human health resulting in various symptoms (allergic shock, neurological toxicity, cardiotoxicity, mitochondrial toxicity, etc.). Conventional methods including physical, chemical, and biological treatments are not capable of large-scale removal of antibiotics from water, and these methods can cause secondary pollution. Therefore, efficient strategies are needed relying on the elimination of persistent and stable antibiotic residues from water. Advanced oxidation processes (AOPs) are environmentally friendly technologies currently under development and based on the generation of hydroxyl radicals as powerful oxidizing agents. This study summarized a comprehensive overview of the implemented water treatment methods, primarily AOPs in removing antibiotics, and discussed potential treatment solutions for future research.

Keywords: Advanced oxidation processes, antibiotics, Fenton, ozonation, photocatalysis.

INTRODUCTION

Antibiotics are medicines especially active against bacterial infections with specific actions on microorganisms that can decrease or further stop the multiplication of these microorganisms. The clinical usage of antibiotics is not only limited to treating infectious diseases but also extends to modern medical treatment procedures such as organ transplants and open-heart surgeries. Unfortunately, the misuse of this modern medicine has caused a rapid increase in antimicrobial resistance and rendered some infections effectively untreatable with clinically approved almost all known antibiotics (Hutchings et al., 2019; Khmaissa et al., 2024).

Antibiotics are probably the most effective class of drugs in human medicine, and they are also widely used in animal husbandry as veterinary antibiotics including penicillin, macrolides, tetracyclines, and sulfonamides. The widespread use of antibiotics in animal husbandry can be detected in animal manure, and they can lead to the growth of antibiotic-resistant bacteria (ARB) in agricultural soil and end up in surface and groundwater. Additionally, antibiotic residues in the environment act as microbial inhibitors causing considerable adverse outcomes on animal life activities and plants. These structural and functional impacts on microbial communities can result in direct toxic effects on the plants and follow alterations in the carbon and nitrogen cycle that microorganisms participated in. Besides, the extensive antibiotic accumulation in the environment causes a remarkable increase in ARB and antibiotic-resistance genes (ARG), posing a potential threat to global human health. Among drug-resistant infections, antibiotic-resistant bacteria infection can cause notable damage to the control system, and even large intakes of antibiotics can induce intestinal diseases associated with the imbalance of the microbial community in the gastrointestinal tract (Conco et al., 2022; Khmaissa et al., 2024; Yang et al., 2024). An estimation was reported that 10 million people will die annually by 2050 unless action is taken due to alarming severe drug resistance (O'Neill, 2016).

Recently, scientific research has begun to address the remediation of antibiotics in wastewater. In this regard, modern wastewater treatment plants are essential barriers preventing the release of antibiotics and associated effluents (ARB and ARG) identified as contaminants of emerging concern (CECs) in water systems (Drane et al., 2024; Godoy and Sánchez, 2020). The study aimed to assess the water pollution caused by traces of antibiotics and also suggested innovative water treatment solutions.

WASTEWATER TREATMENT PLANTS

Wastewater treatment plants (WWTPs) use a variety of technologies, classified as primary, secondary, and tertiary treatment methods, to treat wastewater containing antibiotic traces.

Primary wastewater treatment is a physical screening and settling step to remove large solid particles and involves units of screens and primary clarifiers. The process is called chemically enhanced primary treatment since coagulants (aluminum salt, ferric iron salt, polymers, etc.) are added in primary units. Moreover, additional chemicals should be considered to prevent salting problems. Adsorption is a common primary treatment process applied to eliminate non-traditional pollutants from WWTPs and transfer them to another medium with incomplete degradation (Drane et al., 2024; Garrido-Cardenas et al., 2020; Zhang and Li, 2011). Granular activated carbon and powdered carbon are not only used in the removal of antibiotics in WWTPs but also commonly applied in drinking water treatment plants (Berges et al., 2021).

The secondary step is predominantly characterized by biological treatment methods such as aerobic and/or anaerobic processes. Activated sludge-loaded WWTPs highlighted that sludge as an adsorbent presents a challenge in separating sludge from an aqueous phase depending on varying seasons. Furthermore, the operational parameters of WWTPs containing sludge loading rate and hydraulic retention time affect the removal efficiency of toxic chemical pollutants. This implies that secondary wastewater treatment is specific to WWPTs, and each case study should be assessed individually (Drane et al., 2024; Wang et al., 2024).

The disinfection processes such as chlorination, ultraviolet (UV) radiation, ozonation, and membrane filtration constitute tertiary wastewater treatment (Drane et al., 2024). Zhuang et al. (Zhuang et al., 2015) have studied three disinfection methods (chlorination, UV radiation, and ozonation) for the inactivation of ARG (sul1, tetG, and intI1) on a laboratory scale and reported that chlorination and UV radiation process achieved a better performance than ozonation.

The effectiveness of WWTPs especially depends on the specificity of CECs and the usage pattern of CECs (Moles et al., 2024). The concentration, type, and detection frequency factor of CECs detected in WWTPs differ significantly in terms of consumption levels and usage patterns (Wang et al., 2022). Antibiotic removal efficiencies of a series of antibiotics in sewage treatment plants have been investigated and reported that removal efficiency is related to antibiotic concentrations in the effluent (Li et al., 2024). Another study on the removal efficiency of CECs among various WWTPs highlighted the inconsistency of the complex selection pressure between antibiotic and ARG and also the crucial role of mobile genetic elements in the spread of antibiotic resistance (Zhang et al., 2024b).

ADVANCED OXIDATION PROCESSES

Advanced oxidation processes (AOPs) are highly efficient and competitive oxidizing technologies for water and wastewater treatment. These novel methods are considered a promising solution to the mineralization of CECs and are mainly used in bench and pilot scales. The mechanism of AOPs is based on the generation of reactive oxygen species such as hydroxyl radicals, superoxide radicals, and hydroperoxyl radicals.

The most extensively used AOPs for eliminating antibiotics from pharmaceutical wastewater are related to photolysis under UV irradiation, homogeneous photocatalysis with Fenton reagent, heterogeneous photocatalysis, and ozonation. Furthermore, these processes can be applied by combining different varieties of AOPs (H_2O_2/O_3/UV) and combinations with other treatment methods (adsorption/O_3, activated carbon adsorption//O_3/membrane filtration) (Garrido-Cardenas et al., 2020; Godoy and Sánchez, 2020; Michael et al., 2013; Moles et al., 2024).

Ozonation and granular activated carbon adsorption techniques are combined to remove ARG and organic pollutants (Yang et al., 2019). Moreover, O_3/peroxymonosulfate (PMS) (Deniere et al., 2022; Lu et al., 2022) and O_3/PMS/biological activated carbon (Zhang et al., 2024a) processes are hot topics on the removal efficiency of antibiotics and limited research has been reported until now. A tertiary wastewater treatment study (H_2O_2/UV-C, PMS/UV-C, and PMS/Fe(II)/UV-C) is applied for the removal of antibiotics and ARG from a full-scale WWTP in Spain (Rodríguez-Chueca et al., 2019).

Recently, several WWTPs have implemented a combined activated carbon adsorption and ozonation treatment method as a cost-efficient process in Germany and Switzerland. Since reverse osmosis membranes are cost-intensive, this membrane filtration process also provides additional benefits concerning salinity and metal reduction. Reverse osmosis membranes are utilized in potable reuse schemes in the United States of America, Singapore, and Australia (Rizzo et al., 2019).

CONCLUSIONS

The increasing use of antibiotics in human medicine and animal husbandry has adverse impacts, and this contamination should be addressed as a global health and environmental issue. It is essential to ensure that antibiotic residues, ARB, and ARG, are satisfactorily eliminated from the environment, minimizing potential risks to human health.

From a practical point of view, recent advancements in wastewater treatments, especially utilizing AOPs, are primarily based on bench-scale experiments and pilot-scale in batch mode. However, for large-scale implementation in real systems, it is imperative to evaluate the design and application of combined treatment technologies. Additionally, other parameters such as process optimization, risk assessment, and pollution control should be monitored for comparison and further assessment as most current studies focus on evaluating and achieving successful degradation efficiency performance of antibiotics.

As a result, more comprehensive research is needed to reinforce the investigation of the mineralization of CECs using different AOPs-based combined treatment methods for large-scale applications. Furthermore, designing cost-effective and environmentally friendly treatments is critically important, serving as more efficient alternatives to currently available treatment technologies used in WWTPs that are still needed in the future.

ABSTRACT

A major water pollution problem today is related to the contamination of industrial effluent-induced textile dyes. Improper discharge of industrial wastewater can be the main source of water contamination and a potential threat to aquatic life and human health since it is highly resistant to conventional treatment methods. Photocatalysis arises as a promising alternative method to eliminate azo dyes. Rare earth metal oxides, particularly neodymium (III) oxide (Nd_2O_3) have emerged as catalysts in photocatalytic applications. In this study, Nd_2O_3 nanoparticles were characterized by FT-IR, SEM, and Raman spectroscopy. FT-IR spectroscopy revealed the characteristic bands related to the metal-oxygen groups. Reactive Red 194 (RR-194) is an azo dye containing an azo group as a chromophore, widely used in the textile industry to color cotton fabrics. The photocatalytic degradation efficiencies of RR-194 dye were compared under both UV and solar-simulated light (SI) conditions. Test conditions such as catalyst dose (0.25 g/L and 0.50 g/L) and initial RR-194 dye concentration (10 mg/L, 20 mg/L, 30 mg/L) were also investigated. Results revealed that the maximum decolorization rate of RR-194 was observed with the increased catalyst dosage and decreased initial dye concentration.

Keywords: Azo dye, decolorization, heterogeneous photocatalysis, neodymium (III) oxide, Reactive Red 194.

INTRODUCTION

Water pollution related to industrial growth, especially from the expansion of textile industries, presents an essential public concern. However, dyes do not fully bind to the fabric in dyeing, and the characteristics of discharged wastewater contain approximately 11-15 % of unbound dyes, salts, chemical variants, and non-biodegradable organic substances as textile effluents. Even low concentrations of dyes in textile wastewater can disrupt the ecosystem and cause notable harm to aquatic life on a larger scale. Therefore, efficient wastewater treatment is crucial to meet the required standards before discharging into the water environment. However, achieving a complete dye elimination treatment process that leads to minimal waste emission is a remarkable challenge due to the recalcitrant nature of synthetic dyes, mainly derived from coal and petroleum intermediates (Ahtasham Iqbal et al., 2024; Khan et al., 2024; Palak et al., 2024; Sofia et al., 2024).

Effluent treatment plants are widely accepted approaches for treating industry effluents, enabling further reuse in different processes. However, the selected method depends on the composition, characteristics, and concentration of effluent, and implementing a single process falls short of entirely degrading the dyes. Although biological systems are quite popular with an economic nature, they suffer from slow kinetics and insufficient degradation performance. Similarly, inferior efficient treatment techniques such as flocculation, filtration, and sedimentation cause secondary pollution (Ahtasham Iqbal et al., 2024; Khan et al., 2024; Palak et al., 2024).

Advanced oxidation processes (AOPs) refer to exceptional chemical oxidation processes via direct or indirect commonly used for a comprehensive range of dyes and persistent organic compounds that cannot degrade efficiently through conventional methods. AOPs can be classified as Fenton, ozonation, ultrasonic, electrochemical oxidation, H_2O_2/UV, and photocatalysis based on the generation of principle and oxidizing species. Among AOPS, photocatalysis is a superior and environmentally friendly treatment that produces highly reactive hydroxyl radicals upon exposure to light and operates under low operational costs. Metal oxides, particularly TiO_2 and ZnO have been extensively used as photocatalysts (Ahtasham Iqbal et al., 2024; Khader et al., 2024; Khan et al., 2024; Palak et al., 2024). Although Nd_2O_3, a rare earth compound has been applied in distinct fields, there are only limited photocatalytic studies. Some of the related studies reported so far are the photocatalytic removal efficiencies of methylene blue (Ahmed et al., 2022; Sokkalingam et al., 2024; Zinatloo-Ajabshir et al., 2017b), Rhodamine B (Mortazavi-Derazkola et al., 2015), Eriochrome black T (Zinatloo-Ajabshir et al., 2017c), Eosin Y (Zinatloo-Ajabshir et al., 2017a) in the presence of Nd_2O_3.

In the present study, the structural and morphological properties of Nd_2O_3 particles were identified using FT-IR, SEM, and Raman spectroscopy. Reactive Red 194 (RR-194) was chosen as an azo dye used in the textile industry, particularly cotton dyeing. The photocatalytic degradation of RR-194 under both UV and solar-simulated light (SI) conditions were tested. In addition, catalyst dose and initial dye concentration parameters were investigated.

MATERIAL AND METHOD

Neodymium (III) oxide (Nd_2O_3, analytical grade) was obtained from Sigma Aldrich and used without further treatment. All aqueous solutions were prepared with distilled water (conductivity 2 µS/cm at 25 °C). The chemical structure of RR-194 dye is given in Figure 1.

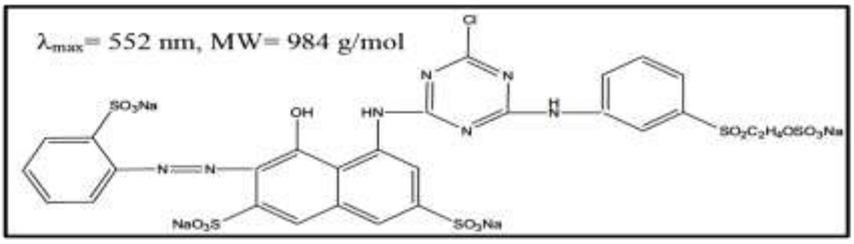

Figure 1. The chemical structure of RR-194.

FT-IR spectroscopy was employed using a Thermo Scientific Nicolet 6700 spectrometer equipped with an attenuated total reflection accessory. FT-IR measurement was carried out in 32 scans at a resolution of 4 cm^{-1} in the 4000–400 cm^{-1} range. Dispersive Raman spectroscopic measurement was performed on a Thermo Scientific DXR Raman Microscope with an Ar^+ laser power (10 mW at λ=532 nm) and a resolution of 4 cm^{-1}. SEM analysis was performed on FEI-Philips XL30 Scanning Electron Microscope with an accelerating voltage of 10 kV.

The photocatalytic activity tests were performed in a cylindrical Pyrex reaction vessel under UV and SI conditions and the reactor was irradiated from the top. A 125W black light fluorescent lamp ($\lambda =_{max}$ 365 nm) and an OSRAM Ultra-Vitalux lamp (300 W) were used as the UV and SI light sources respectively. The photocatalytic experiments were tested using Nd_2O_3 dose (0.25 g/L and 0.50 g/L) and initial RR-194 dye concentration (10 mg/L, 20 mg/L, 30 mg/L) without pH adjustment. The photocatalyst was dispersed in 50 mL of RR-194 solution and the irritated solution was immediately filtered through 0.22 μm cellulose acetate filters. The absorbance values of the solutions were performed on a Thermo Scientific Genesys 10S double-beam spectrophotometer using 1 cm quartz cells.

RESULTS AND DISCUSSION

FT-IR spectrum of the Nd_2O_3 specimen is presented in Figure 2 (a). A strong band observed at 3606 cm^{-1} corresponded to the O-H stretching of physisorbed water molecules (Zinatloo-Ajabshir et al., 2017c). The characteristic metal-oxygen bands at 661 cm^{-1} and 459 cm^{-1} were attributed to the Nd-O stretching vibrations (Sokkalingam et al., 2024). The appeared band at 1473 cm^{-1} could belong to C=O implying atmospheric CO_2 (Ahmed et al., 2022). Raman spectrum of the Nd_2O_3 is represented in Figure 2 (b). The four characteristic Raman modes of Nd_2O_3 at 183 cm^{-1}, 296 cm^{-1}, 360 cm^{-1}, and 472 cm^{-1} were observed (Sokkalingam et al., 2024). SEM images of Nd_2O_3 exhibit various polyhedral-shaped particles with aggregation (Figure 3).

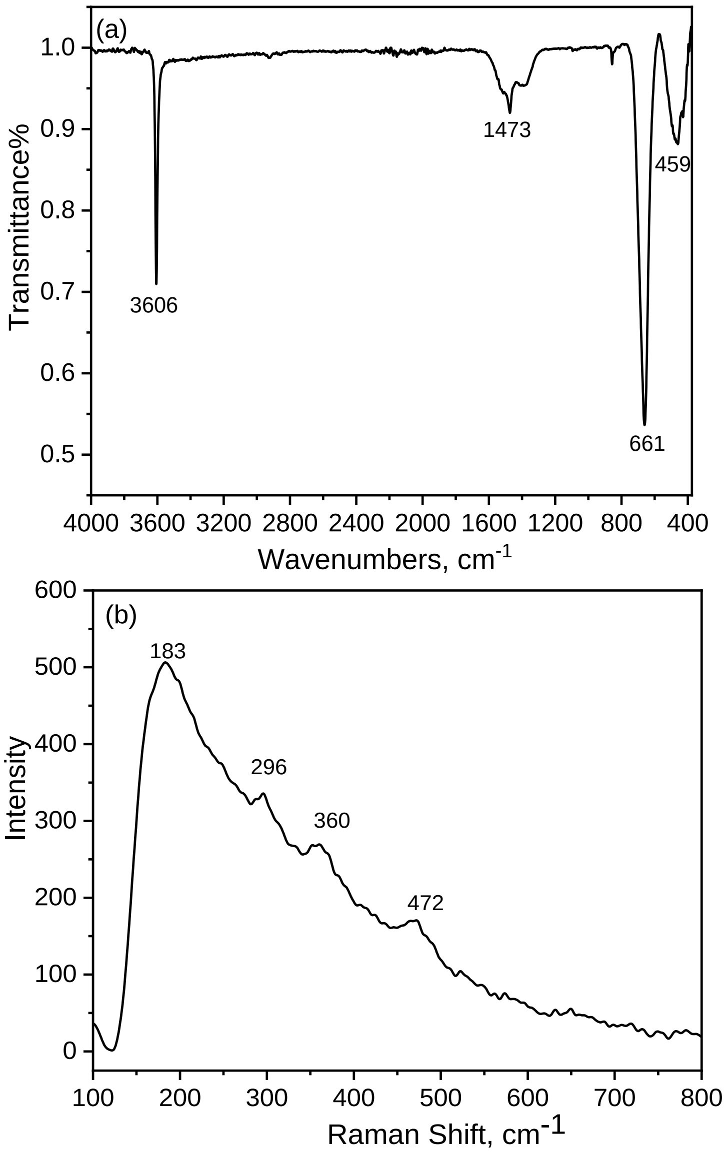

Figure 2. (a) FT-IR spectrum and (b) Raman spectrum of Nd_2O_3 specimen.

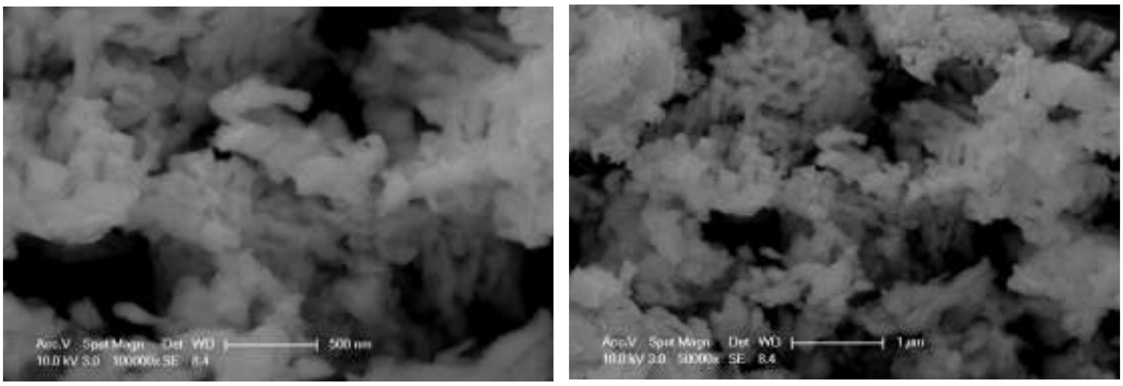

Figure 3. SEM images (left) x100000 and (right) x50000 of Nd_2O_3 specimen.

The degree of RR-194 decolorization in the presence of Nd_2O_3 was calculated by the following equation (1).

Decolorization, %= $((A_{,o} - A)/A_o))$ x100 (1)

where,

$A_{,o}$ = initial absorbance of RR-194 and A = absorbance of RR-194 at irradiation time t.

The degree of RR-194 decolorization was examined upon doses (0.25 g/L and 0.50 g/L) of Nd_2O_3 at 10 mg/L initial concentration of RR-194 dye under 300 min irradiation. To determine the effect of the light source, the experiments were tested under both UV and SI conditions (Figure 4 (a)). It was found that SI experiments revealed higher removal percentages than UV light conditions.

As catalyst concentration increased to 0.50 g/L, the removal percentages of RR-194 at 300 min irradiation were almost doubled (Figure 4 (b)). The highest removal efficiency of RR-194 in the presence of 0.50 g/L Nd_2O_3 under 300 min SI irradiation time was 46%. The reason could be the enhancement of photons and adsorbed dye molecules.

The initial RR-194 dye concentration effect at three different concentrations (10 mg/L, 20 mg/L, and 30 mg/L) was performed under UV light for 60 min in the presence of Nd_2O_3 (0.25 g/L and 0.50 g/L) (Figure 4 (c)). The removal efficiency decreased with increasing initial RR-194 concentration up to 0.50 g/L dose of Nd_2O_3 because the increased dye concentration may affect the light penetration into the reaction solution, leading to a low catalytic performance at higher dye concentrations. However, the removal values remained almost unchanged at higher concentrations (20 mg/L and 30 mg/L) of RR-194 with 0.25 g/L catalyst dose.

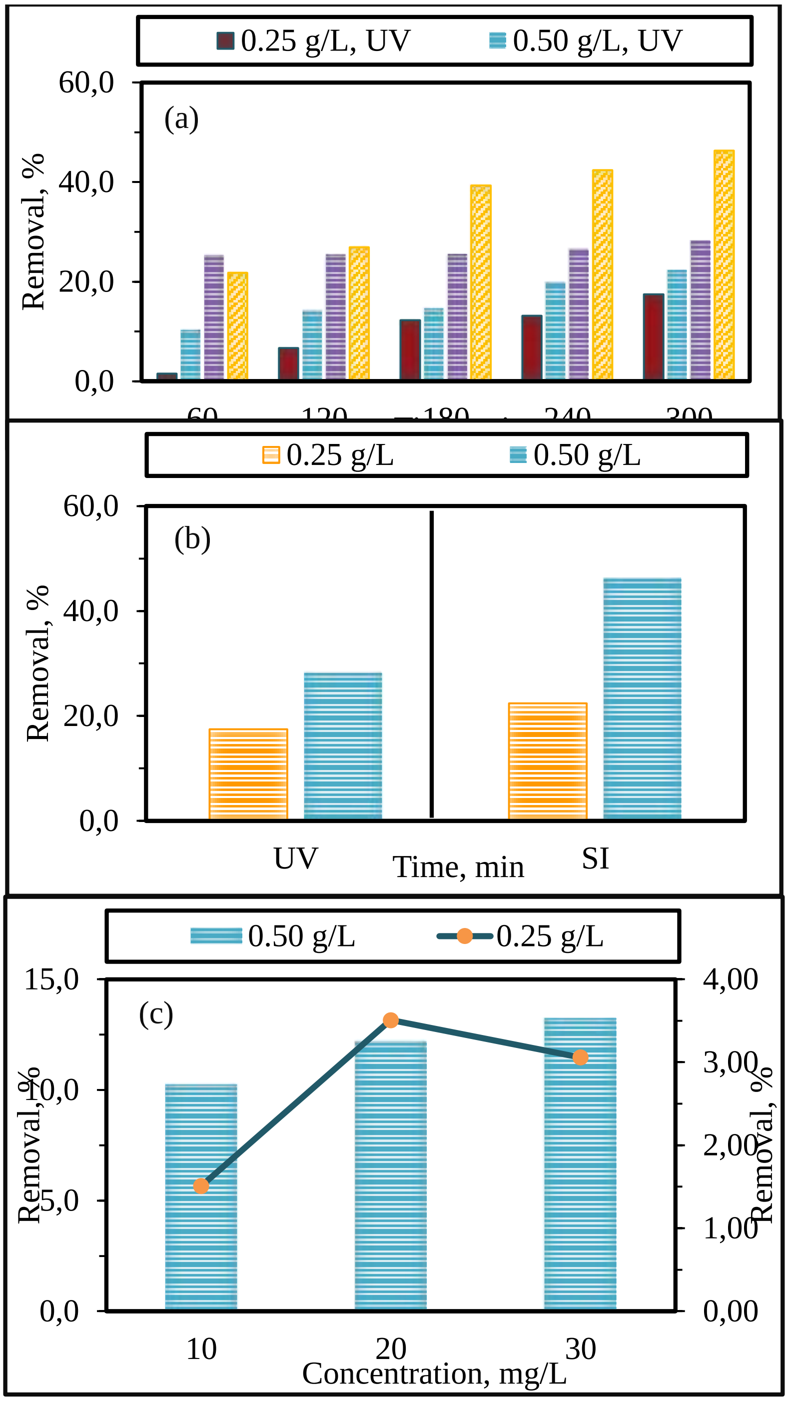

Figure 4. (a) Removal efficiencies of RR-194, (b) Dose effect of Nd_2O_3 specimen, and (c) Initial RR-194 dye concentration effect.

CONCLUSIONS

The decolorization performances of RR-194 in the presence of Nd_2O_3 specimen under both UV and SI systems was investigated. The removal efficiencies of RR-194 under the SI system were significantly higher compared to UV light conditions. The result indicated that a higher dose of Nd_2O_3 (0.50 g/L) was favorable. Additionally, a higher RR-194 dye concentration caused a decrease in light penetration. The structural properties of Nd_2O_3 were determined using FT-IR and Raman spectroscopy techniques. FT-IR confirmed the evidence of characteristic bands of Nd_2O_3 related to the metal-oxygen groups. SEM images revealed a variety of polyhedral-shaped particles with agglomeration.

ABSTRACT

In this study, risk management and sustainability issues in agricultural enterprises producing watermelon in Karatas district of Adana province were examined. In the agricultural enterprises within the scope of the study, issues such as demographic characteristics, risk sources encountered in agriculture, risk management strategies, farmers' reasons for agricultural production, thoughts of continuing agricultural production in the future, and information sources for agricultural production were investigated. In the study, data obtained from primary and secondary sources were used. The primary source of the study was the data obtained from the surveys applied to 32 farmers producing watermelon in the 2022 production period in Karatas district of Adana province. Similar studies conducted nationally and internationally, reports and records of relevant institutions and organizations are the secondary sources of the study. According to the results obtained from the study; changes in input costs, changes in interest rates, changes in product yields, lack of adequate support for basic inputs such as fertilizers, pesticides, irrigation and diesel fuel, and the high difference between consumer and producer prices are important risk sources affecting watermelon production. According to the data obtained from the surveys applied to farmers in farms producing watermelon; planning expenditures, increasing solvency, planning borrowing, and preventing excessive use of existing resources have been identified as important strategies to manage risk.

Keywords: Risk Management, Risk Resources, Sustainability, Watermelon, Adana

INTRODUCTION

Every year, 101 million tons of watermelon are produced in approximately 3 million hectares of land in the world. The amount of watermelon exported in the world is 4.5 million tons. The total amount of world watermelon imports is 4.2 million tons. In watermelon production, China, Türkiye and India respectively; Spain, Mexico, Italy in watermelon exports; The USA, Germany and Canada are the leading countries in watermelon imports.

Agriculture is one of the leading sectors in Turkey, which has favorable geographical conditions and climate, a rich soil structure and biological diversity. Watermelon is a product of great economic importance in Turkish agriculture. According to the "Plant Product Balance Tables" prepared by TÜİK (2024), regarding watermelon production in the 2022/2023 period; production amount 3394783 tons, production losses 91659 tons, supply/use 3348971 tons, usable production 3303124 tons, imports 45847 tons, domestic use 3204983 tons, fresh consumption 2884485 tons, exports 143988, per capita consumption 33.8 kg., degree of sufficiency 103.1% values are given. According to these data, Türkiye is a self-sufficient country in watermelon production. The top countries in Turkey's watermelon exports by country in the 2021/22 production year are Bosnia (14.3%), Russia (13.8%), Georgia (10.3%), Iraq (8.4%), Syria (7.8%) and other countries (45.5%). Iran ranks first in watermelon imports. In addition, the majority of watermelon production is consumed fresh (TUIK, 2024). In Turkey, the regions where watermelon is produced the most are; Aegean, Mediterranean, Southeastern Anatolia and Marmara regions. On a provincial basis, the highest production is made in Adana (19.9%). In watermelon production, Adana province is followed by Antalya (13%), Mersin (7.3%), Bursa (5.6%), Adıyaman (3.7%), Diyarbakır (3.5%), Manisa (3.5%), Samsun (3.2%) and other provinces follow (Kaya, 2022).

In a study conducted in Antalya, the problems faced by producers in watermelon production were determined as high input prices, fight against diseases and pests, climatic conditions, insufficient supports, problems in irrigation, labor, labor supply and cost. The problems of watermelon producers in the marketing process vary depending on the producer and business conditions, but are expressed as the lack of number and variety of buyers, excessive fluctuation and uncertainty of prices, low prices, long payment terms, lack of bargaining opportunities, and product losses, respectively (Buyukkalay, 2019).

In the agricultural sector, whose development is important for Turkey, production is exposed to natural risks that are not under the control of the producer, despite today's developing technology. In this respect, agriculture is described as an open-top factory. Developed countries have been pursuing protectionist policies under the name of 'Risk Management Programs in Agriculture' for years due to the natural, economic, social, technological and personal risks they face. With these programs, after the productivity losses resulting from natural risks that threaten agricultural production, they also take the income losses resulting from economic risks from the agricultural sector and transfer them to insurance systems (Gungor, 2006).

Although farmers manage only part of the production process, risk management at the business level is extremely important. Because failure to cope with the risks inherent in agricultural production will result in loss of income and livelihood for millions of people in developing countries. Additionally, all other decision makers in the agricultural supply chain must face risks in their decision-making processes. However, farmers in developing countries have insufficient capacity to manage agricultural risk at the enterprise level (Akcaoz et al., 2024).

Since agricultural production is open to natural conditions; adverse climatic conditions such as floods, drought, hail, frost, diseases and pests often cause devastating damage to the producer's income. These devastating damages are the most important factors that threaten the continuity of agricultural production. In order to prevent these risks that prevent the continuity of agricultural production, technical protection methods are primarily used. Farmers who want to protect themselves from the risks affecting agricultural production, make a better living and improve their living standards diversify their products and work in various activities outside the business. However, these measures taken by farmers to protect themselves from various risks cannot protect the income of the farmer family and may cause the farmer's income to decrease due to the expenses he makes (Ozsayin, 2005). There is an extensive literature examining farmers' perceptions, attitudes and behaviors towards risk sources and risk management strategies in agricultural enterprises nationally and internationally. Some of these studies on plant production are; Pellegrino (1999), Nicol et al. (2007), Ali and Kapoor (2008), Akcaoz et al. (2009), Adanacioglu and Olgun (2010), Sookhtanlo and Sarani (2011), Cetin and Esengun (2012), Almadani (2014), Agir et al. (2015), Bagheri and Fami (2016), Iqbal et al. (2016), Alp (2017), Rizwan et al. (2017), Usman et al. (2017), Akhtar et al. (2018), Bal (2018), Iqbal et al. (2018), Akhtar et al. (2019), Hayran (2019), Ucar and Engindeniz (2019), Ahmed et al. (2020), Hakorimana and Akcaoz (2020), Ozer and Tumer (2020), Agir and Erdem (2022).

In this study, risk management and sustainability issues were examined in agricultural enterprises producing watermelon in Karataş district of Adana province. In the agricultural enterprises within the scope of the study; demographic characteristics, risk sources encountered in agriculture, risk management strategies, farmers' reasons for agricultural production, thoughts of continuing agricultural production in the future, information sources for agricultural production, etc. topics have been researched.

MATERIALS AND METHODS

In the study, data obtained from primary and secondary sources were used. The primary source of the study is the data obtained from the surveys to be applied to farmers producing watermelon in Karataş district of Adana province. A survey was applied to 32 farmers producing watermelon in Karataş district of Adana province in the 2022 production period. The farmers who were surveyed were selected randomly and a face-to-face survey was conducted. In the farms within the scope of the survey, demographic characteristics, risks encountered in watermelon production, strategies that can be applied against risks, farmers' opinions about sustainability in watermelon production, information sources regarding agricultural activities, etc. Topics are included. The data obtained in this survey application were summarized and interpreted in tables. Likert scale was also used while obtaining primary data. Survey data were analyzed in the SPSS package program.

Similar studies conducted nationally and internationally, reports and records of relevant institutions and organizations are secondary sources.

RESEARCH FINDINGS

Demographic characteristics

Demographic characteristics were also included in the survey form applied to farmers in farms producing watermelon in Karataş district of Adana province. In this context, the gender, age, education level of family members, average family size, farmers' experience in agricultural production and watermelon production, working conditions in the farm and outside the farm were investigated (Table 1). The total number of family members in the farms within the scope of the research is 118, of which 53.39% are male and 46.61% are female. In the farms examined, 56.78% of the family members are in the 15-49 age group, 22.88% are over 50 years old, 11.02% are in the 7-14 age group and 9.32% are in the 0-6 age group. 56.25% of the surveyed farmers are in the 15-49 age group and 43.75% are in the over 50 age group. 53.39% of family members in farms are primary school graduates, and this rate is 62.5% in farmers. It was determined that the average experience period of the farmers in the research in agricultural production was 31.81 years, and the average experience period in watermelon production was 25.46 years. According to the findings of the research, 38.92% of family members work in their own businesses. The rate of family members working in non-agricultural jobs is 9.32%.

Land Characteristics in the Examined Farms

The total land width in the 32 enterprises within the scope of the research is 11591 decares and the average land width per farm is 362 decares. The total number of parcels in the farms is 78 and the average number of parcels per farm is 2.44. In the farms examined in the study, data regarding the ownership status of the lands, topographic condition, soil structure, soil fertility and land type were investigated. Considering the number of parcels of the farms, it is seen that 11.54% consists of rented land and 88.46% consists of freehold land. When the total land width is taken into consideration, it is seen that 13.04% consists of rented land and 86.96% consists of freehold land. In the farms within the scope of the research, 92.66% of the total land is flat and 7.34% has a slightly rugged topographic structure. Of the total land assets of the examined farms, 91.77% consists of high and 8.23% medium productive land. The soil structure of the total land assets in the farms is sandy and the land type consists of irrigated fields (Table 2).

Risk Sources in Farms

Sources of Production Risk

Crop and livestock production performance depends on biological processes that are affected by weather conditions, diseases and pests. Insufficient rainfall or drought can cause low yields. Hail or heavy rains can damage or completely destroy crops. Pest or disease outbreaks can also cause major productivity losses in crop production and livestock. In agricultural production, when farmers plant seeds and fertilize their fields, they do not know how much rain will fall, whether there will be hail or a storm. They cannot predict whether there will be a problem with pests or diseases. But they still have to continue their production activities.

In the research, the sources of production risks encountered in businesses producing watermelon are given in Table 3. Farmers' evaluations of production risk sources in the examined farms were determined on a Likert scale. Accordingly, some of the sources of production risk that farmers express as very important in watermelon production are; changes in crop yields, low productivity due to plant pests, lack of information about the production method, frost, excessive rainfall, insufficient rainfall, inadequacy of agricultural tools and machinery, changes in climate conditions, low productivity due to plant diseases, crop damage due to floods, inadequacy of analysis laboratories, difficulties in finding foreign labor and crop losses during harvest (Table 3).

Sources of Financing Risk

Financing risk occurs when money is borrowed to finance a farming business. This risk can be caused by uncertainty in future interest rates, the lender's willingness to provide funds when needed, and the farmer's ability to generate the income necessary to repay the loan. Small farmers who borrow money at high interest rates may have difficulty paying their debts. Lower than expected prices combined with low yields can make debt repayment difficult and even lead to the sale of the business. The opinions of farmers about financing risk sources in the examined farms are given in Table 4. According to the farmers surveyed in the study, some of the most important sources of financing risks encountered in watermelon production are; changes in interest rates, changes in input costs, debt structure, debt status, inadequacy of financing, capacity and availability of credit resources, financing without equity capital, insufficiency in farm capital and inflation.

Table 4. Sources of Financing Risk in the Examined Farms

Financing risk	Mean	Std. Deviation	Scale (%)					
			1	2	3	4	5	Total
Changes in interest rates	1.00	0.00	100.0	-	-	-	-	100.0
Changes in input costs	1.00	0.00	100.0	-	-	-	-	100.0

Sources of Marketing and Price Risk

Market and price risk relates to the volatility of prices and uncertainty of markets for agricultural products. Since agricultural product prices vary significantly from year to year, they affect the supply of goods and therefore the production decisions of the farmer. Demand is affected by factors such as consumer incomes, export policies, the state of the general economy, and the supply of competing products. In addition, some price movements show seasonality. Costs are another source of price risk. Input prices vary less than product prices. However, there is also uncertainty in input prices. Since the production cost per unit depends on yield and prices, its variability is quite high. In short, input and product prices in agricultural production are the elements that cause marketing and price risks.

The opinions of farmers regarding marketing and price risk in the farms examined in the study were determined with the Likert scale and the obtained data are summarized in Table 5. Among the marketing and price risks expressed by farmers in the watermelon producing farms in the research area as very important are; changes in the prices of the crops, lack of information about marketing and sales, lack of market guarantee for the crops, problems encountered in preservation (storage), inability to grow products of suitable variety and quality for the market, problems encountered in transportation and lack of infrastructure in wholesalers.

Table 5. Sources of Marketing and Price Risk in the Examined Farms

Marketing and Price Risk	Mean	Std. Deviation	Scale (%)					
			1	2	3	4	5	Total
Changes in the prices of the crops	1.00	0.00	100.0	-	-	-	-	100.0
Lack of information about marketing and sales	1.00	0.00	100.0	-	-	-	-	100.0

Personal Risk Sources (Human Originated Risks)

Human-caused risk refers to agribusiness risks resulting from illness or death and the personal situation of the farming family. Accidents, illnesses and death can negatively impact the performance of a farming business. It is common in many countries for the workforce to move away from rural areas. Migration may cause labor shortages in agricultural production activities. Political and social unrest may also limit labor availability. Farmers cannot be absolutely sure that they will be able to find the labor force required for crop and animal production activities in sufficient numbers at the required time. As agricultural enterprises grow, technology advances, and other risks increase, human-related risks become more important. Farmers are more knowledgeable and experienced in production-related issues than in risk-related issues. Human-related risks can be examined in three groups: the farmer and his family, the person managing the business and the employees of the business.

Farmers' opinions regarding personal risk sources in the farms within the scope of the research are given in Table 6. According to farmers, although the health/disability/death status of the business owner or worker is very important among the personal risk sources, work accidents occurring in the farm and problems/disputes in family relations are not important.

Table 6. Personal Risk Sources in the Examined Farms

Personal Risk	Mean	Std. Deviation	Scale (%)					
			1	2	3	4	5	Total
The health/disability/death status of the business owner or worker	1.40	0.66	68.8	21.9	9.4	-	-	100.0
Insufficiency of family workforce	2.46	0.94	9.4	56.3	12.5	21.9	-	100.0
Work accidents occurring in the farm	3.65	0.93	-	12.5	28.1	40.6	18.8	100.0
Problems/disputes in family relations	3.65	1.09	-	25.0	6.3	46.9	21.9	100.0

Scale * 1:Very important, 2:Important, 3: Neutral, 4:Not important, 5:Not at all important

Legal, Institutional and Political Risk Resources

Institutional risk refers to unforeseen changes in service delivery from institutions that support farming. Such institutions can be both formal and informal and may include banks, cooperatives, marketing organizations, input dealers and government agencies. Some of the institutional risk arises from the uncertainty of government policy affecting agriculture, such as price support and subsidies. The risks faced by farmers are often a result of decisions made by policy makers and managers. Subsidies, food quality regulations for export products, and the level of price or income support payments are examples of decisions made by the government that can have a major impact on agribusiness.

In the study, institutional and political risks were also evaluated within the scope of risk sources encountered in agricultural production. Farmers' opinions regarding institutional and political risk sources in the examined enterprises are given in Table 7. Accordingly, changes in the economic situation of the country, lack or insufficient government support, and changes in the general and agricultural policies implemented by the government were evaluated as very important for farmers.

Table 7. Legal/Institutional and Political Risk Sources in the Examined Farms

Legal, Institutional, Political Risk	Mean	Std. Deviation	Scale (%)					
			1	2	3	4	5	Total
Changes in the economic situation of the country	1.00	0.00	100.0	-	-	-	-	100.0
Lack or insufficient government support	1.00	0.00	100.0	-	-	-	-	100.0
Shanges in the general and agricultural policies implemented by the government (General and agricultural policy)	1.00	0.00	100.0	-	-	-	-	100.0

Scale * 1:Very important, 2:Important, 3: Neutral, 4:Not important, 5:Not at all important

Risk Management Strategies in Farms

Farmers have to find ways to cope with risk and protect themselves from decisions made today without knowing what will happen tomorrow. Risk management strategies are used to reduce the likelihood of a “bad” outcome occurring. Farmers trying to manage risk must identify possible sources of risk, recognize possible outcomes, decide on available alternative strategies, evaluate the consequences of each possible outcome, and evaluate the changes between the cost of risk and the gains to be achieved (Kahan, 2008).

Production Risk Management Strategies

Production risk arises from uncertainty regarding factors that affect the quantity and quality of agricultural products (e.g. weather, disease, pests, etc.). It also occurs with the use of new technologies. Various strategies can be used to reduce production risk. Some of those; risk-reducing inputs, risk-reducing technologies, diversification, insurance, non-business income, flexibility, etc. can be expressed as.

Farmers' opinions about the production risk management strategies that can be applied against the production risks encountered in the watermelon producing farms within the scope of the research are given in Table 8. Among the production risk management strategies, producing at the lowest cost possible, increasing supports for agricultural inputs, obtaining crop insurance, combating diseases with drugs, making differentiation in the farm, diversifying the farm and enlarging the farm land have been determined as very important.

Although land consolidation and regional production planning are institutional and political risk management tools, according to farmers, they are considered among the production risk management strategies and are expressed as very important. Having employees insured was stated as a production risk management strategy, but it was evaluated by farmers as not important in managing production risk.

Table 8. Production Risk Management Strategies in the Examined Farms

Production Risk Management Strategies	Mean	Std. Deviation	Scale (%)					
			1	2	3	4	5	Total
Producing at the lowest cost possible	1.00	0.00	100.0	-	-	-	-	100.0
Increasing supports for agricultural inputs	1.00	0.00	100.0	-	-	-	-	100.0
Obtaining crop insurance	1.00	0.00	100.0	-	-	-	-	100.0

Scale * *1:Very important, 2:Important, 3: Neutral, 4:Not important, 5:Not at all important*

Financing Risk Management Strategies

Financial risk occurs when money is borrowed to finance the business. This risk is caused by uncertainty about future interest rates and repayment schedules, changes in loan collateral, and the farm's ability to generate the cash flow needed to repay the loan. Issues to be considered in financial risk management; credit availability and cost and repayment schedule, the farmer's liquidity or ability to generate cash flow, the farmer's ability to maintain and increase capital.

Financing risk management strategies were also investigated in the farms included in the study, and the findings are given in Table 9. According to the farmers surveyed in the study, financing risk management strategies such as planning expenses, reducing debt, increasing solvency, saving, finding capital resources, regulating the excessive use of existing resources, making financial analyzes and making non-farm investments are very important.

Table 9. Financing Risk Management Strategies in the Examined Farms

Financing Risk Management Strategies	Mean	Std. Deviation	Scale (%)					
			1	2	3	4	5	Total
Planning expenses	1.00	0.00	100.0	-	-	-	-	100.0
Reducing debt	1.00	0.00	100.0	-	-	-	-	100.0
Increasing solvency	1.00	0.00	100.0	-	-	-	-	100.0
Saving	1.00	0.00	100.0	-	-	-	-	100.0
Finding capital resources	1.00	0.00	100.0	-	-	-	-	100.0
Regulating the excessive use of existing resources	1.09	0.39	93.8	3.1	3.1	-	-	100.0
Making financial analyzes	1.09	0.39	93.8	3.1	3.1	-	-	100.0
Making non-farm investments	1.25	0.67	84.4	9.4	3.1	3.1	-	100.0
Keeping business records regularly	2.09	1.37	53.1	12.5	12.5	15.6	6.3	100.0
Debt management should be carried out by experts (Accountant, Agricultural Engineer, etc.)	2.68	0.89	3.1	50.0	21.9	25.0	-	100.0

Sell capital assets	5.00	0.00	100.0	-	-	-	-	100.0

Scale * *1:Very important, 2:Important, 3: Neutral, 4:Not important, 5:Not at all important*

Marketing and Price Risk Management Strategies

Marketing risk arises due to the variability in product prices and the uncertainty of future market prices that the farmer faces when making production decisions. Various methods can be used to reduce price variability and set a satisfactory price before products are ready for sale. Table 10 gives risk management strategies that farmers can apply against marketing and price risk. Accordingly, farmers evaluated the strategies of improving transportation and transportation facilities against marketing and price risk, having information about past crop prices, having information about the market where the crop will be sold, and improving storage facilities as very important. According to farmers in the farms examined, contract production is not important as a marketing risk management strategy.

Table 10. Marketing and Price Risk Management Strategies in the Examined Farms

Marketing and Price Risk Management Strategies	Mean	Std. Deviation	Scale (%) 1	2	3	4	5	Total
Improving transportation and transportation facilities	1.03	0.17	96.9	3.1	-	-	-	100.0
Having information about past crop prices	1.03	0.17	96.9	3.1	-	-	-	100.0
Having information about the market where the crop will be sold	1.28	0.52	75.0	21.9	3.1	-	-	100.0
Improving storage facilities	1.43	0.91	75.0	12.5	9.4	3.1	-	100.0

Sustainability of Agricultural Activity

Decisions regarding agricultural enterprises are made in line with the goals and objectives of the farmer. In order to make these decisions, farmers need to know the basic elements of decision making. Basic decision-making process or cycle; It consists of the stages of determining goals and objectives, determining methods to achieve goals and objectives, evaluating different opportunities and alternatives, selecting opportunities and alternatives, planning and implementing the selected opportunities and alternatives, reviewing and evaluating the selected opportunities (Kahan, 2008).

All of the producers within the scope of the research stated that they had agricultural insurance in the last five years and were registered in the farmer registration system. All of the farmers in the farms examined stated that they would not give up agricultural production under any circumstances. Farmers reported that 68.75% of the farms kept business records. People who are influential in decision-making regarding agricultural activities in the examined farms were investigated and the obtained data are given in Table 11. It has been determined that farmers are the dominant decision makers in decisions regarding investment, savings, financing and marketing in farms, the family decides together on non-farm matters (84.4%), and the farmer and the family decide together on decisions about expanding the business.

Table 11. People Influential in Decision Making Regarding Agricultural Activities in the Examined Farms (%)

Decision Type	Farmer	Farmer's Wife	Farmer's Children	Family Together	Total
Investment decisions	56.3	15.6	12.5	15.6	100.0
Savings decisions	59.4	12.5	12.5	15.6	100.0
Financing decisions	62.5	12.5	9.4	15.6	100.0
Decisions about the future	6.3	28.1	6.3	59.4	100.0
Business expansion decisions	43.8	6.3	6.3	43.8	100.0
Marketing decisions	84.4	-	6.3	9.4	100.0
Decisions regarding production pattern	-	-	-	100.0	100.0
Decisions regarding non-business matters	9.4	3.1	3.1	84.4	100.0

The reasons why farmers continued agricultural activities in the examined farms were also investigated, and the findings are given in Table 12. In this context, the surveyed farmers expressed the following as very important reasons for agricultural production: he has land for agricultural production, he can make a profit, it is difficult to do another job, he is his own boss, he likes to do agriculture, it is difficult to change jobs and there are no good opportunities outside of agriculture.

Table 12. Reasons of Farmers for Agricultural Production in the Farms Examined

Reasons	Mean	Std. Deviation	Scale (%) 1	2	3	4	5	Total
Having land for agricultural activity	1.00	0.00	100.0	-	-	-	-	100.0
Make a profit	1.00	0.00	100.0	-	-	-	-	100.0
It is difficult to do another job	1.00	0.00	100.0	-	-	-	-	100.0
Being your own boss	1.00	0.00	100.0	-	-	-	-	100.0
Enjoying doing agriculture	1.03	0.17	96.9	3.1	-	-	-	100.0
It is very difficult to change jobs	1.18	0.73	90.6	6.3	-	-	3.1	100.0
Lack of good opportunities outside agriculture	1.34	0.97	87.5	-	6.3	3.1	3.1	100.0
Helping the family with this work	2.31	1.40	43.8	15.6	12.5	21.9	6.3	100.0

Scale * *1:Very important, 2:Important, 3: Neutral, 4:Not important, 5:Not at all important*

The elements that are thought to help farmers continue agricultural activities in the farms within the scope of the research were determined using the Likert scale and the findings are given in Table 13. Among the factors that will help farmers continue their agricultural activities in the examined farms, the elements stated as very important are; finding a loan when needed, having government support, guaranteeing product prices, becoming widespread of contract production, agricultural engineers in agricultural organizations visiting the enterprise, providing support against natural disasters (flood, hail, frost, etc.), being informed about product prices in advance, infrastructure improving the facilities (road, communication, etc.), having/increasing storage services, not encountering difficulties in recruiting workers, increasing credit opportunities, agricultural engineers from pharmaceutical dealers visiting the business, having transportation services, not having too much debt, and having non-agricultural income.

Table 13. Elements that Can Help Farmers to Continue Agricultural Activities in the Examined Farms

Elements that Can Help Farmers to Continue Agricultural Activities	Mean	Std. Deviation	Scale (%)					
			1	2	3	4	5	Total
Finding a loan when needed	1.00	0.00	100.0	-	-	-	-	100.0
Having government support	1.00	0.00	100.0	-	-	-	-	100.0
Guaranteeing product prices	1.00	0.00	100.0	-	-	-	-	100.0
Becoming widespread of contract production	1.00	0.00	100.0	-	-	-	-	100.0
Agricultural engineers in agricultural organizations visiting the enterprise	1.03	0.17	96.9	3.1	-	-	-	100.0
Providing support against natural disasters (flood, hail, frost, etc.)	1.03	0.17	96.9	3.1	-	-	-	100.0
Being informed about product prices in advance	1.03	0.17	96.9	3.1	-	-	-	100.0

Convenience in matters such as packaging supply	4.28	1.24	9.4	-	12.5	9.4	68.8	100.0
Information about packaging	4.56	0.91	3.1	-	9.4	12.5	75.0	100.0

Scale * *1:Very important, 2:Important, 3: Neutral, 4:Not important, 5:Not at all important*

In the research, the opinions of farmers in the surveyed farms regarding their future goals and objectives were evaluated (Table 14). In the research, farmers' future goals and objectives were examined using the Likert scale. Farmers expressed it as very important for the majority of the goals and objectives presented to farmers. Considering the importance of watermelon production for the research region, it can be said that the results obtained are not surprising and all elements are considered very important for the farmer. Some of the most important future goals and objectives of farmers in the farms examined are; to reduce risks, to be recognized among other farmers, to improve living standards, to increase income, to invest in the business, to expand the business, to obtain high quality products.

Table 14. Future Goals and Objectives of Farmers in the Examined Farms

Future Goals and Objectives of Farmers	Mean	Std. Deviation	Scale (%)					
			1	2	3	4	5	Total
To reduce risks	1.00	0.00	100.0	-	-	-	-	100.0
To be recognized among other farmers	1.00	0.00	100.0	-	-	-	-	100.0
To improve living standards	1.00	0.00	100.0	-	-	-	-	100.0
To increase income	1.00	0.00	100.0	-	-	-	-	100.0
To invest in the business	1.00	0.00	100.0	-	-	-	-	100.0
To expand the business	1.00	0.00	100.0	-	-	-	-	100.0

Information Resources

Good risk management decisions are based on accurate information, which requires reliable data. Good information is one of the most useful elements a farmer can have to help him make rational risk management decisions. While there are many sources of information available, the most appropriate place to look for information depends on the type of risk the farmer needs to manage. It is possible to collect information sources that can be used in decision-making in agriculture under the headings of business records, non-business information sources and other information sources.

In case of any problems related to agricultural activities in the farms examined within the scope of the research, the people whose information can be used are stated as the headman, relatives, neighbors, other farmers, agricultural consultants, agricultural engineers of the provincial and district directorates of Agriculture and dealers. The frequency of meeting with experts on agricultural activities in the farms examined is once a week (59.4%) and once every fifteen days (40.6%) (Table 15).

Leaders in bringing innovations in agricultural activities in the farms within the scope of the research were examined and the findings are given in Table 16. In the farms examined, it is seen that 15.6% of the producers determine the cooperative, 6.3% the headman, and 56.3% the agriculturalist/extension personnel as the pioneer in bringing innovations. The issue of which communication tools are generally used regarding agriculture in the examined farms was investigated. Within the scope of the research, it was determined that 96.9% of the farmers benefited from the internet, all from television, 15.6% from newspapers and 9.4% from brochures (Chart 15).

CONCLUSION

In agriculture, the ability of businesses to continue their activities successfully depends on preventing risks as much as possible and reducing their recurrence and impact. No matter how experienced those involved in agricultural production are in agriculture, they often face many risk factors. As mentioned before, there are many risk sources affecting agriculture. The main risk sources that often arise are diseases, natural conditions, fluctuations in the prices of products, etc. can be specified as. Knowing the risk sources encountered in agriculture and taking various precautions accordingly is an important issue.

In this study, socio-economic characteristics, risk sources, risk management strategies and sustainability of agricultural activities in watermelon producing farms in Karataş district of Adana province were investigated. All of the farmers in the farms examined stated that they would not give up agricultural production under any circumstances. The most important elements that will help farmers continue watermelon production in the farms within the scope of the research are; finding a loan when needed, having government support, guaranteeing product prices and increasing non-agricultural job opportunities. Primary goals and objectives of producers; to reduce risks, to sell the product at the highest price in the market, to have no problems in product transportation, and to produce products of the quality desired by the market.

In the study, risk sources that negatively affect watermelon production in the surveyed enterprises in Karataş district of Adana province;

- changes in product yields,
- low productivity due to plant diseases and pests,
- lack of information regarding the production method,
- inadequacy of agricultural tools and machinery,
- changes in climatic conditions,
- inadequacy of analysis laboratories,
- difficulties encountered in finding foreign labor,
- product losses occurring during harvest,
- changes in interest rates,
- changes in input costs,
- debt structure, indebtedness status,
- lack of financing,
- capacity and availability of credit resources,
- financing without equity capital,
- inflation,
- changes in watermelon prices,
- lack of knowledge about marketing and sales,
- lack of market guarantee for the products,
- problems encountered in storage and transportation,
- inability to grow products of suitable variety and quality for the market,
- health/disability/death status of the business owner or worker,
- changes in the economic situation of the country,
- lack or insufficient government support,
- determined as changes in the general and agricultural policies implemented by the government.

As a result, the findings obtained from the study reveal the problems and risks faced by watermelon producers. Risk management strategies that can be applied in the research area to mitigate the effects of these risks encountered in watermelon production and to ensure continuity in production and sustainability in businesses are;

- to produce at the lowest cost possible,
- getting crop insurance,
- fighting diseases with medicine,
- to diversify and differentiate the business,
- enlarging the business land,
- planning expenses,
- reduce debt,
- increase solvency,
- saving money, finding capital resources,
- making financial analysis,
- making investments outside the business,
- improving transport and transport facilities,

- having information about past product prices and the market,
- improving conservation opportunities.

ABSTRACT

The composting of cattle manure is a crucial process for transforming this organic waste into a soil amendment that is rich in nutrients. This practice plays an instrumental role in reducing the amount of waste sent to landfills and in mitigating greenhouse gas emissions. This environmentally friendly method sustainably enriches soils,which improves crop quality and plant health. There are two main types of composting: biological and chemical. While beneficial, biological composting is slow and requiresrigorous management of environmental conditions to optimise decomposition by microorganisms.In contrast, chemical composting is faster and more economical,where chemical additives are used to accelerate decomposition. In this study we investigated a chemical method using nitric acid to oxidise cattle manure.The excess acid was neutralised with potassium hydroxide, leaving harmless residues such aspotassium and nitrates, which are also powerful fertilisers. Scanningelectron microscopy and energy dispersive X-ray spectroscopy (SEM-EDX) analyses showed that the concentration of nitric acid had a significant effect on compost quality.The results show a decrease in carbon concentration and an increase in nitrogen and potassium concentrations with higher nitric acid concentrations used in the composting process, illustrating the oxidation of organic matter and the incorporation of nitrogen and potassium into thecompost. The C/N ratio, which is crucial for decomposition and plantnutrition, is optimal within a range of nitric acid concentrations from 0.05 Nto 1.00 N, facilitating the production of high-quality compost. The texture of thesamples analysed by SEM also varies with nitric acid concentration, with higher and more uniform degradation of organic matter and a finer texture with improved porosity.

Keyword: Cattle Manure Composting, Chemical Composting, SEM-EDX, Soil Amendments, Fertilizer Production.

INTRODUCTION

Cattle manure composting is a vital process for efficiently converting it into a highly beneficial, nutrient-rich soil amendment.(Larney et al., 2006). By reducing the amount of manure sent to landfills and greenhouse gas emissions, this practice promotes the recycling of organic materials and contributes to environmental preservation. The compost produced can be used to enrich soils in an ecological and economical manner, thereby improving crop quality and plant health.

Cattle manure composting can be achieved either biologically or chemically. Biological composting relies on the action of natural microorganisms, such as bacteria and fungi, which decompose the manure in the presence of oxygen. This aerobic process produces nutrient-rich compost that benefits soil structure and fertility. However, biological composting has some

drawbacks. It is much slower than chemical composting, requiring careful management of temperature, humidity, and aeration conditions to optimize the process. Additionally, due to handling and exposure to organic materials, there is a potential risk of pathogen spread, including viruses such as COVID-19, though this risk can be mitigated by proper composting practices and health safety measures (Zeqiri &Biçoku, 2021).
In contrast, chemical oxidation uses chemical additives to accelerate manure decomposition (Jensen et al., 2013). In this case, care must be taken to ensure that the chemicals used are not hazardous and that chemical residues in the compost do not affect its quality and environmental impact. Chemical composting is significantly more economical than biological composting.
In our study, aiming to replace the traditional composting process, we conducted the chemical oxidation of cattle manure using nitric acid. The excess nitric acid at the end of the process is neutralized using potassium hydroxide. The remaining residues of this process are potassium and nitrates, which are not only harmless but also constitute potent fertilizers, thereby enriching our compost.

MATERIALS AND METHODS

Scanning electron microscopy and elemental analyses

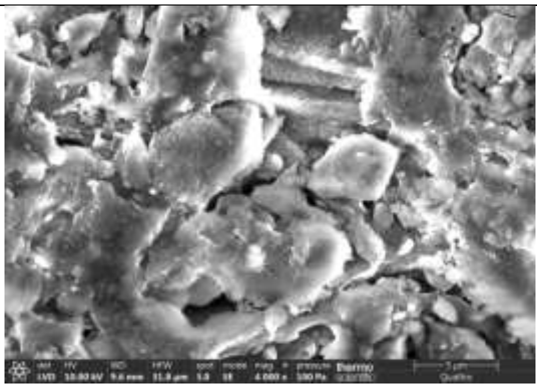
Scanning electron microscopy (SEM) images and elemental analyses were performed using a Thermo Fisher Scientific Helios G4 UC system, equipped with Energy Dispersive X-ray Spectroscopy (EDX). The EDX analysis was conducted at an accelerating voltage of 20 kV and a beam current of 1.6 nA, with a spectrum acquisition time of 60 seconds.

Compost Preparation

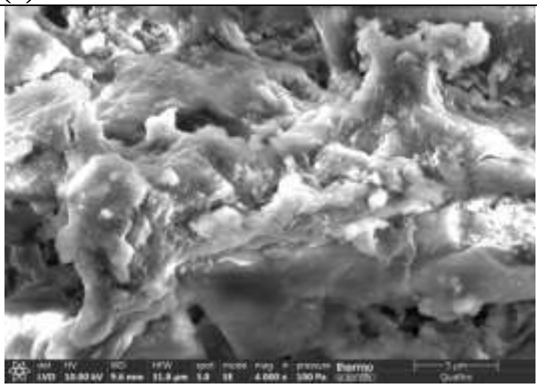
A fixed amount of collected manure is weighed before and after drying to determine the moisture content. Once this step is completed, the manure is ground using a ball mill to obtain a homogeneous texture. Particles smaller than 250 micrometers are recovered by sieving and then stored dry in bags for later use. Three grams of this dried and ground manure are mixed with 15 ml of nitric acid (at concentrations of 1 M, 0.5 M, 0.1 M, 0.05 M, and 14 M), until a paste is formed. Finally, the paste's pH is adjusted using a potassium hydroxide solution to achieve a neutral pH. The resulting product is dried for characterization.

RESULTS

The pH of the compost obtained for samples treated with nitric acid showed an acidic pH, ranging from 3 to 5 depending on the acid concentration used before neutralization with KOH. After neutralization, the pH was adjusted between 6.5 and 7.5. The texture of the obtained samples appears to depend on the concentration of nitric acid used during their preparation. Higher concentrations of nitric acid result in more uniform degradation of organic matter, leading to a finer texture with improved porosity.
The texture of the prepared samples is shown in Figure 1. Image (a) presents raw cattle manure at a magnification of x4000. Images (b), (c), (d), and (e), also at x4000 magnification, show cattle manure samples treated with nitric acid at concentrations of 0.05 M, 0.5 M, 1 M, and 14 M, respectively.

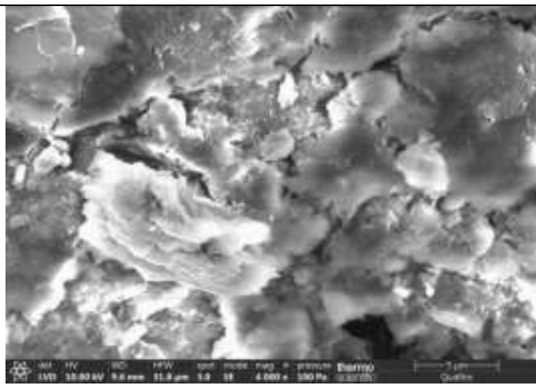


(a) Raw cattle manure



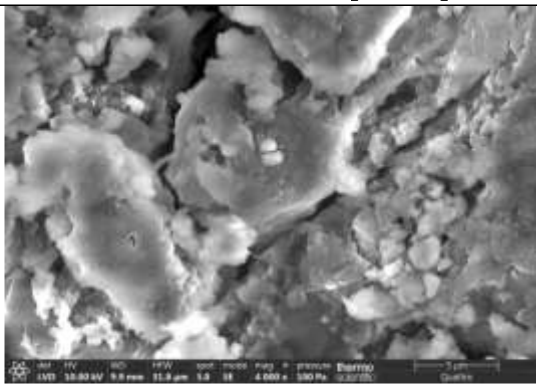
(b)

Cattle manure treated with $[HNO_3]$ = 0.05 M



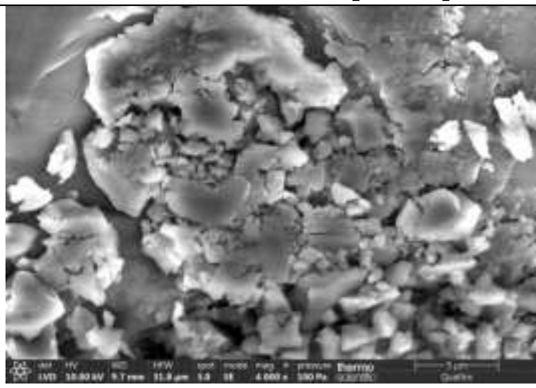
(c)

Cattle manure treated with $[HNO_3]$ = 0.5 M



(d)

Cattle manure treated with $[HNO_3]$ = 1 M



(e)

Cattle manure treated with $[HNO_3]$ = 14 M

Figure 1 SEM Images of (a) Raw cattle manure, (b) Cattle manure treated with [HNO3] = 0.05 M, (d) Cattle manure treated with [HNO3] = 1 M and (e) Cattle manure treated with [HNO3] = 14 M

SEM-EDX is often used for the characterization analysis of composts (Manohara et al., 2017, Diquattro et al., 2018,Khare et al., 2023). The images show the presence of two types of structures in each sample. The first consists of particles of varying sizes and shapes, which may be dispersed or clustered. The images also demonstrate the formation of particle aggregates, which are sets of interconnected particles, indicating the presence of organic matter.

The quality of the obtained product was characterized by scanning electron microscopy coupled with energy-dispersive X-ray spectroscopy (SEM-EDX). This technique was used to study the shape and structure of the compost samples as well as their chemical composition. The effect of nitric acid concentration on the quality of the obtained compost was the first parameter we

studied. For this purpose, we used the following concentrations: 0.05 M, 0.5 M, 1 M, and 14 M.
EDX analysis allowed us to identify the elements present in the compost, and the results are presented in Table 1. We focused particularly on the following elements: C, N, O, Al, Si, P, K, and Ca, which compose the compost. Special attention was given to C and N as they are key indicators of compost quality.

Table 1: EDX Analysis Results of raw cattle manure, cattle manure treated with $[HNO_3]$ = 0.05 M, cattle manure treated with $[HNO_3]$ = 0.5 M, cattle manure treated with $[HNO_3]$ = 1 Mand, cattle manure treated with $[HNO_3]$ = 14 M

Table 1: EDX analysis results of raw cattle manure and cattle manure treated with $[HNO_3]$ at concentrations of 0.05 M, 0.5 M, 1 M, and 14 M.

Element (%)	Raw cattle manure	$[HNO_3]$ = 0.05 M	$[HNO_3]$ = 0.5 M	$[HNO_3]$ = 1 M	$[HNO_3]$ = 14 M
C	40.21	43.87	36.68	38.30	8.51
N	0.08	4.97	6.47	5.63	10.07
O	42.67	41.89	39.92	45.94	39.16
Al	2.28	1.09	1.60	1.32	1.24
Si	5.42	1.05	1.65	0.96	0.18
P	0.77	1.37	2.24	0.78	0.12
K	1.01	1.22	7.62	2.04	39.67
Ca	7.57	3.67	2.31	3.04	0.39
C/N	502,63	8,83	5,67	6,80	0,85

The results show a decrease in carbon concentration with increasing nitric acid concentration during treatment, a consequence of the oxidation of organic matter. Nitrogen concentration in the compost increases in parallel with the nitric acid concentration used, which is expected as nitrogen comes from the acid. Additionally, potassium concentration in the compost increases with higher nitric acid concentrations because more potassium hydroxide is needed to neutralize the compost when the acid concentration is high. These observations highlight the significant impact of nitric acid concentration on the final chemical composition of the compost.
The C/N ratio decreases with the increase in nitric acid concentration used during oxidation. It remains favorable within a broad range of nitric acid concentrations from 0.05 N to 1.00 N.
Maintaining an optimal C/N ratio is essential for supporting decomposition and providing the necessary nutrients to plants after compost application (Azim et al., 2018). Achieving an optimal result over a wide range of nitric acid concentrations reduces manufacturing constraints.

CONCLUSION

This study highlights the effectiveness of chemical oxidation with nitric acid for cattle manure composting, demonstrating its potential to produce high-quality compost quickly and economically. Using nitric acid to oxidize manure, followed by neutralization with potassium hydroxide, not only accelerates the decomposition of organic matter but also enriches the compost with essential nutrients such as nitrogen and potassium. SEM and EDX analyses revealed that nitric acid concentration plays a crucial role in the final compost quality, influencing both its chemical composition and texture. In particular, the C/N ratio, a key indicator of compost quality, was found to be optimal within a range of nitric acid concentrations from 0.05 N to 1.00 N. This flexibility in nitric acid concentrations facilitates the production of high-quality compost without requiring extremely precise control of composting conditions. Chemical oxidation with nitric acid represents a promising method for valorizing cattle manure, providing a practical and eco-friendly solution for agricultural waste management and soil improvement.

ABSTRACT

The Indian meal moth (*Plodia interpunctella*, (Lepidoptera; Pyralidae)) is one of the most economically significant pests of stored products globally. Stored product pests cause direct or indirect damage to contaminated food products. This pest lead to weight losses in products, deterioration of seed qualities, and degradation of quality and nutritional values, thereby negatively affecting the national economy. Interest in using entomopathogen as an alternative to chemical insecticides for the control of the pest is increasing day by day. Among entomopathogens, protist pathogens play a significant role as natural suppressive factors in pest insect populations. This study aimed to determine the seasonal distributions of protist pathogens in different populations of *P. interpunctella* in Türkiye during the five years (from 2019 to 2023). During the study, 6.367 *P. interpunctella* larvae, pupae, and adults (4.091 dead larvae, 609 living larvae, 1.330 adults, and 337 pupae) were dissected and examined under a light microscope from 14 different provinces in Türkiye (Ankara, Aydın, Bolu, Denizli, Gaziantep, Isparta, Istanbul, Izmir, Kastamonu, Malatya, Ordu, Samsun, Siirt, and Trabzon). As a result. microsporidian, neogregarine, and coccidian pathogens were observed during the dissections. When the seasonal distributions of microsporidia and neogregarine pathogens were examined seasonally, and significant differences were detected in each season of the year. However, coccidian pathogens could not be analyzed seasonally as they were not observed in different periods. This study is the first to examine the seasonal distribution of protist pathogens in *P. interpunctella* populations in Türkiye in detail. The results confirmed once again that *P. interpunctella* populations in Türkiye contain a considerable amount of protist entomopathogens.

Keywords: *Plodia interpunctella*, protist pathogen, seasonal distribution, Türkiye.

INTRODUCTION

The Indian meal moth, *Plodia interpunctella* (Hübner) (Lepidoptera: Pyralidae), holds a significant position among pests that cause substantial economic damage to stored products (Rees, 2004). *P. interpunctella*, which infests products and leads to both damage and degradation of nutritional quality, feeds and causes damage only during its larval stage. During feeding, it produces silk webs, contaminating food materials. As a result, the infested products suffer from weight loss, reduced commercial value, and decreased seed quality (TAGEM, 2008; Kaymakçı, 2022). The majority of the products damaged by *P. interpunctella* are foods consumed by humans. Fumigation with chemical insecticides is not considered suitable due to the harmful side effects on the environment and human health. Additionally, *P. interpunctella* has been reported to show resistance to many insecticides (Attia, 1977). Due to these impacts, it has become necessary to develop eco-friendly control methods that have no harmful side effects on the environment and non-target organisms. The most promising results in controlling *P. interpunctella* have been obtained from trials using its natural enemies (Schöller and Filinn, 2000; Grieshop, 2005; Shojaaddini et al., 2012). Interest in the use of entomopathogens as an alternative to chemical insecticides in controlling this pest is increasing day by day (Yaman, 2012). Among entomopathogens, protist pathogens play a significant role as natural suppressive factors in pest insect populations. This study aims to determine the seasonal distributions of protist pathogens in different populations of *Plodia interpunctella* in Turkey over a period of five years (2019-2023).

MATERIAL AND METHOD

During the study, 6.367 specimens including larvae, pupae and adults of *P. interpunctella* were collected from fourteen regions (Ankara, Aydin, Bolu, Denizli, Gaziantep, Isparta, İstanbul, İzmir, Kastamonu, Malatya, Ordu, Samsun, Siirt, Trabzon) of Türkiye (Table 1).

Microscopic Examination

P. interpunctella larva, pupa and adult samples were dissected in Ringer's solution and then prepared wet smears including host fat body, malpighian tubules, gut and hemolymph were examined for presence of protist infections under a light microscope at a magnification of 400–1000 ×. When an infection was found, the slides were air-dried and fixed with methanol, then stained with freshly prepared 5% solution of Giemsa stain. They were then washed in running tap water, air-dried and examined under a microscope.

RESULTS AND DISCUSSION

During the study, 6.367 of *P. interpunctella* samples including larvae, pupae and adults were dissected and searched for protist pathogens such as microsporidia, coccidia and neogregarines in the fourteen localities of Turkey between the years 2019-2023. Protist infections were confirmed by observation of their characteristic spores/oocysts. Three different protist pathogens, microsporidium, coccidian and neogregarine were observed in *P. interpunctella* populations.

The seasonal density of the microsporidia pathogen was examined in detail. According to the data obtained throughout the study, the infection rate was quite high in the first six months of 2019 (January, February, March, April, May, and June), reaching 42%, but it was found to drop to as low as 20% in the second half of the year (Figure 1).

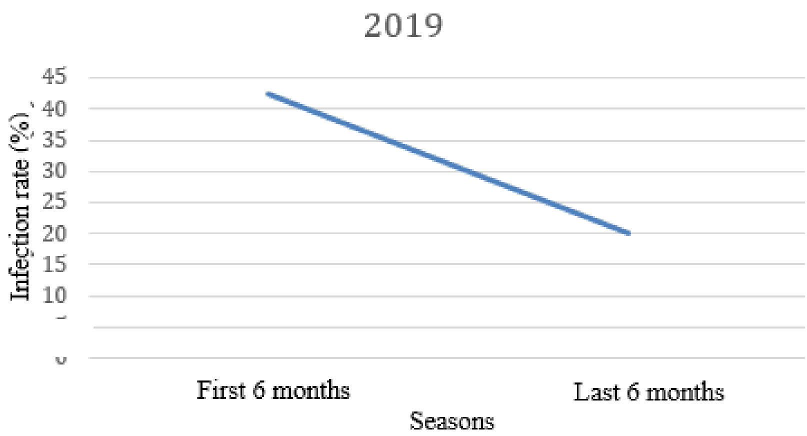

Figure 1. The microsporidia density detected in 2019

In the first six months of 2020, the infection rate was observed to be 13%, while in the last six months of the year, it increased to as much as 29% (Figure 2).

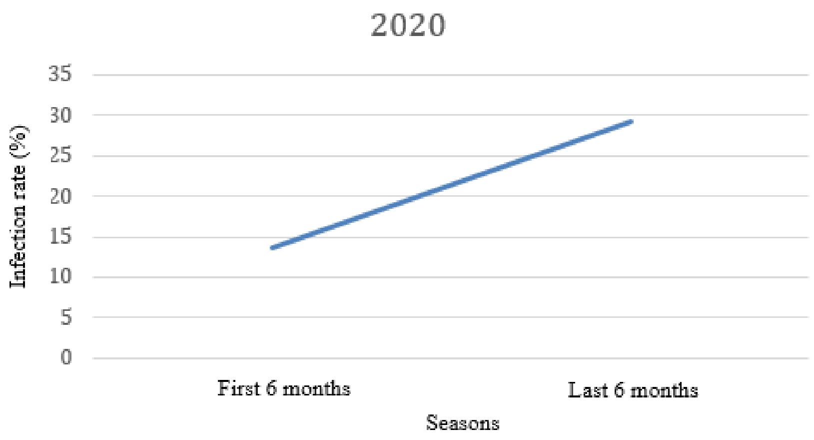

Figure 2. The microsporidia density detected in 2020

When looking at the infection intensity in 2021, it was observed that, similar to 2019, the infection rate was high in the first six months of the year, followed by a decline in the last six months (Figure 3).

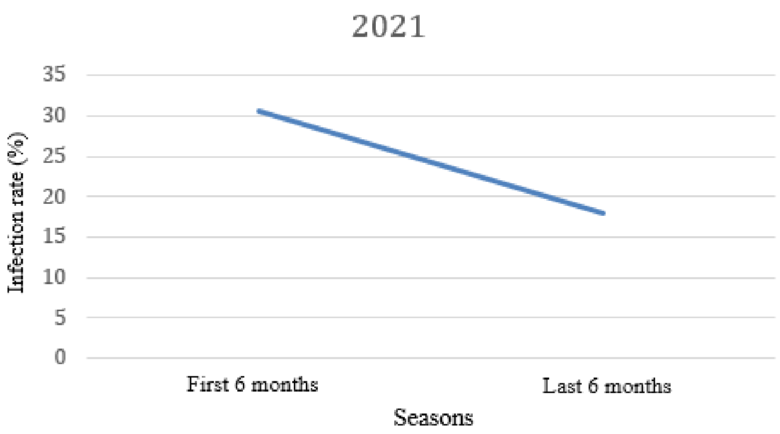

Figure 3. The microsporidia density detected in 2021

When examining the infection rate in 2022, it was found that, similar to 2019 and 2021, the infection was high in the first half of the year, followed by a slight decrease in the second half (Figure 4).

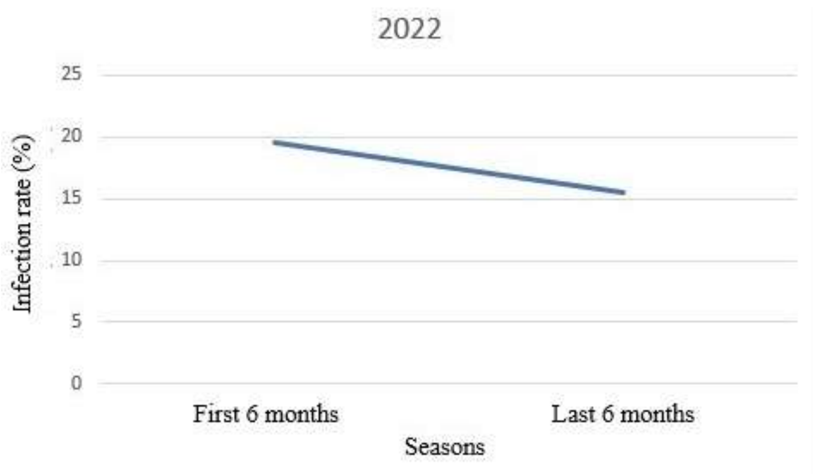

Figure 4. The microsporidia density detected in 2022

In 2023, the infection rate was found to be consistent, with the same level of infection observed in both the first and second halves of the year (Figure 5).

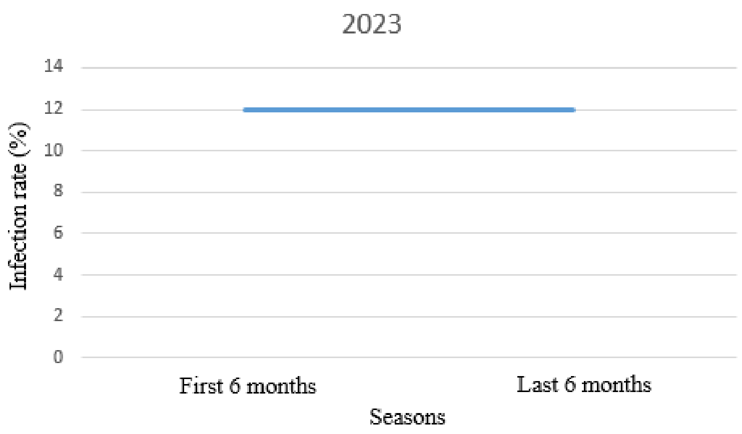

Figure 5. The microsporidia density detected in 2022

It is known that the development of *P. interpunctella* is influenced by temperature, with development accelerating at optimal temperature levels and slowing down at temperatures below this level. In storage facilities or homes where temperature is uncontrolled, *P. interpunctella* larvae are known to enter a diapause stage during cold months. However, when favorable environmental conditions are restored (especially in early spring or when homes remain warm even during winter months), a significant increase in moth populations occurs (Mason, 2002; Güngör, 2014). It has also been reported that if the temperature does not drop too low, the moth does not enter the diapause stage (Prevett, 1971). In our study, seasonal findings of *V. plodiae* isolate TR density generally showed a high infection density in the first six months of the year (Figures 1, 3, 4, and 5). This increase is thought to be due to the temperature and humidity levels in home and storage environments. When looking at the infection density in the last six months of the year, an increase in the infection rate was observed in 2020 (Figure 2). It is believed that the increase in infection during these months was due to the provision of optimal temperature conditions for *P. interpunctella* development, given that these are the warm months of the year. Throughout the study, it was possible to find heavily infested products even in winter, especially in field studies conducted in homes.

When the seasonal density of the neogregarine pathogen was examined, it was found that infection density increased in both the first and second halves of the year in 2019, 2020, 2021, and 2023 (Figures 6, 7, 8, and 10). This continued high infection rate in the second half of the year is also thought to be due to the optimal temperature conditions in home environments, which accelerate the development of *P. interpunctella*. Only in 2022 was it observed that the infection density decreased from 19% in the first half of the year to 15% in the second half (Figure 9).

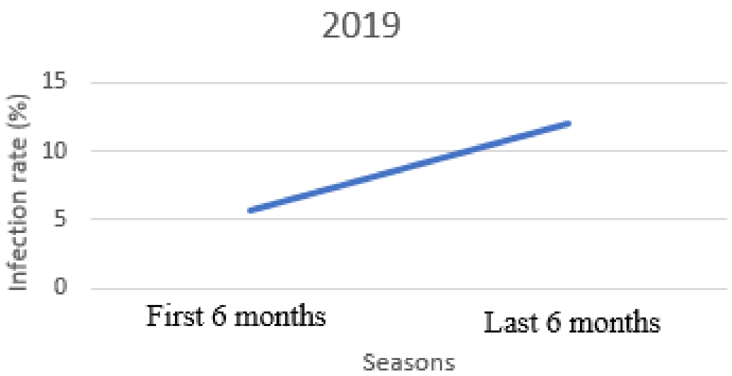

Figure 6. The neogregarine density detected in 2019

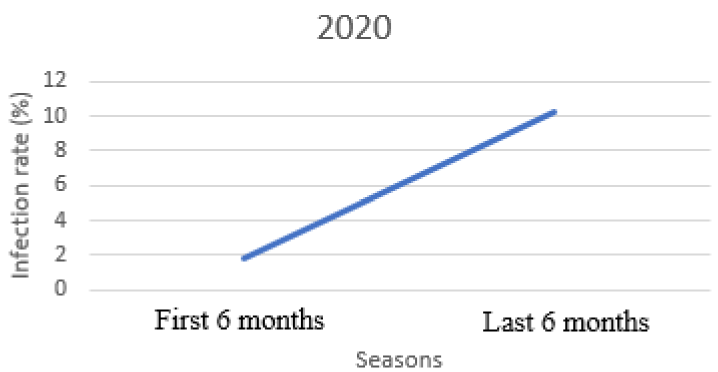

Figure 7. The neogregarine density detected in 2020

Figure 8. The neogregarine density detected in 2021

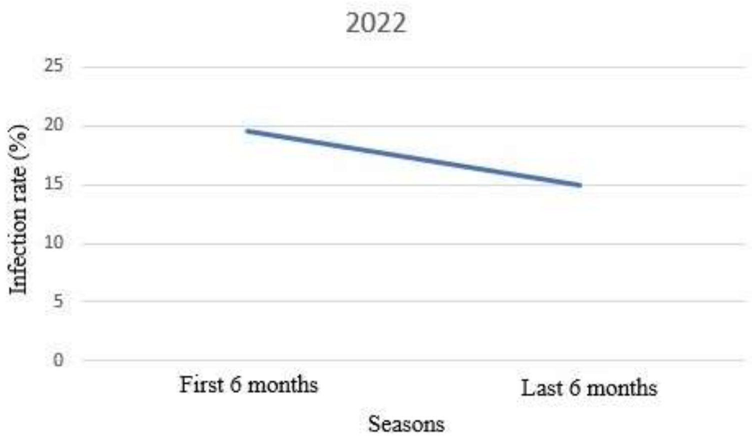

Figure 9. The neogregarine density detected in 2022

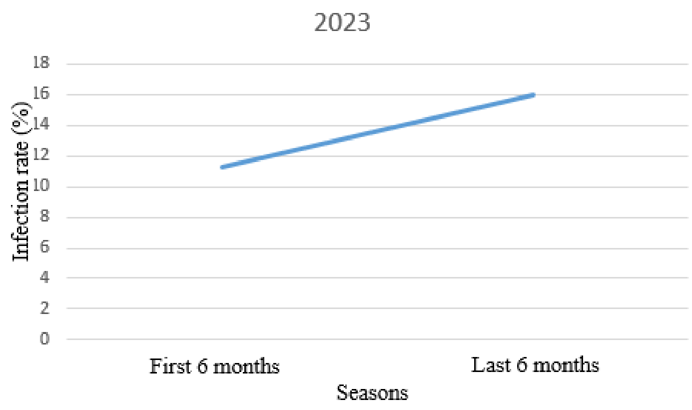

Figure 10. The neogregarine density detected in 2023

According to the study results, seasonal variations in the density of the detected pathogens were observed. These changes could be related to population density, and it is speculated that in dense populations, the rate of infection might be higher due to the increased horizontal transmission within the population.

When the seasonal distributions of the microsporidia and neogregarine pathogens were examined (the first six months of the year: January, February, March, April, May, June and the last six months of the year: July, August, September, October, November, December), significant differences were observed in each season. However, the coccidia pathogen could not be analyzed seasonally as it was not detected during different periods, making analysis impossible.

CONCLUSIONS

This study is the first to detail the seasonal distribution of protist pathogens in *P. interpunctella* populations in Turkey. The results confirm once again that *P. interpunctella* populations in our country contain a significant density of protist entomopathogens. McLaughlin (1971) noted that protozoan pathogens are generally the most suitable organisms for long-term pest population control. The current study has identified that the entomopathogenic protists detected are significant suppressive factors in the natural populations of the pest and are found to be widespread throughout the country. The obtained results encourage the use of protists in biological control against *P. interpunctella*.

ABSTRACT

Different geographic and climatic conditions can create very favorable environments for the development of many plant pests. The protection of agricultural products is very important both to ensure food safety and to contribute to the country economy. The interest in the use of entomopathogens (EPOs) as an alternative to chemical insecticides in the control strategies against plant pests is increasing day by day. Among the entomopathogens, protistan pathogens play an important role as natural suppressor factor in pest insect populations. The present study includes presence of protistan pathogens in the populations of three important Chrysomelidae pests, *Chaeotocnema tibialis*, *Phyllotreta atra* and *Leptinotarsa decemlineata* from the village Tsilkani in Mtskheta, Georgia. During the study, 160 samples of Chrysomelidae pests were dissected and searched for protistan entomopathogens. Gregarine pathogens were found in the populations of two Chrysomlidae pests, *Chaeotocnema tibialis* and *Phylloteta atra* in Georgia for the first time. However, any infection was not found in the examined *Leptinotarsa decemlineata* population. The gregarine infection rates were considerably low, 14% for *P. atra* and 15.6% for *C. tibialis* when compared with their occurrence in the populations of the both pests, 8.6-70.3% in *P. atra* and 63.2% in *C. tibialis*, in Türkiye. The present study includes the first records on the occurrence and prevalence of gregarine pathogens in the populations of Chrysomelidae pests in the village Tsilkani in Mtskheta Georgia. However it is needed to increase the number of populations and samples from different locations to represent the entire Georgia. Furthermore, it is needed to investigate other pathogens and parasites and identify each of them at the species level.

Keywords: Chrysomelidae pests, *Chaeotocnema tibialis*, *Phylloteta atra, Leptinotarsa decemlineata*, Georgia

INTRODUCTION

Chrysomelidae is one of the most species-rich and species-diverse groups of the order Coleoptera. This family is commonly known as leaf beetles and has approximately 36000 species in more than 2000 genera into 12 subfamilies (Bouchard et al. 2017). Leaf beetles are insects that depend on the area and structural features of the habitat. Therefore, increasing plant diversity is thought to increase the richness of these insects (Teles et al., 2020). Leaf beetles (family Chrysomelidae) primarily feed on the leaves of plants and they can cause significant damage quickly when occurring in large numbers. This may become an undesirable situation in agricultural and forest areas and Chrysomelidae species may become widespread agricultural pests. On the other hand, different geographic and climatic conditions can create very favorable environments for the development of many plant pests. Like other insect groups, leaf beetles are affected differently by different habitats.

Today, agricultural pests are generally controled with chemical pesticides. Chemical pesticides cause insecticide resistance, environmental pollution, toxicity to mammals and other non-target animals (Isman, 2006). Common use of chemical insecticides result in increasing attention given to natural products. Alternative control methods are needed for an effective and efficient fight against plant pests (Freitas et al., 2020).

Biological control using entomopathogens is a promising alternative control. Among the entomopathogens, protistan pathogens can play an important role as natural suppressor factor in pest insect populations in natural conditions. Therefore, studying the presence of protistan entomopathogens in pest populations can provide useful information for detecting natural factors in pest populations.

The present study includes presence of protistan pathogens in the populations of three important Chrysomelidae pests, *Chaeotocnema tibialis*, *Phyllotreta atra* and *Leptinotarsa decemlineata* in Georgia.

MATERIAL AND METHOD

160 adult samples of three important Chrysomelidae pests, *Chaeotocnema tibialis*, *Phyllotreta atra* and *Leptinotarsa decemlineata* were collected from the village Tsilkani in Mtskheta in Georgia. After macroscopic examination, they were dissected in Ringer's solution and wet smears were prepared. Host fat body, malpighian tubules, gut epithelium, and hemolymph were examined for the presence of the protistan entomopathogens under a light microscope at × 400–1000 magnification (Yaman et al., 2019). When an infection with the spore/oocysts of pathogen was observed, a part of the material was used for the preparation of Giemsa-stained smears. Giemsa-stained slides were examined under a light microscope.

RESULTS AND DISCUSSION

The members of the family Cyrysomelidae are frequently infected by protistan entomopathogens. Protistan entomopathogens infecting Cyrysomelidae have aroused interest as potentially suppressing factors of chrysomelid populations. For that, several new protistan entomopathogen species have been isolated and characterized from these insects recently. Geographic conditions and host plants may influence the diversity of protistan entomopathogens in insects. Therefore, the protistan entomopathogens of three important Chrysomelidae pests, *Chaeotocnema tibialis*, *Phyllotreta atra* and *Leptinotarsa decemlineata* in Georgia were determined and compared with the presence of their infections in Türkiye.

During the study, 160 samples of three important Chrysomelidae pests were dissected and searched for protistan entomopathogens. Gregarine pathogens were found in the populations of two Chrysomelidae pests, *C. tibialis* and *P. atra* in the village Tsilkani, Georgia for the first time. Seven of 45 *C. tibialis* beetles examined (15.6) in the population of *C. tibialis* collected in Tsilkani , Georgia were found to be infected by the gregarine pathogen. The gregarine infection was considerably low (15.6%) for *C. tibialis* populations in Georgia when compared with its occurrence in *C. tibialis* populations in Türkiye (Table 1). Yaman (2004) observed gregarine infection in 96 of 152 beetles examined (63.2%) in the population of *C. tibialis* in Trabzon, Türkiye.

The gregarine infection was also considerably low (14%) for *P. atra* population when compared in Georgia when compared with its occurrence in *P. atra* populations in Türkiye (Table 1).

Yaman (2004) observed considerable high gregarine infection reaching 70.3% in the populations of *P. atra* at different localities of the Middle and East Black Sea Region of Türkiye.
On the other hand, no protistan entomopathogen other than the gregarine pathogen were observed in the examined *P. atra* and *C. thibialis* beetles in Georgia.. Contrast, two new microsporidian species, *Nosema chaetocnema* (Yaman and Radek, 2003) and *N. tokati* (Yaman et al., 2008) were recorded from *C tibialis* populations in Türkiye. Furthermore, already known microsporidium species, *Nosema phyllotretae* was recorded from *P. atra* populations in Türkiye (Yaman et al., 2005).

During the study, we also investigated protistan entomopathogens *Leptinotarsa decemlineata* population inGeorgia. For this, 15 larvae and 50 adults of *L. decemlineata* were examined for any protistan entomopathogens. Unfortunately, any infection was not found in the examined larvae and adults of *L. decemlineata* (Table 1). However, Yaman et al. (2011) recorded the microsporidium pathogen, *Nosema leptinotarsae* in *L. decemlineata* population in Türkiye. Yaman et al. (2011) found the microsporidian pathogen in both larvae and adults of *L. decemlineata*.

Table 1. Protistan entomopatogen infection in three important Chrysomelidae pests, *Chaeotocnema tibialis*, *Phyllotreta atra* and *Leptinotarsa decemlineata* from village Tsilkaniin Mtskheta, Georgia.

Pest species	Number of examined samples	Number of infected samples	Infection rate (%)	Infection rates in Türkiye
Chaeotocnema tibialis	45[a]	7[g]	15.6	63.2[g] (Yaman, 2004)
Phyllotreta atra	50[a]	7[g]	14	8.6-70.3[g] (Yaman, 2002)
Leptinotarsa decemlineata	50[a]	0	0	1.89[n] (Yaman et al. 2011)
	15[l]	0	0	4.51[n] (Yaman et al. 2011)

[g] Gregarine infection, [n] Nosema, [a] Adult, [l] larva

CONCLUSIONS

The present study includes the first records on the occurrence and prevalence of gregarine pathogens in the populations of Chrysomelidae pests in Georgia. When compared the infection rates and infective pathogens, it is seen that it is a considerable difference in the term of infection rates and infective protistan pathogen species between the populations of three important Chrysomelidae pests, *Chaeotocnema tibialis, Phyllotreta atra* and *Leptinotarsa decemlineata* in Georgia and Türkiye. However, it is needed to increase the number of populations and samples from different locations to represent the entire Georgia. Furthermore, it is needed to investigate other pathogens and parasites and identify each of them at the species level.

ROLES OF BENTHIC MACROINVERTEBRATES IN THE FOOD WEB

ABSTRACT
Benthic macroinvertebrates are small animals that spend all or part of their lives in water. They play a critical role in aquatic ecosystems. It is an integral part of the aquatic food web. By eating leaves, algae and bacteria in the environment, they convert organic matter into a food source that fish and other vertebrates can use. Fish are considered highly effective top predators for aquatic creatures in the food web. Fish are known to have strong effects on the abundance, species richness and community structure of macroinvertebrates and constitute the primary diet of many of them. For this reason, the number of insects is much higher in ponds and coastal vegetation where there are no fish. Coastal vegetation can play a very important role as a refuge for invertebrates that are vulnerable to predation. In this study, the roles and importance of benthic macroinvertebrates in the food web, which are found in increasingly decreasing water resources today, are examined.

Keywords: Benthic macroinvertebrate, Food web, Water resources

INTRODUCTION

Aquatic macroinvertebrates live in all types of freshwater environments, from pristine mountain streams to wetlands and sewage ponds. If a few rocks in shallow water in any healthy pond or stream are turned over, many water bugs can be seen. Larvae or nymphs of well-known flying insects such as mayflies and dragonflies are found. Some creatures, such as freshwater snails and mussels, spend their entire lives in water. Creatures such as dragonflies and mosquitoes live in water in their larval and pupal stages, but outside of water in their adult stages (URL 1; 2). They are often found attached to rocks, vegetation, logs and branches, or buried in bottom sand and sediments. They are reliable bioindicators because they spend all or most of their lives in water, are easy to collect, and have different tolerances to pollution (URL 3). Because they cannot escape pollution and are relatively immobile, unlike fish, they have the capacity to integrate the effects of stress factors over time (URL 2; 3).

The Importance of Benthic Macroinvertebrates in Aquatic Life

Macroinvertebrates are very important for aquatic ecosystems. They are food for vertebrates and their biodiversity is a testament to the quality of their habitat (Brysiewicz et al., 2022). Assessing the abundance and diversity of benthic macroinvertebrates in a water body provides an insight into the biological status of the water body. In general, water bodies in healthy biological state support a wide variety and high numbers of macroinvertebrate taxa, including those intolerant to pollution. Areas showing only pollution-tolerant species or little diversity or abundance indicate a less healthy water body. Biological status is the most comprehensive indicator of water body health. When the biology of a water body is healthy, the chemical and physical components of the water body are generally in good condition as well (URL 2, 6).

Aquatic macroinvertebrates play important roles in many ecological processes in aquatic ecosystems. Breakdown of leaf litter occurs through the presence of invertebrates that cut or chew leaf material (Wallace et al., 1982; Cuffney et al., 1990). Especially in small streams, the amount of defoliation generally increases when the numbers of invertebrates decrease (Webster and Benfield, 1986). In addition, macroinvertebrates that consume algal resources also have significant effects on algae in terms of biomass and primary production (Lamberti and Resh, 1983). Grazing macroinvertebrates is also beneficial as they recycle nutrients into the environment (Vanni, 2002). As primary consumers of aquatic foods, macroinvertebrates form an important link at trophic levels (e.g. fish) in networks between primary resources (e.g. algae and detritus) and higher-order resources (Díaz Villanueva et al., 2012). However, their role is not only to provide energy to upper trophic levels, but also to regulate energy flow through aquatic food webs (Wallace and Webster, 1996).

Classification of Benthic Macroinvertebrates According to Their Feeding Types

Each taxon has its own specific role in the ecosystem determined by the way it feeds. Scientists can categorize benthic macroinvertebrates into groups called functional feeding groups. Taxa in similar functional feeding groups are often found in similar habitats. Some taxa prefer fast-moving riffles, others prefer slow-moving pools or other habitat. A complex and healthy ecosystem supports a variety of functional feeding groups. Macroinvertebrates are divided into four classes according to their morphological (e.g. mouth part specialization) and behavioral characteristics, according to the mechanisms they use when consuming resources (e.g. feeding style) (Ramírez et al., 2014).

♦ Scrapers get food by scraping algae off rocks and other hard surfaces in the stream channel. It lives in parts of streams where sunlight can reach the bottom to allow algal growth. These areas are often in shallow, fast-moving riffles. As a result, many scrapers have adapted to stay attached to rocks in fast currents. Scrapers may include snails, certain mayfly larvae, and limpets (Lock et al., 1984).

♦ Shredders feed on leaves, twigs, and other pieces of organic matter that fall into a stream. They need lots of trees overhead (a dense canopy cover) to supply these materials. They chew up debris into smaller particles These smaller particles then become a source of food for Collectors. Shredders include stonefly larvae and scuds (Ramírez et al., 2014).

♦ Collectors eat fine organic matter. This includes leaf fragments, bacteria, fine sediment, and waste products from other organisms. There are two categories of collectors: filtering and gathering. Filtering collectors feed by filtering food out of passing water. They do this with hair-like fans or by spinning a fine net. Gathering collectors feed by gathering food from the bottom. Collectors are most common in slower-moving, low gradient streams where sediments collect. Even so, Collectors live in all types of stream reaches. Collectors include worms, blackfly larvae, and many mayfly and caddisfly larvae and midges (Hershey, 1987).

♦ Predators eat other macroinvertebrates and even fish. Predators can live anywhere in a stream but are less abundant than other feeder types. There must be enough prey to support predators, or they will not be present at all. Predators include the larvae of dragonflies, damselflies, and dobsonflies, among others. Adult aquatic beetles are predators. The larvae of some beetles, flies, stoneflies, caddisflies, and mayflies can be predators. But those taxa contain other functional feeding groups as well (Ramírez et al., 2014).

The Importance of Benthic Macroinvertebrates in the Freshwater Food Web

The habitats of macroinvertebrates are rocks and sediments at the bottom of the stream, plants in the water and around the stream, leaf litter and decomposed organic matter falling into the stream, and submerged logs, branches, woody debris. Macroinvertebrates need shelter and nutrition in these habitats. In choosing the best shelter, they tend to congregate in areas that provide the most food and the most dissolved oxygen.

Benthic macroinvertebrates, an integral part of the aquatic food web, transform energy stored in the organic environment. They eat leaves, algae, and bacteria, and are in turn eaten by fish, amphibians, birds, and other vertebrates. Thus, they transform the substance in the aquatic environment into a food source that fish and other vertebrates can use. When benthic macroinvertebrates die, the cycle repeats, releasing nutrients to be reused by aquatic plants and animals (URL 4; 6).

Macroinvertebrates are an important food source for other aquatic animals. Aquatic insects help recycle nutrients from the bottom of ponds or streams into the food web. Young life stages, often called larvae or nymphs, eat algae and waste that settle at the bottom of the water. Many other animals feed on aquatic insects. Fish take aquatic insect larvae and nymphs as food along the pond or stream bed. Some fish catch adult insects from the water surface or jump to the water surface to eat flying adult insects. Birds and amphibians may eat aquatic and flying insect adults. If the macroinvertebrate community does not develop, the nutritional impact on all animals in the ecosystem that depend on it will be felt as a problem (URL 5).

The function of specific macroinvertebrates can best be understood by describing their functions in their ecosystems. Classic examples include the role of decomposer insects (e.g. facilitate the decomposition of leaves) in contributing to the decomposition processes of organic matter (Cummins et al., 1989), as well as in the production of fine particles that are carried downstream, deposited at the bottom and used by other consumers such as foragers (Cummins and Klug, 1979). Others provide downward spiraling by controlling primary production, detritus breakdown, and nutrient mineralization.

Over the past few decades, changes in land use through the conversion of global forest cover to exotic plantation are contributing to both habitat and biodiversity loss and species extinction. The richness and abundance of macroinvertebrates are clearly evident in streams dominated by natural riparian vegetation. Living things are at higher rates in natural forest areas than in areas with exotic vegetation. Collectors are the most abundant functional feeding group here. Their availability varies in different parts of the stream.

Vegetation, dead leaves, and large woody debris at the edge of headwaters of forest areas are an important source of energy and nutrients for stream food webs (Vannote et al., 1980). In these environments, the relatively high water velocity and wide shade of the canopy provide autochthonous production (Vannote et al., 1980; Wallace et al., 1997). Therefore, changes in coastal vegetation can alter the quality of leaf litter inputs in aquatic communities and affect processes such as trophic structure and composition in aquatic ecosystems (Abelho and Graça, 1996; Martínez et al., 2013).

Several studies conducted in headwaters show higher fragment richness, higher invertebrate density and richness in streams dominated by native forests compared to streams dominated by exotic patches in other forests. Because macroinvertebrate communities represent intermediate trophic links between primary and tertiary consumers as sources of fish feed (Bertrán et al., 2013; Cornejo-Acevedo et al., 2014; Fierro et al., 2014; Fierro et al., 2015; Jensen et al., 2012).

Low to moderate populations of macroinvertebrates can affect the fish-carrying capacity of streams. If the availability of prey is limited, this will affect predatory fish (Pequeno et al., 2010). Therefore, changes in any macroinvertebrate community cause changes in the functioning of aquatic ecosystems and restructuring of food chains (Richards et al., 1996; Tiziano et al., 2014).

Fish are known to have strong effects on invertebrate abundance, species richness and community structure. Coastal vegetation can play a crucial role as a refuge for invertebrates vulnerable to fishing. The responses and mesohabitat preferences of macroinvertebrate taxa in coastal and open waters in the presence of fish do not show any differences. On the contrary, in fish-free waters, the total density of aquatic insects in the coastal vegetation is much higher in number and richer in terms of species. They prefer coastal areas in non-significantly higher numbers in waters containing fish, but species richness is independent.

Predator–prey relationships between fish and aquatic macroinvertebrates are crucial in structuring freshwater communities (Bendell and McNicol, 1995; Batzer et al., 2000). Fish are considered highly effective top predators of aquatic organisms in the food chain, and many insect species are their primary food (Kottelat and Freyhof, 2007). Studies involving manipulation of fish presence or abundance have yielded dramatic results on changes in the density, species composition, and size structure of macroinvertebrate communities (Leppä et al., 2003; Nieoczym et al., 2020). Many macroinvertebrate taxa are virtually absent from fish-dominated waters (Nieoczym and Kloskowski, 2015; Toro et al., 2020). Fish also have a strong influence on the distribution of macroinvertebrates within water bodies (Schilling et al., 2009). However, species with defensive adaptations can survive in the presence of fish (Pope and Hannelly, 2013).

Many species of fish use vegetation near shore to reduce predator pressure. They are also found in the open water zone when fish are not available (Kloskowski et al., 2020). However, species with antipredators, such as the secretion of toxic substances, and those with morphological features for adaptation or defense against fish do not need shelters such as a habitat containing vegetation (Nieoczym et al., 2023).

Interactions between fish and invertebrates in large water bodies consisting of different mesohabitats are affected by the presence of complex structured vegetation character of streams (Kajgrova et al., 2021). Vegetation affects abiotic parameters such as increased habitat and resource diversity in waters, depth of light penetration, temperature, dissolved organic matter and oxygen concentration in water (Lürig et al., 2021). In habitats with complex macrophyte structure, the hunting efficiency of fish is higher than in open waters where there is no or sparse vegetation (de Mendoza et al., 2012). In natural environments, prey within vegetation is much less conspicuous to predatory fish. Moreover, dense vegetation harms fish and reduces the predator's ability to move and track its prey (Wirsing et al., 2010). Many studies have reported that aquatic macroinvertebrates, including Odonata (larvae), Heteroptera and Coleoptera, prefer coastal habitats rich in vegetation that is believed to protect them and even restrict their distribution against predators (Tolonen et al., 2003).

Using Macroinvertebrates as Bioindicators in Aquatic Environments

Aquatic insects tell a lot about ecosystems–in other words, they are bioindicators. Scientists use aquatic insects to check the health of pond and stream ecosystems. Because some macroinvertebrates are very sensitive to poor water quality and human impacts. It is sometimes difficult to find ways to quantitatively measure overall ecosystem health. Ecosystem health depends on many factors (e.g. temperature, nutrient cycling, water chemistry). Scientists create biological integrity indices to measure water quality. Indices are basically an overall health score based on a community of ecosystems. The health of the aquatic ecosystem is a number that looks at the richness of EPT: different species of Ephemeroptera, Plecoptera and Trichoptera.

Healthy ecosystems have many different species of aquatic insects and no group of creatures that dominates the system. Generally, the presence of different species means a healthier ecosystem. An unhealthy pond or stream ecosystem cannot support a large and especially diverse population of water insects. Some macroinvertebrates are sensitive to pollution, while others can survive in very polluted waters. Often dirty water contains creatures such as worms, daphnia and non-biting midge larvae. In waterways that are degraded and subject to eutrophication (nutrient pollution), there are large amounts of sandflies, Oligochaeta and mosquitoes that disturb the surrounding residents.

Organisms in clean waters are completely intolerant to pollution. These are: Mayfly nymphs, Stonefly nymphs Caddisfly larvae Hellgrammites (dobsonfly larvae) Gilled snails Water pennies Adult riffle beetles. To survive, they need the cleanest water with high levels of dissolved oxygen. In particular, mayflies (Ephemeroptera), stoneflies (Plecoptera) and caddisflies (Trichoptera) are the most sensitive to changes in water quality. The percentage of "EPT" taxa in the aquatic habitat of a stream is an indicator of clean water and well-being. Moderately pollution tolerant: Dragonfly nymphs, Damselfly nymphs, Alderfly larvae, Crane fly larvae, Scuds, aquatic sowbugs Crayfish Freshwater clams, Freshwater mussels. Groups that are tolerant to pollution: Blackfly larvae, Midge larvae, Leeches, Aquatic worms, Lunged snails. They can survive in areas with poor water quality and low dissolved oxygen levels.

The basic principle behind studies on macroinvertebrates is that some are more sensitive to pollution than others, so they are more numerous. Therefore, if a stream site is inhabited by organisms that can tolerate pollution and the more pollution-sensitive organisms there are, a pollution problem is likely to occur.

Therefore, if a stream site is inhabited by organisms that can tolerate pollution and the more pollution-sensitive organisms there are, a pollution problem is likely to occur. If a biological survey shows that stoneflies are absent from the area, the amount of dissolved oxygen has fallen below the point to protect them, which may have prevented them from reproducing or killed them completely. Other factors may also contribute to their extinction, such as pollutants discharged from factories or habitat degradation such as misuse of agricultural land, very high water temperatures, and excessive sand or silt accumulation on stream bottoms (Ramírez et al., 2014).

DISCUSSION AND CONCLUSIONS

Reproductive success and predation risk are assumed to be important factors responsible for the distribution of many aquatic macroinvertebrates across water bodies (Nicolet et al., 2004; Gioria, 2014). Aquatic insect densities and species richness are lower in ponds with fish than in ponds without fish. However, some data show that aquatic insects living in fish-dominated waters can sustain the presence of parasites or predators in food webs (Proctor et al., 2015) and possibly even benefit from the presence of fish (Nieoczym et al., 2023; Pope and Hannelly, 2013).

Coastal habitat is also important for aquatic macroinvertebrates (Burks et al., 2002). Aquatic insects are found in higher abundances in coastal vegetation than in open water areas. Spatial distribution enables many macroinvertebrates to avoid predators other than fish. Aquatic insects are found in high densities in coastal mesohabitats where fish are absent. Large-sized predatory invertebrates, including predatory congeners whose habitat structure attacks their prey by ambush, are a significant threat to smaller species/individuals (Klecka and Boukal, 2014). On the other hand, in the absence of fish, invertebrate predators such as large-sized Dytiscidae may move out of the coastal habitat to feed (Kloskowski et al., 2020). Therefore, small-sized macroinvertebrates prefer the dense vegetation of coastal habitats rather than open water areas to protect themselves from predators, unless there is a morphological or chemical difference (Nieoczym et al., 2023).

Altering or disrupting the ecosystem affects the food chain by causing the loss of existing benthic species. The consequences of each species loss on the food web are unpredictable. If species are disappearing from an ecosystem, probably one after the other, at some point, there are major changes in the ecosystem. When species disappear, extremely expensive costs arise from engineering processes to preserve natural ecosystems. In theory, ecosystem processes are expected to continue when at least one species from each functional group remains and the process rate is sufficient (Covich et al., 1999).

Freshwater habitats have been significantly damaged in the last few decades. With the call for ecological integrity of the European Water Framework Directive, biodiversity has increased especially in aquatic environments. Although Lake Erie was once dead, conservation now increases dissolved oxygen levels and mayflies in bottom water sediments, resulting in the increase of many fish species (Covich et al., 1999; Nieoczym et al., 2023).

Water quality in rivers and indirectly macrozoobenthos communities are affected by agricultural land use in their catchments. Changes in environmental conditions as a result of land use can lead to reductions in biodiversity, biomass, and density of sensitive species of aquatic animals and thus changes in biotic composition. Small aquatic ecosystems are particularly sensitive to human pressures (Wohl, 2017).

GREEN BUILDINGS FOR SUSTAINABLE DEVELOPMENT

Nurcan OZKAN[1]

[1] *Trakya University, Education Faculty, Mathematics and Sciences Education Department, Edirne, Turkey*

ABSTRACT

In this study, a general evaluation of the green building concept, its importance, benefits and certification systems, which is evaluated within the concept of sustainability and whose importance has been increasing in the world in recent years, has been made. Among the most important reasons for the increase in global warming, climate changes, increasing environmental pollution, rapid decrease in natural resources and depletion of energy resources in the world are buildings produced with traditionally built building construction technology. In today's conditions, environmental protection has become more important in housing construction, and interest in new environmentally friendly buildings, called green buildings, has increased. The concept of green building has started to develop all over the world and in Europe in recent years, new institutions have been established in this direction, new certification programs have been created and the concept of green building has started to spread in all countries. The most important features of green buildings are that they contribute to a healthier environment in the future by ensuring that buildings, which have a significant impact on environmental and air pollution, are sustainable. Green buildings are buildings that respect nature, are healthy, comfortable, ecological and can use renewable energies. Green, ecological, climate and environment friendly, zero carbon emission, high performance buildings are rapidly becoming part of our agenda. With the spread of the green building concept, developed countries have developed certification systems to evaluate and classify the environmental impacts of buildings that require certain standards related to sustainable buildings. Certification systems generally evaluate buildings based on several parameters, such as the existence of systems to reduce energy and water consumption, the environmental friendliness of the building materials used, lighting, air quality and comfort related to user comfort within the building, and buildings are certified in this way.

Keywords: Sustainability, Green building, Green building certification systems, Environmentally friendly

INTRODUCTION

It is known that residential buildings constitute the majority of world energy consumption. An important issue that causes great energy waste in these buildings is that, in addition to inefficient consumption habits, the buildings are produced with conventional construction technology (Anbarcı et al., 2012; Benedict and McMahon, 2001; Burnett, 2007; Kaylı and Güneş Gölbey, 2020).

Global warming, thirst, environmental pollution and rapid consumption of natural resources have brought the construction of environmentally friendly, ecological buildings to the agenda in the construction sector. As interest in environmentally friendly building construction increases, structures called green buildings have emerged. Green buildings, which are certified by introducing certain standards, have created a new trend and sector in the construction industry as buildings that are more valuable, respectful to nature, ecological, comfortable and reduce energy consumption (Anbarcı et al., 2012; Doğan and Seçme, 2018).

Sustainable architecture; It is defined as a set of activities in which the damage to nature is minimized during the construction, use and demolition processes of needed buildings, ecological balance is observed, and materials, water and energy are used effectively. With sustainable buildings, it is aimed to protect the health and comfort of the users, not to endanger the existence and future of natural resources during the construction and use phases, and to create waste in a way that does not harm nature (Geçer et al., 2019; Gür, 2007; Yılmaz et al., 2016). Green building evaluation systems and certification programs have been created to concretely determine the negative effects of buildings on the environment (Erten, 2011; Hoşgör, 2014; Yücel Işıldar and Gökbayrak, 2018).

Housing Sector and Green Building Concept within the Scope of Sustainability

The rapid increase in the demand for natural resources and energy as a result of population growth, industrialization, rapid advancement in technology and globalization in the world, and the decrease in non-renewable energy resources direct the society to the use of renewable energy resources. In this context, the concept of sustainability has entered the lives of human beings in order to leave a healthy world to future generations (Saka, 2011).

Buildings have extensive direct and indirect impacts on the environment. Buildings; They use energy, water and raw materials, produce waste and emit potentially harmful atmospheric emissions during construction, use, renovation, re-use and demolition processes. These environmental impacts have necessitated the creation of green building standards, certifications and rating systems aimed at reducing the impact of buildings on the natural environment through sustainable design.

Green building; It is a construction method that produces healthier buildings with less negative impact on the environment, lower maintenance costs, and uses resources efficiently. The term green building, also known as sustainable building, high performance building and green construction; are used interchangeably to describe essentially the same thing.

Green buildings; It is designed with a holistic approach and an understanding of social and environmental responsibility, starting from the land selection of the building and evaluating it within the framework of its life cycle. In addition, they are defined as sustainable structures that are compatible with climate data and local conditions, consume as much as they need, are oriented towards renewable energy sources, use natural and waste-free materials, encourage participation, are sensitive to ecosystems (Sur, 2012). Any building, home, office, school, hospital, community center can be a green building provided that it includes green building features (URL 1).

While green buildings protect and improve the health and productivity of users with natural light and good indoor air quality, they are sensitive to the consumption of natural resources during construction and use, do not cause environmental pollution, create resources for other structures after demolition, or return to their place in nature without harming the environment are structures (Sev, 2009).

Why Should We Go Green?

Buildings are a tremendous source of carbon emissions. They are also places where there is significant room for improvement. Many people are realizing that when going green they can reduce their carbon footprint and actually give the environment a helping hand.

Whether it is constructed, purchased or rented, it is necessary to minimize personal emissions as much as possible in today's conditions. A green home often means financial savings and improved quality of life. And it all starts with a decent-sized house in a decent location.

The construction industry is thinking about how to build more sustainable buildings. Architects and engineers work on designs that will cause minimum harm to nature. The traditional building construction process creates problems, especially regarding energy efficiency, and uninsulated buildings lead to more energy consumption. When green building is mentioned, many processes are encountered such as making the raw materials used more sustainable, the efficiency of the construction process, and minimizing the waste generated in the construction of buildings.

Green buildings, in addition to playing an active role in sustainable architecture, construction and environmental protection, also provide many benefits to their buyers and all other people. Despite lower user and maintenance costs, it offers more comfort, healthier quality of life and longer-lasting use.

Green buildings are buildings that cause less harm to the environment compared to traditional construction practices. Innovative technologies and materials are used in their construction. Insulated construction materials are preferred, thus saving on heating and cooling costs. Rainwater can be collected. It is designed to benefit from renewable energy sources. Some green buildings are built integrated with solar and wind panels. Some buildings can be covered with plants to reduce carbon emissions. The land on which the building is located is utilized at maximum efficiency (URL 1).

What are the Features of Green Buildings?

• Green buildings are buildings that are compatible with the environment and cause minimal damage to nature. When it comes to green buildings, first of all, efficient buildings are mentioned. Insulated buildings reduce energy consumption and increase energy efficiency. However, energy efficient buildings do not only use insulated materials.

• 'Solar heat gain coefficient' is taken into consideration when constructing buildings. In its simplest form, this is the name given to the sunlight entering through the glass. The more sunlight entering a building, the hotter the building becomes. This also reduces energy costs. Buildings that can make maximum use of sunlight also reduce lighting costs. By a similar logic, the construction of airtight walls in building construction keeps moisture out and reduces cooling costs by making the building cooler in the summer months.

• Mechanisms that use water efficiently are also preferred in the construction of green buildings. Siphons and taps that use water efficiently are installed.

• Solar panels and wind turbines are used when constructing these buildings. The energy obtained is stored and used in the energy expenses of the building. In this way, buildings both contribute to the environment and save energy (Figure 1).

• When constructing buildings, materials that do not harm the environment are preferred. Thus, toxic waste is reduced to a minimum. The use of sustainable materials compatible with nature both reduces environmental pollution and contributes to the protection of biodiversity.

• Some green buildings are built with technologies that can harvest rainwater. The captured water is filtered and used within the building. In this way, water costs are also saved.

• There are recycling facilities inside green buildings. Biological waste is converted into compost and fertilizer.

• Most green buildings are constructed so that plants can grow on their exterior walls (Picture 2). These plants both absorb rainwater and contribute to the prevention of air pollution by reducing the effects of carbon monoxide emissions (URL 2).

Figure 1. Green buildings for power plant and sports facility use, CopenHill (Copenhagen, Denmark) (URL3).

Figure 2. Green buildings used for residential purposes with plants grown on their exterior walls (URL 4).

The Increasing Importance of Green Buildings

Buildings are a significant source of carbon emissions. They are also places where there is significant room for improvement. Many people realize that by going green they can reduce their carbon footprint and actually give the environment a helping hand (Figure 3).

Considering the increasing world population and increasing urbanization, the contributions of the construction industry for a sustainable future are becoming invaluable. The increasing importance of green buildings shows that not only states but also private institutions have an important role to play in the construction of a sustainable future.

Figure 3. Example of multi-purpose green buildings (URL 5).

After the industrial revolution, construction focused on supply rather than sustainability. Rapidly increasing demand, especially in the years following the Second World War, brought about rapid urbanization. In the light of scientific research, it is known that concrete is a major contributor to CO_2 emissions. Increasing social, individual and corporate awareness has made a great contribution to the design of sustainable buildings, the rethinking of sustainable construction and the formation of sustainable cities.

It is certain that the terms 'sustainable urbanization' and 'green building' will be heard frequently in the coming years. Technology is gradually developing. Reducing the negative effects of climate change due to global warming and reducing carbon emissions is only possible with a collective effort. An important part of building environmentally compatible lives will undoubtedly be green buildings (URL 2).

What are Green Building Standards?

Each of the green building energy certification systems, which emerged after the decisions and sanctions made by some world states after the industrial revolution, were initially created to serve their own countries. Some of the emerging certification systems have, over time, turned into green building certification systems that are valid worldwide. The prominent ones can be listed as BREEAM, LEED and DGNB.

a. Breeam Green Building Certification Systems

Breeam (The Building Research Establishment's Environmental Assessment Method) certification system is the first green building assessment system developed in England in 1990. For this reason, it is recognized as the most trusted certification system today (Breeam, 2011; Ürük and Külünkoğlu İslamoğlu, 2019). The Breeam evaluation system uses accepted performance measures that adjust a building's features and design. The metrics used represent a broad range of criteria, from energy to ecology. These categories; It consists of building management, indoor health and well-being, energy, water, transportation, materials, waste, land use and ecology and environmental pollution (Saunders, 2008). The criteria that include these issues have a range of environmental weights depending on the countries where the buildings (structures to be certified) are located. Figure 4 shows the weights determined for Europe;

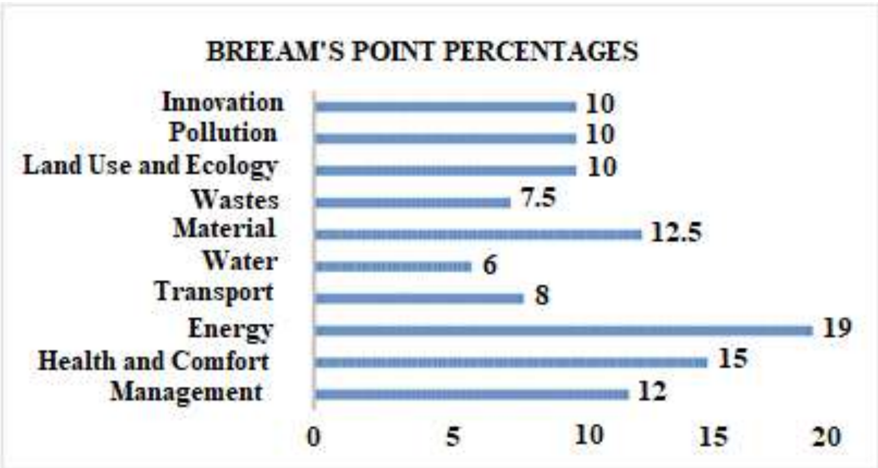

Figure 4. Percentages of the Breeam Certification System (Ürük and Külünkoğlu İslamoğlu, 2019).

Breeam has 5 different certification classes and is evaluated according to the points the building receives. The validity period of the certificate is planned to be three years. After three years have been completed, the building must be updated by applying to the certification system again. Different certification classifications are shown in Figure 5 below (Ürük and Külünkoğlu İslamoğlu, 2019).

Figure 5. Certificate Classes and Scores of Breeam Certification System.

b. Leed Green Building Certification Systems

The Leed Certification system was created in 1998 by the American Green Building Council (USGBC). It is an internationally accepted building certification system. The purpose of the certification system; To ensure that all individuals and organizations working in the construction sector draw their attention to environmental values and make decisions aimed at protecting the natural environment.

Leed is a points-based system and each building project earns Leed points for meeting certain green building criteria. In each of the seven LEED credit categories, projects must specifically meet certain prerequisites and earn points.

LEED certification; It can be used for all building types, including existing buildings, commercial interiors, schools and homes, new buildings under construction and renovated buildings undergoing major renovations. Leed Green Building Certification System has categories according to the type of use and location of the building, as stated in Table 6 (Ürük and Külünkoğlu İslamoğlu, 2019).

Figure 6. Categories of LEED Green Building Certification System

In order to obtain the LEED green building certificate, the building must gain a minimum of 32 points required to meet all the prerequisites in the subheadings of the main headings specified in Figure 7. Figure 7 shows the levels of the Leed certification system (Ürük and Külünkoğlu İslamoğlu, 2019).

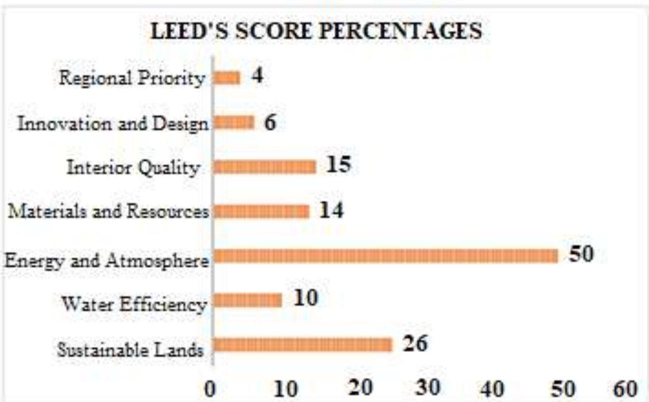

Figure 7. Score Percentages of the Leed Certification System.

The LEED certification evaluation process begins with the project's registration with the American Green Building Council (USGBC). After the documents are completed and sent, the final evaluation is made and the certificate level is determined and the result is notified to the applicant official. In this section, the project owner can accept the evaluation result or use his right to object. After objections, the building is certified according to these results. Leed has 4 different certificate classes (Gold, Platinum, Silver and Leed Certificate) and the building is evaluated according to the points it receives and there is no limit on the validity period of the certificate. Different certification classifications are shown in Figure 8 below (Ürük and Külünkoğlu İslamoğlu, 2019).

Figure 8. Certificate Classes and Scores of the Leed Certification System.

c. DGNB Green Building Certification Systems

DGNB (German Sustainable Building Council) was established in Germany in 2008 together with the Joint Ministry of Transport, Construction and Urban Affairs. It is intended to be used in the planning and evaluation of buildings as green buildings. While designing, LEED and BREEAM were taken as basis (Ürük and Külünkoğlu İslamoğlu, 2019).

The primary goal of the German Sustainable Building Council is the establishment and subsequent development of its own certification system. In this context, the DGNB Certification System was established for office and administrative buildings in 2009. This system was developed and became an international system in 2010, covering existing and new buildings, educational institutions and commercial buildings (Dgnb, 2011).

Figure 9. DGNB overall building assessment criteria

DGNB green building certification system has main objectives such as evaluating the use of energy resources, reducing the amount of energy consumed and using sustainable systems. Score percentages are shown in Figure 10.

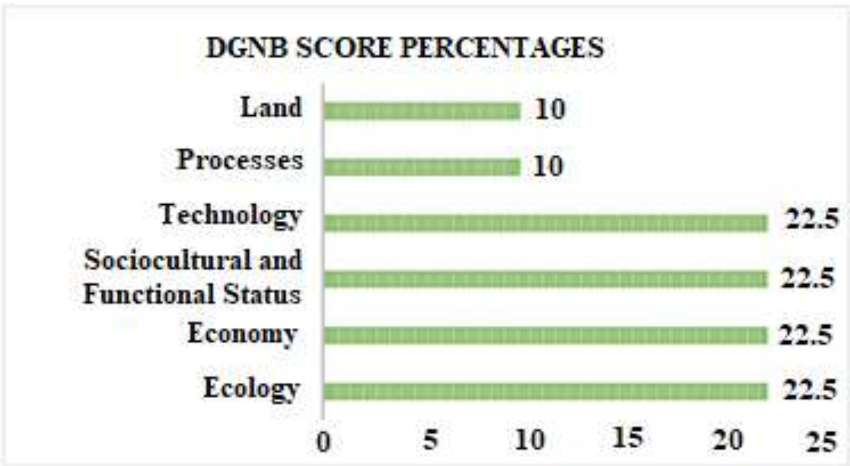

Figure 10. Score Percentages of DGNB Certification System

Each area is designed with different weights in accordance with the profile of the occupants and contains special criteria that can be monitored throughout the entire life cycle of the building. If the building meets the criteria, a DGNB certificate is received in the form of gold, silver or bronze, depending on the degree of fulfillment of the criteria (Figure 11). There is no limitation on the validity period of the certificate (Anbarcı et al., 2012; Dgnb, 2011).

Figure 11. Certificate Classes and Scores of the DGNB Certification System

DISCUSSION AND CONCLUSION

The most important factors of green building projects are their effects on human health and urban fabric. People should be able to live their lives in a healthy environment. In order to prevent the deterioration of human health caused by buildings, it must be ensured that the buildings are healthy. Studies on the sustainability of healthy buildings should be integrated by considering building, environment and human health together, they should be designed in a way to leave healthy living spaces to the next generation, and all segments of the society should be made aware of this issue.

With the increase in sustainability awareness, the issue of green building production has gained importance in the construction sector (Arslan, 2015). Green building projects are practices that have gained importance by taking into account the damage that buildings cause to nature and the environment on a global scale, and subsequently become increasingly widespread within the framework of certain standards and rules with the research and studies carried out on this subject. These standards and rules determine the sustainability criteria of green buildings; It explains how the green building development process should be qualitatively and enables quantitative measurement and evaluation of the building.

In countries that support green building practices, real estate development projects such as shopping malls, offices, hotels, housing projects and industrial facilities should be developed as green buildings. In addition to its environmentally friendly features, it is also important in terms of gaining prestige and increasing the value of the project and the developer company (Şenol, 2009).

The aim of green building design is to produce energy efficient living spaces by minimizing the consumption of natural resources. For this reason, passive and active systems should be used together in air conditioning and lighting, which are the systems that consume the most energy in buildings. To obtain a sustainable building, natural data should first be examined and passive approaches should be taken into account to provide maximum energy from natural resources, and then they should be supported with active systems to meet the targeted certification system requirements.

Each country differs from each other in terms of their climatic characteristics, geographical location, energy consumption and cultural structures. For green building certification systems to be effective and applicable, evaluation criteria must take into account national conditions, both in terms of climate and natural resource capacity, as well as economic and social conditions. For this reason, it is not correct to directly apply certification systems in other countries. Certification systems should be prepared taking into account the local conditions of each country (Arslan, 2015).

It is important to increase investments in green building practices for a sustainable future. In order for green building projects to become widespread, investors should be encouraged and the state and local governments should take initiatives for this. Obtaining a green building certificate should be made mandatory by local governments in new projects and especially in urban transformation projects, which are on the agenda today. In this way, the renewal of newly developing urban transformation areas with a sustainable approach is ensured. At the same time, a more sustainable environment will be offered to future generations thanks to increased investments in green building practices and widespread awareness of sustainable design (URL 6).

As a result, green buildings encompass a holistic approach to sustainability that includes a variety of features and practices to minimize their environmental footprint. By prioritizing energy efficiency, renewable energy sources, water conservation, responsible material selection and other key elements, green buildings contribute to a more sustainable and resilient building environment. Adopting green building principles reflects a commitment to environmental protection and a desire to create healthier, more efficient spaces for users.

VIGOR OF VEGETABLE SEEDS – ESSENCE, HISTORICAL DEVELOPMENT, SIGNIFICANCE AND PERSPECTIVES

Nikolay Panayotov[1]

[1]*Agricultural University – Plovdiv, Bulgaria, 12 "Mendeleev" Str. 4000 Plovdiv*

Corresponding author e-mail:: nikpan@au-plovdiv.bg

ABSTRACT

Most vegetable crops are grown through seeds and this determines the need to establish their viable potential. The main element in this direction is the standard germination test, which is widely applied and is globally recognized for the quality of individual lots. Although germination is the backbone of seed quality, it does not provide sufficiently complete and real information about seed behavior under field conditions. This necessitates looking for other indicators for a more complete assessment of their vital status. Vigor adds to the characterization of the properties and potential of the seeds by noting, in addition to their ability to germinate, the ability of young sprouts to develop under a wide range of environmental conditions. Establishing vigor is particularly important in vegetable seeds which are small and most are hybrid and heterosis and with high price. This article is an overview of the development of the vigor concept historically, its advantages and challenges for agronomic science. The specifics of the individual tests for which there are already recognized protocols for their application and their importance based on own research on the quality of seeds from different species of vegetable crops are followed. Attention is also paid to the modern requirements for creating fast and non-invasive tests. Some newly developed vigor determination methods suitable for use with vegetable seeds are also indicated. The author's new methodology for determining vigor, "Initial Vegetative Seed Productivity", is described in details. The difficulties, the not completely solved problems, as well as the perspectives for the introduction of vigor as a standardized indicator widely adopted worldwide to evaluate the potential of individual lots of vegetable seeds are analyzed.

Keywords: seeds, germination, tests, germination, sowing quality, viability

INTRODUCTION

The beginning of our civilization began when people 10,000 years BC discovered the seed, realized its role and essence and began the development of organized agriculture. This marks the beginning of settled life and the construction of settlements (Daniels and Hysloop, 2003; Isbouts, 2009; Marcos-Filho, 2015). Already in ancient times, man perceived the unique nature of seeds, especially the phenomenon of germination, the weave it into various philosophical teachings and included them in many religious beliefs and rituals, since the time of the ancient Egyptians. This is also evidenced by the works of one of the first recognized botanists, such as Theophrastus (370-285 BC), who, in addition to describing the seed, emphasized its huge role in the existence of not only peoples but also in nature (Evenari, 1980).

With the growth and systematization of targeted studies in the field of seed science, Broniewski et. al. (1976) points out that the basic dialectic laws are manifested in seeds, and their appearance is the result of a long evolutionary process, which makes it extremely adaptable and thus seed-propagating plants occupy a leading role in nature. Research on seeds also provides information on most of the properties and characteristics inherent in plants, since in the seed itself, as a living organism, most of the processes that take place in adult plants are observed. That is why the seed can definitely be considered a peculiar microcosm (Copeland and Donald, 2001).

Of the world's cultivated plants, over 75-80% are propagated and produced by seeds, including the majority of vegetable species (Marcos-Filho, 2015; Welbaum, 2024). The growth of population, the increased urbanization, the economic development, and the changes in eating habits cause an increase in the consumption of vegetables. To meet these needs, a significant increase in production is necessary, which in turn requires the supply of sufficient and high-quality seeds. Because of this, and appreciating the great importance of seed quality, in the 19th century, seed production emerged as an independent and specific branch of agriculture, first in Europe and then in the USA (Kastler, 2005). The large number of types of vegetable crops leads to some fragmentation and careful organization and management of the processes from the production to the market of vegetable seeds is particularly necessary. Data on the world market of vegetable seeds and forecasts for its development point a continuous growth in their sales.

It is pointed out that the global vegetable seeds market in 2022 was approximately USD 8 billion, in 2023 it reached USD 10.92 billion, and it is predicted to exceed USD 12.15 billion in 2024. Forecasts predict that sales of vegetable crop seeds during the period 2028-2031 will increase significantly and reach $18.48 billion, but there are even more daring forecasts that indicate an even much larger amount. This market is very dynamic and highly competitive, as evidenced by the fact that about twelve global companies, eight of which specialize in the production of vegetable seeds, supply seeds for thirty crops and have annual sales of over $100 miloin. This enables between 15% and 30% of the revenue from these sales to be directed to the development and research of new technologies related not only to the production, but also to the evaluation and stabilization of the vital status of the seeds of vegetable crops. The majority, about 80% of the world sales of vegetable seeds is concentrated in ten countries and these are: China, India, Japan, South Korea, France, Italy, Spain, the US, Mexico and Brazil. In recent years, approximately 80-90% of vegetable crops have been produced from hybrid and heterosis seeds, the cost of which is much higher (Shoham, 2024; Report, 2024).

That is why the need for the full and real establishment of the quality and vital status of the seeds stands out in the foreground, to guarantee a stable and sustainable production of vegetables. The backbone for assessing seed viability potential is currently perceived to be primarily the determination of germination by the standard test. Indeed, this is one of the most important, but not sufficient indicators for a complex and complete characterization of the seeds of vegetable crops, and as stated above, in addition to the fact that their price is significantly higher, but also the demand and sales are constantly growing. Several authors point out that the globally accepted and standardized approach to seed quality, only employing of their germination, does not provide complete information about their possibilities and manifestations under field conditions, and therefore it is necessary to look for new approaches in this direction. Scientists in the scope of seed science agree that the best results can be obtained by introducing vigor as an element for the overall characterization of the sowing qualities and potential of seeds, including those of vegetable species. The essence of vigor is to compare and distinguish stronger from weaker lots of seeds and it is appropriate to apply to lots that have high germination (Copeland and McDonald, 2001; Black et al, 2008; Panayotov 2016).

This also determined the direction of this review. Its main aim was to trace the development of the concept of vigor in historical terms, its advantages, weaknesses and challenges for agronomic science, to highlight its great importance for evaluating the seed potential and specificity of its application in vegetable seeds, as well as to outline the prospects in this area. This review has no pretensions to be comprehensive of the abundance and diversity of aspects of the ever-increasing research and emerging trends in the field of vigor, which is impossible.

VIGOR CONCEPT

The potential of the seeds is mainly determined by the indicators of vitality, viability and ability to develop normal seedlings, i.e. the level of vigor. They are important both for scientific research and directly in agronomic practice. To understand the specifics of individual analysis and delineate the meaning of vigor, it is appropriate to briefly indicate the differences in the mentioned terms (Dencheva et al., 1985).

- *Vitality* are those seeds that have a living embryo, determined by various methods;
- Due to the fact that not all seeds that are viable can germinate, due to many different reasons, the term *viability* is introduced, and these are normally germinated seeds under certain laboratory conditions;
- Of course, under production and field conditions, these seeds will not show the same vitality, nor can they be evaluated by this indicator for the possibility of developing plants and forming enough biomass. All this necessitates the search and application of new methods for evaluating the so-called seed *energy* or *force*.

Depending on the point of view and the direction of using the seeds, there are different concepts about the essence of vitality. In most cases, seed producers and sellers perceive the seed as an object that may or may not germinate. However, a deeper insight into the nature of seeds reveals that the seed should be considered as a living organism in which metabolic processes take place, there is enzymatic activity, there is the presence of living and dead tissues and this determines its ability to germinate.

A number of publications emphasize that under the standard method of germination, germination is limited only by the ability of the seed to develop the embryo, i.e. those essential structures for the various types of seeds that determine the possibility of its reproduction, but under favorable conditions, without determining the developmental potential of this sprout and subsequently the young plant under uncontrolled field conditions (AOSA, 1991; Copeland and McDonald, 2001). Although this standard test has good repeatability and can be applied anywhere, it also has its weaknesses.

The main disadvantages of germination by standard test are in several aspects: i) substantial overestimation of seed properties, since the standard test is conducted under controlled, artificial near-sterile conditions that are never encountered in the field; ii) germination is the sum of germination of stronger and weaker seeds, respectively counted at an earlier and at a much later stage, which is a big disadvantage, because under field conditions the weaker seeds would not be developed in this way; iii) there is also a lack of a precise scale for reporting and for distinguishing individual lots as capable of developing weak and strong seedlings, as well as the associated subsequent, expected and natural deterioration of the seeds; iv) does not state the rate, "energy" and "force" for growth, which are essential elements for normal plant development thereafter (McDonald, 1993; Panayotov, 2016).

One of the main postulates in vigor concepts is based on the changes in various processes and properties of the seed leading to its earlier deterioration compared to germination. Delouche and Boskin (1973) described a hypothetical model for the sequence of possible changes causing a reduction in seed potential (Figure 1). According to them the vigor is much more sensitive and any change before germination loss occurs can serve as a basis for its determination. According to this model, degradation of cell membranes occurs first before the decrease in viability is observed. This disruption of the integrity of the cell membranes creates the conditions and determines to a significant extent the greater sensitivity of vigor. It gradually reduces energy, biosynthetic processes and respiration, and only then is the deterioration of germination noticeable. A decrease of the storability, resistance to pathogens and development of abnormal seedlings is reached, and a loss of germination is also reached. This shows that even before the loss of germination, the changes occur in a number of processes that are indicators of changes in vigor values. This is how the individual approaches to the assessment of vigor can be outlined.

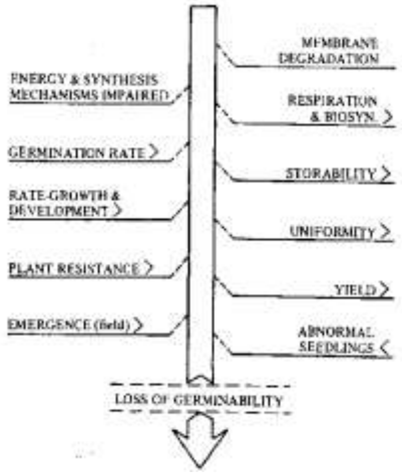

Figure 1. A putative sequence of changes occurring for seed deterioration (by Delouche and Baskin, according Copeland and Mc Donald (2001)

When considering the concept of vigor, it is imperative to note that there is a very strong relationship between vigor and seed germination (Delouche and Caldwell, 1960). The stated opinion about earlier changes in vigor before germination is an excellent prerequisite for earlier prediction of the changes that occur in the life potential of the seeds. In this way, the determination of vigor has points of contact with their storability. Several authors, although in some cases hypothetical, note that significant changes during storage in vigor can be observed long before they have occurred at such a level in germination. Justice and Bass (1978) and Dentcheva (1985) divided the process of changes of these two features into three periods (Figure 2). From the graph, it is clear that during the first stage, vigor loses 25% of its initial value, then germination is 90% and above 90%. In the second, the losses of vigor increase to reach a complete loss in the third period. That's why if it's used only the standard germination test these seeds would be class one. The changes in the curves are often sigmoidal but maybe and approach a weakly linear appearance.

It is analogous to the conclusion of Marcos-Fliho (2015) that initially, the loss of vigor tends to a parallel loss of vitality, then vigor decreases very rapidly and finally, the rate of loss slows, but zero values of vigor are reached and death of all occurs seeds (Figure 3).

In support of this opinion are the conclusions made by Panayotov (2023) when studying the life potential of cape gooseberry seeds during their natural aging. It has been established that, in addition to germination, determination of vigor is of much greater importance for determining seed quality. Comparing the data obtained on germination and vigor after 7 years of storage of harvested seeds, the conclusion is formulated that, compared to the initial values, the decrease in vigor is much faster than that of germination, and this is observed very clearly after the third year of storage, when vigor has decreased by 20-25%, and the germination decreased by about 8-9%. While in the sixth year, vigor loses about 32-35% and germination only 10% (Figure 4).

Similar are the findings of another experiment (Panayotov 2010a), conducted at the Department of Horticulture of the Agricultural University-Plovdiv, Bulgaria with seeds of two typical Bulgarian pepper varieties aged under laboratory conditions. When comparing the changes in germination and vigor, relative to the values for the first year, taken as 100%, it is seen that vigor decreases much faster than germination. In one variety, when germination decreased by 20%, vigor decreased by 58.2%.

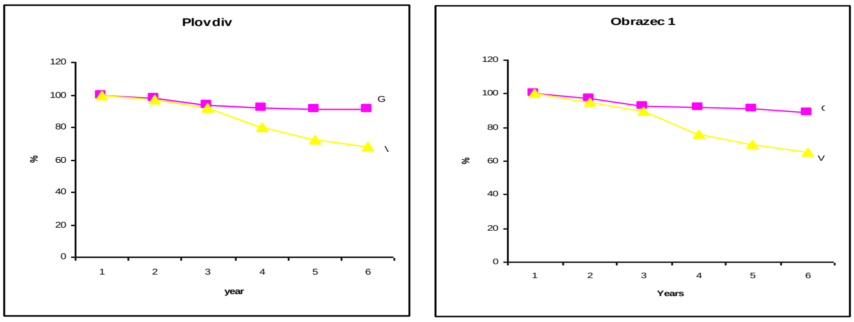

Figure 4. Changes of the germination (G) and vigor (V) after seventh year of storage of cape gooseberry seeds (by Panayotov, 2023)

From the above, the need to search for new ways and methods for full monitoring of the physiological potential of seeds during the various stages of their production, storage, trade and application is outlined. It is necessary to establish the potential not only for the germination of the seed but also for its ability to develop into a plant, due to the presence in it of the above-mentioned "power" or "energy"

HISTORICAL DEVELOPMENT OF THE DOCTRINE OF SEED VIGOR

The historical development of the scientific foundations, theory and practice of seed vigor is very well described by McDonald (1993) and Marcos-Filho (2015). The concept of the presence of such "power" and "energy" in seeds arose as early as the second half of the 19th century.

Much earlier, in 1816, the first seed law was published in the city of Bern, Switzerland, with a view to the regulation of trade, which aimed to introduce the basic conditions and standards to which seeds in trade must meet. The reason for issuing such a law is interesting, it is because unscrupulous traders used to put small pebbles in the packages of clover seeds.

The pioneer in laying the foundations of the doctrine of vitality and especially the vigor of seeds was Frederick Nobbe. In 1869, in En Tharandt, near Dresden, Germany, he established the world's first seed testing institution, the Seed Testing Laboratory, under the name

"Physiological Research and Seed Control Station in Tharandt". This positive example was soon followed in other countries. In 1876, E. H. Jenkins established the first such laboratory in the United States in the state of Connecticut. A decade later, in 1884, such a laboratory was also organized in France, the Station National d'Essais de Semences (Kastler, 2005).

A few years later, in 1876, Nobbe for the first time in his scientific work "Handbuch der Samenkunde" evaluated the physiological potential of seeds and expressed the opinion that they contained the so-called "growth power". In 1911, his student Lorenz Hiltner together with another researcher Ihssen, introduced the term "triebkraft" which means "driving force" and "launch force" or "pushing force" of seedlings. In this way, they denote the "stronger" seeds that form larger roots compared to the "weaker" ones of the same lot that form shorter roots. These two researchers also created one of the first tests to assess vigor called the "brick grit test" (Marcos-Fliho, 2015).

The interest in assessing the quality of seeds and their potential increased and in 1905 in France issued the first seed quality control law, followed by the USA in 1917, where in the state of Connecticut, the first unified and standardized rules for qualification of the seeds and sowing material were published. ("Rules for Testing Seeds") (McDonald, 1993; Heaton, 2015; Panayotov, 2016). Some of the first terms, in this relatively new field of science, to describe the concept of seed vitality included "driving force" and "germination", as well as seedling 'vigor' or energy of seedlings (McDonald, 1993).

According to Marcos-Filho (2015), in this early period, around the 30s of the 20th century, research in this area was also related to the development of other methods and tests for assessing the physiological potential and vigor of seeds, such as the Electrical Conductivity Test from Fick and Hibbard (1925), estimation of germination rate by Stahl (1931), and the first observations of the cold test (Alberts, 1927; Tatum and Zuber, 1943).

After the 1930s, although there were active discussions in the USA to introduce the term "germination energy" to express the speed of this process, the attention of scientists about the potential of seeds and the development of evaluation methods decreased. In this period, as mentioned by França-Neto et al. (1998), in 1940 Lakon introduced the tetrazolium test (Marcos-Filho, 2015).

In the middle of the 20th century, the interest of scientists in the field of vigor was revived again. This happened in 1950 at the Congress of the International Seed Testing Association (ISTA) held in Washington. During this meeting, the President of ISTA, W. J. Frank pointed out that the international trade in seeds, after the Second World War, was growing, but more and more difficulties were encountered due to the discrepancy between the results of the tests carried out in Europe and the USA. According to him, this arises from the different understanding and philosophy of the standard germination test. The differences are expressed in the fact that in Europe the reproducibility of the standard germination test is of greatest importance and this is the basis for international trade, while for America the essential is the ability of the seeds from individual lots to form a normal plant. He recommends smoothing over these differences in philosophy. At the same time, offers a specification of the terminology for establishing the potential of the seeds, distinguishing two directions. One is for the standard germination test, which is mainly prevalent in Europe, to be carried out under artificial and optimal environmental conditions to have repeatable results. The other one is for the test to evaluate the percentage of developed seedlings, conducted under significantly closer to field conditions, a methodology developed more in the USA and a term for its name is proposed. Thus, a new term "Vigour" or "Vigour Test" was adopted to evaluate the physiological potential of seeds under suboptimal and close to real conditions (Franck, 1950). In that year, Franck founded the ISTA Biochemical and Seedling Vigor Committee with two main goals: to define the concept of vigor and to develop a standardized test for its determination.

From that moment, a change in scientific research began, with more emphasis now on methods for determining vigor, to establish the effect of conditions influencing a more complete assessment of the seed's capabilities. Thus began a gradual increase in the importance of vigor as a routine test, especially for grain and vegetable crops. However, as McDonald (1993) points out, it is widely believed that this is primarily a matter of resolution in Europe, where the standard germination test is of primary importance.

A significant boost in scientific research was observed in the 1960s, deepening studies on seed physiology to incorporate them into more complete tracking of seed performance. Efforts to develop universally accepted definitions and concepts of vigor are beginning to be more active. Methods for several tests such as the tetrazolium test, electrical conductivity and accelerated aging are being improved. According to Woodstock (1973) and Marcos-Filho (2015), the number of scientists starting to work in the field of seed science and in particular with a direction towards vigor is increasing. Seed producers and agronomic scientists began to pay more and more attention to the importance of vigor, and this led to the systematization of information and the development of the necessary documentation. Scientific studies are deepening to reveal the mechanisms of seed aging leading to reduced vigor. Emphasis is placed on the importance of such basic processes that begin to deteriorate the vital status of seeds and, accordingly, vigor, such as the degradation of cell membranes, lipid peroxidation, changes in the state of the cytoplasm (Priestley, 1986; Wilson and McDonald, 1986; McDonald, 1999). Studies in this scope are becoming more and more diverse. Scientific fields are expanding the beginning of research on the processes leading to changes in vigor. Thus, vigor becomes more and more a comprehensive indicator, and for its determination, knowledge from a number of sciences is included, and thus the study acquires an increasingly interdisciplinary character, providing an opportunity to reveal much more real information about the essence and character of the power and potential of seeds.

The development of the doctrine of vigor was also inextricably linked to the work of the AOSA Vigor Test Committee established in 1961, the main purpose of which was to indicate the advantages and disadvantages of direct versus indirect vigor tests and to formulate the concepts of vigor testing. It began to develop actively in 1968, but there are still two opinions, according to one the tetrazolium test is the most suitable, i.e., an indirect assessment, and according to others, direct measurements are the most important. In 1974, the idea of standardizing vigor tests arose. In 1983, the Committee already published the main tests that are appropriate to apply and these are: the accelerated aging test, cold test, cool germination test, conductivity test, seedling vigor classification, seedling growth rate and tetrazolium test. During the period 1987-1991, there was active work on the standardization of these tests, the first officially proposed test being for accelerated aging of seeds. The number of laboratories that apply them is also increasing, from 52% in 1978 to 75% in 1990 (McDonlads, 1993).

DEFINITION OF VIGOR

In parallel, the need to create a precise and scientific definition of vigor is growing, because without her presence, the measuring an ill-defined object is difficult, even impossible (McDonald, 1993). Many definitions are offered, but at the beginning, an opinion arises that already accepted, existing seed vigor is so comprehensive that it is very difficult to formulate a correct and precise concept, which is practically not far from the truth. The first attempt at a meaningful definition was made in 1957 by the American botany professor Duane lsely, who proposed that vigor should be understood as "the sum total of all seed attributes which favor establishment under favorable conditions" (lsely, 1957).

A few years later, in 1960, J.C. Delouche (Agronomist in Charge, Seed Technology Laboratory, Mississippi State University, Mississippi State, USA), and W.P. Caldwell (Seed

Technology Laboratory, Mississippi State University, Mississippi State, USA) in an attempt to upgrade this definition, express the opinion that "seed vigor is the sum of all seed attributes which favor rapid and uniform stand establishment", i.e. for germination and creation and development of a plant. Thus, a significant step is taken for a correct and accurate definition of vigor, because on closer inspection it is seen that there is a significant difference between the two definitions. In the definition proposed by J.C. Delouche and W.P. Caldwell foregrounds the stand establishment to emphasize rapid and even development and remove the need for "favorable conditions" present in Duane lsely's definition. Thus, one main point is clarified, namely that the rapid and uniform development of seedlings under field conditions is an extremely important characteristic of seed vigor (McDonald, 1993).

However, the question arises regarding the "sum total of all seed attributes", what are these factors and conditions that determine seed vigor. For greater clarity in the definition, Woodstock (Market Quality Research Division, USDA, Beltsville, Maryland) in 1965 proposed that vigor is "that condition of good health and natural robustness in seed which, upon planting, permits germination to proceed rapidly and to completion under a wide range of environmental conditions." In this definition, the most important point is the wide range of environmental conditions. Pollock and Roos (1972) accept that "seed vigor might be considered as a potential for seedling establishment in the field". Then this idea was widely adopted by seed producers.

A year later, in 1973, Perry supplemented the definition, understanding vigor "physiological property determined by the genotype and modified by the environment which governs the ability of a seed to produce a seedling rapidly in soil and the extent to which the seed tolerates a range of environmental factors." Thus, it is already clearly pointed out that vigor depends on both genetic prerequisites and environmental conditions (McDonald, 1993).

In 1977, ISTA created an official definition of vigor "the sum of all those properties which determine the potential level of activity and performance of the seed or seed lot during germination and seedling emergence". Three years later, in 1980, AOSA refined this definition and it became "...those seed properties which determine the potential for rapid, uniform emergence, and development of normal seedlings under a wide range of field conditions." A positive feature of this definition is that parameters are used that are numerically measurable, such as rapid and uniform germination, as well as the well-known "good development of seedlings". It is also important to emphasize the ability of seeds not only to develop in the field but to do so under a wide range of environmental conditions, i.e. under both optimal and stressful conditions. In this way, the essence of vigor is very clearly distinguished from that of seed germination. It should be emphasized that it is appropriate to subject lots to the vigor test which has already shown good germination in the standard test.

Marcos-Filho (2015) also points out some weaknesses in the understanding of vigor, arguing that the available concepts do not cover the development of plants throughout their life cycle up to yield and that the index by itself does not represent a distinct physiological process. He emphasizes, however, that the emergence of vigorous seedlings, due to their uniform and accelerated development, can lead to an increase in productivity, and seeds with high vigor germinate much more evenly and have better stability. According to him, vigor is manifested as a result of the interaction of many physiologically independent characteristics of the physiological potential of seeds, such as: germination rate, seedling growth, ability to germinate above or below optimal temperatures and other aspects of stress tolerance. This, in turn, makes it difficult to formulate a precise definition, since many and varied factors are involved in the manifestation of vigor, and thus it is much easier to understand the main effects of vigor than to define it. Panayotov (2015) also reported that vigor depends on many factors: genetic features, trauma to the seeds, the chemical composition of the seeds, environmental conditions during development, ripening and harvesting as well as maturity and storage.

VIGOR TEST

According to Marcos-Fliho (2015), vigor tests should be much more sensitive to changes that cannot be detected by the standard germination test. The purpose of the vigor test is to determine the differences in the physiological potential of seeds from different batches with similar germination and their ability for better development of seedlings under field conditions, as well as for higher storability. Vigor cannot indicate the number of plants developed in the field or the storage period, but the correct interpretation of the results allows to select the best batch of seeds and to specify the sowing rate and the appropriate method of sowing. Direct or indirect methods are used to determine the metabolic activity, the physiological state of the seeds and the tolerance to stress conditions. The first test that was officially included in the International Rules for Seed Testing of ISTA in 2001 is the electrical conductivity test, applied to garden pea, bean and soybean seeds. Currently, these rules also recommend the accelerated aging test for soybeans, the controlled deterioration test for *Brassica* spp. and the emergence of primary roots for corn. The need to expand the scientific activity in the field of vigor in the seeds of vegetable crops is also indicated by the fact that in an analysis of the systematized literature on the vitality potential of seeds out of 1158 references, only six were on the subject of seed vigor, and most of them are for field crops and very little for vegetable crops. A number of authors (Panobianco and Marcos-Filho, 2001; Bennett, 2002; Sako et al., 2002, by Contreras and Barros, 2005) support this opinion and point out that the results obtained for vigor from some tests in vegetable crops are insufficient and contradictory and strongly highlight the need to deepen the studies on vigor in the seeds from vegetable crops.

Many scientists, such as McDonald (1999), Copeland and Mc Donald (2001) and McDonald (2001) point out that the creation of a vigor assessment test should be related to the determination of one or more quantifiable parameters related to deterioration in vigor. The results obtained apply to the whole lot, but a lot consists of many seeds, each of which has its own plant development abilities. Tests are an analytical procedure for establishing the potential of seeds and must be standardized to compare data between individual lots. Vigor tests should be applied to batches with proven high seed viability and germination.

Types of vigor tests

The basis of the creation of a vigor test is the measurement of various parameters, one or more morphological, physiological, biochemical or other characteristics. According to Copeland and McDonald (2001), depending on the method of measurement, they are divided into direct or indirect.

Direct tests are carried out under conditions close to the real ones in the field, investigating the possibility of germination and resistance to stressful conditions. A disadvantage of these tests is that the difference in the status of the seeds from individual lots is not manifested when the seeds are placed under favorable conditions. Such is the test of low temperatures.

Indirect tests are most often based on changes in physiological processes in seeds. An electrical conductivity test can be specified in this group. However, a negative feature is that they cannot fully determine the physical and physiological conditions responsible for germination.

According to the indicators that are included for measurement, the tests can also be *physiological, biochemical and physical*. The *physiological* ones measure the germination and development of seedlings, the *biochemical* ones - the changes in chemical reactions such as respiration and enzyme activity, responsible for germination and here belong the electric conductivity and tetrazolium test, while the *physical* ones mainly cover parameters of size, density, texture or other factors of this character related to germination.

The tests can also be grouped as stressful and quick. *Stress tests* include the accelerated aging test, cold test, the test of low temperature, the test of cooling, osmotic stress, and aspects of germination and seedling morphology. Rapid tests admittedly require less time, they are primarily based on some chemical and physical processes. This includes the tetrazolium test, test of conductivity and enzymatic activity tests. There is another group - tests for germination and seedling development, and these are determination of germination energy (first count of germination), normal developed seedlings and imagine analysis (Bennett, 2002; Contreras and Barros, 2005).

Vigor test requirements

Vigor tests have specific requirements for them to be applicable and subject to unification and standardization (Copeland. and Donald, 2001; Contreras and Barros, 2005; Panayotov, 2016). That, they're like that:

- Be more *sensitive* than the standard germination test
- To be *cheap* - to require minimal costs, equipment, laboratories and labor;
- To be *fast* - to provide quick information, to avoid the peak workload of the laboratories, for the analyses to require little time and space for their implementation;
- To be performed *easily* - i.e. no special training of personnel, complex equipment and the procedures themselves should be simplified;
- To be *objective* - the parameters should be expressed numerically and measured quantitatively, which will facilitate the interpretation of the data and will enable the classification of the individual batches the seed performances;
- To be *repeatable* - an extremely important requirement, the results should be similar, if not the same, in the next execution and thus obtain comparability between individual laboratories;
- To have a dependence on *the real conditions* of the field. Many of the tests pay serious attention to this requirement to predict the behavior of the seed under field conditions.

Kinds of Vigor Assessment Tests

The specific diversity of vegetable seeds requires a very good knowledge of the particularities of the individual tests, their positive and negative sides and the possibilities of application depending on the species of the given crop. In this review I focus only on some of the more widely used and more important vigor tests that are more suitable for evaluating vegetable seeds.

Accelerate aging test

This test is one of the most widely used and is relatively well-researched and developed. It is officially recognized and included in the International Rules for Seed Testing of ISTA (2019), as a soybean seed vigor test. It covers many of the characteristics that a vigor assessment test should meet.

As early as 1915, Crocker and Groves (1915) suggested that protein coagulation occurs during seed storage and that this is due to an increase in temperature in the seed mass. Initially, this test was applied to assess the storability of the seeds (Helmer et al., 1962) (by Marcos-Fliho, 2015). The test is based on the notion that when seeds are hydrated at high humidity and temperature, their life potential decreases. Its essence consists precisely of processing the seeds under such conditions, with an average temperature of 41^{o}C and a relative humidity of about

100%. Higher temperatures are not suitable, because instead of creating stressful conditions, it is possible to reach denaturation of the protein and, accordingly, complete death of the seeds. Increasing the temperature above 43^{0}C or 45^{0}C will cause metabolic activity to cease, especially in low-vigor batches (Marcos-Fliho, 2015).

The application of the test is carried out in a specially designed plastic box with precisely defined dimensions (11 x11x 3 cm) and volume (363 cm^3) with a grid for placing the seeds, and 40 ml of water is poured into the bottom. In addition to water, in some cases, especially for smaller seeds, a salt solution can be used - 40 g NaCl in 100 ml of water (Jianhua and McDonald, 1996), thus reducing the absorption of water for the deterioration of seed quality and the development of microorganisms. It is assumed that this moderate increase in seed water content at high temperatures creates conditions closer to those of natural aging compared to the presence of only water at the bottom of the box.

The box is placed in a thermostat with the appropriate temperature. After the specified treatment period, the seeds are subjected to the standard germination test. Batches with higher vigor overcome this aging better and show higher germination (Baalbaki et al., 2009). The application of this test is directly related to the initial moisture content of the seeds.

The test was considered promising and in 1973 Delouche and Baskin improved the methodology. The initial variant of the officially adopted protocol was developed by McDonald and Phannendranath (1978). Marcos-Filho (2015) reports that this method, especially with the use of salt solution, is actively developing tests in many vegetable crops such as pepper, broccoli, carrot, cauliflower, cucumber, eggplant, lettuce, melon, onion, pumpkin, radish, spinach, tomato. Piana et al. (1995) found that accelerated aging of onion seeds for 48 hours at a temperature of 42^0 C are suitable conditions for vigor assessment. To evaluate the vigor of onion seeds, Rodo and Marcos-Filho (2003) indicate that the saturated salt accelerated aging test for 72 hours, at a temperature of 41^{0}C, is a very promising regime.

Panayotov (2014) studied accelerated aging in three batches of pepper seeds at 35^{0}C, 40^{0}C and 45^{0}C for 24, 48 and 72 hours. It was also found that at 45^{0}C, it caused almost complete seed lethality, making this temperature unsuitable for assessing pepper seed vigor. He pointed out that the appropriate regime for accelerated aging and determination of vigor of pepper seeds, where individual lots exhibited the highest physiological sensitivity, was 40^{0}C for 48 hours (Figure 5).

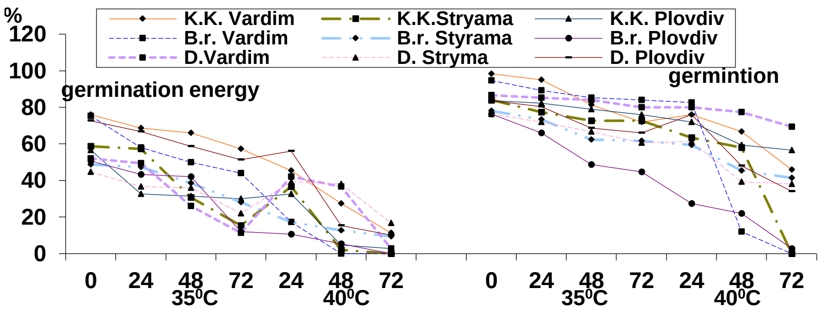

Figure 5. Accelerate ageing regimes for estimation of pepper seed vigor (Panayotov, 2014)
K.K.-Kurtovska kapia 1619. B.r. Bulgarski rotun, D-Delikates

The application of accelerated aging according to Svetleva and Panayotov (2014) is also a suitable method for assessing the viability of bean mutants. They found that the determination of vigor in these seeds is suitable to be carried out also at a temperature of 40^{0}C for 48 hours when high physiological sensitivity and well-defined differences between different seeds are observed (Table 1).

Despite an increase in scientific research on the use of accelerated aging in vegetable seeds, no sufficiently complete and definitive results have yet been formulated to establish a standardized protocol for such a test. It is similar to the opinion of Powell (1995) that the results of accelerated aging of vegetable seeds and small-seeded species are not completely unidirectional, since these small seeds absorb water much faster, their content varies greatly and this leads to a lack of uniformity between the individual lots (Marcos-Fliho, 2015).

Table 1. Sowing qualities of bean seeds after accelerate ageing (Svetleva and Panayotov, 2014, by Panayotov 2016))

Variants / Mutant	Germination energy (%)			Germination (%)		
	1	2	3	1	2	3
Control	61.6	80.0	71.6	84.3	88.3	86.7
24 h /40^0C	70.0	79.6	71.6	83.3	84.6	85.7
24 h /45^0C	45.0	45.0	48.3	46.66	55.0	66.6
24 h /50^0C	18.3	21.6	41.6	30.6	33.3	61.66
48 h /40^0C	61.6	78.3	65.0	72.6	81.6	74.0
48 h /45^0C	3.33	45.0	28.3	3.33	48.3	35.0
48 h /50^0C	1.66	11.6	21.6	1.66	18.3	28.3
72 h /40^0C	8.33	30.0	45.0	8.33	40.0	45.0
72 h /45^0C	5.0	13.3	13.3	6.7	13.3	16.6
72 h /50^0C	1.66	3.33	3.3	1.66	5.0	5.0

1 – Mutant with 0.0031 M NEC, 2; 2- Mutant with 0.0125 M EMS; 3- Mutant 0.0125 M EMS

The seeds of vegetable crops are characterized by different weight of 1000 seeds, and the porosity of the seed coat, which also determines the different absorptive capacity. This requires that the exact amount of seeds placed in the box be precisely specified. Furthermore, the appropriate regimes for accelerated seed aging of a lot of the major vegetable crop species, both in terms of temperature and duration of treatment, have not been firmly established. All this determines the need for additional and in-depth research to develop and standardize tests for accelerated aging in vegetable species. Advantages of this test is that it is sensitive, not expensive, easy for application, objective and repeatable. A disadvantage of this test is that it is not one of the rapid ones, due to the time required for processing the seeds and subsequent testing by the method of the standard germination test.

Electrical conductivity test (Conductivity test)

It was pointed out above that one of the first changes, when seed quality deteriorates, is a degradation of the cell membranes. This can occur both during storage and mechanical damage. Such seeds have a low ability to restore cell membranes. Placed in water, when it is absorbed, it begins to release substances from the cytoplasm in the medium. Sugars, amino acids, fatty acids, proteins, as well as potassium, magnesium, sodium, manganese and calcium ions are released from the seeds.

These substances have electrical properties and carry an electrical charge that can be measured conductometrically. However, moisture and seed size affect the properties of the solution. According to Ching and Schoolcraft (1968), an increase in the release of substances during water adsorption depends to a large extent on the degradation of cell membranes and the lack of control or management of the permeability. It is indicated that when such seeds are sown and germinated under field conditions, these secretions can be a favorable condition for the development of microorganisms (Panayotov, 2015; Marco-Fliho, 2015; Panayotov 2016).

Marco-Fliho (2015) examines the historical development of this test. He points out that Fick and Hibbard (1925) were the first who express at the opinion that low germination is related to the release of substances during seed soaking. About thirty years later, Priestley (1958) reported that the electrical conductivity of a water solution in which seeds were soaked was inversely proportional to their germination rate. For the first time, however, the possibility of using this discovery to use as a test of vigor was proposed by Matthews and Bradnock (1967), who developed a methodology and a way to evaluate the emergence of seedlings of pea seeds. This is one of the first tests included in the International Rules for Seed Testing of ISTA for garden pea seeds.

Vegetable seeds are characterized by their small size, they quickly change their humidity and are often subject to longer-term storage. In this sense, the conductivity test is often applied to the seeds of these species. Through the use of different methods, a very close correlation with field germination of carrot and pepper seeds was reported using this test, achieving rapid and real information on seed status (Andrade et al., 1995; Torres, 1996).

However, there are some conflicting opinions regarding the applicability and reliability of the conductivity test. Ratajczak and Duczmai (1991) and Prusinski and Borovska (1993) think that this test has less opportunity to predict seed vigor and has very pronounced differences between cultivars, making it difficult to unify. On the other hand, Dong et al. (1998) observed that in increasing the storage time of onion seeds the vigor decreases as well as the electrical conductivity increase and germination and field emergence decrease, but they also reported a negative correlation between electrical conductivity and emergence.

This indicates that the application of the conductivity test is still debatable. Aladzhadjiyan and Panayotov (1994) conclusions are close to this opinion, that during long-term storage of tomato seeds, germination decreases and electrical resistance decreases, i.e. electrical conductivity increases. These authors also found some controversy in pepper seed storage. In support of the specificity of the data obtained is also the study of Ozoban and Demir (2002) in pepper and watermelon seeds, pointing out that the conductivity test does not always provide consistent results to relate to germination and emergence.

In addition to seed storage, studies have been carried out that reveal that this test is also suitable for assessing the potential of seeds during their development. Panayotov and Aladzhadjiyan (1999) and Aladzhadjiyan and Panayotov (1999) reported that as pepper and pea seed development progressed, there were changes in electrical conductivity that were strongly correlated with their germination. They hypothesize that as the growth, formation and maturation of the seeds progresses, the integrity of the cell membranes improves and thus the release of substances from them decreases, which significantly affects the conductivity. According to the authors, this method is suitable to be applied to establish the stage of seed development.

An electrical conductivity test is defined as belonging to the group of rapid tests and is essentially biochemical. The advantages of this test are also that it is inexpensive, numerically measurable, and often the results are accurate, as well as being easy to implement. However, some disadvantages should be pointed out that it shows data only for the seeds placed for analysis and only by assuming that all seeds in a lot will show this character, but it should not be forgotten that each seed is specific with its own characteristics.

Test of controlled seed deterioration

Such a test is well suited to be applied to vegetable as well as small-seeded species. Black et al. (2008) described its essence, pointing out that it aims to identify differences in vigor in small-seeded crops such as vegetables. Basak et al. (2006) indicated that a number of researchers such as Matthews (1980), Powell and Matthews (1981), Powell and Matthews (1984a) and Powell and Matthews (1984b) applied this test to predict field germination and seed storage of some vegetable crops such as cabbage, onions and carrots.

The presumption is that the seeds of the studied batches are under the same conditions, thus aging and deterioration of their potential can be achieved. It starts with equalizing the humidity of the seeds. The seeds are placed on moist filter paper and the moisture in them is periodically measured using the weight method until the required moisture is reached. To balance and evenly distribute the moisture in the seeds, they are placed in impermeable, hermetically sealed envelopes (sealed) of aluminum foil and kept overnight or, depending on the culture, for a longer period (for example, up to 5 days) at a temperature of 5-10° C. After which, for 24 hours, they are placed in a water bath with a temperature of 45°C. To reduce the temperature immediately after removal, the envelopes are immersed in cold water. The seeds thus deteriorated are tested by the standard germination test.

Basak et al. (2006) recommended the application of the controlled deterioration test for 24 hours at 22% seed moisture as a routine method for predicting germination and storage duration of pepper seeds. The effectiveness of the test is also confirmed by the results of Rodo and Marcos-Filho (2003) for onion seeds brought to a humidity of 24%.

Of interest are the experiments that have been carried out by Eksi and Demir (2011) to reduce the time to conduct this test. When assessing the vigor of onion seeds, they modify the standard controlled deterioration test so that seed moisture, equilibration and aging are completed within one day, and the standard germination test is completed within four days. They found a very strong correlation between the data obtained from the traditional test and the new, modified one.

By its nature, this test approaches the principles of the accelerated aging test. A disadvantage of this test is that it is not fast, it requires a long preliminary preparation of the seeds and then a germination test. In addition, as Matthews (1993) points out, the required seed moisture and aging duration should be established for each crop. In this direction is the opinion of Rodo and Marcos-Filho (2003) that it is a laborious test needing prior standardization of seed moisture

A perspective for scientific researchers working on the controlled deterioration test is to direct their studies to create and modify the test to shorten its duration. Nevertheless, this test has significance and provides high sensitivity for the vigor evaluation of vegetable crop seeds.

Cold test

Among seed scientists, this is one of the oldest tests for assessing seed potential, so it should be given the attention it deserves. With it, the seeds are in a state of stress. The test setup consists of using a strip of soil in filter paper or directly in soil, where for a certain period the seeds are placed at low temperatures. The presence of low temperatures on the one hand and microorganisms on the other create stressful conditions for water absorption. After passing a certain period in which seeds are in an environment of low temperatures, they are placed at optimal temperatures so that they can germinate normally (Panayotov, 2015).

Marcos-Fliho (2015) points out that although this test was mainly created for maize seeds, it is also suitable for vegetable crops such as carrot, eggplant, beans, lettuce, and onion. By using soil, it is possible to evaluate more sensitive seed lots compared to the standard germination test. The stressful conditions to which seeds are subjected are created by the combination of low temperatures, high environmental humidity and pathogens. The stress of suboptimal temperatures is due to fact that, when water is absorbed, the integrity of membrane systems is degraded and substances leak out of cells, including sugars. The restoration of cell membranes under such conditions is quite difficult and this increases the discharges from the seeds.

On the other hand, in the presence of soil, the microorganisms also act as a stress factor. Thus, the rate and percentage of germination and emergence are lower and the vigor of the given lots are evaluated by the surviving seeds in such an environment. According to him (Marcos-Fliho, 2015), research on this test began as early as 1926-27 with the experiments, respectively, by Dickson and Holbert (1926) on infecting seedlings in soil and by Alberts (1927) on the effectiveness of fungicides. In 1940, it was already introduced for corn seed control, but according to the author, as TeKrony (1983) pointed out, it only became popular in Europe in 1976.

Good results, near to germination and emergence under field conditions of onion seeds were reported by Piana et al. (1995), treating the seeds for seven days at a temperature of 10^0C and under room conditions.

Although many laboratories emphasize the usefulness of this test in vegetable crops, there are also known failures. Its negative features are the differences in individual soils, their humidity and pH, and the presence of different pathogens, which is why very often differences in data are obtained and there is a lack of repeatability, and this prevents its standardization. One way to overcome these difficulties is to include perlite or vermiculite in the medium, but using conditions very close to real life.

Tetrazolium (TZ) test

It is one of the most widely used tests that provides substantial opportunities for vigor assessment without the need to wait for the results of a standard germination test. The beginning of this test was set in 1940, by the German Prof. Georg Lakon. To distinguish living from dead seeds he first used selenium salt, but the results were not reliable. Subsequently, he turned to the application of tetrazolium salt and found its higher efficiency in staining the tissues. According to Marcos-Filho (2015), even before that, as Moore (1969) points out, attempts to assess seed viability by applying dyes were conducted in 1922 by Turina in Yugoslavia and in 1925 by Neljubow in Russia.

The test is based on distinguishing between living and dead tissues in the embryo and whole seed based on their relative rates of respiration when hydrated. During respiration, the activity of many enzymes increases, but dehydrogenase enzymes are important here, which are an indicator of the rate of respiration and vitality of the seeds. First, the seeds are placed to swell in a moist medium and all tissues are fully hydrated. Then they are placed in a 1% solution of tetrazole (2,3,5,-triphenyl tetrazolium chloride or bromide) in a thermostat at a temperature of 35^0C for about two hours. For some species, it can be longer. This duration is important, because with a longer stay, the results may not be real, and the vitality may be overestimated. Many species of seeds can absorb the solution when whole. However, there are those in which, for the solution to enter, it is necessary to break their integrity in a mechanical way (Copeland and McDonald, 2001).

For the seeds of some vegetable crops, the method of preparation is well known. Bean seeds are soaked at 20^0C for 15 hours or at 30^0C for three hours, with the help of a needle the coat is peeled, and the exposed seeds are washed with water and soaked in the tetrazolium solution for 16-24 hours. The seeds where the embryo root or cotyledons are well-colored are defined as viable. A similar procedure is recommended for pumpkin seeds. After soaking in water at a temperature of 20^0C for 20 hours, the coat of the swollen seeds is removed with a needle and soaked in the tetrazolium solution. Fully colored seeds or those in which only the tip or at most 1/3 of the length of the radicle is not colored, as well as such seeds that have small uncolored spots on the cotyledons at the opposite end of the radicle or have no uncolored spots near the radicle are considered viable. (Panayotov, 2015).

The mechanism of action is caused by the fact that the colorless tetrazolium solution is absorbed by the seeds, by means of the reduction process it is mixed in the tissues of living cells and takes up the hydrogen that is released by dehydrogenase. As a result of the dehydrogenation of tetrazole in living cells, a stable, insoluble red-colored substance called triphenylformazan or just formazan is formed. In contrast, no such substance is formed in dead tissues. This is how living and dead tissues are distinguished. Above all, depending on the place of coloring (topographical coloring) and the intensity of the red color, vitality is also determined. In this way, experienced analysts by color divide the seeds into categories from strong to weak. It should be noted that in addition to live seeds that are fully colored and dead that are colorless, partially colored seeds are also observed. The location of staining, in the embryo or the endosperm, and not so much the intensity of the color is of greater importance for the viability assessment (Copelan and McDonalds, 2001; Panayotov, 2015). The location, the degree of coloring and the presence of spots in the tissues as indicators of the vital state of the seeds are also highlighted by other authors, and depending on this, some divide the seeds into categories such as vigorous, viable but not vigorous or non-viable (Marcos-Fliho, 2015).

The importance of the location of staining was also emphasized by Sales et al., (2022). Applying the tetrazolium test to kale (*Br. oleraceae,* var. *acephala*) seeds, they mainly observed the staining in the places of the seed that are important for germination. The seeds depending on the place of staining are grouped into viable and non-viable groups and also subdividing them into different categories depending on the place and intensity of staining (Figure 6).

This test is very promising for establishing the level of vigor. Andrade et al. (1995) indicated that it could determine the viability of carrot seeds in 3 hours, while the standard test required about 14 days. In vegetable crops, a greater opportunity for its application is outlined in species from *Cucurbitaceae, Brasiicacea* and *Fabaceae,* i.e. seeds whose coat peels easily.

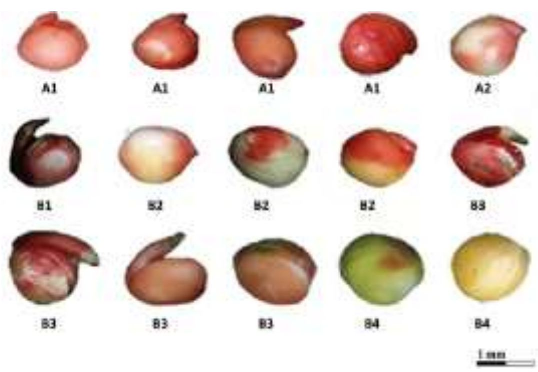

Figure 6. Classes for determination of viability in kale seeds by the tetrazolium test: Category A (viable): A1 – well-developed embryonic structures, intact and with pink staining, and A2 – less than 50% of the embryo unstained, without reaching the embryonic axis, and tissue with normal and firm appearance, Category B (not viable): B1 – embryo with intense red staining; B2 – more than 50% of the cotyledons unstained; B3 – embryo axis region unstained; and B4 – embryo completely unstained (by Sales et al., 2022)

Positive aspects of the Tetrazolium test are that it is fast, belongs to the group of biochemical tests and most importantly provides accurate and precise information about seed vigor and has a strong positive correlation with their real field performance. It is also very suitable for vegetable crop seeds, but further studies are required to establish species-specific protocols.

A disadvantage is the subjective factor, the assessment by the evaluator (analyst) regarding the degree and place of staining. It requires preliminary preparation of the seeds, which can cause difficulties from a technical point of view in the case of small-seeded species. A well-trained staff is also needed. Phytotoxicity can also occur with incorrect application.

Seedling vigor classification test (Test by seedling morphological behaviors)

The morphological characteristics and behaviors of seedlings have long been used to evaluate the physiological potential of seeds. Seeds with higher vigor absorb more fully the reserve nutrients of the seed and redirect them better to the growing parts of the embryo, which has a positive effect on the growth and development of the seedlings. One of the first signs of seed deterioration is the slower development and protrusion of the embryo root. The strength of this deterioration is directly proportional to the duration of the sprouting phases, especially the second phase, the so-called “lag-phase”, i.e. depending on the level of deterioration of the seeds, the time required for metabolic recovery of the damage on the seed will also depend before it continues to germinate. The speed of germination and uniformity of seedling development are also important in this regard (Marcos-Fliho, 2015).

To determine to what extent the individual parameters and properties of seedlings are suitable for assessing vigor, several studies were conducted, including the determination of germination, germination rate, emergence, development and formation of dry weight of seedlings, embryo root development, and others. Special attention is paid to the rate of germination, as it is a much more sensitive indicator than the percentage of germination and therefore more suitable for vigor determining.

Actually, this test expands the standard germination test by additionally allowing seedlings to be classified as strong and weak, but also as abnormally developed. In this direction, Wellington (1970) also made an extremely large contribution, studied and established deviations from the normal development of seedlings of many crops, and his catalog is widely used by researchers in the field of seed science.

In conducted the experiments in the Department of Horticulture of the Agricultural University-Plovdiv, Bulgaria, experiments on the storage of pepper seeds for ten years, Panayotov (2010a) found that the duration of storage has a strong influence on the development of seedlings. Until the 4th year, the deviations are relatively small, after which they begin to increase significantly to reach 90% and above 90% in the tenth year (Table 2). In other studies, with storage of cape gooseberry seeds (Table 3), Panayotov (2023) reports that, despite reported high germination, seedlings with deviations from normal development are observed from the second year, and with loss of germination, their percentage reaches approximately 40%. More common abnormalities are unopened cotyledons, lack of hairs on the radicle, underdeveloped or short radicles, and lack of lateral branches. Correlations with results of another vigor test are strong and positive, indicating that seedling development and its changes are a suitable way to assess vigor. Such an opinion about the importance of the development of seeding and its relationship with vigor is also expressed by Bewley et al. (2013).

The positive side of this type of test is that they do not require specific and additional equipment, the same approaches and terms are used as for the standard germination test. Disadvantages and difficulties originate from the circumstance, that it is not a quick test. To be able to analyze the seedlings, to categorize them into strong and weak, very good knowledge is required. Here, too, there is a subjective factor of the analyst's views and capabilities.

Close to this test is the *Seedling growth rate test (Test of dry bio-matter).* It is based on the idea that new biomass is synthesized when the seeds germinate. These substances are directed for the active growth of seedlings and dry weight is formed. The dry weight of normally formed seedlings is determined by the standard method in an oven at a temperature of 80^0C for 24 hours. The results of these tests are considered to correlate well with vegetative development under field conditions. A disadvantage is that equipment is required and above all those minor differences in humidity and light affect seedling growth. Further standardization is also required for individual species, as seedling growth is genetically controlled.

Test of "Initial vegetative productivity of the vegetable seeds"

This is a new method developed by N. Panayotov in the Department of Horticulture, at the Agricultural University-Plovdiv, Bulgaria (Panayotov, 2013; Panayotov, 2016). The concept of "Initial vegetative productivity" means the development of the seedling fresh weight from the seed, based only on the reserve substances contained in the seed itself, thus eliminating the use of nutrients from the germination medium and so the development of seedlings is only based of the capabilities of the seed, i.e. of the nutritional ingredients available in it. This is also the main hypothesis on which the test was developed. Apart from the fact that the development of seedlings is only based on the reserve substances in the seed, as an additional factor and somewhat stressful conditions, the possibility of seeds from batches with better vigor to overcome the resistance of the sand cover more easily and quickly is also included, to appear on the surface and as a result of most nutrients to form a larger vegetative weight.

SR-Short embryo root, BR- Lack of branches in embryo root, HR-Lack of hairs on the embryo root, H-Lack of hairs of hypocotyls, C-Unopened cotyledons

The test is based on sowing the seeds in physiologically clean river sand, with a particle size of 3 mm, sterilized for 4 hours at 105^0C, placed in disinfected containers, in a layer of at least 10-15 cm, levelled and compacted. The seeds are sown at the same depth, depending on their size and species, density depends on the crops, but usually with a distance between the seeds three times their largest size, which is its length. The covering layer is of the same sand of equal thickness, levelled. Sowing 100 seeds in 4 replicates is recommended. It is watered with distilled water with a pH of 7-7.5, in the same quantities for all replicates. The containers are placed under conditions of temperature and humidity, depending on the prescriptions for the respective species for seed germination and growth, with an assured light regime day/night, according to the real conditions, in the perception of the moment of sowing the seeds of the field in a given region. All the time, the humidity required for the species is maintained (Figure 7).

Observations and reports are carried out when there is a visible stoppage of development and lack of growth of seedlings, growth retardation. This usually occurs at the stage of fully formed cotyledons or a well-formed first pair of true leaves and the beginning of a third. The number of seedlings is counted in two groups - with only cotyledon leaves developed and the second group - with at least the first pair of true leaves developed, and their percentage is determined depending on the total number of sown seeds. On 15 plants of each replicate, carefully removed with a spatula to the depth of the base of the container, the adhered sand was washed, and absorbed with filter paper and the weight of seedlings was measured separately for each of the two groups on a scale accurate to the second mark. The data are averaged for each replicate and then averaged for each of 4 replicates and the biomass developed from one seed is determined.

The vigor index (Y) in percentage is determined by the equation:

$$Y = \frac{(m_1 p_1) + (m_2 p_2)}{100}$$

m_1 - weight of the plant in the cotyledon phase (mg)
p_1 – percentage of plants in cotyledon phase
m_2 - weight of the plant in the first pear og true leaves phase (mg)
p_2 - percentage of plants in phase one true leaf

Additionally, in the final assessment of vigor for individual batches, the time in days that was required for seedling development is indicated. Thus, vigor is determined as a result of morphometric measurements and phenological observations.

Figure 7. Experimental setting for determination of vigor of pepper seeds trought the Test of Initial Vegetative Productivity (Panayotov, original)

This methodology belongs to the group of direct, morphological tests, through its application a better comparative assessment is achieved between individual batches. The advantages are that it is cheap, as it does not include special and expensive equipment, it is accessible - no additional training of personnel is needed, and the results are real and accurate, and only by one experiment are observed three main factors - resistance of the sand, seedling development based only on the nutritional components in the seed and the time required for seedling development. Also, the results are presented numerically. As a disadvantages, this test is not fast and requires an area for placing the containers, as well as some influence of the subjective factor of the analyst to evaluate the end of seedling growth.

The reliability of this test is confirmed by the experiments carried out with naturally aging pepper seeds aged 1-10 years, as well as with three batches of seeds of the same crop with different origins of seed production (Panayotov, 2013). The aging of seeds causes a decrease in the biomass formed (Table 4). The sensitivity of the test is also evident at the stage of leaf formation in the tested variants. Seedlings, with well-developed true leaves, respectively, and cotyledons are counted until the third year, and their percentage compared to one-year seeds is lower at 20-30%. Formation of seedlings with only cotyledons is reported up to 7-8 years, and the reduction of their percentage compared to those from seeds in the year of production is between 50-60% depending on the variety. After this period no seedlings develop at all.

For one-year seeds, the vigor index for initial vegetative productivity is around 60-65, and after 7-8 years of storage, it drops to 3. The presence of these large differences indicates that this test has very good sensitivity and is suitable for vigor assessment. Moreover, when compared to other tests, a similarity in trends is found (Figure 8). The obtained curves between this test and for the other two tested (according to Elliot, 2001) and for one seed (Panayotov, 2010b) are similar. At the same time, a decrease in the test data for initial vegetative productivity occurs significantly earlier than those for germination and for the other studied tests, and it once again confirms its higher sensitivity. With a decrease in germination from the initial values by 20-30%, the vigor decreases by approximately 70%, and in the other two tests by 30 - 50%. All this shows that the decrease in vigor according to this test occurs earlier and is an excellent prerequisite for predicting seed deterioration.

Table 4. Vigor by Initial vegetative productivity of storage pepeer seeds (Panayotov,2013)

Vigor data for seeds from batches of different origins showed considerable variation between cultivars tested, with vigor index values ranging from 48.51 to 70.19 depending on cultivar, seed origin and seedling development (Table 5). This again shows the higher sensitivity of this test and obtaining real results. Also, from Figure 9 observed a trend match with other tests, as well as a preceding decrease in vigor versus germination and the results of other tests, proving the advantages of the Initial vegetative productivity of the vegetable seeds test and its sensitivity.

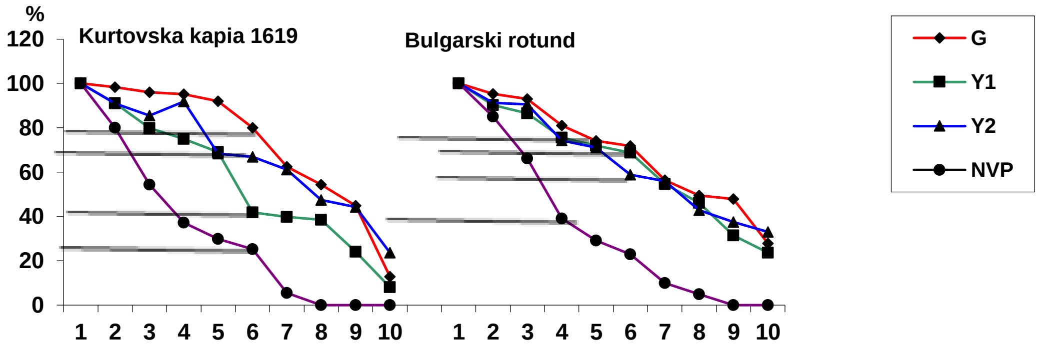

Figure 8. Changes of germination (G), vigour index of samples (У1), vigour index of one seeds (У2) and vigour index by initial vegetative productivity (IVP), (1-10 age of pepper seeds as Table 4) (Panayotov, 2013)

Non-invasive tests.

Evaluation of vigor without destruction of the seeds, i.e., so-called non-invasive tests, finds more and more application in increasing research in this area. Their importance increases because they are usually fast, very often automated, and mainly involve physical analyses of individual seed properties that are strongly correlated with vitality and vigor. In most cases, these are rapid tests and information on vigor is obtained at the time of examination. However, the use of these tests is still weak, insufficient and limited.

The application of UV light reveals the possibility of a non-destructive way of determining vigor based on the fluorescence. Placed under such light, the seeds react differently depending on their degree of vitality. Seeds that are vitality and have high vigor do not fluoresce. Evidence for the appropriateness of this test and the accuracy of the results Lee et al. (1997) found in their experiments with Chinese cabbage and radishes. Non-fluorescent i.e. live seeds of these two crops, in the investigation of this test, examined by the standard germination test showed germination rates of 97-98% and 84-87%, respectively. Radish seeds that had fluoresced, i.e. those that could be defined as dead, had a germination rate of only 4-7%.

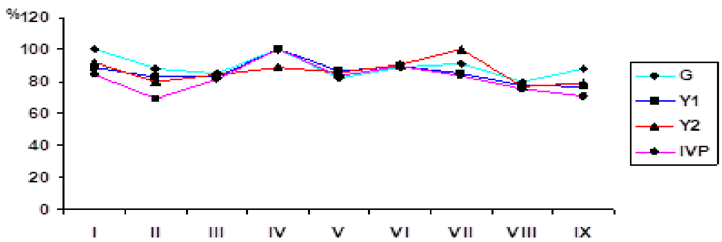

Figure 9. Trend of germinability (K), vigour index of whole sample (У1), vigour index of one seed (У2), initial vegetative productivity (IVP) of pepper seeds with different origing. (I -IX as in Table 5) (Panayotov, 2013)

The fluorescence has also been used by other researchers to assess vigor and seed sorting (Cicero et al, 2009). Jalink et al. (1998) reported a rapid and relatively accurate method for determining maturity, vigor and viability of whole seeds based on chlorophyll fluorescence data. The correlation between reducing the green color of the seeds and increasing their vitality is very strong. Vegetable crop seeds that showed a weak chlorophyll fluorescence signal had higher vigor and developed normal seedlings. The opposite is true for seeds with low germination, where the fluorescence signal is much stronger.

Dead seeds were found to release significant amounts of sinapin, amino acids, and proteins, while healthy and vigorous seeds with high vigor released minimal amounts of these constituents. On this basis, Lee et al. (1995) developed a new non-destructive test for vigor assessment.

Another guideline for non-destructive testing is the use of Near-infrared spectroscopy (NIR) combined with multivariate seed calibration. In advance, the seeds from the individual lots are separated and sorted into two groups: viable and non-viable using X-ray sorting. The NIR reflectance spectra are recorded using a fiber optic probe, and through various corrections (multiplicative and orthogonal) the systematic noises in the spectra are removed. The accuracy of seed separation in both groups using these models was almost 100%. The main source of spectral variation is seed moisture, but lipids and proteins also give their reflection to accurate separation. Predicting the physiological status of seeds by non-destructive NIR spectroscopy is rapid and has a high potential to eliminate non-viable seeds (Soltani et al., 2003).

Image diagnostics of seeds

X-ray vigor test.

The possibilities offered by radiographic studies to assess the potential and vigor of seeds are promising. Vigor tests developed on this basis are completely non-destructive and, most importantly, they are fast. The studies in this scope are new, they are implemented through the inclusion of smart technologies and are very promising due to the accuracy of the results and obtaining the information in a relatively short time. They mainly focused on the anatomical status of the seeds and above all the tissues of the embryo and endosperm and at the same time also showed deficiencies in the structures of the seeds, related to their vitality.

The possibilities of X-ray studies also have been evaluated by ISTA (2019), as in its rules it is emphasized that this method distinguishes full, empty, insect-attacked or physically damaged seeds by anatomy-morphological characteristics, as well as the ratio between them, visible on the radiographs. Suitable for imaging of small objects, such as the seeds of vegetable crops, are low energy (shorter wavelength) X-rays, low voltage mode (low kilovolt apparatus) which improves resolution and keep in mind that high mAs overexpose (darkenc) the image or these are the so-called "soft" X-rays apparatus. Exposure time is also important. The basis of this method is that different seed tissues, depending on their thickness and density, absorb X-rays to a different degree. The evaluation of on the X-ray picture is based on the internal anatomy of the seeds, dividing them into the groups indicated above.

The disadvantages of these tests are that they are expensive, require additional specialized equipment, and require prior training, both for preparing the X-ray and evaluating the results.

Chavagnat and Bastien (1991) emphasized the positive aspects of X-ray analyses that there was a very good correlation with high significance between the seed germination test and radiography. In this technique according to Burg et al. (1994), with the help of X-rays in tomato seeds, the anatomical and morphological changes in the seed sprouts, as well as the reasons leading to a decrease in vitality, primarily related to the status of the embryo and endosperm have been revealed.

According to Gomes-Junior et al. (2012) X-ray densitometric tests of seed status are non-destructive and should find wider application, considering, that assessment of seed anatomy is accurate and its relationship to germination and vigor is significant. An X-ray study of the internal anatomy of pumpkin, cantaloupe, and watermelon seeds a typical density profile of specific areas within the seed that could identify the causes of poor germination and low vigor of each seed has been registered.

To obtain a precise image Dos Santos et al. (2009) recommended a radiation exposure regime of 20 Kv for 1.5 min which revealed very well the anatomical profiles of tissues in the embryo and endosperm. According to the radiographic data, the seeds can be classified into the following groups by signs related to germination: full seeds, empty seeds, those with disturbed embryo and embryo cavities, and seeds with endosperm and inconspicuous embryos. The potential capabilities and reliability of the information from this test are demonstrated by the high correlation found with the data from the standard test.

Downie et al. (1999) established by X-ray analysis, the anatomical condition during individual stages of tomato seed development using a similar radiation regime of 15 kV and 2.5 mA for 1.5–3.0 min. X-rays are examined under a dissecting microscope, thanks to which this analysis makes it possible to establish differences in the structure and anatomy of the seeds associated with manifestations of vigor. As a result, three classes of seeds are formed: with an indistinguishable space between the embryo and the endosperm; with limited but noticeable space between the embryo radicle and the micropylar tip of the endosperm and/or cotyledons and endosperm; with a large space between the tip of the embryo root and the micropylar endosperm, and between the endosperm and the cotyledons.

The results of the X-ray analysis were also confirmed and proved on scanning electron micrographs of the same seeds (Figure 10). The seeds of the third group were found to occur more in mature fruits and show a distinct point at the most distal end of the root tip, but it is important that with them the required puncture force is smaller. Although the established availability of free spaces can serve as a diagnostic of seed development, the authors point out that further research is needed to create a predictive model.

Digital imagine analysis

The state-of-the-art techniques for determining seed potential and vigor are various computer seed imaging approaches. In this field, extremely active work has been done in the last two decades. Through them, much more extensive and accurate information about the morphology and biology of the seeds is obtained. This allows the improvement of the sorting and qualification processes of the individual lots. The automatically recorded data on some basic morphological characteristics of the seeds, such as size, shape, and color, related to germination evaluation, successfully complement those of the standard germination test and also allow the identification of cultivars and weed seeds.

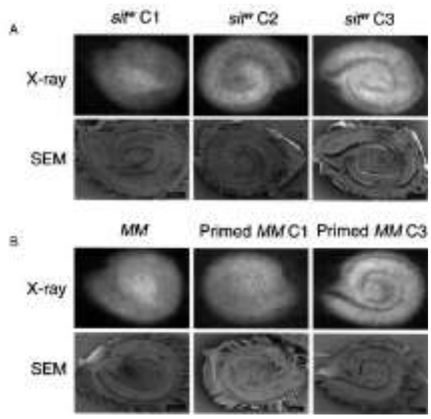

Figure 10. X-radiographs (upper panels) and scanning electron micrographs (lower panels) of tomato seeds (by Downie et al., 1999)

These tests are also associated with the application of computed tomography to study the internal morphology and function of the seeds. Developments are growing to integrate data from human assessment of seed status and the creation of computer vision in laboratories. Recently, a great deal of attention has been paid to interdisciplinarity in research, by combining information from digital images with that obtained from genomic and proteomic analyses, contributing to more accurate characterization of seeds using non-invasive methods and obtaining a more comprehensive view of seed research (Dell'Aquila, 2007).

Constantly looking for new opportunities to standardize tests, increase their accuracy, shorten the time for conducting them and improving the repeatability of information. For all this, the introduction of computer technology for establishing the status of the seeds provides very good opportunities. Research and implementation of these methods will increase. The results obtained so far on the images of seeds and seedlings are extremely significant and interesting, computerizing their morphological features and providing a direct, computerized assessment of vigor (Marcos-Fliho, 2015).

Among the first, according to Marcos-Fliho (2015), to introduce computer-based image analyses of seeds and seedlings based on embryo root length in carrot and lettuce was McCormac and colleagues (McCormac et al, 1990), as well as Howarth and Stanwood (1993) also with lettuce. Indisputably the greatest advance came when developed by Sako et al. (2001) automated the Seed Vigor Imaging System (SVIS®) with which they assessed lettuce seed vigor. In the images of seedlings, with the help of special software, the individual parts are identified and marked, and after computer processing, the length of the embryo root, the hypocotyl, the ratio between them and the entire seedling, as well as the vigor and uniformity of the seedlings are determined. Subsequently, this system was also applied to several vegetable crops, such as cucumbers and eggplants. Computerized image analysis systems are becoming increasingly sophisticated and based on SVIS®, the Seed Vigor Automated Analysis System (Vigor-S) was created, improving the efficiency and objectivity of the obtained vigor information. (Marcos-Fliho, 2015). Marcos-Fliho (2006) scanned 3- and 4-day-old melon seedlings and, based on the computer images, established vigor, such as the obtained results for vigor index, uniformity, and seedling length are comparable to data from tests already adopted.

Applying a number of tests, including the Seed Vigor Imaging System (SVIS), Peñaloza et al. (2005) points out that the SVIS data are objective and well distinguish the strong from the weak lots, and at the same time are in good correlation with those obtained from the salt saturate accelerate aging test and this gives them reason to recommend SVIS for a vigor assessment.

In addition, Zhang et al. (2022) also included multispectral analysis for vigor estimation as a new rapid and non-invasive method with high sensitivity and accuracy. 19 different wavelengths are used, and the information from morphological studies and that from multispectral for seeds of different maturity and age are analyzed and it is concluded that through multispectral imaging and multivariate analysis, vigor, viability, germination percentage can be accurately predicted of the seeds. To obtain the images, they use the multispectral imaging instrument VideometerLab4 (Videometer A/S, Herlev, Denmark).

The positive sides of this type of tests are that they are non-invasive, fast and with good accuracy, but the disadvantages are that they are expensive, involve specialized equipment, usually require the presence of large databases and require very good preliminary training of personnel.

RECOMMENDATIONS AND TASKS FOR FUTURE RESEARCH

Determination of seed vigor of vegetable crops is taking on a wider scope and it is gaining more and more importance, both in scientific research and in seed production, qualification, marketing and use of sowing material. Despite the great activity carried out up to this point, there are important questions that have not yet been fully resolved, and this necessitates the strengthening of scientific research first and, subsequently, for their implementation on a larger scale in practice. Vigor tests should become a routine and well-standardized method for seed quality in vegetable crops where seed production is much more specific, many varieties are heterozygous and more expensive. At the present stage, and in general, the accuracy of vigor tests depends a lot on the species specifics of the seeds. Similar are the guidelines outlined by McDonald (1993), Marcos-Fliho (2015) and Panayotov (2016).

The main tasks and recommendations in front of the the vigor test system of vegetable seeds are:

- Standardization of the existing and widely applied tests, with good repeatability, to eliminate some debatable and contradictory opinions about the meaning of germination, which is an indisputable basis for reflecting the vital potential of seeds and the role of vigor;
- Specifying the procedures, parameters and regimes of application of many of the tests, according to the species specificity of the vegetable seeds. To conduct scientific activities to avoid the indicated disadvanatges in the discussed vigor tests;
- Creation of internationally recognized protocols for the application of vigor tests, since some of them, regardless of their importance, lack them;
- Development of new, modern and perfect tests based on smart and information technologies, expansion of computerization of the process for assessment of vigor. They must meet the accepted requirements, especially in terms of accuracy, their relationship with germination and performance under field conditions, as well as provide the information in a short time (rapid tests) and be associated with minimal financial investments;
- Expanding the training of specialists and analysts, starting from the university education system, as well as through additional courses;
- Deepening interdisciplinary research, including more and more fields of science to create vigor methods and to evaluate the overall potential of seeds;
- Upgrading the understandings and perceptions of the philosophy, essence, biology and meaning of seeds based on new discoveries and information from modern branches of science, such as digital and imaging methods for diagnostics, biophysics, biotechnology and molecular biology in general;
- Inclusion of more broadly of molecular and cellular markers. By in-depth insight into the physiological and biochemical processes of the seeds and above all the protective mechanisms of the seeds related to the change in the activity of some enzymes leading to the deterioration of the seeds. The deterioration of the seeds, as stated above, is associated with changes at the cellular level, of DNA and impaired cell replication, and this is a prerequisite for deepening the molecular analyses;
- Revealing the relationship with changes in protein profiles and especially the possibilities of removing and suppressing free radicals, largely responsible for seed deterioration;
- Applying chlorophyll fluorescence increasingly to identify the status of seeds and especially their maturity, since the presence of chlorophyll in mature seeds limits the manifestations of vigor;
- To look for methods and means for numerical and quantitative expression of the vigor;
- A very important task is the development of predictive models for the changes occurring in the seeds and increasing the predictability of the various processes related to decreasing the seed's quality and opportunities to take proper preventive measures to avoid them;

- Establish regional and international scientific groups to conduct periodic forums for cooperation, create programs, refine the research and improve technical support.

CONCLUSIONS

Undoubtedly, the evaluation of the vigor of the seeds of vegetable crops is of great importance and complements very seriously the understanding of the overall biology and the essence of the seed its upward historical development also speaks for this.

Research on seed vigor is being deepened by incorporating different and modern branches of science to create more accurate and widely applicable tests in many species of seeds.

The understanding of the essence and concept of vigor is improving, both in scientific circles and among growers and traders, who are showing much greater interest and attention to this very important characteristic of the seeds. However, its application at the current stage is not the required level, and the biggest challenge in front of the vigor is the standardization of the tests and they to be applicable in many crops.

Vigor is designed to compare the quality of individual batches of seeds. Starting from the definition of vigor, its assessment should be based on data from research in different scops, Thus, in a much more comprehensive way, the processes taking place in the seed will be understood in depth, and its manifestations in field conditions will be revealed more fully.

For the seeds of vegetable crops, at the current stage the following tests are more suitable and more widely applied: Accelerate aging, Electrical conductivity, Tetrazolium and Initial vegetative productivity of the vegetable seeds, but with great prospects are also X-ray vigor test and Digital image analysis

Deepening the studies on the vigor of vegetable seeds, revealing more and more of its features, and improving the tests and their wider introduction into practice are a good prerequisite for the near future for vigor to become, along with the currently existing criteria, as a mandatory element in quality and standardization of vegetable seeds and to determine the minimum requirements that individual lots must meet worldwide.

ABSTRACT

In the present the effect of ultrasound on the sowing parameters of seeds from Zinnia elegans Jack. was studied. The experiments were carried out in the Department of Horticulture at the Agricultural University-Plovdiv, Bulgaria with three different varieties of this species. The seeds were treated with ultrasound for 2, 4, 6 and 8 minutes. The seeds were placed for germination according to the prescription of ISTA Rules. The following indexes were investigated: germination energy (first count) germination (final count), length of embryo root and hypocotyls as well as fresh weight of seedlings were observed. The mean germination time, uniformity of germination, and time of 50% germinated seeds were calculated. The highest increase of germination energy and germination was registered in variants 2- and 4-minute ultrasound. The differences with controls were between 1.0% and 25%. The highest correlation coefficients between the length of embryo root and hypocotyls were established. The regression analysis performed between germination and periods for sounding was registered and shows that there are polynomial dependencies with high determination coefficients.

Keywords seeds, energy of germination, germination, mean germination time, seedlings

INTRODUCTION

Zinnia is a widely used garden plant, both for landscaping in parks and gardens and for cut flowers. One of the difficulties encountered in its cultivation is related to its low sowing qualities and poor seed germination (Thamayanthi et al., 2011; Zamiran et al, 2013). Similar conclusions were formulated by Afzal et al. (2016), pointing out that from an agronomic point of view, one of the promising ways to overcome these disadvantages in zinnia seeds is their pre-sowing treatment.

Studies have been conducted to treat seeds of this crop with various agents. Ahmad et al. (2017) recommends the chemical treatment of zinnia seeds. Treatment with aqueous solutions of various compounds causes an improvement in sowing qualities. The best results were reported for seed treatment with calcium and potassium chloride, especially on germination and on the time to germination of 50% of the seeds.

According to Szopińska and Dorna (2023), the application of microwave irradiation to zinnia seeds can be used as an alternative to standard chemical seed treatment. In their experiments with zinnia seeds, they found that the strongest improvement in seed status was obtained with microwaves with an output power of 650 and 750 W. Rifna et al. (2019) point out that the use of ultrasound has a very positive effect on improving germination processes. Treatment of zinnia seeds with four different magnetic strengths of 15, 100, 400 and 800 μT showed that the best germination and emergence was found at 400 μT (Zamiran et al, 2013). Afzal et al. (2016) also found a high efficiency of physical treatment of seeds of this species with a magnetic field. The most significant increase in germination and seedling growth was obtained using 100 mT for 15 minutes.

Regarding soil contamination, Thamayanthi et al. (2011) reported that inhibition of zinnia seed and plant development was observed in the presence of cadmium. Rasool et al. (2020) investigated different ways of treating zinnia seeds. Hydro-priming with 3% moringa leaf extract significantly increases germination, accelerates sprouting and increases the length of the embryonic root. Treatment with magnetically treated water also showed a stimulating effect on the germination of 50% of the seeds, germination and plant development. The effect of combining these two methods of processing is much more significant, as the processes of germination and plant development, as well as yield characteristics are greatly improved.

To increase seed viability, Yaldagard et al. (2008) recommend using ultrasound. Khmelev and Popova (1997) point out that with such processing the seeds should not be more than 30% of the volume of water, and the duration of exposure is especially important. The importance of sonication time is also emphasized by Goussous et. al. (2010). Studies on the application of ultrasound for the treatment of zinnia seeds are very limited or almost non-existent, which determined the purpose of this study. The main aim of the present study was to determine the effect of sonication of zinnia seeds on their sowing qualities.

MATERIAL AND METHODS

The experiments were carried out in the scientific laboratory of the Department of Horticulture at the Agricultural University-Plovdiv, Bulgaria with three zinnia varieties Giant bright red, Giant white and Giant purple. Seeds were sonicated for 2-, 4-, 6-, and 8-minute. Untreated seeds were used as controls. The treatment was carried out with an Ultrasonic bath Nahita, 620-1 of the company Auxilab, S.L., Spain with parameters, frequency 40 KHz and volume 0.6 L.

For the germination test, seeds were placed in 10 cm Petri dishes lined with Watman 1 filter paper moistened with 5 ml of water. Experiments were carried out in four replicates with 100 seeds each, following the ISTA (2013) requirements.

Germinating energy (first cont|) and germination (final count) were recorded, and at the moment of germination determination, the length of the embryo root and hypocotyl on 15 seedlings from each replicate was measured. The fresh weight of a seedling was determined by measuring all the seedlings and dividing by their total number. Mean germination time (MGT) and uniformity of germination were calculated (described by Panayotov, 2015). The time for germination of 50% of the seeds was found by the equation of Farooq (2005). The correlation dependences between the fresh mass of the seedling and the length of the embryo root and the hypocotyl were determined. The regression relationship between the duration of ultrasound treatment and germination was established and the results were processed to ANOVA (Fowel and Cohen, 1992)

RESULTS AND DISCUSSION

In Table 1 the data on germination energy and germination of zinnia seeds after sonication is presented. The germination energy of the control seeds, depending on the variety, ranges from 14.3% for Giant white to 16.0% for Giant bright red. As a result of the action of the ultrasound, it increases to the variant of 4 minutes in all three varieties. The data between the three varieties are close, with the highest values of 21.3% reported for Giant bright red. The increase is between 5 and 7%. Stronger suppression was found after 6 and 8 minutes of exposure, except for Giant purple seeds. The reduction is in the range of 4-5%. Germination energy indicates the amount of earlier germinated seeds that have better viability (Panayotov 2015). In this sense, it can be seen that in the zinnia these seeds are relatively few.

For a more complete assessment of seed status, germination was used (Black et al., 2006). A similar trend as for sprouting energy is observed for this indicator, but at the same time, there is also a varietal reaction. The largest increase for Giant bright red with 14.66% and for Giant purple with 25.33% was found at 4 minutes of sonification. In the case of the Giant white variety, maximum values were registered at a lower duration of 2 minutes, and the increase compared to the control was 9.33%. At 6 and 8 minutes, germination slightly decreased, more pronounced for Giant purple, followed by Giant bright red.

The effect of ultrasound is debatable. One of the most widespread opinions is that during seed sonication, as a result of the waves, the pores of the seed coat are enlarged (López-Ribera and Vicient, 2017; Aladjadjiyan, 2007). In this way, the uptake of water and oxygen is accelerated, which has a positive effect on germination (Nogueira et al., 2024). This researcher also points out that this processing has a great influence on biochemical and molecular processes, especially on the breakdown of starch and activation of the enzyme α-amylases in the endosperm.

Chen et al. (2023) also emphasized the presence of cracks on the seed coat, which causes accelerated water absorption and its immobilization in the seed. In addition, the presence of changes in the metabolism of the seed, such as an increase in protease, amylase, lipase and peroxidase activity and especially phenylalanine ammonia lyase, as well as the accumulation of phenols and an increase in antioxidant activity, is also discussed. It can be assumed that the reported stimulation of zinnia seed vigor is related to the occurrence of these changes. The data for germination are statistically proven.

Table 1. Viability parameters of zinnia seed after treatment with ultrasound

Variants	Germination energy (%)			Germination (%)		
	Giant bright red	Giant white	Giant purple	Giant bright red	Giant white	Giant purple
Control	16.0	14.3	15.3	80.0	80.0	69,33
2 min.	19.7	18.3	19.3	93,33	89,33	86,66
4 min.	21.3	21.0	20.0	94,66	82,66	94,66
6 min.	17.7	16.0	20.0	92.0	82,66	92.0
8 min.	17.7	16.3	20.0	89,33	80.0	88.0
LSD p= 0.05%	3,3	2,0	4,1	8,2	7,5	11,2

The regression relationships between exposure and germination (Figure 1) confirm the indicated changes in germination, the dependence is of a polynomial type with high coefficients of determination for the varieties Giant bright red and Giant purple, respectively R^2= 0.89 and R^2= 0.97, and for Giant white the coefficient is average with R^2=0.44. These coefficients of determination show that in 44 to 97% of cases, sonication of zinnia seeds will produce the indicated trend. Using these coefficients, the influence of the factorial variable on the variation of the resulting variable can be determined.

Using the germination time of 50% of the seeds, a more complete assessment of their qualities is obtained (Trayanov 2021). The values of this indicator for zinnia seeds vary between 2 and 4 days (Table 2). The shortest period to reach 50% germination was observed with sonication of 4 minutes. The difference compared to untreated seeds, depending on the variety, is 2 days for Giant white and Giant purple and 1.33 days for Giant bright red. Weak inhibition was observed for the 6 and 8-minute variants, with an increase in this period of approximately one day. It can be pointed out that the variety's responsibility, in contrast to germination, is weaker or almost absent here. The lowest results are reported for the 8-minute option.

Improvement of this parameter in the pre-sowing treatment of zinnia seeds was reported also by Rasool et al. (2020) and Afzal et al. (2016).

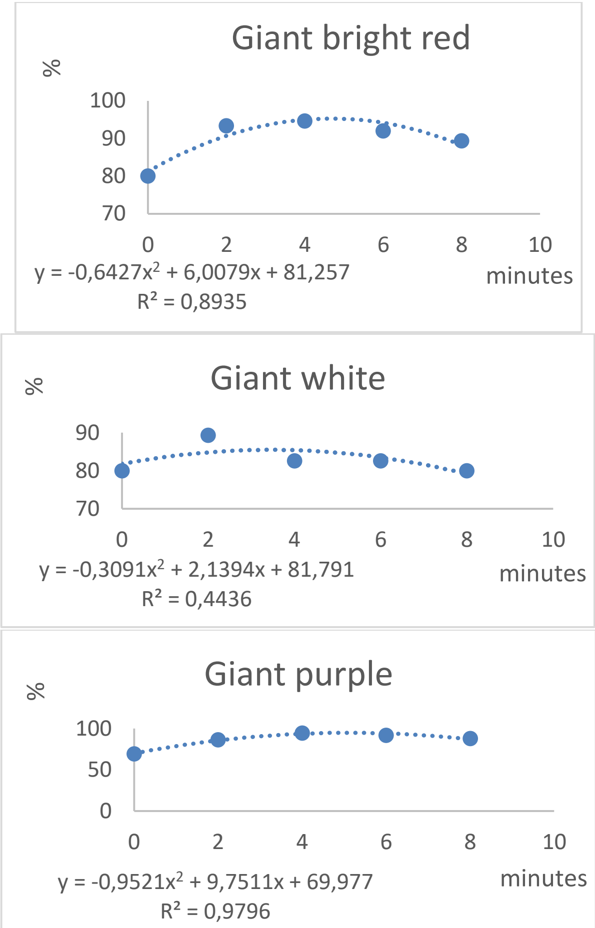

Figure 1 . Regression dependence of germination and the duration of ultrasound treatment of zinnia seeds

Table 2. $T_{50\%}$ germination of different zinnia varieties after ultrasound treatment (days)

Variants	Giant bright red	Giant white	Giant purple
Control	3,33	4.0	4.0
2 min.	2,66	2,66	3,33
4 min.	2.0	2.0	2.0
6 min.	2,33	2,66	3.0
8 min.	3.0	2,66	3.5
LSD p= 0.05%	1,2	1,4	1,6

To more fully trace the impact of ultrasound, it is appropriate to determine the mean germination time (Table 3). Seed treatment reduces the time required for seed germination in almost all exposures and cultivars. In the shortest time, the seeds germinated at 4 minutes of sounding for the variety Giant bright red, followed by Giant purple, and the differences compared to the control were 0.96 and 1.53 days, respectively. After this variant, the values decrease but are still higher than those of untreated seeds except for the Giant white variety at 6 and 8 minutes.

The effect of sounding is also established on uniformity, which indicates the simultaneity of germination, which is a prerequisite for easier seed germination. The seeds treated for 4 minutes showed the greatest uniformity of germination in all three varieties. The largest difference compared to the control was found in Giant purple, almost 7%, followed by the seeds of the other two varieties, for which the increase was 3.5%. Increasing the period of sounding leads to weak inhibition especially at 8 minutes, except the variety Giant purple. In Giant white, suppression was also observed at 6 minutes of ultrasound.

Table 3. Sowing indexes of zinnia seed after treatment with ultrasound

Variants	Mean germination time (days)			Uniformity of germination (%)		
	Giant bright red	Giant white	Giant purple	Giant bright red	Giant white	Giant purple
Control	3,35	3,37	4,09	14.0	14.7	11.0
2 min.	3,12	2,94	3,28	14.8	15.3	14.3
4 min.	2,41	2,80	2,56	17.4	18.3	18.1
6 min.	3,26	3,48	3,02	16.6	13.3	15.3
8 min.	3,10	3,41	3,49	13.3	13.9	14.5
LSD p= 0.05%	2,0	1,9	1,2	2,2	2,6	3,0

The morphological features of the sprouts describe their development very well and complete the picture of the vital status of the seeds and the possibility of normal formation of young plants. The data are shown in Table 4. Stronger embryo root developed after sounding the seeds of Giant bright red (4.97 cm) for 4 minutes, while for the other two varieties, it was at 2 minutes, respectively 4.41 cm for Giant white and 4.51 cm for Giant purple. The increase in its length over the control was between 20.91% (Giant purple) and 87.8% (Giant bright red). The two higher exposures caused inhibition except for the Giant bright red variety.

Hypocotyl length was greatest after exposure to 2 minutes of ultrasound. Maximum values were measured for Giant purple, which is 52.68% above the control, followed by Giant white with an increase of 14.8%. All the tested durations of ultrasound treatment promote stronger development of the hypocotyl, compared to untreated seeds, except the variety Giant white, in which inhibition is established as early as 4 minutes. Both embryo root and hypocotyledon length decreased uniformly after 2 min of exposure.

The fresh weight of a seedling (Table 5) is an important indicator of its morphological development. It is directly related to vigor, which also determines the possibility of further development of young plants (Panayotov, 2016). In all exposures, the application of ultrasound increased fresh weight. The highest values for all three tested cultivars were recorded for processing for 4 minutes. Giant white seeds developed the largest weight – 0.95 mg or 86.26% more than the control. In the other two varieties, the weight was 0.64 mg and 0.68 mg for Giant bright red and Giant purple, respectively, and the increase compared to untreated seeds was approximately between 25 and 30%. At 6 and 8 minutes, a stimulating effect is also found, but weaker than for the 4-minute option. As the seed sonication time increased after 4 min, a uniform decrease was observed. Improvement of the morphological seedling development after the pre-sowing treatment of the zinnia seed establishes also Afzal et al. (2016).

Correlational dependences were established between the length of the embryo root and the hypocotyl to the fresh weight of the seedling. A stronger relationship is found for hypocotyl length, the correlation being strong and positive with a coefficient of r=0.67 to r=0.96. Embryo root length has a weaker influence, where the correlation is also positive but weak to moderate.

Table 4. Morphological characteristics of of zinnia seed after treatment with ultrasound

Variants	Length of embryo root (cm)			Length of hypocotyl (cm)		
	Giant bright red	Giant white	Giant purple	Giant bright red	Giant white	Giant purple
Control	2,93	3,32	3,73	2,20	4,22	3,91
2 min.	4,20	4,41	4,51	3,27	4,83	5,97
4 min.	4,97	3,47	4,37	3,27	3,90	5,63
6 min.	4,30	2,60	3,47	2,43	3,80	4,50
8 min.	4,70	1,97	3,07	2,42	3,17	4,42
LSD p= 0.05%	2,6	2,8	1,5	1,6	1,8	2,2

Table 5. Fresh weight of one sprout of different zinnia varieties (mg)

Variants	Giant bright red	Giant white	Giant purple
Control	0,51	0,51	0,46
2 min.	0,51	0,91	0,58
4 min.	0,64	0,95	0,68
6 min.	0,61	0,62	0,61
8 min.	0,58	0,62	0,56
r*	0,21	0,57	0,53
r**	0,96	0,75	0,67
LSD p= 0.05%	0,3	1,4	2,0

r* - correlation between fresh weight and length of embryo root,
r** - correlation between fresh weight and length of hypocotyl

CONCLUSIONS

Ultrasound treatment of zinnia seeds has a strong influence on their sowing qualities. The highest germination energy and germination were found after the application of exposure of 2 and 4 minutes. A polynomial relationship with high coefficients of determination was established between processing time and germination.

The strongest positive effect on the germination time of 50% of the seeds, as well as the mean germination time and uniformity, is also found at 4 minutes of ultrasound.

Seedlings from seeds treated with ultrasound have improved vegetative development, with the length of the embryo root and the fresh weight of one seedling being the highest when applied for 4 minutes, and for the hypocotyl-exposed for 2 minutes.

To improve the sowing qualities of zinnia seeds for practice, it is recommended to apply ultrasound treatment for 4 minutes.

ABSTRACT

Cherry fruit is a drupe which is highly appreciated by consumers. Many cultivars have been developed around the world, based mainly on physical characteristics, such as size and color. Not all cultivars are suitable for a specific region and trials should be made before deciding which cultivar is best suited for this specific pedoclimatic conditions. Tweleve cultivars grown in the same are, Arnissa, Western Greece, were assessed for their physical, organoleptic and phytochemical characteristics. Fruits were provided by the Co-operative of Arnissa and were harvested at the commercial maturity of each cultivar. Cultivars assessed were “Samba”, “Kordia”, “Lapins”, “Germesdorfer”, “Grace Star”, “Durone Nero III”, “Crystallina”, “Regina”, “Skeena” and local ones such as “Opsimi”, “Tragana Edessas” and “Evlogimeno” while samples of “Regina” (REGA) from a specific location in the area were also assessed. Physical characteristics measured were fruit weight and size (diameter (wide and narrow), length and flesh weight, as well as skin color, expressed as Hue angle and Chroma indexes). Furthermore, total soluble solids, pH and titratable acidity were assessed in the pulp as well as total phenols, total flavanols, total flavonoids and antioxidant capacity, based on Diphenyl picryl hydrazyl (DPPH) and ferric reducing antioxidant power (FRAP) assays. Results indicated that there were significant among cultivars regarding the measured parameters. Principal component analysis indicated that “Tragana Edessas” as well as “Durone Nero III” were distinguished from the other cultivars based mainly on their phenol content and antioxidant capacity. The highest fruit weight was determined in “Durone Nero III” and “Crystallina” fruits, while “Durone Nero III” also presented the highest total soluble solids, in contrast to “Evlogimeno” and “Germesdorfer” which presented the lowest. These significant differences among cultivars should be taken into account, along with the maturity period and tree load when someone needs to select the proper cultivar or cultivars for specific pedoclimatic conditions.

Keywords: antioxidant capacity, cherry, organoleptic characteristics, phenolic compounds

INTRODUCTION

Sweet cherry is a highly valued premium food product with high market prices, highly appreciated by consumers and of high commercial importance in many countries in the world (Ricardo-Rodrigues et al. 2022). Among the factors determining consumer’s appreciation are the fruit size and color and sweetness (Serrano et al. 2009). The total soluble solids (TSS)/titratable acidity (TA) ratio has an important impact on the perception of sweetness and flavour, and therefore on the overall acceptance by consumers (Crisosto et al. 2003). Nowdays people seek not only pleasent taste in a fruit but also functional properties which may reduce incidence of degenerative diseases due to their antioxidant potential (Kris-Etherton et al. 2002). Substances that are responsible for the antioxidant properties of the fruits are mainly ascorbic acid, polyphenols, tocopherols, carotenoids etc. Cherry fruit is rich in anthocyanins, which, as part of the polyphenol group, play an important role in the antioxidant property of the fruits as well as in fruit color.

Nonetheless, the organoleptic, nutritive and functional properties of the fruit differ among cultivars (Serrano et al. 2009) and depend on many factors such as vary the maturity stage of the fruit, the cultural practices, and environmental factors (Aglar et al. 2023).

The aim of the present research was to assess the physical, organoleptic and functional properties of the fruit of several sweet cherry cultivars, cultivated under the same pedoclimatic conditions and similar cultural management (as possible as it can be), all harvested at full maturity stage, ripe ready to eat.

MATERIAL AND METHOD

The trial was conducted at the Agricultural Co-operation of Arnissa, Central Macedonia, Greece (Figure 1). The fields were located near the lake Vegoritida, which offers mild weather conditions, suitable for cherry growing.

Twelve cherry cultivars were selected (Table 1), located in seven different farms, cultivated by four different farmers. The cultivation management applied was similar to all farms, based on information received by the farmers. Nonetheless, “Regina” fruits were selected by a second farm too (REGA) in order to assess if the specific pedoclimate conditions and cultural management of the farmer may play a significant role in fruit’s properties. Fruits were harvested at ready to eat maturity stage by the farmers and send to the laboratory within the day.

Table 1. List of the cultivars assayed.

Crystallina (CRY)	Grace Star (GS)	Regina (REG)
Durone Nero III (DN3)	Kordia (KOR)	Skeena (SK)
Evlogimena (EVL)	Lapins (LAP)	Tragana Edessas (TRA)
Germesdorfer (GRS)	Opsimi (OPS)	Samba (SB)

Malformed fruits or fruits sowing any symptoms of wound were discarded and the rest of the fruits were assessed for their physical, organoleptic and functional properties.

Fruit size (diameter – wide and narrow - and length) was determined with a digital caliper, fruit weight with an electronic balance and skin color with a Minolta Chromameter.

Figure 1. Location of Arnissa village, where the trial took place.

Fruits were de-stoned and the flesh was then homogenized with a home-homogenizer and the pulp produced was put in falcons tubes and stored in the freezer till analysis, which were all were done according to Roussos et al. (2022). The total soluble solids (TSS) of the pulp were measured with a digital refractometer, pH with a pH-meter and total acidity (TA) with titration, on the de-freezed pulp. Total phenols, total flavanols, total flavonoids, and the antioxidant capacity of the fruit (based on two assays, the Diphenyl Picryl Hydrazyl (DPPH) assay and the Ferric Reducing Antioxidant Power (FRAP) assay) were determined after pulp extraction with 100% methanol, twice in a water bath at 45^{o}C with periodical stirring, for 45 min each time. The extracts were centrifuged and the supernatant was used for the determination of the functional properties of the fruit as described by Roussos et al. (2022). The total phenols were expressed in mg gallic acid per g of fresh weight, the total flavanols in mg catechin per g of fresh weight, total flavonoids in mg catechin per g of fresh weight and antioxidant capacity in μmol Trolox per g of fresh weight, for both method assays.

The trial was conducted as a completely randomized design with three replications and the data were analyzed as a one-way Anova and the significant differences were determined based on Tukey HSD test at a=0.05. Principal component analysis also took place in order to describe cultivars relation using fewer variables.

RESULTS AND DISCUSSION

Fruit weight varied among cultivars, with the lowest being determined in TRA and the highest in CRY and DN3, reaching high values, higher than that reported for other cherry cultivars by Lanauskas et al. (2023). The same stood also for fruit size (diameters and length) as well as for the flesh weight. It is notable that Regina (REG and REGA) did not present significant differences, although they derived from different orchards, indicative that some traits of the cultivar are not influenced by cultivation management. Nonetheless, the color differed significantly, both between REG and REGA as well as among cultivars. The highest Hue angle was detected in SK fruits while the lowest in SB. The Chroma index was highest in OPS and lowest in KOR. Similar differences among cultivars have been detected by other researchers too, indicating that the genotype has an important influence on the physical traits of the fruit (Dever et al, 1996, Girard and Kopp, 1998. Lanauskas et al. 2023).

Table 1. Physical characteristics of the various cultivars assayed.

Significant differences among cultivars were also detected regarding organoleptic characteristics. The pH value was lowest in SK and highest in REG, which presented significant difference from REGA. pH values ranged from 2.24 to 2.80, lower than that described by Seradilla et al (2012) probably a result of different pedoclimatic conditions and of course genetic material. The TSS was highest in DN3 and lowest in OPS ranging from 13.30 to 25.17, similar to that reported by Dangi et al. (2024), Serrano et al. (2009) and Lanauskas et al. (2023). The titratable acidity ranged from 0.80 in TRA to 1.59 in SB, higher than that reported by Dangi et al. (2024) who also reported higher values of TSS:TA ratio but similar to that reported by Serrano et al. (2009) and Serradilla (2012). In our experiment this ratio ranged from 10.71 in OPS to 24.91 in TRA, indicative of the influence of the genetic material.

There were significant differences among cultivars concerning the functional properties of the fruit, as indicated in Table 3. The highest total phenols were determined in the fruit of TRA followed by those of DN3, while the lowest in GRS. Similarly, TRA presented the highest total flavanols and total flavonoids concentration while the lowest were determined in GRS. The total antioxidant capacity of the fruit according to the DPPH assay was highest in TRA and lowest in GRS which also presented lowest FRAP values. Differences in the total phenolic content and antioxidant capacity among cultivars have been found by other researchers too, indicative of the effect of the genetic material on the functional properties of the fruit (Serrano et al. 2009; Serradilla et al. 2012; Dangi et al. 2024). It must be noted though, that REG and REGA presented significant differences regarding total flavanols, total flavonoids, DPPH and FRAP activities, which clearly indicate that the cultivation management plays also a significant role, among other factors.

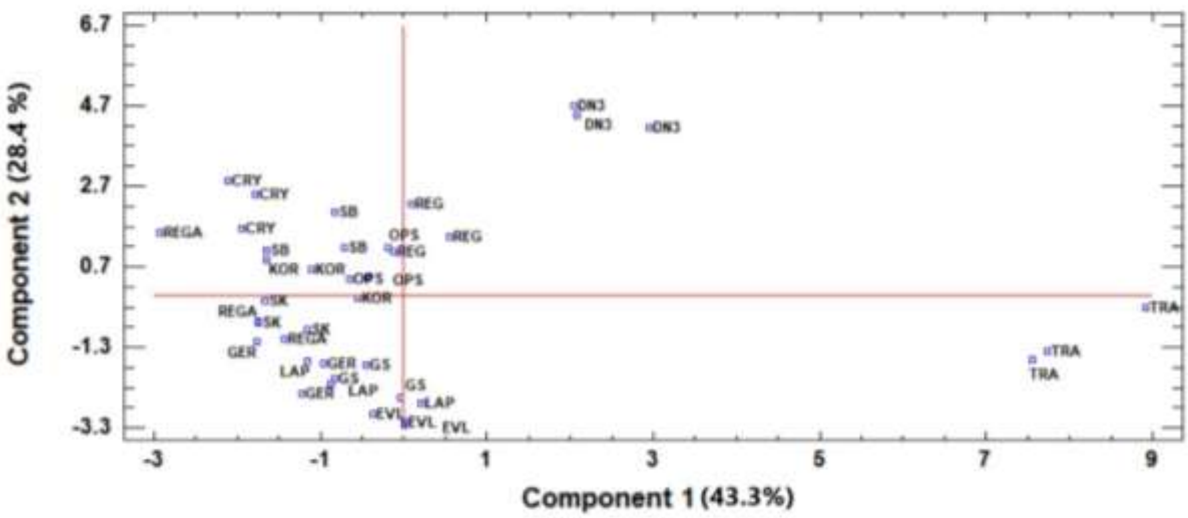
Means within the same column followed by the same letter do not statistically differ based on Tukey HSD test at α=0.05.

The principal component analysis (Figure 2) presented interesting results, as TRA was clearly separated from the other cultivars as well as DN3, while REG and REGA were also separated, indicating that the genetic material is not the only factor influencing fruit physical, organoleptic and functional properties.



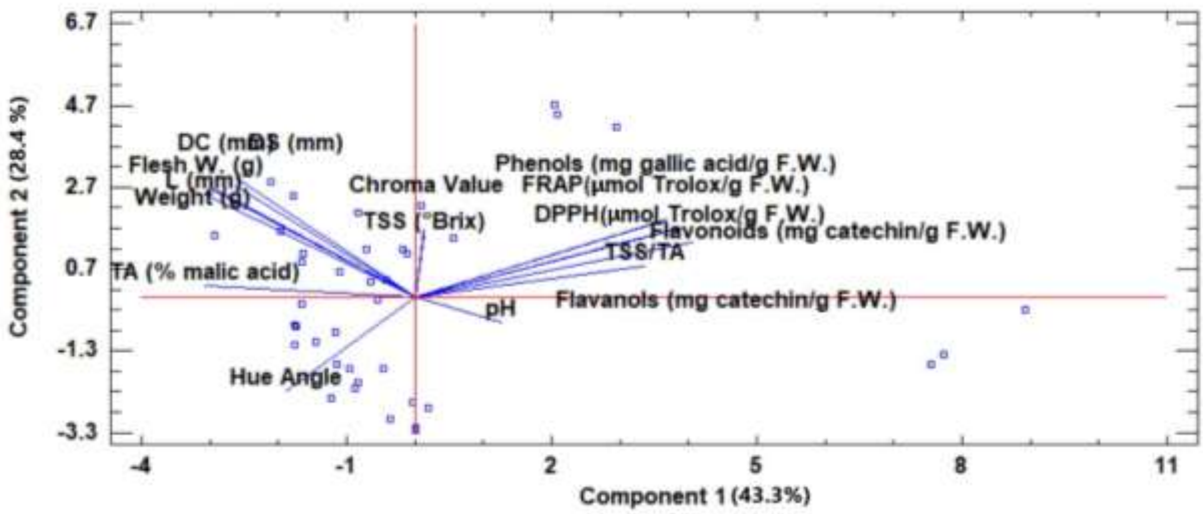


Figure 2. Scatterplot (above) and plot of components (below) of the principal component analysis taking into account all measured variables.

CONCLUSIONS

Based on the present study, it became clear that there are significant differences among cultivars regarding all three physical, organoleptic and functional properties. Unfortunately, the attractive appearance of a fruit does not always accompanied by the best functional properties, as it was clearly indicated by the data presented. It was also clear that the genetic material is not the only factor influencing the fruit traits studied here, as the same cultivar, deriving from two different orchards, presented both similar as well as different fruit characteristics.

ABSTRACT

The olive oil industry is considered one of the most important sectors in agriculture, especially for the countries in the Mediterranean basin. One of the key challenges the sector faces is the recycling and use of olive mill wastes. The aim of this trial was to investigate how a mixture of a soil amendment with olive mill waste can be utilized in olive groves. Olive mill waste derived from a two-phase olive mill was mixed with attapulgite and applied as a soil amendment to mature, bearing olive trees of the cultivar "Megareitiki," grown under rainfed conditions. The application was made in early spring, and the two constituents were mixed in a 1:1 ratio. The mixture was applied at a rate of 8 kg per tree. Untreated trees served as controls, while a third treatment involved the soil application of attapulgite at a rate of 4 kg per tree. At harvest in early November, the length of annual shoot growth was measured, and the trees were individually harvested and their yield measured. A sample of approximately 1.5 kg of olive fruits was used for oil extraction in an Abenchor-type laboratory olive mill to determine oil percentage. The olive oil produced was assessed for acidity, peroxide number, UV absorbance (K values), polyphenols, and antioxidant capacity. At the same time, soil samples were taken from 0-30 cm and 30-60 cm depths to assess soil physicochemical properties, and leaf samples were taken to assess tree nutrient status. The treatments did not have any significant effect on shoot growth (ranging from 15.2 to 16.4 cm), yield, olive oil percentage, or oil quantity per tree. Olive oils produced under the different treatments were all classified as Extra Virgin Olive Oil based on the measured variables, with none of the treatments having a significant effect on them. The addition of attapulgite resulted in higher concentrations of N-NO_3, B, and Na in the soil (0-30 cm), while the mixture of olive mill waste and attapulgite resulted in higher P and Mn concentrations. At the depth of 30-60 cm, higher P concentrations were found in the control and attapulgite treatments, while higher Fe concentrations were found in the control. Attapulgite addition to the soil resulted in higher B and Mn, while the application of the mixture of olive mill waste plus attapulgite increased the concentration of N-NO3. In the leaves, the addition of the mixture resulted in a significant increase in P and Mg, with no other differences observed. It seems that olive mill waste can be used in a mixture with attapulgite to increase some minerals in the soil without affecting olive tree production or olive oil quality. However, a longer experimental period is required to fully understand the possible effects of this mixture on both soil properties and leaf mineral nutrient concentration, yield, and olive oil properties.

Keywords: nutrients, olive oil, phenolics, soil properties

INTRODUCTION

The olive tree is the iconic tree of Mediterranean basin, highly appreciated not only for the nutritional value of its product, but also for its tolerance against abiotic stress factors, such as salinity and water stress (Denaxa et al. 2020). Olive oil is considered as one of the basic ingredients of a healthy diet, and its value is worldwide recognized. During the olive oil extraction though a significant amount of wastes are produced. The olive mills that are nowadays operating to extract the olive oil from the fruit are categorized as two-way and three-way mills, based on the number of phases produced at the end of the oil extraction procedure. The two-way olive mills apart from the olive oil, produce also a fluid mixture of olive paste residues (consisted of olive pulp and stone as well as water and water soluble substances, among others). This waste is extemely difficult to handle without any environmental concerns. A lot of research has been focused on the exlpoitation of olive mill wastes (OMW), exploring various methods of making this waste a valueable product (Chatzistathis and Koutsos, 2017).

The aim of the present trial was to investigate the possibilty of using OMW in a mixture with attapulgite, in order to be able to use it as soil amendment in olive trees.

MATERIAL AND METHOD

OMW deriving from a two-phase olive mill was used in the present trial along with attapulgite (AGLEV SI 100, GeoHellas, Greece). The attapulgite was selected after an initial trial in various test plants in pots (spinach, strawberry, olive trees, lettuce, pelargonium) where zeolite and attapulgite were tested in various ratios with OMW and the growth of the plants as well as signs of toxicity symptoms were assayed (data not presented). The trial was conducted at the Pure Olea Estate and Olive mill olive groves in Viotia county central Greece (Figure 1). The OMW was mixed with attapulgite in a ratio 1:1 and the mixture was applied in mature, rainfed, productive olive trees cv "Megareitiki" at a dose rate of 8 Kg per tree in early spring. Attapulgite applied alone at a dose rate of 4 Kg per tree was the other treatment, apart from the control.

At harvest, each tree was separately harvested and the production was weighed. At the same time the length of new shoot growth was measured on at least ten shoots per tree. Then a sample of at least 1.5 Kg of olive fruits were transferred to the laboratory where they were processed in a laboratory olive mill (Callis Company, Athens, Greece) and the olive oil percentage was calculated. The paste was put in the mixer for 35 min under 26±2 ^{o}C and afterwards centrifuged for 3 min. The olive oil was collected and stored in 50 mL falcon-type tubes, filled to the top to minimize air presence till analyses. The olive oils were analyzed for free acid concentration (expressed as a percentage of oleic acid), peroxide value (expressed as meq. O_2/kg oil), and specific extinction values (K232 and K270) based on EU Commission Regulation N 2568/91/EEC (Commission 1991). Polyphenols were isolated through liquid-liquid extraction with methanol/water (80: 20 v/v) solution (Cecchi et al. 2018). The total phenols (TPHEN, as mg gallic acid equivalents Kg-1 oil), the total o-diphenols (oDs, as mg caffeic acid equivalents Kg-1 oil), and the total flavonoids (FLOIDS, as mg caffeic acid equivalents Kg-1 oil) antioxidant capacity (as μmol Trolox Kg-1 oil) based on the diphenyl picryl hydrazyl assay (DPPH) and on the ferric reducing power assay (FRAP) were determined according to Roussos et al. (2009).

Soil sampling took place in November from three different places per plot in a "W" pattern (nine soil cores per orchard) by the use of a 5 cm diameter auger to a 30 cm depth after removal of the aboveground biomass. At the same time nearly 40 healthy leaves were collected around the canopy of each sampled tree, at a height of approximately 1-2 m above ground, from non bearing shoots. Leaves were placed into paper bags and transferred to the laboratory, where they were carefully washed with running tap water and three times with de-ionized one, before drying them in an oven at 70 ^{o}C till constant weight and ground then into fine powder. Soil and leaf analysis took place according to Gasparatos and Roussos (2011). Briefly, soil samples were air-dried and ground to 2 mm prior to analysis. Particle size analyses were made using the hydrometer method, with a 2-h reading for clay concentration (Gee and Bauder, 1986). Available metal contents were extracted from the soils by shaking 10 g samples for 2 h with 20 ml 0.005 DTPA (diethylene-triamine-pentaacetic acid) adjusted to pH = 7.3), prepared as described by Lindsay and Norvell (1978). Plant material was dried at 70 ^{o}C for 48 hours, weighted and ground. 0.5g of the plant sample was dry-ashed in an oven at 500 ^{o}C for 4h and the ash was subjected to wet digestion in concentrated nitric acid. Fe, Mn, Cu, Zn concentrations were determined by using a Varian SpectrAA-300 atomic absorption spectrometer. Quality control was assured by duplicate samples and procedural blanks.

Figure 1. Location of trial location.

The trial was conducted as a completely randomized design with four replications and the data were analyzed as a one-way Anova and the significant differences were determined based on Tukey HSD test at a=0.05.

RESULTS AND DISCUSSION

As can be seen in Table 1, the application of attapulgite with or without OMW did not have any significant effect on shoot growth or yield and olive oil production. This could be partly attributed to the short period of time and due to the fact that only a single application was performed per year. This is further supported by the findings of López-Piñeiro et al. (2008)

which observed significant influences of OMW addition after five consecutive years of application. Variable efficacy of OMW application in plants has been reporterd by other researchers, such as Assimakopoulou et al. (2020) working with OMW in pepper plants, where either plant growth remained unaffected or slightly enhanced or even reduced, depending on the dose rate of OMW and the application rate of zeolite added with OMW.

Table 1. The effect of the various treatments on shoot growth and yield components.

Treatments	**Shoot length (cm)**	**Yield (kg/tree)**	**Olive oil per fruit (% w/w)**	**Olive oil per tree (kg)**
Control	15.2 a	65.86 a	24.48 a	16.13 a
Attapulgite	16.4 a	64.16 a	25.58 a	16.25 a
Attapulgite + OMW	16.1 a	59.60 a	26.73 a	15.90 a

Means within the same column followed by the same letter do not statistically differ based on Tukey HSD test at α=0.05.

On the contrary, the application of attapulgite alone resulted in reduced olive oil (OO) acidity compared to other treatments, although the oil produced from all treatments was characterized, based on these indices, as Extra Virgin Olive Oil (EVOO) (Table 2).

Table 2. The effect of the various treatments on olive oil quality indices.

Treatments	**Free acidity (% oleic acid)**	**K232**	**K270**	**ΔK**	**Peroxide value (meq. O_2/kg)**
Control	0.38 a	1.42 a	0.07 a	-0.002 a	10.0 a

Attapulgite + OMW	0.33 ab	1.52 a	0.08 a	-0.003 ab	10.0 a

Means within the same column followed by the same letter do not statistically differ based on Tukey HSD test at α=0.05.

There was not any significant influence of any of the treatments tested here, regarding total phenols, total flavonoids and antioxidant capacity of the OO, apart from the detected reduction of total o-diphenols by the presence of attapulgite alone. This was probably the effect of reduced water stress imposed by the application of attapulgite in the soil, as it can reserve water and reduce water losses, relieving partly the olive tree from water stress, which otherwise would increase phenolic compounds to counteract possible reactive oxygen species production. On the other hand, the addition of OMW with attapulgite did not have any significant impact on oil properties, although different results have been reported (Mechri et al. 2009).

The treatments had a significant effect on some of the soil properties as can be seen in Tables 4 and 5. Attapulgite alone increased the concentration of nitrate nitrogen, sodium and boron in the soil (0-30 cm depth), while in combination with OMW it increased phosphorus and manganese concentration. In 30-60 cm depth, attapulgite addition increased the concentration of boron and manganese compared to control, while in combination with OMW it increased the concentration of nitrate nitrogen. Similar results on soil nitrogen, sodium, phosphorus and other nutrients by OMW has been reported by other researchers too (Fernández-Hernández et al. 2014; Magdich et al. 2022), who assigned these changes to increased mineralization though increased microbial activity.

Phosphorus concentration in the leaves increased under the combined effect of attapulgite plus OMW, probably a result of the increased P concentration found in the upper soil level (Table 6). Unlike our present results, Mechri et al. (2011) reported decreases in leaf nutrient levels by the application of OMW, but this difference could be assigned to different soil properties, different cultural management, experimentation conmditions and cultivar.

able 3. The effect of the various treatments on olive oil phenolic compounds and antioxidant capacity.

Treatments	**Total phenols**	**Total o-diphenols**	**Total flavonoids**	**DPPH**	**FRAP**
Control	270.2 a	27.6 a	0.76 a	1100.0 a	1292.9 a
Attapulgite	325.4 a	15.57 b	0.56 a	887.4 a	1000.3 a
Attapulgite + OMW	258.4 a	22.6 ab	0.68 a	1023.6 a	1220.1 a

Means within the same column followed by the same letter do not statistically differ based on Tukey HSD test at α=0.05.

The total phenols are expressed as mg gallic acid equivalents Kg^{-1} oil, the total o-diphenols as mg caffeic acid equivalents Kg^{-1} oil, and the total flavonoids as mg caffeic acid equivalents Kg^{-1} oil, antioxidant capacity (DPPH and FRAP) as μmol Trolox Kg^{-1} oil.

CONCLUSIONS

Based on the present study, it became clear that both the application of attapulgite alone as well as in combination with OMW could be a valuable cultivation practice in improving soil properties and leaf nutrient concentration. Furthermore, the combined application of attapulgite plus OMW could be a method for recycling OMW giving added value to wastes produced during the various agronomic practices. Nonetheless, more research is needed to further examine the long-term effects on olive production and olive oil quality as well as on soil properties and leaf nutrient concentration.

ABSTRACT

This study revealed the effects of different stratification temperatures and bacterial inoculation on the germination success of rosehip seeds belonging to the SRG17 genotype, which is superior in terms of fruit quality among the rosehip genotypes selected from Yozgat province. In the study, single, double and triple combinations of control, EM.A microbial fertilizer, hot and cold stratification treatments were used to increase the germination rates of seeds of the SRG17 genotype. As a result of the study, it was determined that the rosehip seeds germinated 17 days after sowing in the 4th (cold and humid stratification - 150 days), 6th (warm and humid stratification - 4 weeks and cold and humid stratification - 150 days) and 7th (EM.A microbial fertilizer + warm and humid stratification - 4 weeks + cold and humid stratification - 150 days) applications. The best result in terms of germination percentage was obtained with 9.58% from the seeds planted in the 6th application, that is, after 4 weeks of hot and humid stratification and 150 days of cold and humid stratification. In the measurements made on rosehip plants that were germinated and grown until the dormancy period, no statistical difference was found in terms of root collar diameter, stem number and shoot number. In terms of shoot length, the 6th and 7th applications (38.90±3.92 cm and 33.10±16.17 cm, respectively) were found to be statistically different from the 4th application (29.15±10.42 cm). In shoot diameter measurements, the 7th application was found to be statistically different from the other applications with the highest value of 2.49±0.57 mm. In terms of root dry weight, the 6th and 7th applications (7.27±0.65 g and 6.15±2.56 g, respectively) were found to be statistically different from the 4th application (5.46±1.87 g). At the end of the study, it was concluded that the best results on the germination success of different stratification temperatures and bacterial inoculation in the germination of seeds of the SRG17 rosehip genotype were obtained from the combination application of 4 weeks of warm and humid stratification and 150 days of cold and humid stratification.

Keywords: Rosehip, Seed, Stratification temperatures, Bacterial inoculation

INTRODUCTION

Plants have been widely used for centuries to meet a significant portion of people's basic needs such as nutrition, heating and shelter. The rapid increase in the world population, the unconscious use of plant resources to meet the daily needs of people, land clearings, the replacement of native (traditional) varieties with improved varieties, the use of weed killers, the consumption by uprooting from nature instead of production, natural disasters, road and dam constructions, unconscious urbanization and industrialization cause the decrease and rapid loss of plant genetic resources. Both the development of new varieties to increase agricultural production and the transfer of natural (wild) plant species, which are raw materials, to future generations without erosion will be possible through the objective identification, collection and protection of existing plant diversity. (Şehirali and Özgen, 1987; Ercişli and Eşitken, 2004; Tan, 2010).

Rosehip (Rosa spp) is a perennial shrub with many stems and deep roots, upright or climbing form, 0.5 - 4.0 m. tall, although it varies in different species. It has both hairy roots and taproots that go down to 4 m. The fleshy red colored soft roots are used in the dye industry and the eyes on them tend to give root suckers. The leaves are ellipse shaped, toothed, compound leaves with 5 or 7 leaflets. The flowers are pink, yellow, cream, white or light red, with 5 petals and 5 calyxes, have a pleasant smell and a beautiful appearance. However, in some species the number of petals can be much more than 5 like in roses. Rosehip has a hermaphroditic flower structure and has many male and female organs. Its fruit is a false berry. The fruit shape is round, egg shaped or ellipse. The fruit is fleshy, shiny, green before ripening, and varies from brick red to red when ripe. The outer part of the fruit is hairy or hairless depending on the species, the inside of the fruit is more or less hairy and contains many seeds. If not collected, it can remain on the plant in winter. The ripening period of the fruits is between July and October, depending on the species and the climatic conditions of the region (İlisulu, 1992; Türkben, 2003, Güneş, 2013).

Rosehip fruits, which are produced as tea, fruit juice and marmalade, are reported to be especially rich in vitamin C and are the richest plant among cultivated and naturally grown plants (Ağaoğlu et al., 1987). User (1967) reported that since the human body cannot synthesize and store vitamin C, it is necessary to take it daily from outside, that vitamin C ensures the normal formation of collagen, which is an important component of the skin and connective tissues, and bone development, and the healthy development of teeth, that with its antioxidant properties, it neutralizes harmful substances known as free radicals, that it ensures the normal level of cholesterol in the blood, that it helps the body's defense system to function normally by preventing the symptoms that occur in colds and flu, and that it also ensures the use of some vitamins and minerals such as vitamins E, A, B2, B5, folic acid, iron and calcium (Güneş, 2013). Rosehip is used as a raw material in the pharmaceutical industry in many European countries, and its roots and fruits are used in folk medicine in the treatment of hemorrhoids and as a painkiller, and its leaves and flowers are used in the treatment of colds and rheumatism, and bronchitis (Honda et al. 1996).

In fruit species that are pollinated or open to pollination, seed propagation (except for seeds that are formed apomictic) is not a recommended method. Because in seed propagation, it is not possible to obtain a standard fruit variety without losing the variety characteristics. The reason for this is that cross-pollination (allogamy) is common in fruit species and varieties, and as a result, the genetic structures of fruit species show a heterozygous character to a large extent. If the seeds of fruits formed as a result of cross-pollination are used in the production of fruit species, the new individuals formed may not be the same as the mother and father plants in terms of all characters. While this is generally the case in fruit species, the situation is slightly different in the Caninae section of rosehip. Rosehip species show a polyploid structure in terms of chromosome numbers (n=7, 2n=14 can vary from 2n=56 in rosehip species). For example, in rosehips in the Caninae section, the chromosome number can be 2n=28, 35 or 42 depending on the species. In the Caninae section, regardless of the level of chromosome multiples (polyploidy), only 7 chromosomes are transferred from the father plant to the daughter plant during the meiosis division phase. Depending on the polyploidy status, 21, 28 or 35 chromosomes are transferred from the mother plant to the daughter plant. In this case, the daughter plant receives many genetic characters from the mother plant. Therefore, it would not be wrong to say that there is no major opening in seed production in the species of rosehip that fall into the Caninae section. Since the Rosa canina species has a chromosome number of 2n = 35, it will show very little opening when propagated by seed, and this propagation method can be applied (Güneş, 2013).

In our study, the seeds of the SRG17 genotype, which was found to be superior in terms of fruit quality among the rosehip genotypes selected from Yozgat province, were examined and the effects of different stratification temperatures and bacterial inoculation on the germination success of rosehip seeds were revealed.

MATERIAL AND METHOD

The research was conducted at Yozgat Bozok University in 2023. The trial was established in a randomized plot design. In the research, single, double and triple combinations of control, EM.A microbial fertilizer, hot and cold stratification applications were used to increase the germination rates of seeds of the SRG17 genotype (Table 1). The study was carried out with 3 replications and 100 seeds in each replication. A total of 8 applications x 3 replications x 100 seeds = 2400 seeds were used. Seeds were removed from rosehip fruits, cleaned and washed. In all combinations where EM.A would be applied, the seeds were inoculated with bacteria for 20 minutes in microbial fertilizer diluted at a ratio of 1:100 and then taken to stratification. Statistical analysis was performed with SPSS statistical program.

Table 1. Single, double and triple combinations of EM.A microbial fertilizer to be applied to seeds, hot and cold stratification applications

Serial Number	Applications
1	Control
2	Warm and humid stratification (4 weeks)
3	EM.A microbial fertilizer + Warm and humid stratification (4 weeks)
4	Cold and humid stratification (150 days)
5	EM.A microbial fertilizer + Cold and humid stratification (150 days)
6	Warm and humid stratification (4 weeks) + Cold and humid stratification (150 days)
7	EM.A microbial fertilizer + Warm and humid stratification (4 weeks) + Cold and humid stratification (150 days)
8	EM.A microbial fertilizer

In order to break the dormancy, rosehip seeds were stratified in 1 kg plastic containers (20.60 x 11.20 x 6.90 cm) in perlite at a depth of approximately 1 cm. The seeds were then subjected to hot and humid stratification at 25±1 ºC, and then to cold and humid stratification at +4ºC. During the stratification period, the humidity of the stratification media was regularly checked to ensure that the media remained moist. The seeds removed from stratification were planted in peat media.

The first stratification study Hot and humid stratification (4 weeks) + Cold and humid stratification (150 days) application (no. 6) and EM.A microbial fertilizer + Hot and humid stratification (4 weeks) + Cold and humid stratification (150 days) application (no. 7) were carried out on 04.11.2022. The seeds were first placed in water, and those that floated on the water were discarded. The remaining seeds were spread on blotting paper.

In the 6th combination application, the seeds were placed in perlite for hot stratification at room temperature for 4 weeks.

In the 7th combination application, the seeds were first inoculated with bacteria in EM.A diluted at a ratio of 1:100 for 20 minutes and then placed in perlite for hot stratification at room temperature for 4 weeks.

The boxes belonging to both combinations were moistened with water in the form of a spray, with humidity control in between.

On 02.12.2022, the boxes belonging to both combinations were placed in the refrigerator for cold stratification at 4 degrees to be kept for 150 days. These two combinations were kept in cold stratification (150 days) together with all other combinations until they were planted in vials on 05.05.2023.

The second stratification study was carried out on 29.11.2022 in the Cold and moist stratification (150 days) application (no. 4) and EM.A microbial fertilizer + Cold and moist stratification (150 days) application (no. 5). The seeds were first placed in water, and those that floated on the water were discarded. The remaining seeds were spread on blotting paper.

For the 3rd application, the seeds were cold stratified in the refrigerator at 4 degrees to be kept for 150 days.

For the 4th combination application, the seeds were first inoculated with bacteria in EM.A diluted at a ratio of 1:100 for 20 minutes, and the boxes that were stratified were cold stratified in the refrigerator at 4 degrees to be kept for 150 days.

The boxes belonging to both combinations were moistened with water in the form of a spray by checking the humidity in between. These two combinations, along with all other combinations, were kept in cold stratification (150 days) until they were planted in vials on 05.05.2023.

The third stratification study was carried out on 01.04.2023 in the Hot and humid stratification (4 weeks) application (no. 2) and EM.A microbial fertilizer + Hot and humid stratification (4 weeks) application (no. 3). The seeds were first placed in water, and those that floated on the water were discarded. The remaining seeds were spread on blotting paper.

For the application no. 2, the seeds were hot stratified in perlite at room temperature for 4 weeks.

For the combination application no. 3, the seeds were first inoculated with bacteria in EM.A diluted at a ratio of 1:100 for 20 minutes and then hot stratified in perlite at room temperature for 4 weeks.

The boxes of both combinations were moistened with water in the form of a spray, with humidity control in between. These two combinations were kept in hot stratification (4 weeks) with all other combinations until they were planted in the trays on 05.05.2023.

In the fourth and last application, the EM.A microbial fertilizer (no. 8) and Control (no. 1) applications, which were planted without stratification of the seeds, were carried out on 05.05.2023. The seeds were first placed in water, and those that floated on the water were discarded. The remaining seeds were spread on blotting paper.

In the Control application no. 1, the seeds were planted in the vials without any treatment.

For the application no. 8, the seeds were inoculated with bacteria in EM.A diluted at a rate of 1:100 for 20 minutes and then planted in the vials. (Figure 1).

Figure 1. Planting seeds in trays

RESULTS AND DISCUSSION

On 05.05.2023, the seeds planted were regularly checked and the emergence rates of the plants were recorded daily. The first emergences were detected on 22.05.2023. In rosehip plants; germination percentage (%) and germination duration (days) of the applications were determined (Table 2).

Table 2. Germination percentage (%) and germination time (days) of rosehip seeds

Serial Number	Applications	Germination percentage (%)	Germination time (days)
1	Control	0	-
2	Warm and humid stratification (4 weeks)	0	-
3	EM.A microbial fertilizer + Warm and humid stratification (4 weeks)	0	-
4	Cold and humid stratification (150 days)	2,08	17
5	EM.A microbial fertilizer + Cold and humid stratification (150 days)	0,42	17
6	Warm and humid stratification (4 weeks) + Cold and humid stratification (150 days)	9,58	17
7	EM.A microbial fertilizer + Warm and humid stratification (4 weeks) + Cold and humid stratification (150 days)	6,67	17
8	EM.A microbial fertilizer	0	-

The seedlings that reached a size of 5-10 cm (Figure 2) were transplanted into pots prepared with 2 parts of peat + 1 part of perlite on 13.06.2023 and their growth was observed (Figure 3).

Figure 2. Growing rosehip plants from seed

Figure 3. Transplanting germinated and growing rosehip plants into pots

In the dormant period of rosehip plants that were germinated and placed in pots, root collar diameter, stem number, shoot number, shoot length and diameter, root length, root dry and fresh weight, stem dry and fresh weight were determined. The obtained data were subjected to variance analysis using SPSS 25.0 statistical package program, and the differences between the means were checked with Duncan multiple comparison test (Yurtsever, 1984).

In June, regular watering and fertilization were applied to rosehip plants placed in pots in the greenhouse (Figure 4). In plants that shed leaves in December, root collar diameter, stem number, shoot number, shoot length and diameter, root length, root dry and fresh weight, stem dry and fresh weight measurements were made in February.

Figure 4. Rosehip plants placed in pots in the greenhouse

Data on some morphological characteristics detected in the plants from the 4th, 6th and 7th applications that survived the study are given in Table 3.

The root collar diameter in rosehip plants varied between 5.04±1.08 mm (7th application) and 5.17±0.07 mm (6th application). The number of stems was determined as 1.20±0.45 (6th application), 1.40±0.55 (4th application) and 1.60±0.55 (7th application). The number of shoots was counted as 2.40±1.34 (7th application), 2.60±0.55 (6th application) and 2.60±1.14 (4th application). The highest shoot length was measured as 38.90±3.92 cm from the 6th application and 33.10±16.17 cm from the 7th application. The shoot length obtained from the 4th application was statistically in a separate group with 29.15±10.42 cm. In terms of shoot diameter, the 7th application gave the highest value statistically with 2.49±0.57 mm. Shoot diameters of 2.12±0.26 mm and 1.91±0.32 mm were measured in the 4th and 6th applications, respectively.

Table 3. Some morphological characteristics of rosehip plants

Serial No.	Applications	Root collar diameter (mm)	Number of stems (pcs)	Number of shoots (pcs)	Shoot length (cm)	Shoot diameter (mm)
1	Control	0,0 b	0,0 b	0,0 b	0,0 c	0,0 c

8	EM.A microbial fertilizer	0,0 b	0,0 b	0,0 b	0,0 c	0,0 c

Root length, root fresh and dry weight, shoot fresh and dry weight data in rosehip plants are given in Table 4.

Root length varied between 13±3.61 cm (4th application) and 17±2.22 cm (6th application). Root fresh and shoot fresh weights were weighed after removing rosehip plants from pots and cleaning roots from peat and perlite residues (Figure 5). Root fresh weight was weighed as 21.72±1.22 g (6th application), 19.29±11.08 g (7th application) and 15.76±5.60 g (4th application). In terms of root dry weight, applications no. 6 with 7.27±0.65 g and no. 7 with 6.15±2.56 g gave the highest statistical value. In application no. 4, root dry weight was weighed as 5.46±1.87 g. Shoot fresh weight was determined as 5.24±1.60 g (7th application), 4.82±0.27 g (6th application) and 4.33±1.16 g (4th application). There was no statistical difference between the germinated plants in terms of shoot dry weight. Shoot dry weight varied between 2.20±0.60 g (4th application) and 2.68±0.84 g (7th application).

Table 4. Root length, root fresh and dry weight, shoot fresh and dry weight data

Figure 5. Measurement of fresh and dry weights of roots and stems

CONCLUSIONS

As a result of the study, it was determined that the planted rosehip seeds germinated 17 days after planting in the 4th (Cold and humid stratification - 150 days), 6th (Hot and humid stratification - 4 weeks and Cold and humid stratification - 150 days) and 7th (EM.A microbial fertilizer + Hot and humid stratification - 4 weeks + Cold and humid stratification - 150 days) applications. The best result in terms of germination percentages was obtained with 9.58% from the 6th application, i.e. the seeds planted after 4 weeks of hot and humid stratification and 150 days of cold and humid stratification.

In the measurements made on rosehip plants that were germinated and grown until the dormancy period, no statistical difference was found in terms of root collar diameter, stem number and shoot number. In terms of shoot length, the 6th and 7th applications (38.90±3.92 cm and 33.10±16.17 cm, respectively) were found to be statistically different from the 4th application (29.15±10.42 cm). In shoot diameter measurements, the 7th application was found to be statistically different from the other applications with the highest value of 2.49±0.57 mm. No statistically significant difference was found between the 4th, 6th and 7th applications in terms of root length, root fresh weight, shoot fresh and dry weight. In terms of root dry weight,

the 6th and 7th applications (7.27±0.65 g and 6.15±2.56 g, respectively) were found to be statistically different from the 4th application (5.46±1.87 g).
Studies have shown that rosehip seeds have difficulty germinating due to their hard, impermeable outer shell, and that only one or a combination of pre-treatments may not be sufficient (Foster and Wright, 1983; Tansı et al., 1996; Ercişli, 2000; Belletti et al., 2003, Hoşafcı et al., 2005, Anderson and Byrne, 2007). Among these pre-treatments, stratification has been determined to be an effective method for breaking dormancy when applied hot and cold (Zhou et al., 2009). Another method used to break dormancy in seeds and increase germination percentage is microbial inoculation into seeds or germination medium. It has been reported that microorganisms soften the hard-coated seed pericarp and facilitate germination (Morpeth and Hall, 2000, Kazaz et al., 2010). In our study, no germination occurred in the seeds planted after the application number 1, which was the Control application, which did not have any application, application number 2, which was hot and humid stratification for 4 weeks, application number 3, which was hot and humid stratification for 4 weeks together with EM.A microbial seed coating, application number 5, which was cold and humid stratification for 150 days together with EM.A microbial seed coating, and finally application of only EM.A microbial seed coating. The highest germination was obtained from the combination application of hot and humid stratification for 4 weeks and cold and humid stratification for 150 days. At the end of the study, it was concluded that the best result on the germination success of different stratification temperatures and bacterial inoculation in the germination of seeds of the SRG17 rosehip genotype was obtained from the combination application of hot and humid stratification for 4 weeks and cold and humid stratification for 150 days.

e-mail: diellon.salihaj@uklo.edu.mk

ABSTRACT

Rose ash disease caused by the pathogen Sphaerotheca pannosa var.rosae is one of the most problematic diseases in horticulture, which in all countries of the world causes great financial losses in the field of horticulture. In my country, in Kosovo but also in other Balkan countries, the growth of cultivated areas with this decorative plant is increasing every day.Farmers who cultivate roses have suffered huge losses, precisely because of the presence of this disease in the cultivars that the market is looking for. In our 2-year study, carried out during the 2022-2023 vegetation, we diagnosed the presence of the pathogen Sphaerotheca pannosa var.rosae. The presence of the pathogen was identified by sampling leaves, shoots and flowers, in which a white mold was found.We sent such samples to the plant protection laboratory in the Department of Phytopathology, from where it turned out to be the Pathogen Sphaeroteca pannosa var.rosae.In the laboratory, the vegetative reproductive organs of the pathogen - Conidia with the typical form of this pathogen were identified, where we made their morphological identification, measuring the length and width expressed in micrometers, which we have included in our tabular results. We also identified the intensity of the spread of this disease and found that the pathogen has an increase in virulence from April to September. We have calculated the intensity of the spread of this pathogen according to the Townsend GR and JW Heuberge formula. The 2-year results of this study have shown that protection with adequate fungicides against this disease should continue from the beginning of the vegetation until the end of autumn.

Key words: Disease, Pathogen, Horticulture, Sample, Conidia.

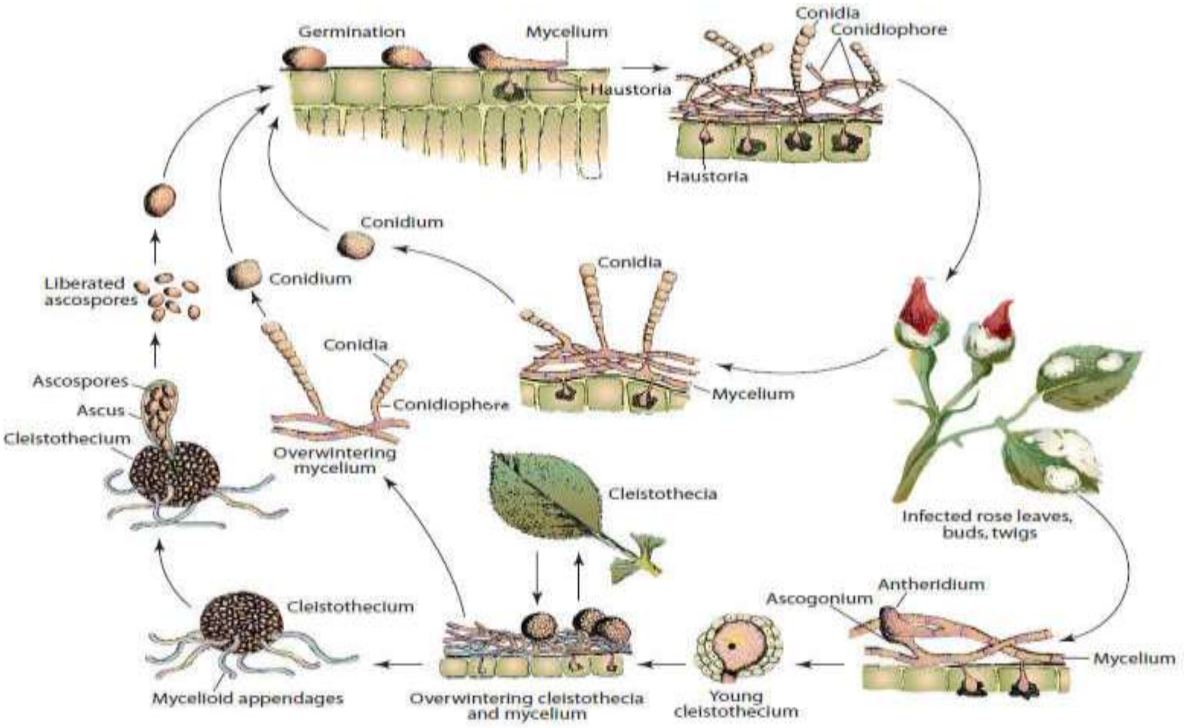
INTRODUCTION

The rose as a decorative plant is cultivated for centuries all over the world, including our country as well, and is increasingly becoming part of the households. The cultivation of this crop besides the necessary agrotechnical conditions, also requires a professional protection from diseases and pests. One of the most common diseases that attack the rose is powdery mildew caused by the pathogen *Sphaerotheca pannosa var.rosae*. The pathogen overwinters in the form of mycelium in infected buds and in the form of generative reproductive organs such as cleistothecium

This disease occurs at the beginning of vegetation, with the emergence of the first buds and continues until the end of vegetation - leaf fall.

When the mycelium overwinters in the rose buds, and the vegetation begins in the spring there is systemic infection on all the leaves that emerge from the infected buds, including the flower The growth of the infected plants is stunted and flowers remain sterile, whereas during the winter the infected stems can not resist low temperatures and as such they perish.

The pathogen overwinters in the dormant buds of the plant as mycelium or as cleistothecium (reproductive organs)
When the pathogen overwinters in the form of cleistothecium the primary infection is caused by ascospores. Throughout vegetation the pathogen forms conidia, which continuously infect the leaves, shoots and flowers of the rose. The climate conditions such as temperature and humidity are of the great importance in infection development.
The optimal temperature for pathogen development is 18-25 ^{o}C. Conidia as vegetative organs of reproduction are formed at a temperature of 21-27 C in a relatively low air humidity (Susuri L Phytopathology 1995).



.

Fig 1.Biological cycle of pathogen *S.Pannosa var,rosae*

MATERIALS AND METHODS

The experiment was conducted during the 2023 vegetation by monitoring this disease from the beginning of the bud opening to the end of vegetation
To indicate the susceptibility of this plant to the pathogen of *Sphaerotheca pannosa var.rosae* the experiment was carried out on chemically untreated cultivars with fungicides
The main objective of this paper was: Diagnostication of the pathogen both macroscopically and microscopically. The measurement of vegetative organs of reproduction – conidia. The occurrence intensity of powdery mildew disease. To accomplish the first objective of this experiment, we sampled the vegetative parts, leaves, rosebuds and flowers of the rose to observe the symptoms of the disease in the infected parts of the plant. Samples were taken twice during vegetation(in the first decade of June and September) from the leaves and flowers in every trunk, ten each.
The second objective of this paper , was the measurement of the vegetative organs of the pathogen.

For obtaining this experiment the taken samples were delivered to the laboratory, to identify microscopically whether the pathogen S.Pannosa is present in the samples.

After morphological identification of the pathogen, we measured the length and width of the conidia in table 1. To accomplish the third objective, we sampled randomly the leaves of the stems.To calculate the index of plant affected by the pathogen we used the *Townsend GR* and *JW Heuberger formula*

$$i = \frac{\sum (n \bullet x)}{5 \bullet N} \bullet 100$$

$\sum$ = Sum of infected leaves by cathegory

n = leaves number of each cathegory

X = certain cathegory

5 = number of cathegory

N = Total number of analyzed leaves

Fig.2.The symptoms of disease caused by pathogen *Sphaerotheca pannosa* ,(Authentic picture)

RESULTS AND DISCUSSION

The observation and measurement of vegetative reproductive organs -conidia of powdery mildew disease caused by *Sphaerotheca pannosa var.rosae* was done from samples of infected leaves and flowers which resulted with clear symptoms of infection(Fig.1). The infected samples were observed in microscope to see the fungal oids that belong to the imperfect form of *Oidium farinosum* pathogen.

The measurement was made with the help of an ocular micrometer, which is a round glass, in the middle of which there is a 5 mm long line, divided into small lines with a distance of 0.1 mm each. The ocular micrometer can be placed in all types of microscopes. To obtain the value of the ocular micrometer, we set the objective micrometer first then proceeded with direct measurements of the reproductive organs of the pathogen - oids. In order to get the results of these measurements we made approximately 50 measurements for each sample, by dividing the number of measurements to get the average of the widths and lengths of the conidia shown in the table below.

Fig.3. Images of oids

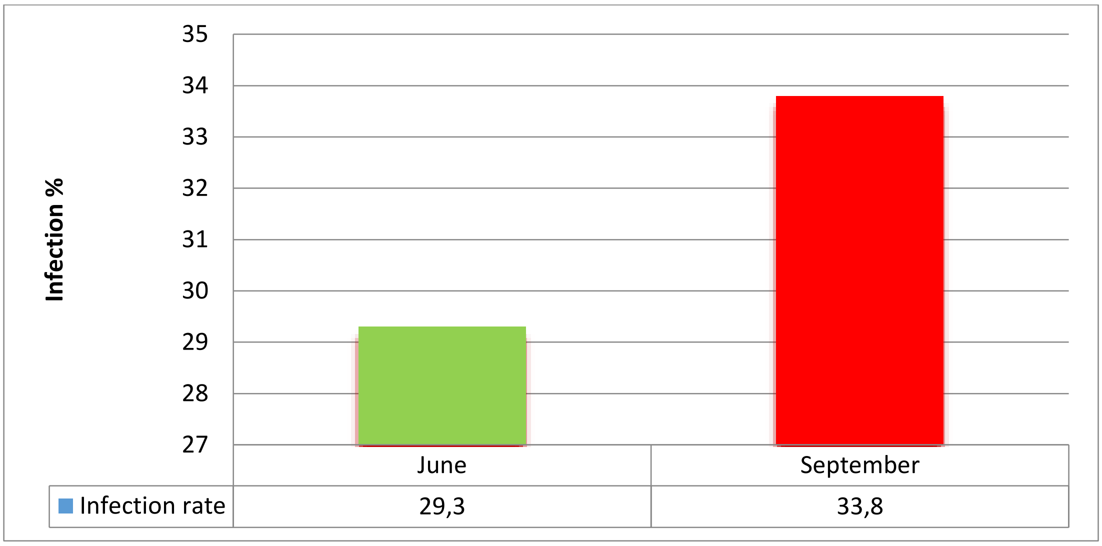
Tab.1 The size measurements of oids *Sphaerotheca pannosa* ***var.rosae***

Sampling time	Observation time	Size (µm-micrometer)
Sampling in June	09. 06. 2023	10,20 - 12.50 x 19,50 - 24,10
Sampling in September	07. 09. 2023	11,30 -13,70 x 21,40 - 26,20

The shown results from the tables indicate that the size of the conids (oids) has changed depending on the study phase.

As can be seen from the table, the size of oids observed at the beginning of June is 10.20 - 12.50 x 19.50-24.10 µm, whereas their size of the same cultivars made in September is 11.30 - 13.70 x 21.40 - 26.20 µm. In the second objective of this paper two assessments were made to determine the intensity of the powdery mildew to rose cultivars caused by *Sphaerotheca pannosa var.rosae*. The first was done in early June and the second in early September by random sampling of 100 leaves from 10 different plants.Then we calculated the index of affected plants by pathogen, by applying the formula of Townsend GR and JW Heuberger. By applying the methodology for achieving this objective the following results were obtained based on years of study.

Tab. 2 Intensity of affectedness of powdery mildew in different sampling stages



CONCLUSIONS

From the study of determining intensity of affectedness with rose powdery mildew caused by Sphaerotheca pannosa var.rosae, we came up with following conclusions: The first symptoms of powdery mildew disease observed by macroscopic and microscopic methods have been noticed by the end of April in the newly emerged leaves from the bud. Later on the disease was noticed in all the green parts of the rose, such as leaves, flowers, and rosebud. During this study it was found that the measured size of oids expressed in micrometer has changed depending on the study stage. The size of oids measured in June were 10.20 - 12.50 x 19.50 - 24.10 µm, while the size made from the same cultivars in September were 11.30 - 13.70 x 21.40 - 26.20 µm. As a result of the assessments it was found that the intensity of the affectedness has increased from June, when the first assessment was done until the second assessment, which was done in September. June assessments were 29.3, compared to 33.8 in September. In this study there were found that first symptoms of S.pannosa appeared from the opening of first buds and subsequently the infection continuously increased to the end of vegetation, which makes this pathogen very dangerous. Also in this study we found that in dry season with no precipitation and high temperatures the disease severity is adversely affected. From the conclusions drawn from this study, we conclude that monitoring of rose powdery mildew disease caused by Sphaerotheca pannosa var.rosae should be done annually to see the susceptibility of the rose to this pathogen. This will serve as a recommendation to farmers who are interested in planting this ornamental crop which is increasingly expanding with new cultivars. Given that the impact of this pathogen is high on untreated plots, it is indispensable for our agro-climatic conditions to carry out more profound studies to see the effectiveness of the pesticides and the most effective point in treating the rose powdery mildew.

ABSTRACT

Fluoride is an essential element for living organisms, found in water, air, and food. Fluoride-containing dental products and fluoridated water are the primary sources of fluoride in the human body. Overexposure to fluoride can harm different organs and tissues, including the skeletal, neurological, digestive, respiratory, and urogenital systems. Reviewing the literature uncovers multiple studies that utilize antioxidant molecules to mitigate the detrimental impacts of fluoride. N-acetylcysteine (Nac), a chemical possessing antioxidant characteristic, directly interacts with oxidative substances to decrease the levels of reactive oxygen species (ROS) upon cellular entry, functioning as a scavenger of reactive oxygen molecules. Nac, which has high antioxidant and anti-inflammatory capacity, is used to treat various diseases related to oxidative damage. With the increasing evidence of fluoride toxicity on the male reproductive system, interest in studies in this direction has increased. However, there is a limited amount of study on the therapeutic properties of Nac in counteracting the harmful impacts of sodium fluoride (NaF) on TM3 Leydig cells. The TM3 Leydig cell line, which is involved in the production of testosterone in the male reproductive system, was exposed to different concentrations of NaF (50 ppm) and Nac (1 mM) for 24 h in this research. The study assessed cell viability and micronucleus formation at specific concentrations of NaF and Nac, focusing on the genotoxic effects of fluoride in the Leydig cell line. Based on the collected results, it was determined that NaF reduced cell viability in Leydig cells and caused genotoxic damage. Furthermore, it was found that the administration of Nac enhanced the survival rate of cells and mitigated the extent of genotoxic damage in Leydig cells that were affected by NaF exposure. Consequently, our study discovered that Nac may possess a therapeutic effect on TM3 Leydig cells in mitigating the harmful effects of NaF toxicity.

Keywords: Fluoride, Leydig cells, n-acetylcysteine, cell viability, genotoxicity.

INTRODUCTION

Fluorine is an environmental pollutant that is widely found in nature and is frequently exposed to by living organisms (Zhao et al., 2022). Fluorine is a highly reactive element due to its high electronegativity. Its low stability causes fluorine to be found in nature as compounds rather than in isolation (Johnston et al., 2020). Fluorine forms compounds mainly with the sodium, aluminum, calcium, and hydrogen, while sodium fluoride can be considered among the most common forms in nature (Han et al., 2021). Fluoridated water and dental products that contain fluoride significantly contribute to the absorption of fluoride in the human body. Fluoride shows its effect on the human body, unlike other pollutants, depending on the concentration. While it has beneficial effects on tooth and bone development below 1 mg/L concentration, according to the World Health Organization report, exposure exceeding the upper limit (1.5 mg/L) causes a health problem known as fluorosis (Pal et al., 2023). Moreover, the utilization of fluoride-contaminated groundwater for irrigating food crops leads to the degradation of plant growth, reduced yield, and subsequent biological accumulation (Koley et al., 2024).

Studies have shown that excessive fluoride exposure damages various organs and tissues in the body, such as the skeletal, nervous, digestive, respiratory, and urogenital systems (Lacson et al., 2021). Numerous toxicology studies reveal adverse effects of fluoride toxicity, including reduced male reproductive capacity, decreased sperm quality, changes in testicular organ weight, and histopathological changes in reproductive tissues (Cao et al., 2016; Li et al., 2018). In addition, excessive fluoride consumption negatively affects sperm characteristics, fertility, and reproductive hormone levels. In another study, it was observed that NaF caused some abnormalities in the reproductive system and also induced oxidative stress by producing reactive oxygen species (ROS) in the sperm and liver of mice. Accordingly, it was observed that fluoride affected DNA, lipids, proteins, and enzymatic systems (Yu et al., 2018). When genotoxicity studies were examined, it was seen that high fluoride intake disrupted the cell cycle in various tissues and cells, induced apoptosis, and caused DNA damage (Herrera-Calderon et al., 2019).

The World Health Organization considers N-acetylcysteine (Nac) as an essential drug and uses it as a mucolytic agent in respiratory diseases (Seyedasgari et al., 2024). Nac, a plant antioxidant found in some food products, is the precursor of glutathione (Liu et al., 2021). In addition, NAC protects the activity of biological macromolecules by reacting with reactive oxygen species (ROS) via sulfhydryl groups while contributing to the strengthening of intracellular defense through the synthesis of glutathione (GSH) (Pan et al., 2022; Seyedasgari et al., 2024). Examining studies on the male reproductive system reveals that NAC positively impacts spermatogenesis and testicular function. Accordingly, it is also thought that NAC can be used in the treatment of diseases caused by oxidative stress in the male reproductive system (Tenório et al., 2021). Another study reported that infertile men treated with NAC had improved sperm count, sperm motility parameters, and sperm chromatin integrity (Seyedasgari et al., 2024).

This study selected Leydig cells as a model to investigate the harmful effects of NaF, a prevalent fluorine component in nature, on the male reproductive system. The genotoxicity induced by the administration of NaF on Leydig cells, which are crucial for testosterone production and have a significant impact on the male reproductive system, was assessed using the micronucleus test. Furthermore, the potential of Nac to mitigate NaF-induced genotoxicity was examined for the first time in Leydig cells.

MATERIAL AND METHODS

Cell Culture

The TM3 Leydig cells utilized in the investigation are non-tumorigenic cells derived from the testicular tissues of mice aged 11–13 days. The cells were purchased from the American Type Culture Collection (Manassas, VA, USA). The Leydig cells were cultured in a medium consisting of a 50:50 mixture of DMEM-F12, supplemented with 5% horse serum and 2.5% fetal bovine serum. The cells were cultured in a sterile incubator at a temperature of 37 °C with a controlled atmosphere of 5% CO_2 and 95% air. Two different doses of NaF (10 and 50 ppm) were administered to TM3 Leydig cells for 24 h. Among the two concentrations, the 50 ppm NaF concentration exhibited a significant reduction in cell viability, specifically by 63.56%. Therefore, the 50 ppm NaF concentration was chosen for further experimentation. Furthermore, the Nac concentration selected for this investigation was decided to be 1 mM, based on *in vitro* studies that have demonstrated its antioxidant effects at this concentration. For the final situation, the experiment consisted of four distinct groups: control, NaF, Nac, and NaF+Nac.

Cell Viability

The viability of Leydig cells was assessed using the 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide (MTT) kit from Roche, Germany. The effects of NaF (10 and 50 ppm) and Nac (1 mM) on Leydig cell viability were investigated. The cells were placed at a density of $5x10^3$ cells per well in 100 µL of assay media in a 96-well plate. Following the incubation period, 10 µl of MTT I solution was introduced into each well, and the plates were subsequently incubated for 4 h at a temperature of 37 °C in a CO_2 incubator. Subsequently, a volume of 100 µl of MTT II solution (SDS) was added to each well and left to incubate overnight in a CO_2 incubator. The ELISA equipment was used to measure absorbances at a wavelength of 540 nm. The untreated control cells were considered to have 100 % viability. The viability of the groups treated with NaF and Nac was expressed as a percentage relative to the control. The experiments were repeated three times.

Cytokinesis-blocked micronucleus (CBMN) assay

The experiment was conducted following the method described by Fenech (2007), with some modifications. TM3 Leydig cells were grown in 6-well plates at a density of $1.5x10^5$ cells/mL and allowed to adhere overnight. The cells were exposed to NaF at a concentration of 50 ppm and Nac at a concentration of 1 mM for 24 h. After the exposure period, the experimental medium was taken out, and the cells were treated with a medium containing cytochalasin B at a final concentration of 4 µg/mL for 20 h. After being harvested, the cells were promptly centrifuged, the liquid portion was separated, and the cells were subsequently mixed with a hypotonic solution containing 1% formaldehyde and 0.075 M KCl. The mixture was then left to incubate for 5 min. After being treated with Cornay's reagent (3:1 methanol/glacial acetic acid), the cell suspensions were centrifuged again. Subsequently, the cell solution was dropped onto slides and dried using air. The slides were immersed in a solution of 4% Giemsa in phosphate buffer (composed of Na_2HPO_4 (0.06 M) and KH_2PO_4 (0.06 M), with a pH of 6.8) for 8 min. For the purpose of determining the occurrence of micronucleus (MN), cytoplasmic bridges (NPBs), and/or nuclear buds (NBUDs), a brightfield microscope (Olympus IX71) was employed to examine each slide and record the results. Two independent scorers assessed the microscope slides in a blinded and random manner. The number of mononucleated and binucleated cells containing MN, NPBs, and/or NBUDs was determined at a minimum of 1000 cells per concentration.

Statistical analysis

Descriptive statistics for the values were performed using GraphPad Prism 9 software (GraphPad Software, San Diego, CA, USA). The Shapiro-Wilk test was employed to assess the normality of the values, and it was determined that the results followed a normal distribution. Therefore, the experiment utilized one-way analysis of variance with Tukey's multiple comparison test for all analyses. The threshold for statistical significance was established at $p<0.05$, $p<0.01$, and $p<0.001$ for all tests.

RESULTS

Cytotoxicity results

Figure 1 displayed the cell viability rates (%). After 24 hours, there was a noticeable drop in MTT values between the control group and the NaF group due to the increasing levels of NaF ($p<0.01$, $p<0.001$). When comparing the group exposed to NaF alone with the group treated with both NaF and Nac, a substantial rise in MTT values was observed in the NaF+Nac groups ($p<0.01$, $p<0.001$). From the cell viability data we acquired, it was evident that NaF had a cytotoxic effect on Leydig cells. However, it was established that Nac might serve as a potent antioxidant to ameliorate the detrimental impact of NaF on Leydig cells.

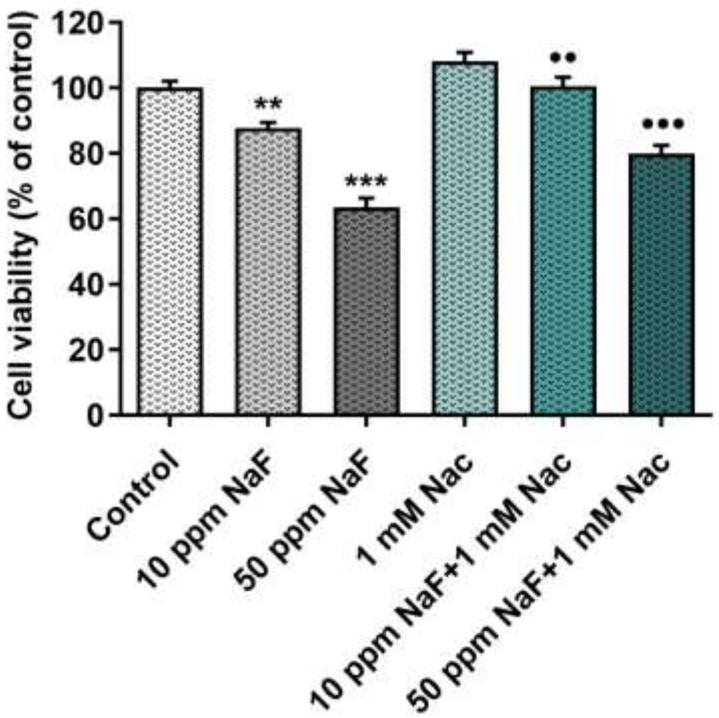

Figure 1. Effects of NaF and Nac on the cell viability in Leydig cells. (**$p<0.01$; ***$p<0.001$; *: compared with control; •: compared with NaF groups).

Genotoxicity results

Figure 2 represents the appearance of micronuclei, bud formation, and cytoplasmic bridges generated by NaF and Nac in Leydig cells, and Table 1 contains the results of analyzing these parameters by comparing them to the control group. The administration of a 50 ppm NaF concentration resulted in a statistically significant increase in binucleated and mononucleated cells with micronuclei and bud compared to the control group ($p<0.001$). The NaF+Nac group showed significantly lower micronucleus rates and bud formation than the NaF alone group ($p<0.001$). Examination of binucleated cells revealed a significant rise in cytoplasmic bridge formation in the groups treated with 50 ppm NaF ($p<0.05$), whereas no protective effect of Nac was noticed.

DISCUSSION

Studies have proven that excessive NaF exposure has many harmful effects on organisms (Johnston et al., 2020; Zhao et al., 2022; Ghosh and Ghosh, 2019). Studies on the male reproductive system have shown that NaF leads to disorders by altering the structure of the epididymis and testis and reducing serum testosterone levels (Pal et al., 2023; Yu et al., 2018; Cao et al., 2016). Determining acceptable levels of NaF requires a thorough understanding of these detrimental consequences. The critical role of Nac, which has strong antioxidant properties, in reducing the harmful effects of NaF on Leydig cells was examined for the first time in this study.

Previous investigations revealed that NaF diminished cell viability in various cell lines (Yu et al., 2018; Zhang et al., 2024; Jiang et al., 2020; Yang et al., 2015). In a study, to determine the effect of NaF on cell viability, cell viability was measured in Leydig cells in the presence of increasing NaF concentrations (0, 5, 10 and 20 mg/L) for 24, 48, 72, 96 and 120 hours. The study conducted by Song et al. (2014) showed that exposure to NaF at concentrations of 10 and 20 mg/L had a strong inhibitory effect on the proliferation of Leydig cells. To validate the detrimental effects of fluoride on Leydig cells, the cells were exposed to higher concentrations of NaF (1.2 and 4 mM), following a similar approach as the previous work. Based on the MTT results, the cell viability showed a significant decrease in the groups treated with 1, 2, and 4 mM NaF (Li et al., 2024). In another study, cytotoxicity caused by fluoride varnishes used for the prevention of caries in dentistry practices was measured in human gingival fibroblast cells (hGF). The metabolic activity of hGFs after exposure to different concentrations of fluoride varnishes was analyzed by MTT. According to the results of the study, it was determined that the metabolic activity of hGFs decreased significantly after exposure to fluoride varnishes compared to the control groups (López-García et al., 2021). In one of the studies conducted to demonstrate the protective effect of Nac, it was revealed that Nac played an important role in suppressing cytotoxicity against patulin (PAT)-induced cytotoxicity using human embryonic kidney cells (HEK293). Compared to the PAT applied alone groups, Nac was found to increase cell viability by 102.07%, 389.48% and 412.21% at concentrations of 2, 4 and 10 mM, respectively (Liu et al., 2021). A study with spermatogenic cells focused on the ameliorative role of Nac against malathion toxicity. Malathion caused a significant decrease in the viability of spermatogenic cells at different concentrations (1 and 100 nM) compared to the control group. Nac was found to have a significant ameliorative role against both malathion concentrations (Bhardwaj et al., 2018). In a study with Sertoli cells, it was observed that cells exposed to NaF decreased cell viability, while Nac protected against cell viability (Yang et al., 2015). Consistent with other research, this in vitro investigation utilizing Leydig cells revealed that a concentration of 50 ppm NaF resulted in decreased cell viability. However, the presence of Nac offered substantial defense against the harmful effects of NaF.

Genotoxicity means the loss of DNA integrity as a result of adverse effects occurring in the genetic material of the cell (Savale, 2018). Today, many methods are used to determine genotoxic damage. The micronucleus test is commonly preferred in scientific studies. A laboratory experiment using human bone cells demonstrated that when the NaF concentration was 100 µg/ml, a statistically significant increase was observed in the number of binucleated cells containing micronuclei and nucleoplasmic bridges at 48 hours of exposure compared to the control. Volobaev et al. (2020) observed a considerable increase in the number of binucleated cells having micronuclei, nucleoplasmic bridges, and nuclear protrusions when the NaF content in the culture medium was 200 µg/ml, compared to the control group. In a study using zebrafish erythrocytes, the frequency of micronucleated erythrocytes (%), as determined by the micronucleus test, was shown to be considerably higher on days 30 and 60 of exposure to F. The administration of fluoride also resulted in the occurrence of additional nuclear abnormalities, including the formation of segmented, lobed, and notched nuclei in erythrocytes (Mondal et al., 2023). In another study, the micronucleus assay was used to evaluate the effect of Nac on ionizing radiation (IR)-mediated genotoxicity. It was observed that 10 Gy IR increased the number of micronuclei, which was significantly reduced by Nac (Kurashige et al., 2016). Consistent with the previously described research, our findings revealed that 50 ppm NaF increased micronucleus, bud, and cytoplasmic bridge formation, while 1 mM Nac reduced these nuclear abnormalities and potentially ameliorated genotoxic damage.

In conclusion, this study evaluated the therapeutic effect of Nac against toxic effects caused by NaF using Leydig cells as an in vitro model. In our study, it was determined that NaF significantly suppressed cell viability and induced genotoxicity in Leydig cells. It was found that Nac could protect Leydig cells from genotoxicity induced by NaF. Thus, Nac effectively prevented MN production and subsequently protected against cellular damage induced by NaF.

MULTI-TRAIT SELECTION INDEX FOR SIMULTANEOUS SELECTION OF WINTER BARLEY GENOTYPES

Boryana Dyulgerova
Institute of Agriculture – Karnobat, Agricultural Academy, Bulgaria

e-mail: bdyulgerova@abv.bg

ABSTRACT

This study aims to assess winter barley genotypes for the selection of desirable ideotypes based on their grain yield and yield-related characteristics. Field trials were conducted using a Complete Block Design with four replications at the Institute of Agriculture – Karnobat, Bulgaria, during the 2021/2022 and 2022/2023 growing seasons. The traits measured included spike number per m^2, plant height, lodging, spike length, spikelet number per spike, grain number per spike, grain weight per spike, 1000-grain weight, and grain yield. A significant effect of genotype, year, and their interaction was observed ($p < 0.01$) for the performance of 21 barley advanced breeding lines and varieties across the nine traits. Moderate to high broad-sense heritability ($30\% < H^2 \leq 60\%$) was noted for all traits except for lodging and grain yield ($H^2 < 30\%$). The ranking of genotypes by the multi-trait genotype–ideotype distance index (MGIDI) varied between the two years. The advanced line G12 was identified as a promising genotype in both years, indicating its potential for inclusion in multi-environment trials for testing as a candidate variety. The promising genotypes selected based on their performance for multiple traits closest to the ideotype could be further utilized in winter barley breeding programs targeting grain yield improvement.

INTRODUCTION

The escalating global demand for grain, driven by population growth and dietary shifts, has intensified pressure on barley production. As a fundamental component of malting, brewing, and livestock feed, barley plays a pivotal role in food security and economic stability. Developing barley varieties that combine high yield with desirable agronomic and quality traits is a complex challenge for breeders. Traditional selection methods, often focused on individual traits, have limitations in capturing the intricate relationships between multiple characteristics. A cornerstone of crop improvement, multi-trait selection aims to enhance multiple desirable traits simultaneously. While this approach holds immense potential, it is fraught with challenges. Genetic correlations between traits, the complexities of assigning economic weights, and the influence of environmental factors on genotype performance significantly complicate the selection process. Moreover, phenotypic evaluation, data analysis, and the achievement of optimal genetic gain across multiple traits demand advanced methodologies.

To address this complexity, researchers have explored various selection indices (Sanhueza et al., 2002; Vieira et al., 2016; Rocha et al., 2018). A promising advancement in this area is the multi-trait genotype-ideotype distance index (MGIDI), introduced by Olivoto and Nardino (2021). By considering multiple traits simultaneously and employing factor analysis to account for trait interdependencies, MGIDI offers a robust approach to genotype selection. The MGIDI is determined using BLUPs, which can remove environmental variance and deliver precise estimates of individual breeding values. Consequently, BLUPs are increasingly favored by

plant breeders for accurate genotypic value estimation (Triki et al., 2023). Moreover, this method is not affected by the issue of multi-collinearity (Olivoto and Nardino, 2021). Its successful application in crops such as wheat (Pour-Aboughadareh and Poczai, 2021; Dastfall et al., 2024), rice (Jalalifar et al., 2023; Palaniyappan et al., 2024), maize (Singamsetti et al., 2023), and oat (Klein et al., 2023) underscores its potential as a valuable tool for accelerating crop improvement.
This study aims to assess winter barley genotypes for the selection of desirable ideotypes based on their grain yield and yield-related characteristics.

MATERIALS AND METHODS

Twenty-one six-rowed winter barley (*Hordeum vulgare* L.) genotypes were included in the study, comprising the Bulgarian national standard variety Veslets (G1), along with the varieties Izgrev (G2), IZ Bori (G3), Bozhin (G4), Zemela (G5), and sixteen advanced breeding lines (G6 to G21)
The study was conducted over two growing years, 2021/2022 and 2022/2023, at the experimental field of the Institute of Agriculture-Karnobat, Southeastern Bulgaria (42°39' N, 26°59' E). The soil of the experimental field was slightly acidic (pH 6.2) Pellic Vertisol. The experiments were designed using a complete block with four replications on 10 m^2 plots, with a sowing rate of 450 germinated seeds per m^2. Standard technology for growing winter barley breeding materials at the Institute was employed.
The plant height (PH, cm), spike length (SL, cm), number of spikelets per spike (NSS), number of grains per spike (NGS), and grain weight per spike (GSW, g) were measured on 20 randomly selected plants in each replication of each genotype. The number of spikes per m^2 (SPM) was determined by courting of spikes before harvest in 0.25 m^2 area from the middle of plots and converted to 1 m^2. Lodging was rated on a scale 9-1, where 9 indicates a high level of resistance to lodging. Grain yield (GY, t ha^{-1}) and 1000-grain weight (TGW, g) were determined on a plot basis.
Data analysis and graph construction were performed using R (version 4.3.0) in the R Studio integrated development environment. Two-way analysis of variance (ANOVA) was used to identify significant differences among the genotypes and growing seasons. The genetic parameters and multi-trait genotype-ideotype distance index (MGIDI) were calculated using the R package 'metan' (Olivoto and Lúcio, 2020). Heritability estimates are classified as low (5-10%), medium (10-30%) and high (30-60%) (Dabholkar, 1992).

RESULTS AND DISCUSSION

Analysis of Variance and Genetic Parameters

The result of combined analysis of variance (Table 1) revealed highly significant variation ($p < 0.001$) between genotype, year, and genotype by year interaction for all studied traits.
The lowest value of phenotypic variance (Vph) was observed for grain weight per spike, whereas the highest was recorded for the number of spikes per m^2 (Table 2). Broad-sense heritability (H^2) estimates were high for spike length and 1000-grain weight, moderate for the number of spikes per m^2, plant height, spikelet number, grain number per spike, and grain weight per spike, and low for lodging and grain yield. Heritability on the mean basis (h^2_{mg}) was moderate to high for most of studied traits. Traits with high heritability should be prioritized for direct genetic selection, while those with moderate and low heritability may benefit from a

combination of genetic and environmental management strategies. The accuracy (Ac) of selection was low for lodging, moderate for grain yield, and high for the rest of the studied traits. Genotype-environment correlation (rge) exhibited high values for most of the traits, indicating the significant role of both genetic and environmental factors in trait expression and performance. The highest value for the coefficient of relative variation (CV ratio) for 1000-grain weight implies that genetic differences are the main source of variation for this trait. As a result, selecting for higher 1000-grain weight will likely produce substantial changes in this trait, making direct selection an effective strategy for improving 1000-grain weight in breeding program.

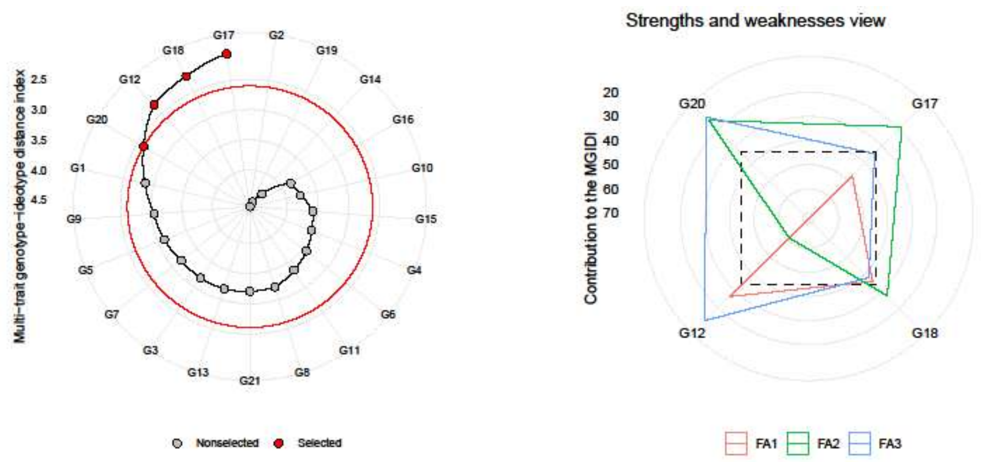
Multi-Trait Genotype–Ideotype Distance Index (MGIDI)

In the 2021/2022 growing season, four breeding lines—G17, G18, G12, and G20—were ranked higher than the standard variety Veslets (G1), applying a 20% selection intensity (Figure 1). The right part of Figure 1 displays the strengths and weaknesses of the selected genotypes. The figure indicates that genotype G12 had strengths related to FA2, suggesting that this breeding line exhibited high values for spikelets and grain number per spike, grain weight per spike, and lodging resistance. The minimal contribution of FA2 for genotype G17 indicates that this genotype had the highest number of spikes per square meter and the highest grain yield for that growing year. Both G20 and G12 exhibited strengths related to FA3, suggesting these genotypes possessed a favorable combination of plant height, spike length, and 1000-grain weight.

Figure 1. Ranking of genotypes based on the Multi-Trait Genotype-Ideotype Distance Index (MGIDI) for 2021/2022 growing season



In the 2022/2023 growing season, variety Zemela (G5) and the breeding lines G7, G10, and G12 were selected (Figure 2). The strengths and weaknesses view of the selected genotypes shows that G5 and G10 had strengths connected to FA1, indicating high spike productivity as a result of high spikelet and grain number and grain weight per spike. The lowest contribution of FA2 for genotype G7 suggests that the genotype is characterized by a high number of spikes per square meter, shorter stems, and long spikes. G12 exhibited strengths related to FA3, suggesting this genotype possessed a favorable combination for grain yield and lodging resistance in this growing year.

The ranking of genotypes based on MGIDI fluctuated significantly between the two study years, underscoring a pronounced genotype-by-environment interaction. Notably, G12 consistently emerged as a top-performing advanced line among the selected genotypes, highlighting its adaptability across varying environmental conditions.

The selection differential and selection gain observed in the MGIDI were negative for studied yield-related traits (Table 2). These findings may be attributed to the prioritization of grain yield, suggesting a potential negative relationship between the studied yield-related traits and actual grain yield.

The MGIDI index achieved the desired selection differential (SD) for all studied traits except plant height in 2021/2022 (Table 3) and for all traits except plant height and the number of spikes per m² in 2022/2023 (Table 4). Despite the undesired positive gains in plant height in both growing years, the index still showed substantial genetic improvements. The most significant genetic gain was observed for grain weight per spike, with selection differentials (SD) of 11.10% in 2021/2022 and 13.60% in 2022/2023.
The less significant gains for other traits can be attributed to the simultaneous selection of multiple traits, which tends to reduce the genetic gain for each trait individually (Almeida et al., 2021). However, the reduction in individual trait gains can be offset by the overall genetic gains across the set of traits. In present study, the MGIDI index delivered total gains of 43.37% in 2021/2022 and 62.24% in 2022/2023 for direct selection, considering traits with desired positive gains. This indicates that the MGIDI index is an effective tool for selecting genotypes with the desired characteristics.

Figure 2. Ranking of genotypes based on the Multi-Trait Genotype-Ideotype Distance Index (MGIDI) for 2022/2023 growing season

CONCLUSIONS

The combined analysis of variance indicated highly significant variations among genotypes, years, and their interaction for all the studied traits. Most traits showed moderate to high heritability (30% < $H^2 \leq$ 60%), except for lodging and grain yield (H^2 < 30%). Genotype rankings based on MGIDI were influenced by year-to-year environmental variation. Advanced line G12 demonstrated consistent high performance across both years, establishing it as a promising candidate for further cultivar development. The identified superior genotypes, exhibiting traits aligned with the ideal plant type, hold potential for enhancing grain yield in future winter barley breeding programs.

ABSTRACT

Fluoride is a naturally occurring element that is abundantly found in nature and belongs to the halogen group. Fluoride compounds are encountered by individuals in several ways on a daily basis, including through the consumption of drinking water, food, and dental products. Research has shown that fluoride has detrimental effects on human health and can lead to toxicity. Furthermore, clinical research and animal trials have conclusively established that fluoride exerts harmful effects on the male reproductive system. Upon reviewing the literature, researchers have conducted numerous studies using antioxidant molecules to enhance the detoxifying effects of fluoride. N-acetylcysteine (Nac) is an amino acid that is produced from L-cysteine and has antioxidant effects. Nac has been globally utilized for more than five decades and is included in the World Health Organization's list of essential medicines. Scientific evidence has demonstrated that Nac effectively safeguards cells and tissues from oxidative stress by eliminating reactive oxygen radicals (ROS). Additionally, researchers have discovered that Nac shields cells from apoptosis by influencing genes involved in programmed cell death. The investigation involved individual and combined application of sodium fluoride (NaF) (50 ppm) and Nac (1 mM) to the TM3 Leydig cell line for a duration of 24 hours. We assessed the cytotoxicity in Leydig cells using the lactate dehydrogenase (LDH) test after exposure and determined apoptosis using the double fluorescence staining method. The findings demonstrated that sodium fluoride induced cytotoxicity in Leydig cells and resulted in apoptosis. Furthermore, studies have established that Nac, renowned for its antioxidant properties, could potentially shield cells from the damaging effects of sodium fluoride.

Keywords: Fluoride, Leydig cells, n-acetylcysteine, apoptosis, cytotoxicity.

INTRODUCTION

Fluorine, a nonmetal in the halogen group, is an environmental contaminant. Fluorine, as an element, does not naturally exist in ionized form, and readily combines with other elements to generate fluoride compounds (Mikkonen et al., 2018; Su et al., 2020). The primary fluoride compounds consist of sodium fluoride (NaF), aluminum fluoride (AlF_3), and calcium fluoride (CaF_2) (Ashoori et al., 2022). Fluoride, an exogenous chemical, is commonly present in drinking water (Chaudhari et al., 2024). Furthermore, the chemical, plastic, and petroleum sectors utilize fluoride compounds that are naturally present in plants and foods (Veneri et al., 2023). Exceeding the limit of 1.5 ppm of fluoride intake, as stated by the World Health Organization, leads to toxicity in both humans and animals (Banerjee and Roychoudhury 2019).

Fluoride has been associated with a range of harmful effects, including the development of diseases such as cancer, brain damage, Alzheimer's, thyroid disorders, and infertility. Research indicates that fluoride triggers oxidative stress, inflammatory responses, and programmed cell death mechanisms such necrosis and apoptosis (Long et al 2003; Rahmani et al., 2020; Veneri et al., 2023; Guo et al., 2024; Taher et al., 2024). Fluoride exposure has been found to result in a decline in male fertility, as observed by Liang et al. in 2020. Fluoride induces testicular oxidative damage in the male reproductive system, leading to damage to the sperm cell membrane. It has been noted that it contributes to the suppression of sperm production and reduced sperm function (Öncü et al., 2007). Several studies indicate that exposure to fluoride leads to a decline in sperm quality, as well as a drop in sperm count and motility (Long et al., 2009; Wang et al., 2009; Chaithra et al., 2018). Research conducted on Leydig cells has shown that exposure to fluoride leads to the production of ROS, an elevation in lactate dehydrogenase levels, damage to mitochondria, and the initiation of apoptosis (Liang et al., 2020). Fluoride exposure is recognized to induce an elevation in reactive oxygen species levels by inhibiting the production of intracellular agents that scavenge free radicals (Zhang et al., 2023). A study investigating the impact of fluoride on testicular toxicity found that prolonged exposure to fluoride led to an increase in the formation of superoxide anion, which in turn had a detrimental effect on the mitochondrial membrane potential. Fluoride exposure has been found to reduce the activities of enzyme antioxidants, such as catalase, superoxide dismutase, and glutathione peroxidase, in the testis. This exposure also affects sperm quality and morphology, leading to toxicity (Radovanovic et al., 2022).

N-acetylcysteine (Nac) is a compound that is derived from L-cysteine, which is a naturally occurring amino acid. Nac, which occurs naturally in meat, fish, grains, dairy products, soybeans, and eggs, possesses anti-inflammatory, antimicrobial, antiapoptotic, and antioxidant properties (Schwalfenberg, 2021; Zhou et al., 2021). Initially, Nac was employed as a therapeutic intervention for individuals suffering with cystic fibrosis, owing to its ability to dissolve mucus. Furthermore, Nac has been frequently utilized as a therapeutic agent to counteract paracetamol overdose (Herzenberg, 2019). Nac has been found to possess several notable qualities, such as the ability to restore glutathione levels, enhance the activity of glutathione S-transferase, stabilize protein structures, and eliminate free radicals (Schwalfenberg, 2021). A study found that the injection of Nac prevented NaF-induced apoptosis. Based on this investigation, Nac has demonstrated a therapeutic impact on apoptosis (Zhang et al., 2023). Studies investigating the effects of Nac on the male reproductive system have shown that it elevates sperm concentration and volume. Additionally, it has been found to decrease sperm DNA oxidation (Zhou, 2021).

This study utilized Leydig cells as a model to demonstrate the harmful effects of sodium fluoride on the male reproductive system. The application of NaF and Nac to Leydig cells, which play a crucial role in testosterone production in the male reproductive system, resulted in the use of the lactate dehydrogenase (LDH) test to measure cell toxicity, and the double fluorescence staining method to detect apoptosis. Thus, we have investigated for the first time whether Nac plays a therapeutic role on NaF-induced cell damage, using TM3 Leydig cells.

MATERIAL AND METHODS

Cell Culture Condition and Treatments

The TM3 cell line employed in the experiment is a non-tumorigenic line derived from Leydig cells of 11-13-day-old mice. We brought it to our laboratory from the American Type Culture Collection (ATCC): The Global Bioresource Center, where we grow it under *in vitro* conditions through regular passages two to three times a week. The cells are grown in 50:50 DMEM/F12 culture medium supplemented with 5% horse serum, 2.5% fetal bovine serum, 2.5

mM L-glutamine, 0.5 mM sodium pyruvate, 1.2 g/L sodium bicarbonate, 15 mM HEPES, and PSA (penicillin, streptomycin, and amphoterin) and incubated at 37ºC in a humidified environment containing 5% CO_2 and 95% air.

This study involved the setting up of several groups, including a control group, a group treated with sodium fluoride (NaF), a group treated with N-acetyl cysteine (Nac), and a group treated with both fluoride and N-acetyl cysteine. NaF concentration was determined as 50 ppm, while Nac concentration was determined as 1 mM. Following the administration of fluoride and Nac to TM3 Leydig cells, the cytotoxicity was assessed using the LDH test, while apoptosis was determined using the double fluorescence staining method.

Determination of cytotoxicity by measuring Lactate Dehydrogenase enzyme (LDH)

LDH is an intracellular enzyme located in the cytoplasm of cells. LDH is released into the external environment when the cell membrane is damaged. The death of cells in a culture or harm to the plasma membrane results in an elevation in LDH enzyme activity. Initially, LDH catalyzes the conversion of lactate into pyruvate. Through this process, NAD+ undergoes reduction and is transformed into NADH/H+. During the second stage, the catalyst substance facilitates the conversion of a tetrazolium salt from NADH/H+ to the red formazan product of H/H+. The quantity of pigment produced is directly proportional to the extent of harm inflicted against the cellular membrane. Each well of the 96-well culture plates was inoculated with 10,000 cells. NaF and Nac concentrations were made in a medium containing 1% HS serum. The samples were then applied for 24 hours and incubated in a 37°C CO2 incubator. After the experiment period concluded, a 100 µl mixture of dye and enzyme solutions was added to each well of the kit. The results were obtained by measuring the absorbance of the increasing color of the red formazan product after 30 minutes of incubation. This was done using a spectrophotometer at a wavelength of 492 nm to assess the cytotoxicity. Once the absorbance readings were acquired, the percentage of the resulting toxicity was computed.

Determination of apoptosis with Double Fluorescent Staining (Propidium Iodide/Hoechst 33342) Method

The approach of double fluorescence labeling was employed to ascertain the occurrence of apoptosis in cells. The Ho342 fluorescent dye specifically attaches to adenine-thymine-rich regions that are exposed in fragmented DNA, allowing it to label apoptotic cells in a blue color. The experimental mixture was generated by combining 20 µl of Ho342 with 3960 µl of PBS, obtained from solutions of Hoechst 33342 (1 mg/ml) and PBS (1M, pH 7.4), respectively. We seeded 10,000 cells per well in 24-well culture dishes. We treated the samples with NaF and Nac solutions that were produced in a medium containing 1% HS serum. The samples were incubated in a 37°C CO2 incubator for 24 hours. After the experimental period, the cells were rinsed with a PBS solution. Then, 0.2 ml of the experimental combination was introduced into each well and left to incubate for 15–30 minutes at a temperature of 37 °C. After the incubation period, the cells were rinsed with PBS one to two times and seen using a fluorescence microscope. The specimens were analyzed using an Olympus IX71 fluorescence microscope equipped with a suitable filter. They were then photographed sequentially at regular intervals using an Olympus DP72 video camera.

Statistical Analysis

In the evaluation of statistical analysis, firstly data distribution was tested for normality using Shapiro-Wilk test. Then, one-way analysis of variance (ANOVA) followed by Tukey's multiple comparisons test was used for comparisons between all groups. Results were expressed as mean ± standard error and $p<0.05$ was considered statistically significant. All statistical analyses were performed using GraphPad Prism 10 software (GraphPad Software, San Diego, California, USA).

RESULTS

Cytotoxicity results

The effect of NaF on cell toxicity was investigated using the LDH kit 24 hours after fluoride was applied to TM3 Leydig cells separately and together with Nac. The cytotoxicity rates (%) obtained are shown in Figure 1. When the control and NaF groups were compared in terms of LDH values, a significant increase was observed in the group exposed only to NaF compared to the control group at the end of 24 hours. When the LDH values of the group exposed only to NaF and the group applied together with Nac were compared, a significant decrease was observed in the NaF+Nac group. Based on the cytotoxicity data we obtained, it was understood that NaF has a cytotoxic effect on Leydig cells. In addition, it was determined that Nac could be used as a very effective antioxidant molecule to improve this negative effect of NaF on Leydig cells.

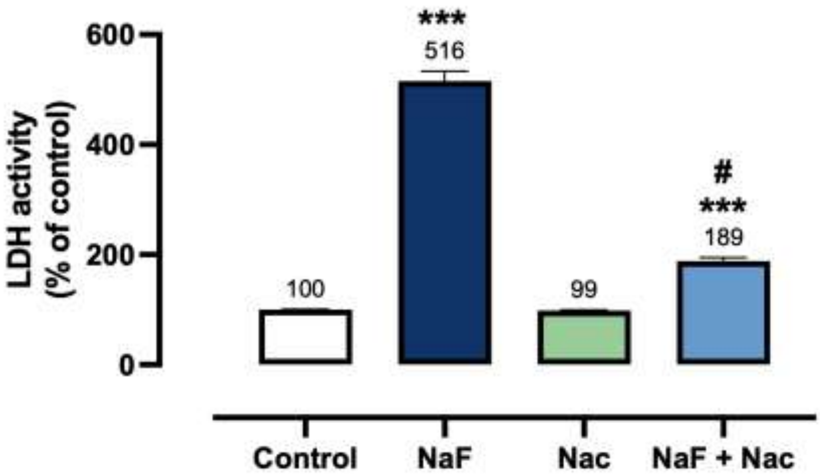

Figure 1. Effects of NaF and Nac on cytotoxicity in TM3 Leydig cells. (*p<0.05; **p<0.01; ***p<0.001; *: compared with controls; #: compared with fluoride group).

Apoptosis results

The percentage of live and apoptotic cells determined using the fluorescent staining method in the experimental groups formed with NaF and Nac in TM3 Leydig cells are presented in Figures 2 and 3, and diagnostic photographs are presented in Figure 4. After the experimental period, the apoptosis rates were compared between the control group and the NaF group. The NaF group showed a substantial rise in apoptosis rates, whereas there was a significant decrease in live cell rates ($p<0.001$). When comparing the group that just administered NaF with the group that applied Nac in addition to NaF, a notable drop in the rate of apoptosis was detected in the NaF + Nac group, while a significant rise in the rate of live cells was observed ($p<0.001$).

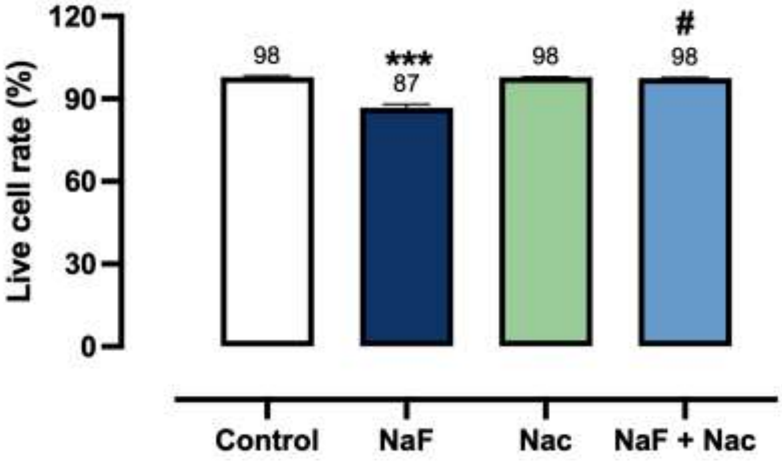

Figure 2. Effects of NaF and Nac on live cell rate in TM3 Leydig cells. (*p<0.05; **p<0.01; ***p<0.001; *: compared with controls; #: compared with fluoride group).

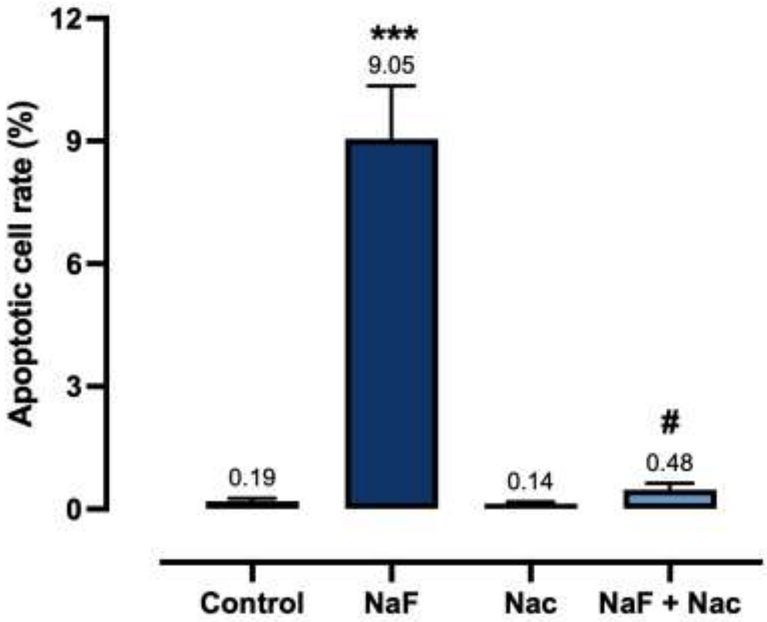

Figure 3. Effects of NaF and Nac on apoptotic cell rate in TM3 Leydig cells. (*p<0.05; **p<0.01; ***p<0.001; *: compared with controls; #: compared with fluoride group).

DISCUSSION

Studies have shown that high levels of fluoride exposure can cause toxic effects on different systems of the body (Fishta et al., 2024; Masnaoui, 2024; Taher et al., 2024). Analysis of clinical research and animal tests clearly demonstrates that exposure to fluoride leads to both structural and functional abnormalities in spermatozoa, resulting in reduced sperm count and infertility. These adverse effects have a detrimental impact on male reproductive functions (Chaithra et al., 2020; He et al., 2023). Based on these studies, safe doses of sodium fluoride (NaF) can be determined, and its use can be limited. The role of Nac, which has strong antioxidant properties, in reducing NaF-induced damage in Leydig cells was investigated for the first time in this study.

Several studies have shown that NaF enhances cytotoxicity (Liu et al., 2008; Kim et al., 2015; Kumar et al., 2018; Pal et al., 2021). The LDH test is utilized to ascertain the level of activity shown by the lactate dehydrogenase enzyme that is discharged into the cytoplasm as a result of cellular damage and death (Castiglione et al., 2024). In a study conducted with human liver cells (L-02), as a result of 48-hour exposure to sodium fluoride (NaF) at different concentrations (100 μg/mL, 200 μg/mL, and 400 μg/mL), a significant increase in LDH level was observed depending on the increasing NaF concentration (Guo et al., 2024). In a study with microglial cells (BV-2), exposure to 0, 0.5, 1, and 2 mmol/L NaF was performed for 24 hours. The results showed that cell membrane integrity was damaged dose-dependently after fluoride exposure and caused an increase in LDH levels compared to the control (Zhang et al., 2024). In a study aimed at illustrating the therapeutic potential of Nac, the human dermal fibroblasts

(HDFs) were grown in a normal medium (5.5 mM glucose) for 72 h, and the experimental groups were grown in medium containing 25-, 50-, and 75-mM glucose concentrations. After 1 mM Nac treatment was applied to cells exposed to 50 mM and 75 mM glucose, a significant increase in LDH was observed in the cultured HDFs, while Nac was observed to attenuate these effects (Rashnavadi et al., 2022). Similar to previous studies, our *in vitro* study using Leydig cells showed that 50 ppm fluoride increased cytotoxicity, while Nac provided significant protection against fluoride toxicity.

Research has shown that the accumulation of reactive oxygen species within cells leads to oxidative stress, which damages important cellular components like proteins, DNA, and lipids. This damage can ultimately result in cell death, a process known as apoptosis (Redza-Dutordoir & Averill-Bates, 2016; Galadari et al., 2017; Cadenas, 2018). Several studies have extensively established that fluoride acts through various apoptotic pathways (Zhang et al., 2016; Ni et al., 2018; Song et al., 2021; Zhou et al., 2022). A study conducted using human lung epithelial cells in a laboratory setting demonstrated that a concentration of 2 mM NaF resulted in an elevation of cell mortality through the activation of caspases after a 24-hour period (Song et al., 2021). A study conducted on cementoblast cells found that treatment to NaF at concentrations of 5 mM and 10 mM resulted in the cells displaying characteristics of apoptosis, such as nuclear condensation and fragmentation, as compared to the control group (Ni et al., 2018). During an experiment involving rat fibroblast cells, researchers noted alterations in the expression of apoptosis-related genes, such as Bax and Bcl2, following a 24-hour exposure to a fluoride concentration of 1 mM. Zhou et al. (2022) found that exposure to fluoride led to a significant drop in Bcl2 expression, while Bax expression was observed to increase. A further investigation explored the beneficial impact of Nac on countering the harmful consequences of 2-ethylhexyldiphenyl phosphate. The study revealed that Nac effectively inhibited cell death (Wang et al., 2024). In parallel with the previous studies, our findings revealed that 50 ppm fluoride triggered apoptosis, while 1 mM Nac inhibited apoptosis.

In conclusion, this study showed that NaF induced cytotoxicity and apoptosis in Leydig cells. Nac suppressed cytotoxicity and reduced apoptotic cell death against the damage caused by NaF. As a result, this study revealed that Nac inhibited cellular damage by preventing apoptosis.

CONVERSION OF BREAD WASTE TO VALUE-ADDED PRODUCTS

Göksel TIRPANCI SİVRİ[1], Ahmet Şükrü DEMİRCİ[1]

ABSTRACT

In many countries, waste bread is one of the most important components of food waste. Due to short shelf life and overproduction, ~10% of bread (900,000 tonnes) is wasted globally along the supply chain from producer to consumer consumption. This leads to a large amount of unused bread in supermarkets and households. However, waste bread has a high potential to be utilized as a renewable raw material. Bread waste is a potential biosource for the production of fermentable sugars. Starchy food waste is easily degradable and therefore a good alternative biomass source. Fermentation is the most researched strategy for the recycling of bakery waste. The saccharification and hydrolysis of starch in bread with the help of enzymes causes the release of simple sugars. These simple sugars can then be utilized by microorganisms and converted into valuable products. Ethanol, hydrogen, lactic acid, 2,3-butanediol, paramylon, and xanthan gum can be produced by microorganisms through further fermentation of the hydrolysate following hydrolysis. In this review, the latest advancements in bread waste recycling are discussed, the potential for producing novel chemicals is explored, and the efficiency of converting bread waste into fermentable sugars for new product development is evaluated.

Key words: Waste bread, biomass, food waste

INTRODUCTION

In our world where 870 million people are malnourished annually, food waste has reached serious dimensions. According to FAO, it is estimated that 1.3 billion tonnes of food with an annual economic value of 1 trillion dollars is wasted. FAO data show that the amount wasted or lost constitutes one third of the world's food production (FAO, 2013). Nowadays, the large number of supermarkets and fast food chains, especially in developed countries, make it easier for people to access food and waste more food. While the growing number of supermarkets and fast food chains in developed countries has made food more accessible, it has also contributed to a significant increase in food waste. Moreover, the increase in food diversity and the appeal of attractive packaging encourage people to purchase more than they need, further exacerbating wastage. As a result, large quantities of various food types are wasted globally, with bread being one of the most significant contributors to this waste (Demirci et al. 2017).

Bread has been the most fundamental food source for people worldwide and the most produced and consumed food product throughout history. Waste occurs when bread is not used for its intended purpose, such as not being consumed by humans or being discarded. Even when bread is given to animals rather than being eaten, it is still considered waste. This is because the resources—such as labor, energy, and income—invested in producing flour and baking bread are effectively lost when the bread is not consumed by people. Therefore, the use of bread instead of grain products that can be used directly as animal feed is considered wasteful in economic terms. In Turkey, 95 million pieces of bread are consumed daily and 35 billion pieces of bread are consumed annually. However, 1,500 tonnes of bread is wasted per day and 542 thousand tonnes per year (TMO, 2013). In 2019, Dutch households wasted over 7.3kg of bread and pastries. This is 20% of the bread produced in the same year (van Gelder, 2020a, 2020b). In Sweden, 80,410 tonnes of bread are wasted every year, which is 8.1 kg per capita per year (Brancoli et al.,2019). It is estimated that a person in Spain consumes about 46-58 kg of bread per year. Bread waste (BW) arises in industrial factories and is removed due to poor wheat quality, errors in baking technology, storage, transport systems or new market demands (commercial crustless bread). According to statistical data, 30% of the total bread produced in Spain (660 million kg out of a production of 2200 million kg) is food waste (Sanchez et al 2014). In the United Kingdom (UK), the bread and sandwich bread sector is one of the largest food industries. The amount of bread waste is estimated to reach approximately 1.2 million tonnes per year (Melikoğlu, 2008). The most important factor causing bread waste is stale or mouldy bread before it can be consumed as a result of inappropriate storage conditions. One of the reasons for bread waste is the lack of knowledge about the methods of utilizing stale bread. According to the Tesco supermarket chain, around 10% of baked goods ended up in the bin in the UK in 2021–2022 (Bedford, 2022). Some of the bread that is not consumed but returned to bakeries is processed into breadcrumbs or animal feed, but a large proportion is unsuitable for such reprocessing due to mould contamination, high degree of staling and other reasons.

Bread waste and by-products are generated throughout the stages of processing, manufacturing, and retail. Various factors influence the quality of bakery products. Many physical and chemical changes occur during the storage of bread with short shelf life. Changes such as taste, aroma, water absorption capacity, crystallinity, opacity, soluble starch content and tightening of the bread cause the bread to spoil. Spoilt bread loses its sensory properties. Although bread is still healthy and nutritious, these changes cause a negative perception in the consumer. As a result, large quantities of bread are thrown away and cause great economic loss. Therefore, waste bread is a very important waste food problem (Melikoğlu and Webb, 2013). BW, being one of the most commonly discarded foods, has the potential to serve as a renewable resource. Fermentation is the most frequently discussed method for recycling bread waste. This waste is rich in starch, proteins, and nutrients, making it ideal for fermentation processes (Mihajlovski et al., 2020). In addition, there are other options proposed by researchers for recycling bakery waste. The aim of this review is to discuss the latest developments in the recycling of bread waste, to investigate the potential to produce new chemicals and to determine the efficiency of using bread waste to produce sugar, which is used to make a new product through fermentation.

Bread waste composition and enzymatic hydrolysis

The nutritional content of bread varies according to the type of bread, but in general 100 g of white bread contains about 50 g of carbohydrates (47 g in the form of starch), 37 g of water and about 8 g of protein. This composition makes bread a perfect and almost complete source of nutrition for many microorganisms as well as for its future consumers (Melikoğlu and Webb, 2013). Bread contains high amounts of starch, which can be easily hydrolysed to monomeric sugars using enzymes. Bread contains 500-750 g kg-1 starch and 3-50 g kg-1 simple sugars (Dewettinck et al. 2008). It also contains 100-150 g kg-1 protein (Thomas and Ingledew 1990). The composition of one slice of bread is shown in Table 1.

Table 1. Composition of a single slice of waste bread

Component	Weight (g)
Water	28.67
Starch	45.34
Nitrogen (N)	1.61
Protein (N x 5.7)	9.18
Phosphorus	0.10
Ash	2.26

Nutrients in foods are in the form of macromolecules such as starch and proteins. To be utilized by microorganisms, these higher molecules must be broken down into usable forms such as sugars and amino acids. Usually, this process is carried out by enzymatic hydrolysis using amylase and protease enzymes (Sarkar et al. 2012). Starch is the main component of the dry weight of bread. However, starch is a substrate for alcohol and other fermentations in industry and waste bread can be utilized as a fermentation nutrient medium for the production of various products. For the starch in bread to be used in the production of fermentation products, it must be converted into fermentable simple sugars. The conversion of starch into individual glucose units involves the hydrolysis of these α-(1 – 4) and α-(1 – 6) linkages, which can be made possible by the action of acid (H_2SO_4/HCl) or enzymes (α-amylase and glucoamylase) (Bello-Perez et al., 2020). Compared to acid or alkaline hydrolysis, enzymatic hydrolysis offers significant advantages, such as lower toxicity, cost-effectiveness, and reduced corrosion. Additionally, enzymatic hydrolysis does not produce inhibitory by-products. As a result of acid hydrolysis, various by-products such as acetic acid, furfural and 5 hydroxymethylfurfural are formed. These products inhibit the growth of microorganisms. Therefore, hydrolysates to be used for fermentation should be subjected to detoxification (Sarkar et al. 2012).

Traditionally, acid hydrolysis has been employed to produce soluble starch from insoluble starch granules by treating the starch with high concentrations of acid at room temperature for an extended period (Höfer, 2015). It was recognized that acids like HCl and H_2SO_4 break glucosidic linkages and modify the physical and chemical properties of native starch.

The enzymatic hydrolysis of starch to fermentable sugars has a typical 2-step method. In the first step, the gelatinized starch solution is liquefied with the temperature-stable enzyme α-amylase (EC 3.2.1.1) to reduce its viscosity and break the α-1.4 glycosidic bonds in the middle of the amylose and amylopectin chain to form short-chain dextrins. In the second step of starch hydrolysis (saccharification), dextrins are saccharified with the enzyme glucoamylase (amyloglucosidase) (EC 3.2.1.3) to yield monomer sugars (glucose) (Demirci et al., 2016). Generally, supporting enzymes such as protease, cellulase, pullulanase etc. are also used to increase the amount of fermentable sugars, to reduce the viscosity of the pellet and to obtain free amino nitrogen that the microorganism can use as food during the fermentation phase (Sapinska et al. 2013). Demirci and colleagues investigated the enzymatic hydrolysis of bread waste during the liquefaction and saccharification stages, using different bread waste loadings. They achieved a maximum glucose conversion yield of 86%, which corresponds to 99% of the theoretical maximum. This was accomplished under optimal conditions of 0.05 g/g substrate loading, 0.03 KNU/g α-amylase, and 3.6 AGU/g glucoamylase (Demirci et al., 2017).

Waste bread utilisation by fermentation

As mentioned earlier, BW is a rich source of high-quality fermentable food-grade sugars, along with other nutrients, making food or bread waste an appealing substrate for fermentation processes. The simple sugars obtained are fermented to produce new products. This type of fermentation is used in biorefineries, in the production of bioethanol, fuels and chemicals, in the brewing industry, etc. (Nigam, 2013).

Ethanol Production

Raw materials that contain high levels of sugar or starch-cellulose, which can be converted into simple sugars, can be used in ethanol production. Food price increases and ethical problems caused by the use of agricultural products in ethanol production and the solution of technological difficulties in the conversion of lignocellulosic agricultural wastes reveal the necessity of discovering new raw materials and using them for this purpose. The utilisation of food wastes in this direction is important and studies on these issues have been increasing in recent years. Studies on the utilisation of waste bread in ethanol production have shown that bread can be a highly efficient ethanol fermentation feedstock.

Ebrahimi et al. (2008) investigated alcohol production by separate hydrolysis and fermentation of waste bread containing 350 g kg -1 raw material and obtained alcohol yield as 350 g/kg bread dry matter. Pietrzak and Kawa-Rygielska (2014) investigated the ethanol conversion of waste wheat-rye bread directly from starch using Granular Starch Hydrolyzing Enzymes (GSHE) and the ethanol yield was determined as 334.81 g kg sugar. Mihajlovski et al. (2020) utilized bread waste to produce bioethanol by employing crude hydrolytic enzymes from the Hymenobacter sp. CKS3 strain. The hydrolysate primarily consists of dextrins, maltotriose, maltose, and glucose. Bread waste hydrolysate contains 19.89 g of reducing sugars per liter, which, when combined with waste baker's yeast, produces 1.73% ethanol (Mihajlovski et al., 2020). More recently, Narisetty et al. (2022) conducted an in-depth study on BW hydrolysis followed by ethanol fermentation. BW was saccharified using both acidic and enzymatic hydrolysis, with both methods optimized for solid and acid/enzyme loading to maximize productivity. The acidic and enzymatic hydrolysis of BW achieved maximum glucose releases of 75.0 g/L and 97.9 g/L, respectively, at a solid loading of 20% w/v, corresponding to 73.5% and 95.9% of the maximum theoretical yield. The resulting hydrolysate was then fermented into ethanol. The fed-batch fermentation using glucose-rich acidic and enzymatic hydrolysates resulted in ethanol titers of 106.9, and 114.9 g/L with a conversion yield and productivity of 0.47, and 0.49 g/g, and 3.0, and 3.2 g/L.h, respectively. Studies have shown that waste bread is a highly efficient and unique resource that can be used in ethanol production. The high carbohydrate content of bread, which can be converted into fermentable sugars, shows that it can be a good raw material for bioethanol production.

Lactic Acid Production

Cox et al. (2022) employed *B. coagulans* DSM1 for lactic acid fermentation of bread waste under non-sterile conditions. The study found that 419.1 g of lactic acid could be produced from 1 kg of waste bread, with 155.4 g of lactic acid being generated from 182.8 g of glucose derived from 370.8 g of bread waste. In a recent study by Olszewska-Widdrat et al. (2020), lactic acid (LA) was produced from sugar bread (SB) using *B. coagulans*. The SB hydrolysate, obtained after liquefaction and saccharification, contained 76.9 g/L of glucose, 9.98 g/L of fructose, and 38.5 g/L of disaccharides. Batch fermentation of this SB hydrolysate by *B. coagulans* resulted in LA titers of 80.0 g/L after 30 hours. Sadaf et al. (2021) utilized various strains of *Lactobacillus paracasei* (SKL-9, SKL-11, and SKL-21) to produce lactic acid from 598 mg of reducing sugars. The results were as follows: SKL-9 produced 53 mg of lactic acid per gram of bread waste, SKL-11 produced 56 mg per gram, and SKL-21 produced 54 mg per gram, which corresponded to 26, 28, and 27 g/L, respectively.

Biohydrogen production

Doi et al. (2009) carried out biohydrogen production by anaerobic fermentation using rhizosphere microflora and obtained a yield of 1.3 mol H_2 mol- 1 glucose. According to Han et al. (2016), 1g of waste bread could generate 0.332 g of glucose which could be further utilized to produce 109.5 ml of hydrogen (1.6 mol H_2 mol^{-1}glucose). Adessi et al. (2018) used a sequential system composed of lactic fermentation and photofermentation, yielding 3.1 mol H_2 mol^{-1} glucose.

2,3-Butanediol production

2,3-Butanediol, also known as 2,3-butylene glycol or dimethyl ethylene glycol, is a chiral compound that can exist as either a colorless and odorless liquid or a crystalline solid. It can be produced economically through the bioconversion of natural resources. 2,3-Butanediol can be converted into 1,3-butadiene, a key component in synthetic rubber production. Its derivatives are utilized in various applications, including as freezing agents, solvents, flavorings, and in the production of plastics. 2,3-Butanediol is used in the food, chemical, pharmaceutical, petrochemical and aerospace industries (Syu, 2001). Maina et al. (2021) evaluated the production of D-2,3-butanediol by *Bacillus amyloliquefaciens* using bakery waste hydrolysates. The highest yield of D-2,3-butanediol achieved from bread waste was 55.2 g/L. Narisetty et al. (2022) utilized *Enterobacter ludwigii* to produce 2,3-butanediol from bread waste. Through acidic and enzymatic hydrolysis, they achieved a glucose yield of 330–530 g per kilogram of bread waste. This glucose was then used by *E. ludwigii* for the production of 2,3-butanediol. The study demonstrated that 150–200 g of 2,3-butanediol can be produced from 1 kg of bread waste that has been saccharified by either acid or enzymatic pre-treatment.

Xanthan gum biosynthesis

Xanthan gum is a non-toxic, water-soluble, biodegradable, biocompatible, and thermally stable substance that remains stable under both acidic and alkaline conditions (Kumar et al., 2018). It is commonly used as a thickener and stabilizer for suspensions and emulsions in the food industry (Nasrabadi et al., 2016). Demirci et al. (2019) demonstrated the successful use of bread waste hydrolysate as a biological source for xanthan gum production. Bread waste was cut into small pieces, pulverized in a laboratory mill, and enzymatically hydrolyzed. The resulting hydrolyzed bread solution was diluted with sterile distilled water to achieve sugar concentrations of 40, 80, and 120 g/L, and then treated with *Xanthomonas campestris* NRRL B-1459, *Xanthomonas axonopodis*, *Xanthomonas hortorum*, and *Xanthomonas axonopodis*. The highest xanthan gum production levels and conversion yields were 12.5 g/L (0.166 g xanthan per gram of sugar) for *X. hortorum*, 10.3 g/L (0.121 g xanthan per gram of sugar) for *X. axonopodis*, 14.3 g/L (0.149 g xanthan per gram of sugar) for *X. axonopodis*, and 12.9 g/L (0.155 g xanthan per gram of sugar) for *X. campestris*. This study indicates that hydrolysates from bread waste could be a promising and cost-effective carbon source for xanthan gum production.

Other fermented products

There are other studies related to the biocycling of waste bread. In other studies where bread was used as raw material; the production of flavour compounds with *Geotrichum candidum* (Daigle et al. 1999), production of amylase and protease enzymes with *Aspergillus awamori* solid phase fermentation (Melikoğlu et al. 2013a; Melikoğlu et al. 2013b), succinic acid production with *Actinobacillus succinogenes* (Leung et al. 2012).

CONCLUSIONS

Bread is an excellent raw material for biotechnological processes as it contains carbon, nitrogen, major and minor nutrients in a balanced way. BW, one of the most commonly wasted foods, can be repurposed as a renewable resource through modern utilisation methods and technologies. Fermentation is a widely discussed strategy for recycling bread waste. It serves as an excellent feedstock for microorganisms such as bacteria, fungi, and yeasts. These microorganisms produce enzymes that facilitate the saccharification and hydrolysis of polysaccharides in the bread waste. Previous studies have shown that waste bread is a highly efficient, unique resource that can be used in the production of high value-added products. This approach will also have an important result in terms of preventing environmental pollution by using wastes in an environmentally friendly manner.

ABSTRACT

Palm oil is a vegetable oil used for many food and non-food applications. The global demand for palm oil will continue to rise, owing to the growing population and expanding economy. To meet increasing demand, the area of land dedicated to palm oil production in producer countries in Southeast Asia such as Malaysia and Indonesia has increased steadily. Palm oil establishment in these areas has resulted in widespread deforestation, deterioration of ecological balance, and increased greenhouse gas emissions. To avoid these problems and fulfill the growing global demand for palm oil, voluntary certification under the International Roundtable Palm Oil (RSPO) and Malaysian Sustainable Palm Oil (MSPO) emerges as an efficient solution. These certifications aim to ensure sustainability, optimization of productivity and efficiency while adhering to transparency, ethical, and legal principles, respecting communities, supporting smallholders, and protecting workers while conserving the ecosystem. A related study examines the impact of sustainability-focused certification on product quality characteristics and stakeholder awareness in palm oil production. An assessment was conducted with approximately 104 individuals involved in the palm oil supply chain, either as producers or users. The assessment covered recognition of sustainability concepts, awareness of health benefits associated with palm oil and brand perception about certification in the context of purchasing products containing palm oil. This study has the potential to serve as a model for studies that will contribute to the advancement of conscious consumption and circular production in palm oil sustainability certification parameters. Preliminary results revealed that producers and consumers are aware of sustainability. Moreover, sustainability certification might positively affect brand recognition and purchase tendency for palm oil products. Developing efficient marketing and informative advertising based on scientific facts is crucial to maintaining and expanding awareness of the sustainability concept of palm oil and its products.

INTRODUCTION

Palm oil, widely used in food, cosmetics, and biofuels, has become a critical subject in environmental and health discussions due to its association with deforestation, biodiversity loss, and greenhouse gas emissions (Wiebe et al., 2019). To mitigate these concerns, sustainability certifications such as the Roundtable on Sustainable Palm Oil (RSPO) have been developed, aiming to promote environmentally responsible palm oil production (RSPO, 2021). Upon the demand of consumers for the use of certified palm oil; the Indonesian government introduced the Indonesian Sustainable Palm Oil (ISPO) standards in 2011, and the Malaysian government introduced the Malaysian Sustainable Palm Oil (MSPO) standards in 2015. In this direction, the establishment of well-planned and traceable palm oil production has a great determination on the protection of the environmental ecosystem in safe and healthy production (Ivancic and Koh, 2016). As of December 31, 2019, MSPO has become mandatory for all Malaysian palm oil producers and 639,407.61 hectares were registered as independent smallholders' plantations, 444,872.36 hectares were registered as organized smallholders' plantations, and 3,600,781.46 hectares were registered as total certified plantations. (MPOCC, 2024a). Making MSPO mandatory ensures that producers adopt a standard; therefore, a rapid increase has been achieved. The main objectives of the MSPO certification include; management commitment and responsibility, health worker safety and employment conditions, compliance with legal requirements, development of new plantations, and transparency (MPOCC, 2024b).

However, the success of these initiatives largely depends on consumer awareness and understanding of the sustainability issues surrounding palm oil (Taufique and Vaithianathan, 2018). Research has shown that socio-demographic factors like education and income significantly influence consumer behavior towards sustainable products (Diamantopoulos et al., 2003; Zhao et al., 2014). Moreover, gender differences have also been observed, with women generally displaying higher environmental awareness than men (Hunter et al., 2004; Zelezny et al., 2000).
Consumers' understanding of sustainability certifications plays a vital role in shaping purchasing behavior. While some studies indicate that sustainability labels influence purchasing decisions, knowledge gaps regarding these certifications persist, limiting their effectiveness. (Grankvist et al., 2004; Hartmann and Apaolaza-Ibáñez, 2012). Younger and middle-aged adults, typically more engaged in sustainability issues, are key drivers of demand for eco-friendly products.
This study seeks to assess consumer awareness and perceptions of palm oil, focusing on the acceptability of palm oil, knowledge of its uses, and the role of sustainability certifications in shaping purchasing decisions. By surveying a diverse sample, the study provides insights into consumer behavior and the factors influencing sustainable purchasing trends.

MATERIAL AND METHODS

This study employed a cross-sectional survey design to collect data on consumer awareness, perceptions, and behaviors related to palm oil and sustainability certification awareness. The survey was distributed online and person to person, simultaneously to a diverse sample of 104 participants across various demographics. The questionnaire included sections on general awareness of palm oil (e.g., familiarity with palm oil used in products), understanding of sustainable palm oil (e.g., knowledge of RSPO certification), and purchasing behavior (e.g., the influence of sustainability claims on buying decisions). Participants were also asked to rate the quality of palm oil-containing products and to identify differences between palm oil and other related oils. All responses were examined and presented as percentages on graphs.

RESULTS AND DISCUSSION

The results of the survey are shown in graphs in Figures. According to the findings given in Figure 1, the survey's participant profile, predominantly female (68.26%) and concentrated in the 25-44 age range, reflects a well-educated and relatively affluent group, with 52.88% holding a master's degree or higher and 40.38% reporting high income. This demographic, often linked to greater environmental awareness and sustainable consumption behaviors, likely contributed to the high levels of awareness and preference for sustainable palm oil observed in the survey, indicating a group well-positioned to make informed, eco-conscious purchasing decisions.

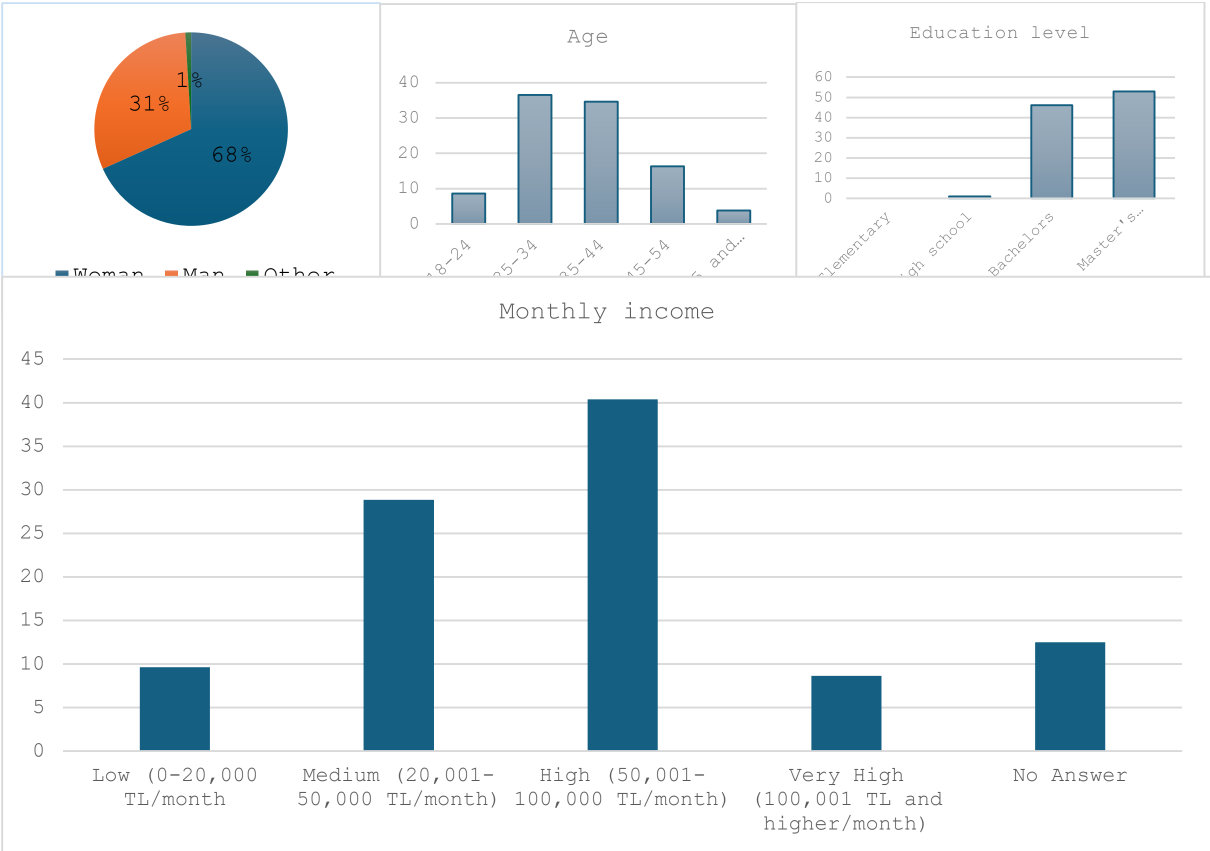

Figure 1. General information about the survey participants

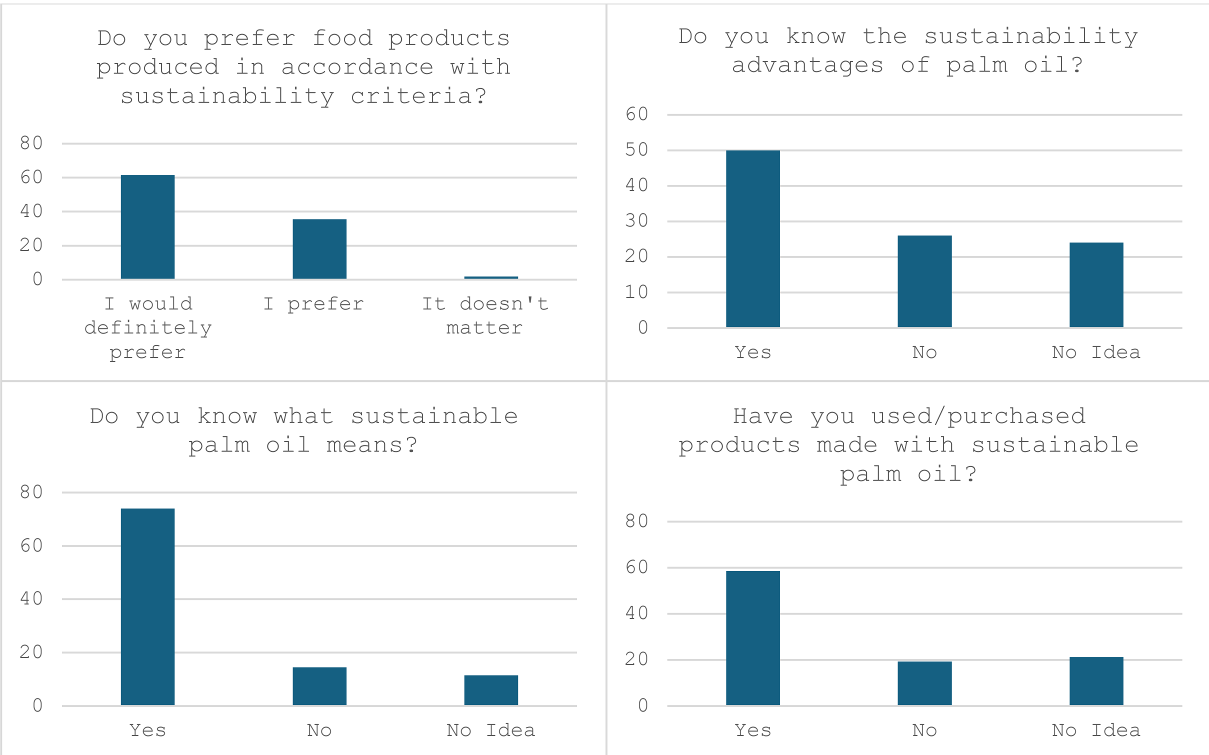
The demographic profile of the survey participants, including their higher education levels, income, and gender distribution, aligns with findings from prior studies that associate these factors with increased environmental awareness and sustainable consumption behaviors. For instance some previous studies highlight that higher education and income are strong predictors of environmental concern and the likelihood of purchasing sustainable products (Diamantopoulos et al., 2003; Zhao et al., 2014). Additionally, in some previous research, it was reported that women tend to show greater environmental awareness, which could explain the higher proportion of female respondents in the survey (Hunter et al., 2004; Zelezny et al., 2000). The predominance of young to middle-aged adults, who are typically more engaged in sustainability issues, further supports the survey's findings of heightened awareness and preference for sustainable palm oil among this demographic (Liere and Dunlap, 1980).

Figure 2. Palm oil acceptability of the customers

The results on palm oil acceptability among customers reveal a complex perception of this ingredient, which is influenced by various factors such as health concerns, awareness of its uses, and sustainability issues (Figure 2). While a significant portion of respondents (57.69%) do not believe palm oil is harmful to health, there is still a notable minority (30.76%) who perceive it as harmful, reflecting ongoing public debates and mixed information about palm oil’s health impacts. Awareness of palm oil's uses is high, with 86.53% of respondents familiar with its applications, indicating that most consumers are well-informed about the prevalence of palm oil in products. However, there is ambiguity regarding the differences between palm oil and other oils, such as "hurma" oil, with respondents almost evenly split on this question, suggesting some confusion or lack of detailed knowledge about different types of oils. This response actually conflicts with the previous findings about how consumers are aware of palm oil, and its uses since “hurma oil” and “palm oil” technically address the same oil. Accordingly, it has been observed that a significant portion of consumers think that they have detailed information about palm oil and its uses, but even this simple difference in expression misleads consumers. This suggests that some marketing-oriented initiatives, such as advertising campaigns, significantly impact consumer perceptions.

These perceptions are crucial because they directly affect consumer behavior. For instance, while many consumers know palm oil and its uses, their health concerns and understanding of its sustainability aspects play a significant role in their purchasing decisions. The survey also shows that environmental sustainability (35.29%) and healthy living (32.35%) are key factors influencing purchasing decisions for products containing palm oil, reflecting a growing consumer trend toward products that align with personal health and environmental values. This aligns with previous studies, highlighting health and sustainability's increasing importance in consumer decision-making processes (Hartmann and Apaolaza-Ibáñez, 2012). Overall, the results suggest that while many consumers generally accept palm oil, its acceptability is contingent upon ongoing concerns and knowledge gaps related to health and sustainability, which can significantly influence consumer preferences and behavior.

Although environmental issues positively affect the consumption of products containing palm oil, it has been seen that it is necessary to evaluate the price factor, which has a share in the consumption phenomenon, together with the product quality. When examined in this direction, the findings indicate a balance between the price and quality of palm oil products. The cost reduction in the prices of palm oil products has not been reflected in their quality at the same rate, and it has been determined that the effect of quality is moderate. The reason for this finding can be shown as the compatibility of palm oil processing methods with sustainability principles (Panapanaan et al., 2009; Gassler and Spiller, 2018).



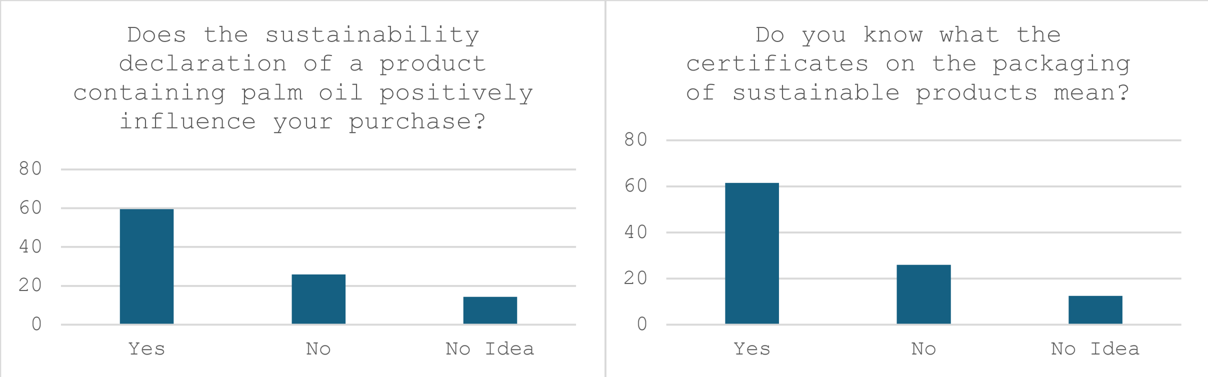


Figure 3. Sustainability awareness and sustainability certification on palm oil

The results on sustainability awareness and palm oil sustainability certification indicate a relatively high level of consumer engagement with sustainability issues, though there are notable gaps in understanding (Figure 3). A significant majority of respondents (74.03%) reported knowing what sustainable palm oil means, and 50% were aware of the specific sustainability advantages associated with palm oil. This level of awareness reflects a growing consumer consciousness around sustainability, particularly in relation to palm oil, which has been widely discussed in environmental and ethical contexts due to its impact on deforestation and biodiversity.

However, despite this awareness, there is still a considerable portion of the population that is either unaware or unsure about the specifics of sustainability certifications. For instance, 25.96% of respondents admitted they do not know what the certifications on product packaging imply, and 24.03% are unaware of the sustainability advantages of palm oil. This suggests that while consumers are increasingly aware of sustainability as a concept, their understanding of the detailed implications of certifications and specific sustainability benefits is incomplete.

The influence of sustainability certifications on purchasing behavior is also evident, with 61.53% of respondents indicating that such certifications positively influence their buying decisions. This aligns with findings from previous research, which demonstrates that sustainability labels and certifications can significantly affect consumer behavior, especially among those already inclined towards environmentally friendly practices (Taufique and Vaithianathan, 2018). Nonetheless, the knowledge gaps identified suggest that for certifications to be fully effective in driving consumer behavior, further efforts are needed to educate consumers on what these certifications represent and how they contribute to sustainable practices. Overall, the results highlight the critical role of informed consumer education in enhancing the impact of sustainability certifications on purchasing decisions.

CONCLUSIONS

The results highlighted the significant role of sustainability certifications in shaping consumer awareness and purchasing behaviors related to palm oil products. The findings indicate that while there is a high level of general awareness about sustainability, gaps remain in understanding specific certifications and their implications. Consumers, particularly those with higher education levels and incomes, prefer products aligned with environmental and health values. However, misconceptions and incomplete knowledge about palm oil and related products persist, suggesting more targeted educational efforts are needed. Future research should focus on exploring the long-term impact of sustainability education on consumer behavior and how marketing strategies can more effectively communicate the benefits of sustainable palm oil. Additionally, examining the role of pricing and quality perception in sustainable product choices could provide deeper insights into consumer decision-making processes.

ABSTRACT

The egg is a food, that is extremely important for balanced nutrition and health for humans due to the nutrients it contains and its high biological value. And it is a protein source that can be easily consumed by people from all walks of life out of its affordable prices. Shelled eggs are one of the best-protected foods against microorganisms on account of their structure. However, the high nutritional value creates a suitable environment for the development of microorganisms and prepares the conditions for the egg to spoil. Therefore, to prevent spoilage, some precautions must be taken. Storing in cold conditions, especially at home in the refrigerator, is a common practice for this purpose. Egg storage conditions and duration are among the most important criteria affecting egg quality and shelf life. The current study investigated the effects of storing eggs in refrigerator shelves or cardboard viols on the internal and external quality criteria of eggs. For this purpose, a total of 125 eggs obtained from 44-week-old Lohman Brown hens were used. Within the scope of the study, the initial, 15th and 30th day internal and external quality characteristics of the eggs were determined. According to the research results, the effect of storing eggs in the refrigerator shelves and the cardboard viol on weight loss (g, %), albumen width, albumen length, albumen height, albumen weight (g), albumen index, pH, Haugh Unit was found to be statistically significant, while the effect on breaking resistance, shell weight (g, %), yolk weight (g, %), albumen weight (%), yolk height, yolk width, yolk index and yolk color *L*, *a** and *b** values was found to be insignificant. Egg weight loss, yolk and albumen index and Haugh Unit were found to be higher in eggs stored in the refrigerator shelves, while pH was higher in eggs stored in the cardboard viols. Although weight loss was higher in eggs stored in the refrigerator shelves, they were of better quality and darker color than eggs stored in the cardboard viols. In light of these results, it is recommended to store eggs on refrigerator shelves without using cardboard viols in terms of the shelf life of eggs.

Keywords: Internal-external quality, egg, storage in the refrigerator, shelf life

INTRODUCTION

Eggs are a precious food in terms of the diversity and biological value of the nutrients in their structure. Especially, the fact that people of all ages can easily consume it and that it is easily accessible puts it at the forefront among other foods. The protection and storage conditions of this special food are very important in terms of preventing it from deteriorating.

Shelled eggs are one of the foods that are best protected against microorganisms due to their natural structure. Fresh eggs are generally considered sterile when they are first laid. In later times, the eggshell may become contaminated with microorganisms due to feces, soil and infections in the chicken. While the egg is forming, it is covered with a layer called cuticle. The cuticle consists of 85-90% protein, some carbohydrates and a small amount of lipids. The cuticle dries immediately after the egg is laid and prevents the entry of bacteria and the exit of water from the egg thanks to its selectively permeable structure (Baker and Balc, 1962). The calcified shell and shell membranes that form the shell of the egg together with the cuticle form a natural physical and chemical barrier against contamination by microorganisms (Özçevik et al., 2023; Anonymous, 2024).

Another protective system is the lysozyme enzyme found in the albumen, which is particularly effective against gram-positive bacteria. In addition, avidin combines with biotin in the albumen to prevent microorganisms from using biotin. Similarly, conalbumin forms a complex with iron, preventing microorganisms from using iron (Anonymous, 2024).

Eggs are a perishable product. Despite being naturally so protected, if they are not stored correctly, their quality decreases. Shortly after laying, changes begin to be observed inside the egg, depending on the ambient temperature and storage time. CO2 and weight loss occur, albumin height and Haugh Unit decrease, yolk weight and pH value increase (Yılmaz and Bozkurt 2009; Brandao et al., 2014; Şekeroğlu et al., 2016; Saleh et al., 2020; Yenilmez et al., 2024).

Different methods are used to preserve the freshness of eggs and prevent the proliferation of microorganisms. It has been observed that these methods have positive effects on preserving egg quality. Cold storage is the most common of these and helps preserve egg quality, prevents microorganism growth and reduces CO_2 loss (Rocha et al., 2013). Although preservation of egg quality depends on the storage period, storage conditions at 10–13 °C and 80–85% humidity are considered sufficient (Keener et al., 2006; Altan 2015). Other methods of preserving eggs are coating with various materials such as propolis (Copur et al. 2008), glycerin (Drabik et al., 2018), different oils (Nongtaodum et al., 2013), lipids, polysaccharides, proteins and plastic, and storing in different atmospheric conditions (Altan 2015; Da Silva Pires et al., 2020; Rachtanapun et al., 2021; Şahansoy et al., 2024).

It is observed that there are many different packaging materials used in the packaging of eggs. Styrofoam, plastic and fiber cardboards, plastic and fiber trays, and plastic packaging bags are used for this purpose. Molded pulp cardboard or polystyrene foam cardboards are used all over the world due to their low cost. The advantage of using polystyrene material is that it has superior cushioning properties, protection against odor and moisture, and is resistant to fungus and mold formation. Another packaging material is transparent plastic packaging that shows the inside. Since the eggs are visible, consumers do not need to open them to inspect (Yüceer and Caner, 2021).

The most commonly used material for egg packaging in Turkey is wrapping eggs in cardboard vials with transparent stretch film (Yılmaz and Bozkurt 2009). Eggs brought home are removed from the stretch film and stored either in cardboard vials or on refrigerator shelves. In the current study, the effects of storing eggs in refrigerator conditions in vials or open on a cabinet shelf on egg quality were investigated.

MATERIAL AND METHOD

A total of 125 eggs obtained from 44-week-old Lohman Brown hens were used in the study. The eggs were provided by the Cukurova University Poultry Department. After the weights of the eggs were taken with a precision scale, 25 of them were separated to determine the initial internal-external quality criteria, and the remaining eggs were randomly distributed equally into 2 groups (50+50). One of the groups was stored in the refrigerator (+4°C) for 30 days in the cardboard vials in which eggs are commonly packaged and sold, and the other group was stored in the open on the shelf section of the refrigerators where eggs are arranged for 30 days (+4°C).

Internal and external quality analyses were performed on days 0., 15. and 30. Egg weight, shell weight, shell percentage, and shell breaking resistance (Texture Analyzer; Stable Micro Systems_TA.XT Plus, England) were measured as external quality characteristics in the eggs. Internal quality characteristics yolk height, yolk width, albumen height, albumen width, albumen length, albumen pH, yolk color *L, a** (redness) and *b** (yellowness) values (HunterLab, ColorFlex EZ, United States), albumen and yolk weight were determined. Albumen weight and percentage, yolk percentage, shell percentage, albumen index, yolk index and Haugh Unit were calculated using the following formulas.

Albumen Weight: *[Egg weight-(Yolk weight+Shell weight)]*

Albumen Ratio (%): *[100-(Yolk ratio+Shell ratio)*

Yolk Ratio (%): *[Yolk weight/Egg weight] x 100*

Shell Ratio (%): *[Shell weight/Egg weight] x100*

Yolk Index: *[Yolk height/Yolk diameter]x100*

Albumen Index: *[Albumen height/{(Albumen length+ Albumen width)/2}]x100*

Shell Thickness: *[Blunt part+Pointed part+Equatorial part]/3*

Haugh Unit: *100 log [Albumen height+7.57–1.7xEgg weight* $^{0.37}$*]*

The data obtained in the study were analyzed using the IBM SPSS 19.0 (2010) package program. Normal distribution of the data was made using variance analysis (ANOVA) and the Tukey test was used to compare the means. The statistical significance level was accepted as P ≤0.05 and the means are presented in the table as mean±SE (Standard Error).

RESULTS AND DISCUSSION

According to the research results, the effect of storing eggs on the refrigerator shelves and in the cardboard vial on weight loss (g, %), albumen height, albumen length, albumen index, pH, Haugh unit (P<0.01) and albumen width and albumen weight (g) (P<0.05) values was found to be statistically significant, while the effect on breaking strength, shell weight (g, %), yolk weight (g, %), albumen weight (%), yolk height, yolk width, yolk index and yolk color *L*, *a** and *b** was found to be insignificant (Table 1).

Tablo 1. Effect of storage in the refrigerator shelves and cardboard viol on egg quality (mean±SE)

Parameters	0. Day	Refrigerator Shelves		Cardboard Viols		P
		15. Day	30. Day	15. Day	30. Day	
Egg weight loss (g)	-	0.67±0.02	1.31±0.17	0.55±0.02	1.14±0.05	0<01

Egg quality is affected by some factors such as genetics, age of the hen, stages of the laying cycle, nutritional level, conditions in the coop, management system, housing system selected, and diseases before laying (Abebe et al., 2023). After laying, storage practices have a significant effect on egg quality (Gerber, 2010) and even short-term storage affects quality (Gavril and Usturoi (2011). Janes et al. (2018) reported that storing eggs at 4°C did not affect egg quality factors. While Kim et al. (2024) reported that storing eggs under refrigerator conditions improves egg quality, Usturoi et al. (2014) stated that table eggs should be stored under refrigerator conditions.

The internal quality of eggs starts to decrease immediately after laying (Roxana and Usturoi, 2012). The longer the storage period, the worse the internal quality of the egg. This is because the loss of carbon dioxide from the eggshell is facilitated by temperature and humidity (Oliveira; Oliveira, 2013). Raji et al. (2009) reported that egg quality decreases with storage period and egg weight decreases during storage, Siyar et al. (2007) reported that egg weight decreases significantly with storage period, and Tayeb (2012) stated that there is an increasing weight loss with increasing storage period. In this study, weight loss decreased in proportion to the time in eggs stored both on the refrigerator shelves (0.67±0.02, 1.31±0.17 g) and in cardboard viols (0.55±0.02, 1.14±0.05 g). The quality and freshness of table eggs are determined by the Haugh unit value, which is determined using egg weight and albumen height (Skřivan et al., 2006). Eggs stored in cardboard viols lost less weight in grams and percentages than those stored on refrigerator shelves and remained fresher (Figure 1).

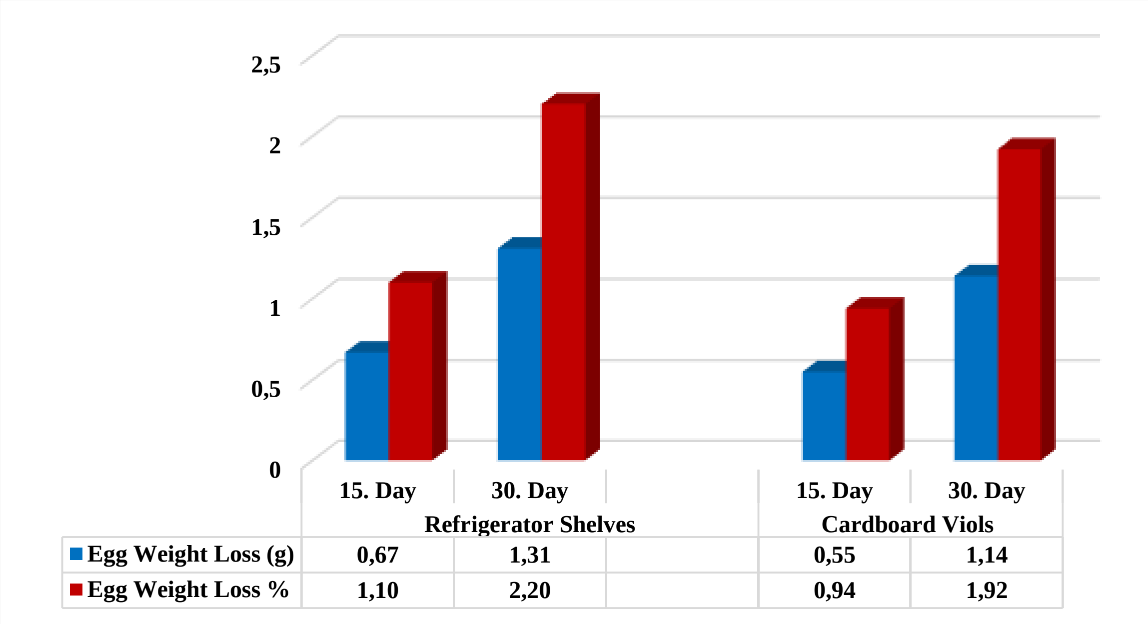

Figure 1. Weight loss in eggs stored in the refrigerator shelves and cardboard viols

Yamak et al. (2021) grouped organic and cage-produced eggs as stretched, unstretched and washed, and stored them in room and refrigerator conditions. The lowest weight loss was in eggs stretched and stored in the refrigerator, and the highest was in washed and stored in the room. In our study, weight loss was found to be less in eggs stored in cardboard viols.

The average albumen height in fresh eggs is 7.54 mm. Siyar et al. (2007) reported that albumen height was significantly affected by storage time, while Raji et al. (2009) stated that it decreased with storage time. Yamak et al. (2021) found the highest albumen height in eggs stored in the refrigerator. In the present study, albumen height was found to be higher in eggs stored on the refrigerator shelves on the 0th, 15th and 30th days (8.29±0.18, 6.61±0.25 and 5.73±0.17) than in eggs stored in cardboard viols (8.29±0.18, 6.06±0.18 and 5.47±0.24).

Siyar et al. (2007) and Khan et al. (2013) stated that albumen weight decreased significantly with storage time. In the present study, albumen weight in eggs stored in cardboard viols was 39.17±0.69, 38.17±0.72 and 36.86±0.82 g on days 0, 15 and 30, respectively, while it decreased over time in eggs stored in refrigerator shelves to 39.17±0.69, 36.52±0.88 and 36.20±1.27 g respectively.

Raji et al. (2009) found that albumen length increased during storage. Our research results were consistent with the literature, albumen length increased with storage time in both groups (refrigerator shelves: 81.95±1.05, 89.64±1.55, 95.11±1.66, cardboard viols: 81.95±1.05, 87.62±1.61, 96.00±2.31). The egg yolk is round and located in the middle of fresh eggs. Over time, as the vitelline membrane degenerates, the egg yolk absorbs water from the egg white, loses its spherical appearance, takes a flattened shape and decreases in height (Anonymous, 2024; Tayar, 2015). Yolk height decreased in both the eggs stored on the refrigerator shelves on the 0th, 15th and 30th days (18.28±0.13, 18.67±0.18, 17.88±0.13) and in the eggs stored in the cardboard vial (18.28±0.13, 18.46±0.20, 17.49±0.32), as reported by Raji et al. (2009).

Khan et al. (2013) reported that different storage periods caused a decrease in the albumen index and yolk index of Fayoumi eggs, Shehata et al. (2023) stated that the yolk index decreased over time, and Raji et al. (2009) also reported decreases in albumen and yolk index during storage. The yolk index was higher in eggs stored on the refrigerator shelves than in the cardboard vial (44.99±0.44, 48.06±0.57, 43.42±0.42) on days 0, 15 and 30 (Figure 1). Similarly, the albumen index was higher in eggs stored on the refrigerator shelves (11.04±0.31, 8.24±0.43, 6.90±0.27) than in the cardboard vials (11.04±0.31, 7.86±0.39, 6.55±0.40).

The rheological properties of albumin, emulsification ability and whipping and gelling properties of eggs are important criteria in the egg products industry (Kemp et al., 2010). The important difference between fresh and stored eggs is albumin pH and egg albumin quality (Nadia et al., 2012). With the increase in storage time, mucin, which gives albumin a mushy structure, loses its structural feature and the albumin becomes watery and albumen height decreases (Şenköylü, 1991). Albumen height, albumen index, Hough unit and pH values, which are the most important indicators of internal quality characteristics, gave better results in eggs stored on the refrigerator shelves than in cardboard viols.

Albumen pH value was higher in eggs stored in cardboard viols (7.69±0.04, 8.83±0.02, 8.52±0.03), while it was lower in eggs stored on the refrigerator shelves (7.69±0.04, 8.79±0.02, 8.47±0.08) (Table 1, Figure 2). Albumen pH in fresh eggs was reported to be between 7.6-8.5. As eggs age, the dense albumen becomes liquid due to numerous chemical reactions occurring in it, probably including the formation of carbonic acid (H_2CO_3) and increasing albumen pH. H_2CO_3, one of the components of the albumin buffer system, dissociates to form water and carbon dioxide (CO_2). Under natural conditions, CO_2 and water present in the shell diffuse and evaporate through the shell pores, decreasing albumen acidity, increasing pH and chemical disintegration of the protein complex. The loss of thickness of the dense albumen is related to the natural dissociation of this complex (Şenköylü, 1991; Oliveira and Oliveira, 2013). The effect of pH on egg quality is closely related to its freshness. It has been confirmed that albumen and yolk pH increases depending on storage time and storage temperature (Siyar et al., 2007; Garcia et al., 2010; Shehata et al., 2023). In the present study, the pH value was lower in the eggs stored on the refrigerator shelves and the eggs remained fresher (Figure 1).

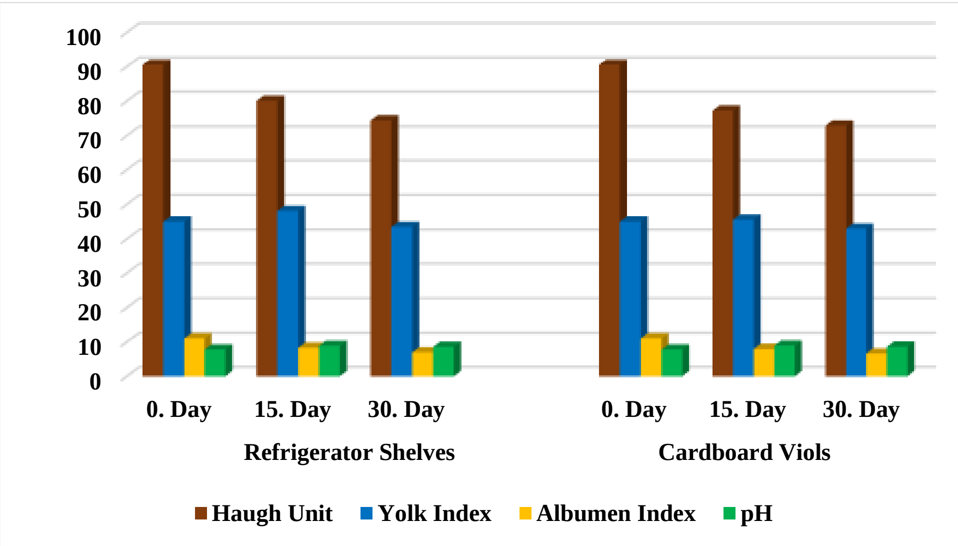

Figure 2. Changes in Haugh Unit, Yolk Index, Albumen Index and pH unit values in eggs stored in the refrigerator shelves and in the cardboard vial

Haugh unit is significantly affected by storage time (Siyar et al., 2007; Okonkwo et al., 2021) and gradually decreases with storage time (Raji et al., 2009; Alsobayel and Albadry, 2011; Tayeb, 2012; Khan et al., 2013; Shehata et al., 2023). Haugh unit was 90.72±0.91, 80.05±1.67, 74.36±1.38 in eggs stored on the refrigerator shelves at days 0, 15 and 30 and was 90.53±0.90, 77.23±1.30, 72.90±1.88 in eggs stored in cardboard viols. The quality of albumen is measured by the Haugh unit suggested by Raymond Haough. In table eggs, this value should be 79 or higher for AA quality eggs, 55-78 for A quality, 31-54 for B quality and 30 or less for C quality (Şenköylü, 1991). In the current study, the quality of eggs stored on the refrigerator shelves was AA quality on the 15th day but dropped to A quality on the 30th day. In eggs stored in cardboard viols, they maintained their A quality feature on the 15th and 30th days.

Egg yolk color is one of the most important parameters of egg quality about market requirements. In developing countries, consumers prefer egg yolks that are yellow-orange (Leeson and Summers, 2008). At the end of the study, the color of eggs stored in cardboard viols was darker (55.65±0.55), while redness (19.30±0.70) and yellowness (56.82±1.26) increased with storage time (Figure 3).

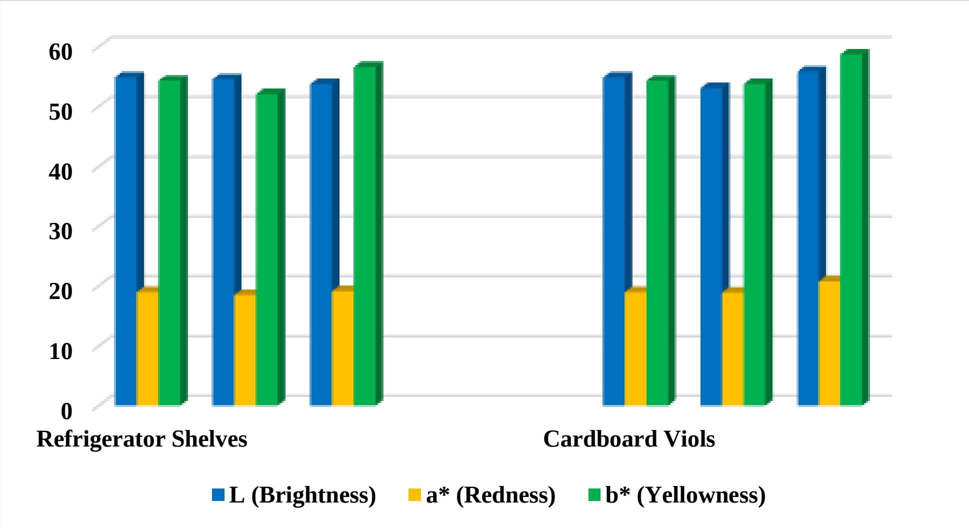

Figure 3. Changes in *L, a** and *b** values of yolk color in eggs stored in the refrigerator shelves and in the cardboard vial

Siyar et al. (2007) reported in their study that egg yolk and shell weight were not affected by storage time, while Khan et al. (2013) found that different storage times caused a decrease in the egg yolk weight of Fayoumi eggs. In the present study, yolk and shell weight were not affected by storage time in both groups.

CONCLUSIONS

The pH of eggs held in cardboard viols was greater, while the egg weight loss, yolk and albumen index, and Haugh Unit were found to be higher in eggs kept on refrigerator shelves. On day 15, the eggs kept in the refrigerator were of AA quality; however, by day 30, they had degraded to A quality. On days 15 and 30, the eggs in cardboard viols remained in their A quality attribute. Keeping table eggs on refrigerator shelves without using cardboard viols is healthier in terms of egg quality.

ABSTRACT

The study used a descriptive approach and had 400 participants from Afgoi District Lower-Shebelle, Somalia. A non-simple random selection was used to acquire information from farmers, educators, and workers. To clarify the effect of naturally occurring fertilizer on crop productivity, the data were evaluated using correlation analysis. The majority of responders (56%) indicated significant agreement with the study's findings that green manure improves crop productivity by directly adding nitrogen to the soil, increasing soil fertility. The majority of responders (47.5%), however, were in agreement that plants grown in green manure receive nutrients from deeper levels of soil and release them in the topsoil. On the other hand, the majority of respondents (54%) firmly concur that green manure improves nutrient availability, both macro and micro. The majority of respondents (51%) firmly concur that green manures are environmentally benign under other circumstances. In addition, the majority of responders (57.5%) highly concur that green manure raises the caliber of products and crops. The majority of respondents (51.5%) indicated high agreement with the finding that adding manure to cropland can help keep or raise the level of soil organic matter. However, the majority of respondents (38%) agreed that animal manure includes both macro and micronutrients in both organic and inorganic forms that are essential for crop production. On the other hand, the majority of responders (45.5%) strongly concur that animal dung from a locally accessible source is cheaper than inorganic fertilizer when needed. Similar to this, the majority of respondents (41%) firmly concur that poultry manure is the best animal manure. However, the majority of respondents (51%) strongly concur that adding animal manure to the soil improves its quality. The majority of respondents (55%) said firmly that crop farming is the primary means of subsistence for Afgoi communities. However, the majority of respondents (37.5%) agreed that improvements have been made to the production system over the past two years. On the other hand, the majority of respondents (49.5%) agreed that using organic fertilizer increases crop output per unit of surface area. Similar to this, the majority of respondents (52.5%) strongly concur that fertilizer quality affects crop production.

Keywords: Animal Manure, Crop Production, Green Manure, Organic Fertilizer

INTRODUCTION

Organic fertilizers are crucial for the growth of plants. Organic fertilizers are typically more economical and easily accessible from local sources than chemical fertilizers (Solomon et al. 2012). The foundation of fertile soil is organic matter (Aboudrare 2009). Organic fertilizers are made from biological or living substances. These fertilizers provide nutrients to the soil gradually over time. Whereas artificially created fertilizers, or those obtained via the mining of non-living materials, are known as inorganic fertilizers. Inorganic fertilizers also referred to as chemical fertilizers, are utilized by plants very quickly. There are many different types of organic fertilizers, including Livestock manure from animals, including cows, poultry, goats, and others. Green manure is made from young plants, especially different kinds of legumes. Compost is made from organic agricultural waste like sorghum, maize stalks, or decaying garbage. Organic fertilizers such as sheep manure from farms and chicken manure may aid in crop growth as an alternative to artificial fertilizers (Khan et al. 2005). Organic fertilizer can improve soil fertility and aid in plant growth. Positive actions, including ammonium (NH_4^+), potassium (K^+), and magnesium (Mg_2^+), are held in biochar, which keeps these nutrients in the soil for an extended period of time and releases them to plants as needed (Lal 1982). The manure from the farm had a long-lasting influence on maize when administered to wheat-based in a wheat-maize crop combination. In soils that had been impaired by erosion, it also performed better at restoring crop yield (Jadoon et al. 2003)). In a field environment, consideration is given to the phosphorus content of maize derived from organic manures, such as crop residue, bio-organic matter, chicken manure, and pressing mud. Researchers discovered that maize includes a significantly high amount of phosphorus (42.68%) compared to other sources, such as poultry manure. When utilized as a source of phosphorus, farmyard manure is substantially more successful than other treatments at boosting the accessibility of phosphorous from soil (Meena et al. 2007). The output of maize grain varies substantially as a result of the addition of organic manures. Although grain production for manure was equal to or, on occasion, greater when phosphorus was obtained from inorganic sources, applying poultry manure produces the highest grain output when compared to another method (Jama et al. 2007).

When applied in place of mineral fertilizers, organic manures increase the grain production of maize (Reddy et al. 2007). Compared to other organic sources, poultry dung offers greater phosphorus that is readily available (Garg et al. 2007). Organic manure sources enhance the accessibility of organic matter, phosphorous, and potassium, as well as plant uptake of these nutrients. Organic amendments also enhance the amount of P and K in the overall plant, as is the height of the plant, LAI, dry matter manufacturing, and LAI. When it comes to plant P and K concentrations, poultry dung offers the best benefits. According to research, increasing the availability of nutrients in the soil from organic manures is what causes improved soil concentrations of nutrients and plant growth (Adnan 2021).

Somalia's agricultural sector faces several challenges, such as low soil fertility, inadequate access to modern farming techniques, and reliance on traditional farming practices. Due to these factors, yields of crops have remained low, and the nutritional security of the population has declined. Organic fertilizers may be used to surmount these obstacles and improve agricultural output in Somalia. However, more study is needed to determine the effectiveness of organic fertilizers in Somalia and how they affect crop productivity. Little is known and appreciated about organic fertilizers among Somali farmers. The vast majority of farmers in Somalia still use outdated methods and need more access to education and training in contemporary agriculture. Farmers are also not fully informed about the benefits of organic fertilizers and how to use them due to a lack of agricultural extensions and instructional programs. Due to growers' inadequate knowledge and understanding of organic fertilizers, their potential impact on crop output may be restricted, given how seldom they are now employed. The availability of organic fertilizers is a benefit of their use. Organic fertilizers could be hard to come by in Somalia, and farmers might not have the resources or expertise to create them themselves. This might promote the use of costly chemical fertilizers that harm the environment. Due to their limited accessibility and availability, organic fertilizers are challenging to utilize and may not have a significant impact on crop output. The unique climate and soil of Somalia may affect the efficacy of organic fertilizer in addition to challenges with knowledge and accessibility. The effectiveness of organic fertilizers may vary depending on factors such as soil pH, nutrient content, and rainfall patterns.

This research aims to investigate how organic fertilizer affects crop production in Afgoi District-lower Shebelle, Somalia. The general purpose of this study is to identify the role of Organic fertilizer on crop production at Afgoi District-lower Shebelle, Somalia. To Identify the role of green manure on crop production at Afgoi District-lower Shebelle, Somalia. To Determine the role of animal manure on crop production at Afgoi District-lower Shebelle Somalia.

MATERIAL AND METHOD

The research approach of the study was the main focus of this chapter. The chapter includes research design, target population, sample size, sampling procedures, research instruments, and Research quality involves collecting the data, collecting the data, interpreting the data, and finally limiting the study while addressing ethical considerations.

Research Design

The study was conducted using a descriptive design. In order to discuss and examine the impact organic fertilizer has on crop production in Somalia's Afgoi District Lower Shebelle. Utilizing A data obtained from the questionnaire. The target population can be easily reached, the design is efficient, and it is less expensive, all of which make it the best option for this study.

Research Population

The target population of the study was 400 from Afgoi District- lower Shebelle, Somalia.

Sample Size

The researchers used Solvent's formula to calculate the sample size, with a maximum acceptable error of 5%.

$$n = \frac{N}{1+Ne^2}$$

N: Stands for the population

n. Stands for the sample size

e. Stands for acceptable error

n= $\frac{400}{1+400(0.05)^2}$= so the sample was 200

Sampling Procedure

The sampling method was non-random sampling anon-simple random sampling was selected to collect information from the accessible populations of farmers, Agro-students, and workers.

This study's findings about the role of organic fertilizer on crop production have been established in a number of ways. The research's conclusions and findings from a structured questionnaire are discussed in this section. This study's overarching goal is to determine how organic fertilizer affects crop output in Somalia's Afgoi District (lower Shebelle). In contrast, the objective of the study is to identify the role of green manure on crop production at Afgoi District-lower Shabelle, Somalia. to determine the role of animal manure on crop production at Afgoi District-lower Shebelle, Somalia.

RESULTS AND DISCUSSION

The Role of Organic Fertilizers

It is known that soil quality and productivity are increased with organic fertilizer application. For this purpose, many organic fertilization materials are widely used (Figure 1). According to the study's findings, the majority of participants (56%) indicated high agreement that green manure improves crop output by directly aerating soil fertility. In contrast, the majority of respondents (47.5%) thought that plants grown in green manure receive nutrients from deeper soil layers and leave them in the topsoil. The majority of responders (54%) strongly disagree, however, that green manure enhances the availability of both macro and micronutrients. Most poll respondents (51%) completely agree that green manures are environmentally favorable in other contexts. Additionally, the majority of respondents (57.5%) firmly concur that green manure raises the standard of produce and crops.

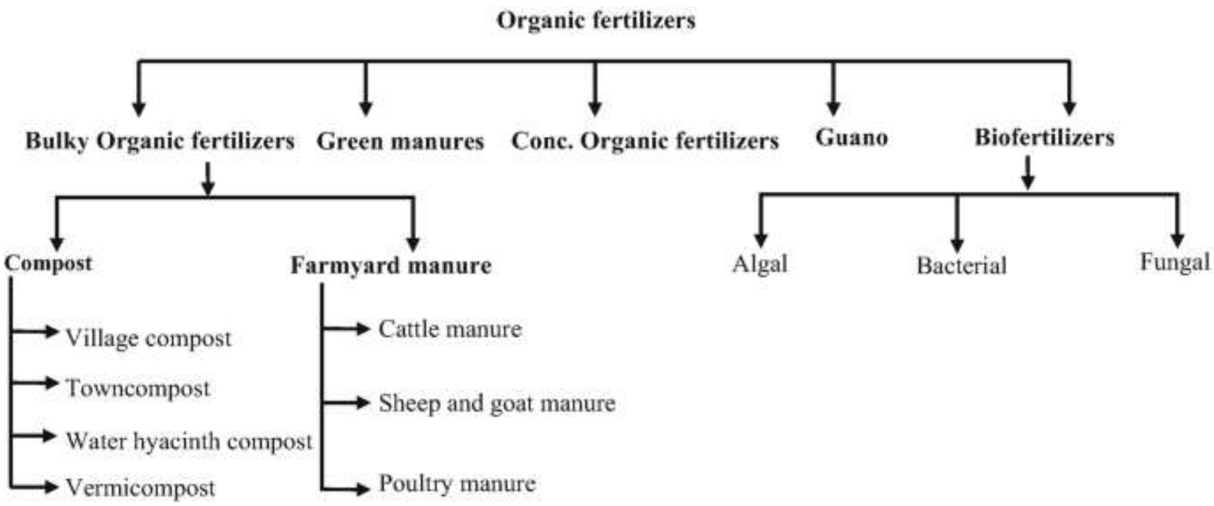

Figure 1. Organic fertilizers used in improving soil fertility (Singh et al. 2020)

Animal Manure

The majority of respondents (51.5%) answered that they strongly agreed with the claim that spreading manure to croplands can help maintain or raise the level of soil organic matter. On the other hand, a large majority of the participants (38%) said they completely concurred with the assertion that animal dung from locally accessible sources contains both micro and macro nutrients needed for crop productivity in organic as well as inorganic forms.

Crop Production

Organic fertilizers are among the most important inputs in plant production. In fact, it is reported that organic fertilizers can be a good alternative in combating stress factors in plant production (Figure 2).

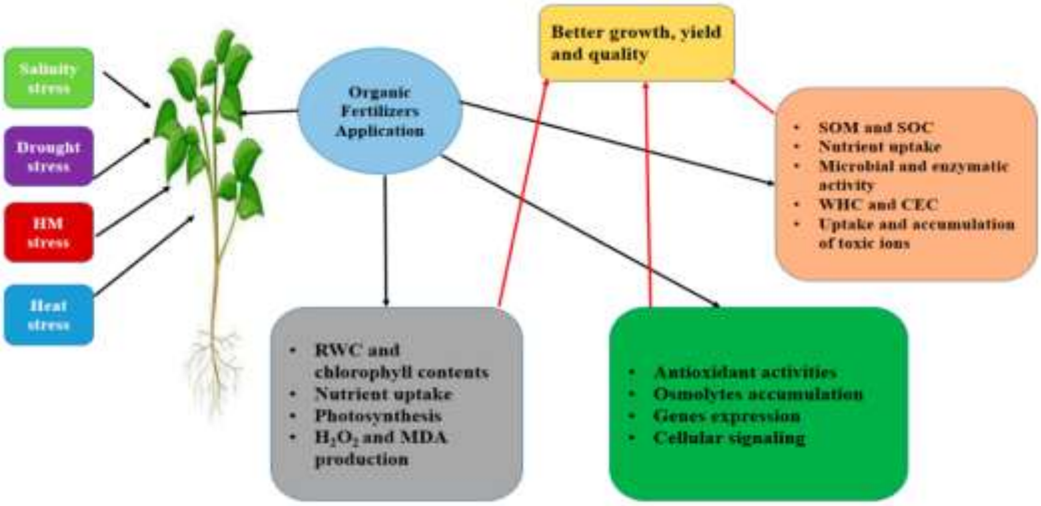

Figure 2. Effects of organic fertilizer application against stress factors in plant production (Liu et al. 2024)

The majority of respondents (55%) said firmly that crop production is the primary means of subsistence for Afgoi communities, according to the data. Conversely, most respondents (37.5%) believed that the production system had improved during the previous two years. Alternatively, the majority of responses (49.5%) agreed that the application of organic fertilizer increases crop productivity per unit of surface area. In a similar vein, the majority of responders (52.5%) strongly concur that fertilizer quality affects crop productivity.

With regard to the result of this study and based on its objectives, the following could be concluded: The objective of the role of Organic fertilizer on crop production indicates that the use of green manure is widely believed to increase soil fertility through the direct addition of nitrogen, as well as by absorbing nutrients from deeper soil layers and leaving them in the surface soil. Respondents also strongly agree that green manure increases the availability of both macro and micronutrients, is environmentally friendly, and improves the quality of crops and produce.

The objective of the role of animal manure on crop production shows that the use of animal manure can help maintain or improve soil organic matter levels and that it contains both macro- and micronutrients needed for crop production in organic and inorganic forms.

Respondents also strongly agree that animal manure from locally available sources is cheaper than inorganic fertilizers and that the best animal manure is from poultry.

Crop productions conclude that crop production is the livelihood strategy for Afgoi communities, with most respondents strongly agreeing with this statement. While a smaller percentage of respondents agreed that the production system has improved in the past two years, the use of organic fertilizers is widely believed to increase crop production per unit of surface area. Respondents also strongly agree that the quality of fertilizers is an important factor in crop production.

CONCLUSIONS

To improve crop production and soil fertility, increase the application of organic fertilizers like green manure and animal faces. To educate farmers about the advantages and appropriate methods for the application of organic fertilizers, services for extension should be made available. Develop and implement operational policies that encourage the creation and application of organic fertilizers. In order to assure the safety and efficacy of organic fertilizers, restrictions and subsidies for their production and distribution may be necessary.

Encourage the use of locally accessible sources of animal dung, particularly poultry manure, as a reasonably priced substitute for inorganic fertilizers. This can entail offering instruction and assistance for small-scale chicken farming. Increase funding for the production of organic fertilizers and the technologies used to apply them. This could result in new, enhanced organic fertilizers that are more successful and efficient at enhancing crop production and soil fertility. Encourage and support farmer cooperatives and associations to promote the use of organic fertilizers and improve crop production. This could include providing access to credit and market information and facilitating collective bargaining for better prices and market opportunities.

ABSTRACT

It is clear that in order to achieve higher and better-quality yields per unit area, it is not enough to only focus on plant breeding; effective plant nutrition through adequate watering and proper fertilization (based on the plant's phenological stage and in appropriate amounts) is crucial for obtaining the desired results. Growing healthy, high-yielding, and high-quality crops primarily involves proper soil management. In this context, a plant grown in soil with low organic matter levels (below 2%) and consequently reduced microbial diversity will struggle to cope with disease agents (especially soil-borne ones), have low vegetative and generative organ development, and ultimately may not benefit significantly from the minerals present in the soil or added through fertilizers. In addressing this common issue, commercial products containing microorganisms with functional benefits for soil and plants (such as bacteria, fungi, algae, etc.) which can aid in plant nutrition, plant protection, and plant growth regulation represent a significant alternative to chemical inputs (such as chemical fertilizers, pesticides, and synthetic growth regulators). However, to maximize the benefits of these products, it is essential to determine not only their capabilities under laboratory conditions (such as nitrogen fixation, phosphorus solubilization, siderophore production, auxin production, etc.) but also their abilities to colonize plant roots, proliferate in the rhizosphere, and compete in various plant and soil types under greenhouse or field conditions. Moreover, factors such as the type of plant production area (field, garden, greenhouse), production model (conventional, organic, ecological, etc.), plant type (cereal, vegetable, fruit), irrigation method (surface irrigation, pressurized irrigation), and especially soil characteristics (texture, organic matter, lime, pH, etc.) must be considered when selecting the appropriate product(s).

Keywords: Biofertilizer, Biological agent, Biostimulant

INTRODUCTION

Fertilizer is one of the inputs used to ensure the continuity of food and agricultural products necessary to meet basic needs such as nutrition and shelter, which have increased due to the growing population and steadily rising living standards. Ensuring the productivity and sustainability of agricultural lands is possible by returning the plant nutrients lost from the soil due to various reasons back to the soil (TAGEM 2018).

Fertilizers used to increase agricultural production and product quality are generally classified into two categories in the agricultural sector: chemical fertilizers and organic fertilizers (Akmermer 2022). The nutrient content of organic fertilizers is significantly lower compared to chemical fertilizers and is not in a form that plants can directly benefit from. For this reason, organic fertilizers are used for soil regulator purposes rather than meeting the nutritional needs of plants (Yetgin 2010). Chemical fertilizers, on the other hand, typically contain plant nutrients in a form that can be readily absorbed by plants and in high concentrations, allowing nutrient deficiencies to be addressed quickly and easily, with lower costs and labor (Evni ve Kan 2024).

Chemical fertilizers, generally produced as nitrogenous, phosphorous, and potassium-based, play a significant role in increasing crop productivity. However, the intensive use of chemical fertilizers not only enhances crop yields but also brings certain disadvantages. Chemical fertilizers alter the physical, chemical, and biological properties of the soil. Continuous use of chemical fertilizers leads to a decline in soil quality, including a reduction in soil organic matter (SOM) content. Excessive use of chemical fertilizers hardens the soil, reduces soil fertility, pollutes the air, water, and soil, and significantly decreases the availability of soil minerals, thereby posing environmental hazards. The continuous application of chemical fertilizers changes the soil pH, potentially increasing acidity. This can lead to a reduction in beneficial organisms, hinder plant growth and even contribute to an increase in greenhouse gas emissions due to the decrease in organic matter (Pahalvi vd. 2021).

In 2021, nitrogenous fertilizers accounted for most of the global fertilizer production, with a volume of 118.55 million tons, representing 55.53% of the total 213.46 million tons produced worldwide (FAO 2024). Regarding consumption, as shown in Figure 1, it was reported that by 2022, 109.29 million tons of nitrogenous fertilizers, 44.1 million tons of phosphorous fertilizers, and 34.66 million tons of potassium fertilizers were used worldwide (IFASTAT 2024).

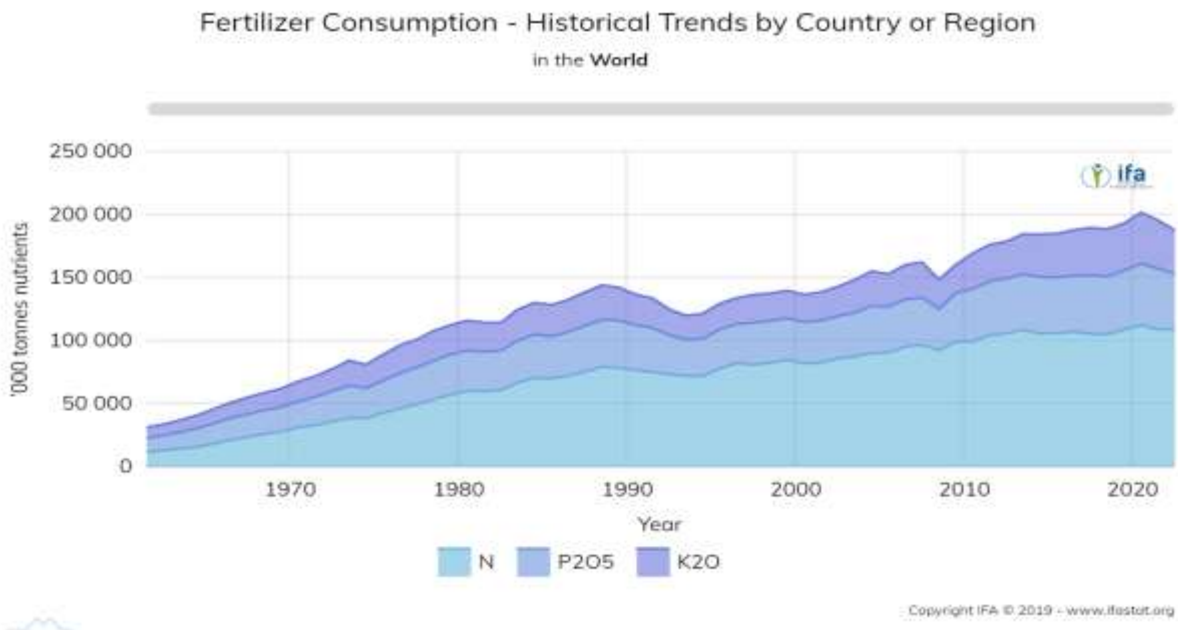

Figure 1. Global consumption amounts of N, P_2O_5, and K_2O fertilizers by year (IFASTAT 2024)

Fertilizer production worldwide is shaped regionally according to consumption volumes and raw material resources. Countries with large populations, such as the USA, China, India, Canada and Russia also have extensive agricultural lands, giving them a significant share in fertilizer usage (Figure 2). These countries are also major fertilizer producers (Kocagöz 2022).

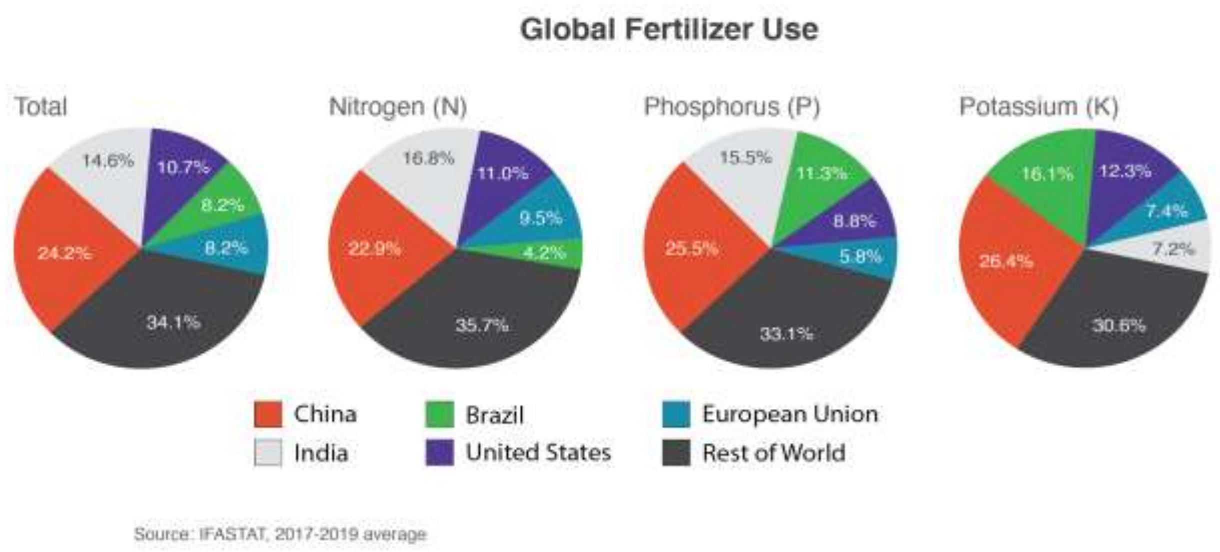

Figure 2. Fertilizer usage percentages in various countries worldwide

One of the most significant issues in the fertilizer sector is the dependence on imports for countries lacking raw materials. The supply of essential inputs, such as natural gas and phosphate rock is largely reliant on external sources. This situation makes fertilizer production companies heavily dependent on imports, which can lead to price fluctuations and increases, as well as challenges in ensuring a continuous supply of high-quality raw materials. Additionally, this dependency, coupled with factors such as raw material-producing countries entering the fertilizer production market, intensifies competition. As a result, the global fertilizer market is dominated by a few countries, creating an oligopolistic market structure (TAGEM 2018).

APPLICATION OF MICROBIAL PRODUCTS IN PLANT PRODUCTION

Given the environmental threats associated with the use of chemical fertilizers and considering the high consumption volumes and associated costs for countries lacking raw materials, there is a clear need for alternative solutions due to the economic disadvantages. One of the primary alternative solutions is microbial products, which are directly related to soil organic matter.

With changing climate and ecosystems, biological approaches aimed at improving plant production continue to gain strong support among engineers and academics focused on sustainability in agriculture. In this context, there is a growing global momentum in exploring a wide variety of rhizobacteria with new properties, such as heavy metal detoxification potential (Ma et al. 2011; Wani and Khan 2010). The rhizosphere, the soil region surrounding plant roots, represents the area of intense microbial activity in the soil (Cantó et al. 2020). Biological fertilizers, also known as bio-fertilizers, are materials composed of living microorganisms that can colonize the rhizosphere and/or penetrate plant tissues. When applied to the plant surface or soil, they fix free nitrogen, process mineral elements from organic and inorganic sources to increase their availability and uptake by plants, and/or stimulate optimal plant growth through the production of secondary metabolites (Çakmakçı 2005). Both prokaryotes (archaea, bacteria and viruses) and eukaryotes (fungi, oomycetes, nematodes, protozoa, algae and arthropods) colonize the rhizosphere. Among these, bacteria and fungi are the most prevalent in terms of population (Buee et al. 2009).

Soil-dwelling microorganisms that enhance plant growth are bacteria living on or around the root surface. They contribute to plant growth and development directly or indirectly by producing and secreting various regulatory chemicals in the rhizosphere. Beneficial microorganisms can help reduce global reliance on chemical fertilizers in agriculture (Ahemad and Kibret 2014). They increase the availability of nutrients such as phosphorus (P), potassium (K), zinc (Zn), selenium (Se), and iron (Fe) in the soil through biochemical processes like dissolution, chelation, mineralization, oxidation, and reduction reactions. Additionally, microorganisms are known to secrete phytohormones, including auxins, cytokinins, abscisic acid, ethylene, brassinosteroids, jasmonic acid, salicylic acid, strigolactones, and gibberellins, which act as plant growth regulators and stress mitigators (Koskey et al. 2021). Various studies have shown that applying rhizobacteria, which promote plant growth under both normal and stressful conditions such as salinity, drought, acidity, or alkalinity, can improve the health and productivity of different plant species (Ahemad and Kibret 2014).

Indirect effects of microbial products include enhancing plant health by suppressing phytopathogens and other harmful microorganisms through parasitism, creating competitive environments for nutrients in the rhizosphere, and producing antagonistic substances such as siderophores, antibiotics, and antimicrobial metabolites. Additionally, these microorganisms generate lytic enzymes like chitinase, glucanase, and protease (Figure 3). Some bacterial genera have been shown to protect plants from fungal and bacterial pathogens. These bacteria employ various mechanisms to inhibit the development of plant pathogens. These mechanisms include colonizing infection sites, competitively excluding pathogens, engaging in antagonistic activities through the secretion of antibiotics and lytic enzymes, and enhancing plant resistance (Bonaterra et al. 2022).

Benefits of PGPR Inoculation to Plants	PGPR Strain(s)	Tested Plant(s)
Tolerance to drought stress	*Pseudomonas fluorescens* DR11, *Enterobacter hormaechei* DR16, *Pseudomonas migulae* DR35, *Bacillus subtilis*, *Achromobacter piechaudii* ARV8, *Phyllobacterium brassicacearum*, *Paenibacillus polymyxa*, *Rhizobium tropici*, *Azospirillum brasilense*	Foxtail millet (*Setaria italica* L.), Maize (*Zea mays* L.), Bean (*Phaseolus vulgaris* L.), *Arabidopsis thaliana*, Tomato (*Lycopersicum esculentum* Mill cv. NEW APPROACHES IN THE USE OF MICROBIAL PRODUCTS

While live microorganisms aim to provide beneficial plant nutrition and health properties, it is important to consider the factors that may limit these benefits. Microorganisms that exhibit positive characteristics under laboratory conditions may not always deliver the desired benefits in natural environments due to various environmental factors. Especially, when dealing with disease agents, it is crucial to thoroughly analyze the relationships between plants and pathogens, as well as the prevalent environmental factors in a specific area, before implementing biological control measures. Instead of relying on a single microorganism, applying a population of microorganisms with cooperative traits is more beneficial, as it creates a stable rhizosphere that provides more effective control against pathogens. In addition to microbial applications, the use of other plant products, such as extracts, biofertilizers and biopesticides, which are natural enemies of pests and/or disease-causing pathogens, also contributes to the success of biological control (Pandit et al. 2022).

In soil, only about 5% of the necessary nutrients are available compared to those in laboratory conditions. Additionally, there is ongoing competition for essential nutrients like nitrogen and carbon, meaning only microorganisms with strong competitive abilities can survive (Shah et al. 2021). Climate change is contributing to a steady increase in soil temperatures (Zhang et al. 2019). This rise impacts microorganisms closely associated with plants, as their optimal growth, diversity, and physiological functions depend on specific temperature ranges (Wu et al. 2010). Deviations from these optimal temperatures can lead to varied outcomes in microorganism-plant interactions. Soil warming notably increases microbial respiration and mortality rates (Wu et al. 2010; Schindlbacher et al. 2011). Moreover, excessive water evaporation and the accumulation of chloride salts, such as sodium chloride (NaCl) and magnesium chloride ($MgCl_2$), raise soil salinity. This increase in salt concentration adversely affects agricultural microbial biomass, seed germination, and plant development by disrupting osmotic potential and ion exchanges (Sindhu et al. 2022).

Host plant and microorganism interactions often determine host specificity, which can lead to a decrease in microbial benefit rates in many crop plant species. In soils with microbial diversity, the lack of specificity in plant species can lead to high competition among microorganism populations (Figueiredo et al. 2011). Additionally, any changes in biochemical compounds produced by plant roots or signaling molecules produced by microorganisms can disrupt potential symbiotic relationships (Chagas et al. 2018). Another important factor is soil pH. The availability of nutrients in the soil solution, for both plants and microorganisms, is greatly influenced by soil pH. The pH is a measure of the hydrogen ion concentration in the colloidal soil solution and affects most chemical reactions in the soil. Acidic soils are dominated by *Acidobacteria*, while alkaline soils are dominated by *Actinobacteria*, causing shifts in microbial populations with changes in soil pH. This can lead to the failure of the desired population to perform its intended function in microbial product use (Shah et al. 2021). Many rhizobacteria exhibit optimal population and efficacy at a pH level of 6.0 (Roe et al. 1998).

The commercialization and application of biological fertilizers involving live microorganisms begins with a technical procedure to isolate ectophytic or endophytic microorganisms from the rhizosphere and plant tissues, especially the roots. This process starts with bioresearch, where plant or soil samples are collected from diverse environments and subjected to microbial isolation in the laboratory. Once rhizobacteria are isolated, they undergo in vitro screening to evaluate their potential for promoting plant growth or serving as biocontrol agents against phytopathogens. Promising strains demonstrating effective plant growth promotion or biocontrol properties are then tested under controlled environmental conditions to assess their impact on plant development. Effective strains are selected based on these tests and further evaluated under field conditions to determine their ability to enhance crop growth. After successful repeated trials, companies typically proceed to commercialize these biological strains as biological fertilizers and/or biocontrol products, following formulation of the final product (Nakkeeran et al. 2005).

An unconventional approach in the field of microbial products that has emerged due to advances in genetics involves enhancing microorganism species and their efficacy, as well as developing new variants. This approach involves intentionally modifying the genetic material of microorganisms, specifically DNA to improve the beneficial traits of microbial strains. Scientists can alter bacterial DNA using techniques such as CRISPR-Cas9, which allows for specific modifications. This genetic manipulation can help bacteria produce chemicals that assist in their proliferation, growth, stress resistance or more efficient nutrient utilization (Bernela et al. 2021; Hasan et al. 2024).

In recent years, leading global agricultural firms have increasingly focused their investments on bio-based product research. Figure 4 lists the revenues and profits of some international companies in the plant protection sector for the second quarter of 2024. Additionally, Figure 5 shows the targeted revenues from bio-based products and the budgets allocated for research and development (R&D) by these same firms for the year 2024. Comparing the data in both figures reveals that firms leading the world in pesticide production are allocating a significant portion of their current revenues to R&D projects aimed at generating revenues from bio-based products over the next decade.

CONCLUSIONS

In today's rapidly evolving climate conditions and the anticipated impacts in the coming years, factors such as rising temperatures and drought, excessive use of chemical fertilizers, salinity from intense evaporation, global warming and reduced water resources due to unregulated water consumption are critical issues affecting agricultural production. Additionally, changing ecosystems due to climate change, the evolution of harmful pathogens and pests and the resulting resistance changes in nature due to pest control measures are pressing and unresolved problems in agriculture. To address these widespread issues and enhance the sustainability of agricultural production, microbial products containing bacteria, fungi, algae and other microorganisms offer a promising alternative. These products provide functional benefits for soil and plants, including plant nutrition, plant protection, and growth regulation, as alternatives to chemical fertilizers and plant protection products.

Some technical details regarding the use of these products emerge as factors determining their effectiveness. Research and advancements in the field aimed at eliminating environmental factors that limit the usefulness of microorganisms are promising. Similar to breeding efforts for plants to achieve higher yields, resistance to diseases and pests and meeting market quality criteria such as color, shape, brightness and taste, the production of live microbial fertilizers and microbial breeding through new technologies that minimize the impact of environmental conditions on microorganisms have opened up new possibilities in the field. It is encouraging to see international pesticide-producing firms investing in scientific research in this area. Additionally, the progress made by some plant nutrition and protection companies in Turkey, which are exploring bio-based product research and commercial applications represents a positive development in agricultural practices.

ABSTRACT

The microbiota in the colon transforms polysaccharides such as pectin and xanthan gum and contributes to the maintenance of colon health by providing the formation of short-chain fatty acids. Various studies have shown that microbiota breaks down these components and form short-chain fatty acids, gas, and various metabolites, but in studies, the microbiota has generally been examined as a community, and the contribution of different bacterial species to biotransformation has not been sufficiently demonstrated. This study investigated whether *Escherichia coli* strains isolated from the human colon, which has not been studied before, produce short-chain fatty acids using pectin or xanthan gum in vitro. The results showed that when cultures containing different concentrations of polysaccharides were compared with control cultures (without polysaccharides), the lowest pH values were observed in cultures containing 5 mg/ml xanthan gum and 10 mg/ml pectin. However, gel formation was observed in the media prepared at these concentrations, and problems were experienced during the pipetting stages. For these reasons, 2 mg/ml xanthan gum and 5 mg/ml pectin concentrations were selected to test the production of short-chain fatty acids. The results of this study showed that these strains could not produce short-chain fatty acids under the conditions examined, but it aims to examine different bacterial strains in further studies.

Keywords: pectin, xanthan gum, microbiota, *E. coli*, short-chain fatty acids

INTRODUCTION

The human digestive system harbors a complex and dynamic population of microorganisms called the gut microbiota. This population of microorganisms includes bacteria, archaea, eukaryotes, and viruses (Koppel and Balskus, 2016). This population is larger than the number of human body cells, and it is estimated that there are at least 100 trillion (10^{14}) microorganism cells in the human gut (Clemente et al., 2012). The gut microbiota has a significant effect on the health and disease status of the host. The microbiota benefits the host by performing physiological functions such as strengthening intestinal integrity, shaping intestinal epithelial cells, obtaining energy, protecting against pathogens, and strengthening the host's immunity. Disturbance of the balance of the gut microbiota (dysbiosis) has been associated with the pathogenicity of many inflammatory diseases and infections (Thursby and Judge, 2017). The composition of the gut microbiota varies significantly among individuals. It is affected by many factors such as genetics, host physiology (age, disease, stress, etc.), medications used, diet, and living environment (Holscher, 2017). Although studies on the presence of microorganisms in placenta have been published in recent years (Aagard et al., 2014; Rodriguez et al., 2015), the common belief is that the intestinal microbiota begins to form at birth (Thursby and Judge, 2017). It is also known that antibiotic use in adulthood causes changes in the composition of the intestinal microbiota and that these changes can be long-term (Modi et al., 2014).

Diet is one of the important factors affecting the intestinal microbiota. There are many published studies, which indicates the influence of diet on microbiota. For instance, when the microbiota of people in a hunter-gatherer society in Tanzania was compared with those of people on a Western-style diet, it was found that the microbiota richness and diversity were higher in hunter-gatherers. This was associated with the fact that the diet of hunter-gatherers, unlike Western societies, included more carbohydrates that can be degraded by the microbiota (Schnorr et al., 2014). It is known that each of the macronutrients (fat, protein, carbohydrates) and many micronutrients can change the intestinal microbiota. The most prominent macronutrient among these is carbohydrates. For example, in a study examining fructose alone, it was found that it changed the composition of the intestinal microbiota (Mastrocola et al., 2018). An animal model study examining sucrose as part of a Western-style high-fat, high-sugar diet, it was observed that the microbiota was rapidly restructured (Collins et al., 2016). Furthermore, nutrients that humans cannot digest are used by bacteria in the large intestine in their basic biological processes. Therefore, changes in the human diet also affect the metabolism of these bacteria.

According to the Codex Alimentarius Commission (CAC) definition, dietary fiber is defined as carbohydrate polymers that are composed of 10 or more monomers and cannot be digested and absorbed in the human small intestine and is examined in 3 categories. These are classified as; edible carbohydrate polymers naturally found in foods; edible carbohydrate polymers obtained from raw food materials by physical, enzymatic or chemical means and having beneficial physiological effects based on scientific evidence; and finally, edible synthetic carbohydrate polymers having beneficial physiological effects based on scientific evidence. However, the definition of how many monomers dietary fiber will consist of may vary from country to country (Holsher, 2017). Dietary fibers can be obtained from plant and microbial sources. The main dietary fibers can be listed as: Cellulose, hemicellulose, guar gum, xanthan gum, alginate, carrageenan pectin, etc. (Guillon et al., 2011). These dietary fibers are broken down by intestinal bacteria when they reach the large intestine. As a result, they affect the stool mass, stool frequency, colon pH, and the energy obtained from these indigestible dietary fibers in individuals. However, the type of dietary fiber is broken down is important in terms of the metabolites formed (Guillon et al., 2011).

Epidemiological studies have shown that there is an inverse relationship between dietary fiber intake and cardiovascular diseases. The main important products formed as a result of the fermentation of these dietary fibers in the large intestine are short-chain fatty acids. The main short-chain fatty acids are acetate, propionate, and butyrate. Short-chain fatty acids play an important role in the health of the host. Butyrate contributes to the integrity of the intestinal barrier in the large and small intestines and provides energy to the epithelial cells in the large intestine (Chambers et al., 2018). In addition, studies have shown that butyrate has an inhibitory effect on colon cancer and the development of tumors. Different dietary fibers are formed with a wide variety of monosaccharide bonds. Although the human digestive system is inadequate in breaking down these bonds, the intestinal microbiota, with its diversity and gene pool, contains enzymes that can break down these bonds and can use unbreakable complex carbohydrates as an energy source (Gentile and Weir, 2018). Nutrition is one of the most important factors that shape and change the intestinal microbiota throughout human life. In addition, it is also a fact that the intestinal microbiota changes or transforms the foods consumed and the components in these foods. In this sense, the intestinal microbiota is one of the most important links in this bioavailability chain.

Pectin is one of the structural polysaccharides of plants and has a structure consisting of a polygalacturonic acid chain (Vandamme et al., 2002). It has a wide usage rate in the food industry due to its gelling, thickening and stabilizing properties. Since pectin can also be considered in the oligosaccharide class, it can also be fermented by intestinal bacteria (Willats et al., 2006). However, the rate of use by bacteria varies depending on the chemical structure and methylation degree of pectin (Hamaker et al., 2014). In some studies, it has been reported that pectic fractions support the development of bacteria such as *Bifidobacterium* and *Lactobacillus*, although it depends on the composition and prebiotic index of pectin. Thus, its benefits in protecting intestinal health and increasing digestion have been observed (Wicker et al., 2014). Gulfi and his colleagues (2007) determined that total short-chain fatty acid production was high as a result of fermenting pectin, which was extracted from apples and has a branched structure, with bacteria in human feces. In a study conducted with mice, Fåk and his colleagues (2015) observed that pectin increased the level of short-chain fatty acids in the cecum and blood, and stated that acetic acid production was low in low-methylation pectins.

Xanthan gum is a microbial polysaccharide produced by *Xanthomanas campestris*, which is widely used as a thickener and stabilizer in food, pharmaceutical and agricultural applications (Rosalam and

England, 2006). Since it is soluble in hot and cold water, it is used in many products in the food industry, and in the pharmaceutical industry, it is also used as a coating material with other polysaccharides such as chitosan (Giavasis, 2013). Xanthan gum, which is considered among the digestible carbohydrates, is also called dietary fiber and its use by intestinal bacteria was also investigated. In a study conducted by Bourquin et al., in vitro fermentation of various dietary fibers with bacteria isolated from feces was investigated, and they found that intestinal bacteria fermented xanthan and could produce high levels of acetic acid (Bourquin et al., 1996). Additionally, Schnizlein et al. (2020) found that in mice fed a diet supplemented with xanthan gum, the production of short-chain fatty acids increased and the efficacy of an antibiotic used to prevent colonization by *Colostroides difficile* bacteria was enhanced.
Studies showed that dysbiosis has been linked with many diseases. Various approaches, such as probiotics, prebiotic supplements, or fecal microbiota transplantation, have been intensively studied to cure the gut microbiota imbalance. Restoration of the levels of short-chain fatty acids is another therapeutic approach to cure dysbiosis (Fusco et al., 2023). Studies where the human microbiota was examined cumulatively showed that microbiota can degrade pectin and xanthan gum and can form acetate, propionate, and butyrate in different proportions. What has not been fully revealed in these studies and is worth examining is the contribution of individual members of the microbiota to this transformation. *Escherichia coli* is a bacterium commonly found in the human intestine. Previous studies have shown that *E. coli* strains can degrade different glucosides thanks to their different Glucosyl Hydrolase (GH) enzymes. In this context, this study investigated whether 2 different *E. coli* strains isolated from the human intestine can degrade pectin and xanthan gum and form short-chain fatty acids in vitro.

MATERIAL AND METHOD

E. coli strains used in the study were obtained from Karadeniz Technical University, Faculty of Medicine, Department of Microbiology. Nutrient Broth (Oxoid) was used to develop *E. coli* strains. After the liquid medium was prepared, the pH was adjusted to 6.8± 0.2. Pectin (pectin from Citrus peel, Galacturonic acid≥74.0) and xanthan gum (Xanthan from Xanthomonas campestris) used in the analyses were obtained from Sigma Aldrich.
The effect of different pectin and xanthan gum concentrations on the growth of *E. coli* strains were tested in the medium, 50 ml containing different concentrations of pectin (1, 2.5, 5, 10 mg/ml) and xanthan gum (0.5, 1, 2, 5 mg/ml). The media were inoculated with fresh *E. coli* F or *E. coli* C cultures and incubated for 8 hours in a shaking incubator (Heidolph, Germany) at 37°C. At the end of the incubation period, microbial growth in the cultures was determined by OD600 measurements made with a spectrophotometer (Thermo Scientific, Multiskan GO, US). The controls without pectin or xanthan gum were also prepared.
After determining the appropriate pectin and xanthan gum concentration, 50 ml media were prepared for each *E. coli* strain. These media were inoculated with fresh *E. coli* F or *E. coli* C cultures and incubated for 24 hours in a shaking incubator (Heidolph, Germany) at 37°C. At the end of the incubation period, pH measurements of the cultures were also made. In addition, fresh cultures of *E. coli* F and *E. coli* C were inoculated together on media containing pectin or xanthan gum (3 parallels, 50 ml medium). These media were incubated for 24 hours in a shaking incubator (Heidolph, Germany) at 37°C, and pH measurements were made at the end of the incubation period. After the prepared cultures were transferred to clean falcon tubes, they were stored at -20°C until analyzed.
GC-MS analysis was performed using the method Schneider et al. used (2006) with modifications. 0.4 ml of 50% sulfuric acid and 2 ml of diethyl ether were added to a sufficient amount (2 ml) of culture; the sample was mixed in an orbital shaker for 45 minutes and then centrifuged at 3000 rpm for 5 minutes. Potassium persulfate was added to remove the remaining water and injected into the device. Shimadzu GC-MS QP2010 Ultra and DB-FastFAME 30 m, 0.25 mm, 0.25 μm (Agilent, US) columns were used in the analyses. The temperature program

was programmed to increase from 100°C to 240°C and lasted for a total of 20 minutes. The split ratio was 10:1, the injection volume was 1 µl, the solvent delay time was 0, He was selected as the carrier gas, and the flow was adjusted to 1 ml/min. He was set to 30 ml/min, H_2 flow to 40 ml/min, and dry air flow to 400 ml/min. The external standard method was used to quantify the samples; acetic acid, butyric acid, and propionic acid standards were run in the device at different concentrations (5, 10, 12.5, 25, 50 mol/l), and their retention times in the column were determined.

RESULTS AND DISCUSSION

Initially, each medium's pH values varied between 6.70-6.98. After the incubation, no pH below these values was observed in any culture. The samples were compared with control cultures to determine the pH decrease due to short-chain fatty acids that may occur due to *E. coli* activity during the incubation process. When the control cultures (without polysaccharides) were compared with the cultures containing different concentrations of polysaccharides at the end of the incubation, it was observed that the lowest pH values were generally in cultures containing 5 mg/ml xanthan gum and 10 mg/ml pectin (except 10 mg/ml for *E. coli* F). Gel formation was observed in the media prepared at these concentrations, and problems were experienced during the pipetting stages. For these reasons, 2 mg/ml xanthan gum and 5 mg/ml pectin concentrations were selected to test the production of short-chain fatty acids.

The retention times determined for these standards are as follows: Acetic acid; 3.2 min, propionic acid; 4.1 min, butyric acid; 5.5 min. These short-chain fatty acids were not detected in any of the examined samples. Noise peaks were observed in the GC-MS chromatograms of the samples; a sample chromatogram is shown in Figure 1.

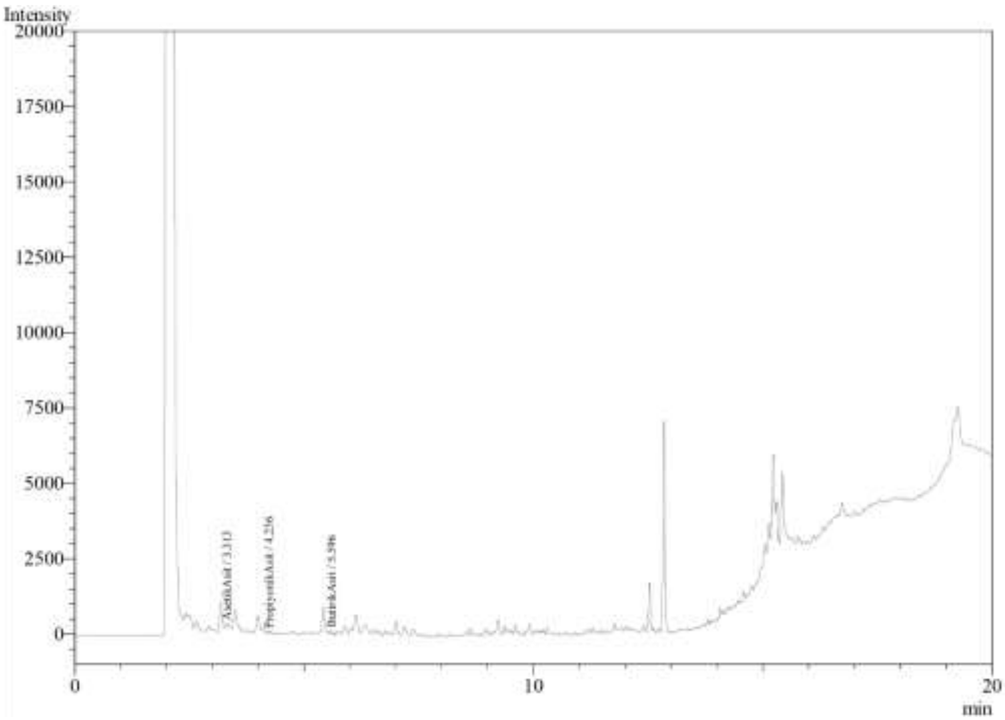

Figure 1. GC-MS chromatogram

CONCLUSIONS

Although there is no definitive information in the literature that *E. coli* can break down pectin or xanthan gum, it has been found that D-galacturonic acid units, which are monomers of pectic components, are broken down by *E. coli* in a unique way (Richard and Hilditch, 2009), and some previous studies have shown that some bacteria members of the Enterobacteriaceae family can break down pectin with their own enzymes (Abbott and Boraston, 2008). The fact that *E. coli* is an important member of the human intestinal microbiota and has strains that can be both pathogenic and probiotic makes this bacterium significant. Therefore, although the existing *E. coli* strains were tested for short-chain fatty acid production in the first step, our aim is to identify new bacterial strains that can produce short-chain fatty acids in the human intestine. In future studies, it is aimed to isolate bacteria that can use these polysaccharides and test the production of short-chain fatty acids in these strains by culturing them in media where pectin or xanthan gum is used as the sole carbon source from human feces solution.

ABSTRACT

The increase in food consumption has revealed the necessity of making the best use of existing food resources. Some genotypes of watermelon, one of the important vegetable species, have snack potential due to their seed characteristics. This study was carried out to determine the seed oil ratio and fatty acid composition values of some edible seeded watermelon genotypes. Oil was obtained from the seeds of twenty-four watermelon genotypes. The oil ratio and composition of the oils obtained were determined. According to the results obtained, it was determined that watermelon seeds contained an average of 15.93% oil (on a dry basis), and this oil contained 59.75% linoleic acid, 20.63% oleic acid, 11.23% palmitic acid, and 7.53% stearic acid. The highest linoleic acid content was determined in genotype number 1, and the highest palmitic acid content was determined in genotype number 11. The results of this study can be used in breeding strategies to develop edible seeded watermelon varieties.

Keywords: *Citrullus lanatus*, Fatty Acid Composition, seed

INTRODUCTION

Plants belonging to the cucurbitaceae family have various health-promoting properties such as anti-inflammatory, antihistamine, muscle relaxant and antiulcer properties. With the increasing awareness of their health benefits, interest in cucurbitaceae is increasing (Akuamoah et al., 2018; Armesto et al., 2020). Watermelon (*Citrullus lanatus*) is a juicy and sweet-flavored vegetable species belonging to the Cucurbitaceae family, which includes 130 genera and 800 species, and is intensively cultivated worldwide. In 2022, global watermelon production exceeded 99.9 million tons on an area of 2.92 million hectares (FAO, 2024). Fruit traits in watermelon genetic resources are highly variable depending on the genotype and climatic conditions. Commonly cultivated watermelon varieties have fewer seeds and fibrous flesh compared to wild species.

The waste produced by agricultural industries worldwide exceeds 2 billion tons (Barbi et al., 2020). According to FAO, these by-products are food losses that cause a decline in the consecutive food production supply chain. There is a worldwide concern about agricultural industrial residues that cause both environmental pollution and economic losses. These losses can be overcome by implementing the environmental economics model that will help manage waste use. After the watermelon fruit is consumed, large amounts of watermelon peel and seed waste occur.

Although watermelon seeds are generally considered a waste product, more and more researchers are showing great interest in using and emphasizing their nutritional value and phytochemical profiles. Watermelon seeds can be consumed as a snack in some countries and regions. In addition to being consumed as a snack, watermelon seeds are also evaluated in the cosmetics, pharmaceutical and food industries. Since watermelon seeds contain sufficient amounts of unsaturated fatty acids, linoleic acid and oleic acid, they provide a cure for various diseases (Sodeke, 2005). In addition, watermelon seed oil is a good source of essential fatty acids and other phenolic substances in varying amounts depending on the watermelon variety (Ouassor et al., 2020). The most abundant fatty acid in watermelon seed oil is linoleic acid. Watermelon seed oil has anti-inflammatory and antimicrobial properties (Eidangbe et al., 2010; Madhavi et al., 2012). In addition, watermelon seeds are rich in Ca, Mg, Fe, and Zn minerals (Sabahelkhier et al., 2011; Garba et al., 2014). Morphological and molecular characterization studies of different watermelon genotypes have been carried out (Toprak et al., 2023; Coskun et al., 2024a, b). However, studies on the fatty acid content of watermelon genotypes with high snack potential are not sufficient. There may also be significant variations in seed fatty acid profile among watermelon genotypes. Therefore, it is important to determine the oil content of watermelon genotypes with high snack potential. This study aims to determine the oil content and fatty acid composition of seeds belonging to different watermelon genotypes.

MATERIALS AND METHODS

In this study, 24 watermelon genotypes with high snack watermelon potential were used. Samples were stored at +4°C for 12 months. Oils were extracted from seed samples of all genotypes simultaneously. Nine grams of dried seed samples from all genotypes were used for oil extraction and a Soxhlet apparatus was used. Hexane (Merck KGaA, Darmstadt, Germany) was used as the solvent. The esterification of fatty acids was done according to the method of David et al. (2003). Fatty acids were analyzed by a GC. Chromatographic separation was carried out using a (30 m × 0.25 mm ID, 0.25 μm film thickness DB-Wax) column equipped with a flame ionization detector (FID). Results were expressed as a % value.

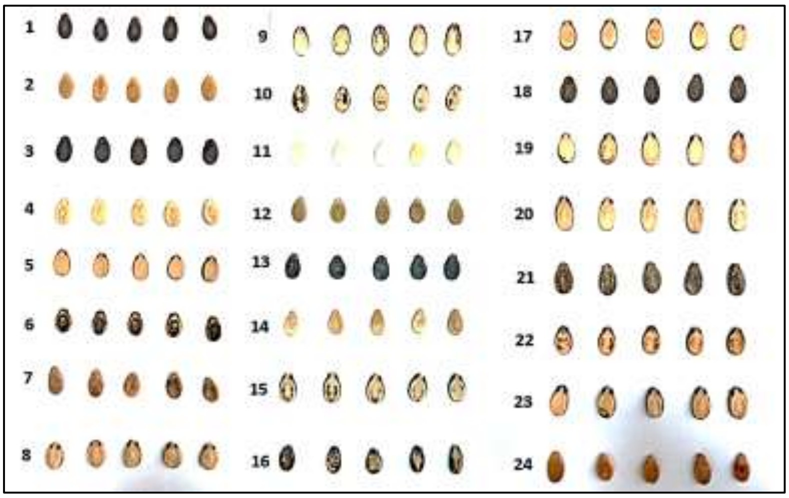

Figure 1. Seeds of different watermelon genotypes

RESULTS AND DISCUSSION

In our study, fatty acid profiles of 24 watermelon seed samples with high snack potential were examined. Saturated and unsaturated fatty acids were determined by GC analysis. In this study, palmitic acid, stearic acid, oleic acid, linoleic acid, arachidic acid and docosahexaenoic acid were measured in watermelon genotypes (Table 1).

Table 1. Fatty acid composition in watermelon genotypes

Genotyp	Oil Content (%)	Palmitic acid (C16:0)	Stearic acid (C18:0)	Oleic acid (C18:1n9)	Linoleic acid (C18:2n6c)	Arachidic acid (C20:0)	Docosahexaenoic acid (C22:6n3)
1	15.59	13.07	5.34	15.08	66.51	0.01	0.01
2	16.63	12.99	9.33	16.45	60.39	0.44	0.40

21	12.50	10.08	7.26	19.88	61.79	0.35	0.64
22	19.97	11.65	6.32	22.71	58.53	0.30	0.50
23	16.24	10.43	6.53	20.97	61.06	0.31	0.71
24	15.27	11.67	10.12	18.29	58.83	0.43	0.65
Mean	15.93	11.23	7.53	20.63	59.75	0.34	0.53

Seed oil content varied between 9.9% and 20.54% among genotypes and the average was 15.93%. The highest oil content was determined in genotype 16 and the lowest oil content was determined in genotype 11. The first five genotypes with the highest oil content are genotypes 16 (%20.54), 10 (%20.42), 22 (%19.97), 20 (%19.73) and 3 (%19.30), respectively. In previous studies, the oil content of watermelon seeds was between 10-35% and this ratio may vary depending on the genotype (Ziyada and Elhussien, 2008; Mahla et al., 2018). In this study, the oil content was determined between 9.99-20.54% among genotypes and is consistent with the literature. The total fat content value in this study is lower than the total fat content value determined by Zarifikhosroshahi and Ergun (2021). This may be due to the difference between genotypes.

In terms of fatty acid content, 6 different fatty acids were determined in watermelon genotypes. The fatty acid with the highest content was linoleic acid. Then, oleic acid, palmitic acid, stearic acid, docosahexaenoic acid and arachidic acid were determined, respectively. In a study, it was determined that watermelon seed oil contained 59.6% linoleic acid (18:2n-6) and 78.4% total unsaturated fatty acids. The dominant fatty acid in the oil was linoleic acid, followed by oleic, palmitic and stearic acids (El-Adaway and Taha, 2001a,b). These results are similar to our findings. In his study, Logaraj (2010) similarly determined the highest linoleic acid, oleic acid and palmitic acid in watermelon seeds. The main composition of the seed oil is unsaturated fatty acids, including linoleic acid, which helps lower cholesterol and high blood pressure levels in humans.

Linoleic acid values were found to be 59.75% on average in all genotypes. The highest value was measured in genotype number 1 (66.51%) and the lowest value was measured in genotype number 14 (40.16%). These values are similar to previous studies (Logaraj, 2010; El-Adaway and Taha, 2001a). The linoleic acid values determined in our study are higher than the values determined by Zarifikhosroshahi and Ergun (2021). The reason for the differences may be the difference in the material investigated. Oleic acid values were found to be 20.63% on average in all genotypes. The highest value was measured in genotype number 14 (38.53%), and the lowest value was measured in genotype number 1 (15.08%). Oleic acid values were found to be higher than some previous studies (Logaraj, 2010; Zarifikhosroshahi and Ergun, 2021). Palmitic acid values were found to be 11.23% on average in all genotypes. The highest value was measured in genotype number 11 (13.69%), and the lowest value was measured in genotype number 20 (9.80%). The palmitic acid values determined in our study are lower than the values determined by Zarifikhosroshahi and Ergun (2021). The reason for the differences may be the difference in the investigated material.

Stearic acid values were found to be 7.53% on average in all genotypes. The highest value was measured in genotype number 7 (10.63%), and the lowest value was measured in genotype number 1 (5.34%). The stearic acid values determined in our study are lower than the values determined by Zarifikhosroshahi and Ergun (2021). The reason for the differences may be the difference in the investigated material. Docosahexaenoic acid values were found to be 0.53% on average in all genotypes. The highest value was measured in genotype number 19 (0.75%), and the lowest value was measured in genotype number 1 (0.01%). Arachidic acid values were found to be 0.34% on average in all genotypes. The highest value was measured in genotype number 14 (0.85%), and the lowest value was measured in genotype number 1 (0.01%).

The development of sustainable economic systems and the evaluation of waste products through the adoption of an environmental economics approach in agricultural enterprises have been the main priorities of the scientific community in recent years. Fatty acids are used as the basic building blocks of biological membranes, long-term energy storage, and precursors of hormones. The human body cannot synthesize omega-3 and omega-6 fatty acids, which are called essential fatty acids, and must be obtained through diet. The results of this study have proven that seeds of watermelon genotypes with high snack potential are a good source of high omega-6 fatty acids. Therefore, seed oil can be considered a well-known and healthy source of human nutrition. Breeding studies can be continued by taking into account the fatty acid composition data within the examined genotypes and thus contributing to a variety of development studies.

ABSTRACT

Melon (*Cucumis melo* L.) is an economically important summer vegetable species with an aromatic taste and high nutritional value, produced in large quantities worldwide. Waterlogging has become one of the most common stress factors threatening crop production and food security worldwide. Waterlogging seriously impairs the growth and productivity of agricultural products. In this study, we aimed to determine the effect of waterlogging stress on melon and whether gibberellic acid (GA_3) can change stress conditions. Waterlogging stress conditions caused significant changes in almost all measured parameters in melon. Only PAR (photosynthetic active radiation) values did not change statistically. It was determined that stress tolerance could be increased in some parameters in the group where GA_3 was applied together with waterlogging stress. SPAD (leaf chlorophyll content) values were defined as 30.36±0.89 in the control group, 23.55±1.69 in the waterlogging group, and 22.65±174 in the GA_3+waterlogging group. It was determined that the GA_3 application reduced visual damage under waterlogging stress conditions. In this study, it was determined that this flooding stress significantly negatively affected the melon. Although GA_3 application could improve some parameters in melon under waterlogging stress, its healing effect on many parameters was limited.

Keywords: giberellic acid; melon; tolerance; waterlogging stress

INTRODUCTION

Plants face various abiotic stress factors such as heavy metals, high temperature and waterlogging throughout their life cycle, which cause significant yield losses (Zhou et al., 2020; Sun et al., 2020). Environmental stress affects plant growth and development (Li et al., 2021; Coskun, 2023). Climate change has caused an increase in extreme weather events (Walter et al., 2016). Global warming and the increasing frequency of extreme weather events cause waterlogging stress to become more severe (Chen, 2018).

Floods affect more than 10% of global arable land yearly (Jackson and Colmer, 2005). Waterlogging stress can occur due to excessive rainfall events, poor soil drainage, sensitive genotype, excessive irrigation or a combination of these (Hidalgo et al 2010; Liu et al., 2020). Excess water in the soil causes saturation of soil pores, reduced oxygen availability and impaired gas exchange in tissues. In response to plant water deficit, changes in root anatomy and architecture (Morris et al., 2017). Excess water in the soil reduces the oxygen in the root environment. This causes hypoxia for the roots (Sasidharan et al., 2007). Long-term anaerobic respiration can cause the accumulation of harmful substances in the rhizosphere. Hypoxia conditions in plants negatively affect plant growth and yield (Salvatierra et al., 2020). Hypoxia can cause a decrease in net photosynthesis in plants (Habibi et al., 2023) and deterioration in water and mineral uptake (Xie et al., 2021). Root hypoxia stress can cause leaf chlorosis, curling, leaf shedding, edge browning, necrosis, yellowing, root rot, wilting and fruit drop (McGee et al., 2021). If waterlogging stress is temporary, plants may recover. However, prolonged waterlogging results in plant death.

There are many strategies to reduce the harmful effects of waterlogging (Ahmed et al., 2013). Soil tillage and drainage systems are used to remove excess water from the soil (Manik et al., 2019). The use of raised beds may also be beneficial (Sayre et al., 2004). In addition to soil management, nutrient application and genetic manipulations can be used to combat waterlogging stress. In the past, little attention has been paid to fertilizer application to alleviate waterlogging. Post-waterlogging plant fertilization can be a practical and cost-effective method to alleviate waterlogging damage (Chae et al., 2018). Plants have evolved complex mechanisms involving gene expression and regulatory networks to mitigate the effects of stress factors (Sun at al., 2020). An important component of the ability of plants to withstand waterlogging is the formation of adventitious roots (Zhang et al., 2017).

Plant species and varieties may respond differently to waterlogging stress. Some varieties can tolerate water stress for a long time. Plants with high tolerance to waterlogging stress can accumulate more nutrients in their roots during stress periods and produce more aerobic tissue. Plant hormones have an important effect on both developmental processes and stress response throughout the lifespan of plants. Previous studies have reported that ethylene, auxin, gibberellin, abscisic acid, salicylic acid, and jasmonic acid are involved in responses to waterlogging stress and mediate many pathways necessary for waterlogging tolerance (Vidoz et al., 2010; Zhang et al., 2021). Although significant progress has been made in the development of waterlogging mitigation practices, the effectiveness of GA_3 application is not yet sufficiently known.

Melon (*Cucumis melo* L.) is an economically important summer vegetable with an estimated production of over 42 million tons worldwide in 2020 according to the Food and Agriculture Organization of the United Nations (FAO). Waterlogging stress can disrupt the normal growth and development of melon and even lead to plant death. Waterlogging stress seriously affects the quality and yield of melon in rainy regions (Zhang et al., 2021). This study aimed to determine the effect of waterlogging on melon plants and the curative effect of GA_3 application.

MATERIALS AND METHODS

The experiment was carried out in Hatay Mustafa Kemal University Research Greenhouse between April 2024 and June 2024. One hybrid melon variety was used as material in the experiment. Healthy and smooth plants were selected for waterlogging stress application. The pots were placed in plastic containers filled with tap water up to the top of the hypocotyls. Waterlogging stress application was continued for ten days and waterlogging depth was kept constant throughout the experiment. Control plants without waterlogging were watered normally in plastic containers. In the other group, GA_3 (50 mg L -1) was applied together with waterlogging stress. For morphological and physiological analysis, leaves were collected after ten days of waterlogging stress and leaves of control plants were sampled at the same time. Two biological replicates were used, 10 seedlings in each replicate. Statistical analysis of experimental data was performed using SPSS. Tukey's HSD test was used to determine the significant difference between the means ($p < 0.01$). The mean ± standard error was used to present to explain statistical analysis results.

RESULTS AND DISCUSSION

The effect of waterlogging stress on some parameters in melon was determined. It was also determined whether GA_3 application had a healing effect on plants under waterlogging stress. For this purpose, root length, plant length, fresh weight, dry weight, stem diameter, leaf number, visual damage, leaf chlorophyll content (SPAD) and photosynthetic active radiation (PAR) measurements were made.

Table 1. Root length, plant length, fresh weight and dry weight values

		Mean±Std. Error	**Minimum**	**Maximum**
Root Length (cm)	**Control**	50.00±8.09a	29.00	75.00
	Waterlogging	21.16±0.98b	17.00	24.00
	GA_3+Waterlogging	20.00±1.84b	14.00	27.00
	Mean	29.23±4.06	14.00	75.00
Plant Length (cm)	**Control**	111.80±9.75a	92.00	136.00
	Waterlogging	63.16±3.60b	56.00	80.00
	GA_3+Waterlogging	64.83±4.86b	44.00	77.00
	Mean	78.05±6.38	44.00	136.00
Fresh Weight (g)	**Control**	24.40±1.49a	20.10	28.90
	Waterlogging	11.12±1.27b	7.61	16.62
	GA_3+Waterlogging	10.46±0.57b	8.82	12.42
	Mean	14.79±1.66	7.61	28.90
Dry Weight (g)	**Control**	2.48±0.16a	1.85	2.76
	Waterlogging	1.16±0.15b	0.84	1.80
	GA_3+Waterlogging	1.06±0.05b	0.94	1.27
	Mean	1.51±0.17	0.84	2.76

Root length was determined as 29.23±4.06 cm on average, plant length as 78.05±6.38 cm on average, fresh weight as 14.79±1.66 g on average and dry weight as 1.51±0.17 g on average (Table 1). Root length was determined as 50.00±8.09 cm in control plants. Root length decreased as a result of waterlogging stress, and GA_3 application did not have a significant positive effect. Plant length was determined as 111.80±9.75 cm in control plants. Plant length decreased as a result of waterlogging stress, and GA_3 application did not have a significant curative effect. Fresh weight was determined as 24.40±1.49 g in control plants. Fresh weight decreased as a result of waterlogging stress, and GA_3 application did not have a significant positive effect. Dry weight was determined as 2.48±0.16 g in control plants. Dry weight decreased as a result of waterlogging stress, and GA_3 application did not have a significant positive effect. Waterlogging stress had negative effects on root length, plant length, fresh weight and dry weight values. No statistically significant effect of GA_3 application was determined on these parameters.

Table 2. Stem diameter, leaf number values and visual damage

		Mean±Std. Error	Minimum	Maximum
Stem Diameter (mm)	**Control**	4.75±0.24c	4.27	5.45
	Waterlogging	4.94±0.12b	4.60	5.42
	GA_3+Waterlogging	5.42±0.24a	4.55	6.21
	Mean	5.05±0.13	4.27	6.21
Number of Leaves	**Control**	12.60±0.40a	12.00	14.00
	Waterlogging	8.00±0.44b	7.00	10.00
	GA_3+Waterlogging	8.00±0.25b	7.00	9.00
	Mean	9.35±0.56	7.00	14.00
Visual Damage Changes	**Control**	0.00±0.00c	0.00	0.00
	Waterlogging	2.16±0.16a	2.00	3.00
	GA_3+Waterlogging	1.50±0.34b	1.00	3.00
	Mean	1.29±0.25	0.00	3.00

The average stem diameter was determined as 5.05±0.13 mm, the average leaf number was determined as 9.35±0.56 and the average visual damage was determined as 1.29±0.25 (Table 2). The stem diameter was determined as 4.75±0.24 mm in control plants. As a result of waterlogging stress, trunk diameter values increased, and the highest trunk diameter values were obtained as a result of GA_3 application. The number of leaves was determined as 12.60±0.40 in control plants. As a result of waterlogging stress, leaf number values decreased, and GA_3 application did not have a significant positive effect. Visual damage was not observed in control plants. As a result of waterlogging stress, visual damage increased, and it was determined that GA_3 application reduced visual damage. No positive effect of GA_3 application was determined in terms of leaf number. However, it was determined that GA_3 application had positive results in terms of visual damage and stem diameter values.

Table 3. SPAD and PAR values

		Mean±Std. Error	Minimum	Maximum
Leaf Chlorophyll Content (SPAD)	**Control**	30.36±0.89a	27.50	32.30
	Waterlogging	23.55±1.69b	17.40	29.90
	GA_3+Waterlogging	22.65±1.74b	15.90	27.70
	Mean	25.23±1.18	15.90	32.30
Photosynthetic Active Radiation (PAR)	**Control**	69.40±0.87a	66.00	71.00
	Waterlogging	69.66±0.88a	67.00	72.00
	GA_3+Waterlogging	61.33±5.53a	38.00	72.00
	Mean	66.64±2.11	38.00	72.00

SPAD was determined as 25.23±1.18% and PAR was determined as 66.64±2.11% on average (Table 3). SPAD values were determined as 30.36±0.89% in control plants. As a result of waterlogging stress, SPAD values decreased, and GA_3 application did not have a significant positive effect. PAR values were determined as 69.40±0.87% in control plants. As a result of waterlogging stress, PAR values were similar to the control group, and GA_3 application did not have a significant positive effect. Waterlogging stress had a negative effect on physiological values related to photosynthesis such as SPAD, and positive effects of GA_3 application were not determined. A total of nine parameters were measured. As a result of waterlogging stress, PAR values did not change and stem diameter values increased. Negative effects of waterlogging stress were determined in the other seven parameters. Again, no remedial effect of GA_3 application was found in the same seven parameters. An increase in stem diameter occurred as a result of GA_3 application. In addition, GA_3 application reduced the degree of visual damage.

One of the most important problems encountered in vegetable cultivation is waterlogging. Plants exposed to waterlogging respond to the damage caused by waterlogging stress by changing their growth morphology. In some soil types, waterlogging causes ion toxicity in the soil, which can affect cell permeability. Suppressed plant respiration negatively affects stomatal status, chlorophyll content, and photosynthesis rate. It has been determined that waterlogging stress causes damage to chloroplasts in plants and negatively affects photosynthesis (Zhou et al., 2023). In this study, photosynthetic parameters such as SPAD and PAR were similarly negatively affected under waterlogging stress. Waterlogging stress creates an oxygen-deficient growth environment in the plant root zone. As a result of oxygen deficiency, nutrient transport by the root system is inhibited and leaf yellowing occurs in the above-ground parts (Wang et al., 2007). In this study, visual damage increased with stress.

As a result of waterlogging stress, plant root respiration is affected (Zhi et al., 2008). This situation causes plants that want to maintain root respiration to grow more roots. In their study, Mi et al. (Mi et al., 2018) determined that adventitious roots formed in waterlogging-resistant melon plants were more numerous and longer. It has been reported that various morphological changes, including aerenchyma development, adventitious root formation, shoot elongation and leaf epinasty, can alleviate the negative effects of hypoxic environment caused by waterlogging stress (Dawood et al., 2016; Herzog et al., 2016; Ni et al., 2019)

In some previous studies, it has been determined that plant nutrient and hormone applications can improve waterlogging stress. In a study, it was determined that nitrogen application in wheat plants under waterlogging stress increased seed production (Kisaakye et al., 2017). Similarly, in different studies, fertilizer application under waterlogging stress conditions has shown positive effects (Robertson et al., 2009; Wu et al., 2014). In some studies, it has been reported in previous studies that gibberellin, abscisic acid, salicylic acid and jasmonic acid mediate many pathways required for waterlogging tolerance (Vidoz et al., 2010; Zhang et al., 2021). In their study, Islam et al. (2022) determined that GA_3 application in *Vigna radiata* plant under waterlogging stress caused improvement in many parameters. In this study, the ameliorative effect of gibberellic acid under water stress conditions was investigated. Waterlogging stress had negative effects in terms of root length, plant length, fresh weight and dry weight values. No statistically significant effect of GA_3 application was determined on these parameters. No positive effect of GA_3 application was determined in terms of leaf number.

However, it was determined that GA_3 application had positive results in terms of visual damage and stem diameter values. Waterlogging stress had a negative effect on physiological values related to photosynthesis such as SPAD, and positive effects of GA_3 application were not determined. In this study, it was determined that this waterlogging stress significantly affected melon negatively, and although GA_3 application could provide improvement in some parameters in melon under waterlogging stress, its improvement effect on many parameters was limited. More studies are needed on the mechanism of waterlogging stres tolerance, screening of waterlogging stres tolerant varieties and introduction of melon varieties.

IMMOBILIZATION OF HEAVY METAL BY CLAYS IN AGRICULTURAL SERPENTINE SOILS

Teuta Bushi[1], Aida Bani[2], Selma Mysilhaka[3], Seit Shallari[2],
[1] Department of Physics, Faculty of Forest Sciences, Agricultural University of Tirana, Albania
[2] Department of Environment and Natural Resources. Faculty of Agriculture and Environment, Agricultural University of Tirana, Tirane, Albania
[3] Departament of Biology, Faculty of Natural Sciences, University "Aleksander Xhuvani", Elbasan, Albania

Heavy metals and metalloids can accumulate in soil, with potentially toxic effects to human health and ecosystems, threatening the sustainable use and management of soil resources.
The concern of high concentration of heavy metals coming from mineralized soil is even greater when we cultivate food plants. Several procedures have been proposed to reduce the concentration of heavy metals in the soil; among them, the application of materials such as bentonite, able to absorb these elements, making them less available to plants.
The present study deals with the use of clay material as an adsorbent and Ni hyperaccumulator plant, *Odontarrhena chalcidica,* for the removal of Ni from solutions of agricultural serpentine soil in Albania, as an alternative reduce nickel availability and to reduce the risk of uptake of nickel by vegetable. *Ex-situ* experiment was conducted with serpentine soil Where we add clays and cultivated *Odontarrhena calchidica* plant. The experiment was conducted in 1 kg plastic plot. We used four doses of clays: 0.0; 10.7; 21.4 and 32.1 g kg^{-1}, corresponding to 0, 30, 60 and 90 t ha^{-1}, respectively. Experiment was with 3 replications for plots with clays and them with clays an Ni hyperaccumulator. After the 60 th day of experiment, the plants collected separating the aerial part, washing with distillated water, conditioned in paper sacks and dried in forced air stove at 65^{o} C during 48 hours. Total metal determination will conduct after digestion of soils and plants, using ICP. We measured available metals in soil of ex-situ experiment before experiment for every treatment and after 60 days. Ex situ experiment help us to know capacity of clay to immobilize metals and capacity of Ni hyperaccumulator plant to extract metal and soil remediation.

Key words: Heavy metals, hyperaccumulator plant, *Odontarrhena chalcidica*, clay, absobent

INTRODUCTION

Clay minerals have attracted much attention for metal stabilization due to their high specific area, liming (pH-increasing) effect, excellent ion exchange capacity and abundant surface hydroxyl groups[1],[2],[3], strong mechanical stability, stable chemical properties, lower cost and environmentally friendly and offer a cost-effective alternative to conventional treatment .
The concern of high concentration of heavy metals coming from mineralized soil is even greater when we cultivate food plants. Several procedures have been proposed to reduce the concentration of heavy metals in the soil; among them, the application of materials such as bentonite, able to absorb these elements, making them less available to plants.
Albanian natural clays have the ability to adsorb heavy metals and decrease their availability in the soil and the possibility of take up and accumulate in agricultural plants. The aim of this study was to evaluate the adsorption ability of natural soil components such as clays to

improve the agricultural serpentine soils. We use the clay extracted by soils collected in Prrenjas area (Domosdova field) [4],[5],[6]
The present study deals with the use of clay material as an adsorbent for the removal of Ni from solutions of agricultural serpentine soil in of Albania, as an alternative reduce nickel availability and to reduce the risk of up take of nickel by vegetable.

MATERIAL AND METHODS

We use the clay extracted by soils collected in Prrenjas area (Domosdova field) [4],[5],[6] (19°30'39" East)
Adsorption experiments carried out using metal solutions of Ni extracted from serpentine soil of Prrenjas.
We analyzed the concentrations of heavy metals before and after interaction with clay.
Experiment ex situ was conducted with hyperaccumulator (*Odontarrhena Calchidica* (Janka) Španiel & al.) plants as test plant.
The experiment was conducted in 1 kg plastic plot. We used four doses of clays: 0.0; 10.7; 21.4 and 32.1 g kg^{-1}, corresponding to 0, 30, 60 and 90 t ha^{-1}, respectively. Experiment was with 3 replications for plots with clays and them with clays an Ni hyperaccumulator.
After the 60 th day of experiment, the plants collected separating the aerial part, washing with distilled water, conditioned in paper sacks and dried in forced air stove at 65° C during 48 hours.
We measured total heavy metals in soil and plant of experiment after digestion of soils and plants by the method of atomic absorption. We measured available (Mehlich 1) metals in soil of ex-situ experiment before experiment for every treatment and after 60 days

Table1. Chemical composition of Prrenjas clay, which is used as an adsorbent in this work

Clay	SiO2%	Al2O3%	Fe2O3%	CaO%	MgO%	SO3%	rSiO2/MxOy
untreated	47.5	13.4	14.97	2.7	9.58	0.11	1.239

Ex situ Experiment with hyperaccumulator plant (*Odontarrhena Calchidica)*

PRRENJAS CLAY

RESULTS AND DISCUSSION

Ex situ experiment help us to know capacity of Clay to immobilize metals.,

Table 2. Results of chemical analysis of of agricultural soil samples from Prrenjas

Parameters	Total	Available
	mg/kg	
Cu	16.5	0.70
Fe	97920	16.37
Mg	23934	1030
Mn	1515.6	6.03
Co	127	5.28
Ni	1458.7	10.6
Ca	3578.7	644.6

Agricultural soil of Prrenjas is a typical serpentine soil. The level Mg. Fe. Ni Mn,Co are very high. The level of Ni available is 10.6mg/kg

Table 3. Results obtained for treatments of Prrenjasi soil with clay and Prrenjasi soil with clay and plants

AS= Agricultural soil

Treatments	**C0(mg/kg)**	**Ce(mg/kg)**	**q=C0-Ce(mg/kg)**	**%Ni adsorber**	**%Ni contributed by plants**
AS +C0	**10.6**				
As+Clay 10.7 g kg^{-1}		7.68	2.92	27.5	
As+Clay 21.4 g kg^{-1}		7.36	3.24	30.5	
As+Clay 32 g kg^{-1}		3.78	6.82	64.3	
As+Clay 10.7 g kg^{-1} +Plant		6.12	4.48	42.2	14.7
As+Clay 21.4 g kg^{-1} +Plant		4.48	6.12	57.7	27.2
As+Clay 32 g kg^{-1} +Plant		3.64	6.92	65.2	0.9

After the 60 th day of experiment a high % nickel was absorbed by clay and a amount of Ni was extracted by plants.

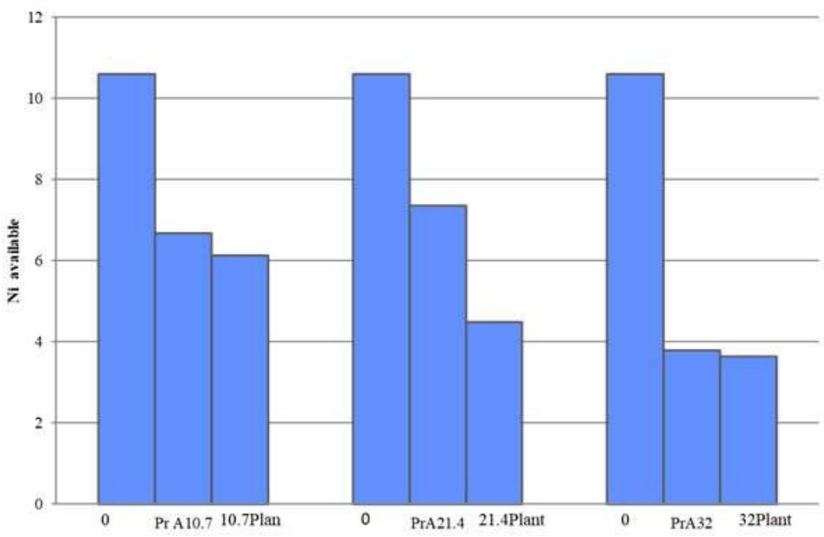

Figure 1. Ni availability in soil with different treatment

CONCLUSIONS

Result told us that clays of Prrenjas are the appropriate clay mineral for the removal of Ni. Based on the first results, the application of clays to reduce the mobility and availability of nickel is promising.

ABSTRACT

Himara coast represents the northeastern segment of the Ionian Sea, which is situated in the southwestern part of Albania. Data from macrozoobenthic community of this area are scarce. Although studies on infralittoral and circalittoral have been more frequent, research and surveys on the shallow rocky coast of Himara have been very limited, and the few existing data on shallow macrozoobenthos have been mainly sporadic. Data represented in this paper were collected in October 2023 from 4 sampling sites along the Himara coast, in shallow water, in supralittoral and midlittoral. These are part of an ongoing long-term study that aims to know and analyze the macrozoobenthic community of this area, including species composition, abundance and quantitative characteristics of benthic invertebrate populations, their relations to algal cover and algae species, as well as other factors influencing characteristics of their populations, in a comparative way between sampling sites and sampling seasons. Preliminary data represented in this paper have shown the presence of about 130 species of benthic macroinvertebrates. At the level of large taxonomic groups, they include cnidarians, polychaetes, mollusks, crustaceans, sipunculids and echinoderms, where the predominant groups in species number and abundance were Gastropoda, Bivalvia, Amphipoda and Decapoda. Algal cover, morphological diversity of substrata, degree of coastal exposure, and environmental impact, mainly from tourism, seem to be the main factors that affect the macrozoobenthic community of this study area

Key words: Benthic invertebrates, Ionian Sea, algal cover, marine and coastal conservation.

INTRODUCTION

The rocky coast of Himara is part of the Ionian Sea and is located in the southwestern part of Albania. Benthic communities on the coast of Himara are little studied, mainly focused on macroinvertebrates, macroalgae and meadows of the seagrass Posidonia oceanica (Beqiraj et al., 2008; Beqiraj & Kashta, 2013; Beqiraj, 2014; Beqiraj & Ballesteros, 2018; Fraschetti et al., 2011; Kashta et al., 2005; Kashta et al., 2007; Kashta & Beqiraj, 2009; Pititto etal., 2009; Ruci et al., 2023.Among the four sampling sites of this study, Porto Palermo Bay has undergone the most extensive research, primarily concerning its proposed designation as a Marine Protected Area (Beqiraj et al. 2008, Beqiraj & Kashta 2013, Beqiraj 2014), proclaimed in July 2022. The other three sites, Guma, Llaman, and Qeparo, have been sparsely studied, and data availableon their benthic communities are very limited. Research on the benthic community in Himara area is crucial for understanding and assessing its biodiversity and natural values of the whole marine and coastal ecosystem in that area, its cultural and socio-economic significance, as well as for environmental conservation and management of the recently proclaimed MPA.Further, the natural resources are vital for sustainable development and directly affect the local economy of this area.

MATERIAL AND METHODS

Benthic invertebrates were collected in October 2023 from four sampling sites, Qeparo, Porto Palermo Bay, Llamani Bay, and Guma, along the Himara coast, in shallow water (Fig. 1 & Fig. 2).

Sampling was carried out according to standard methods for benthic sampling in hard bottoms (according to Bianchi et al.2003, Keklikoglou et al. 2018, Mikac et al. 2020, Salomidi 2003, Zenetos et al. 2000). Samples were taken randomly, within a standard frame of 50 cm x 50 cm, divided in 25 small squares of 10 cm x 10 cm. They were stored in formaldehyde 4% and transported to the laboratory.Taxonomic identification of benthic invertebrates was referred to Cossignani 1992; Cossignani& Ardovini 2011;Clemam checklist; D'Angello &Gargiullo 1991; Gianuzzi-Savelli, 1999, 2001, 2003; Riedl 1991; Rodríguez-Prieto et al 2015. The systematic position of invertebrates was referred to WoRMS (World Register of Marine Species).

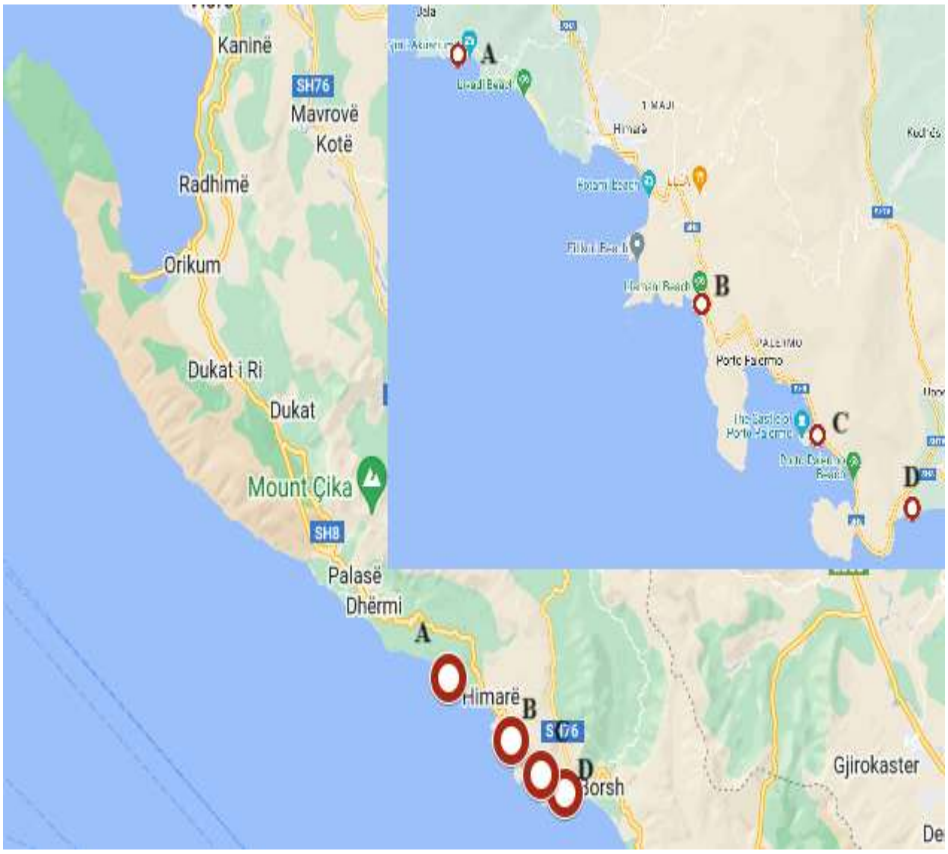

Figure 1. Map of sampling sites: a) Guma; b) Llaman;c) Porto Palermo;d) Qeparo

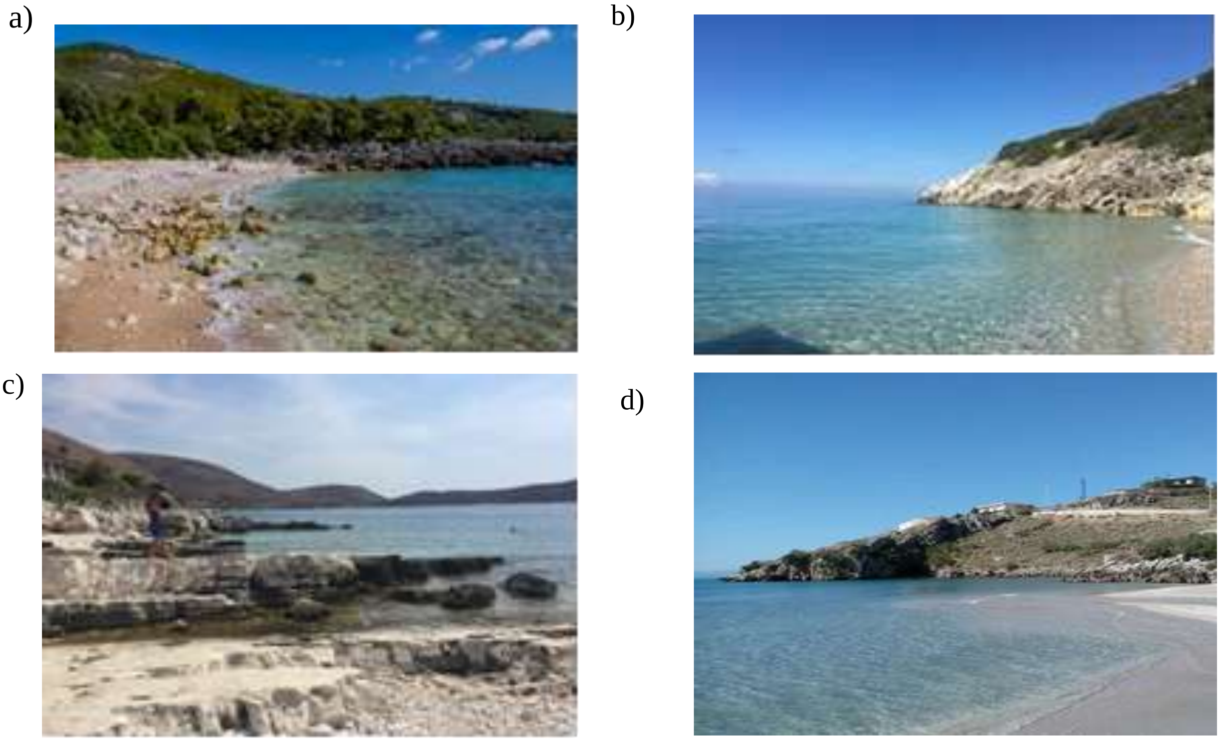

Figure 2. Photos from the sampling sites: a) Guma; b) Llaman;c) Porto Palermo; d) Qeparo

For each taxonomic group it was calculated the number of taxa at each sampling site, the abundance,and the frequency. The frequency has been calculated after the formula, $F = \frac{n}{N} x100$ (Peja 1995), which represents the proportion of the number of individuals of a species (n) in a sample to the total number of individuals (N) in that sample.

RESULTS AND DISCUSSION

130 species of benthic invertebrates were recorded in the study area. Molluscs (Gastropoda and Bivalvia) and crustaceans (Amphipoda and Decapoda) represented the highest number of taxa in the four sampling sites.

As shown in Table 1 and Figure 3, the highest number of taxa for mollusks was recorded in the Guma sampling site with 50. Crustaceans showed a high number of taxa in Qeparo 24, Porto Palermo 40, Llaman 32 and a lower number in Guma, with 18 taxa.

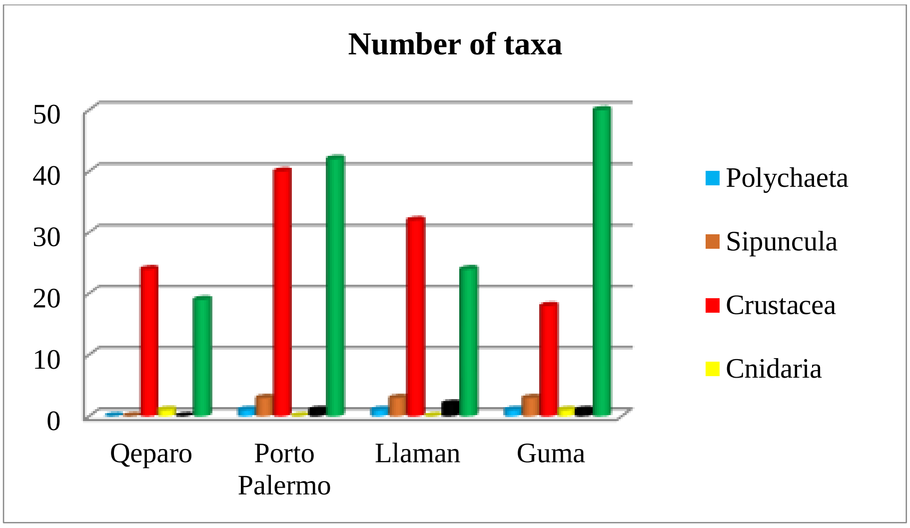

Figure 3. Number of taxa in each sampling site

The highest abundance was recorded for crustaceans (Figure 4). Molluscs were another taxonomic group that showed very large abundances in all sampling sites. Other taxonomic groups, such as Polychaeta, Sipuncula, Cnidaria and Echinodermata showed very low abundance in all sampling sites.

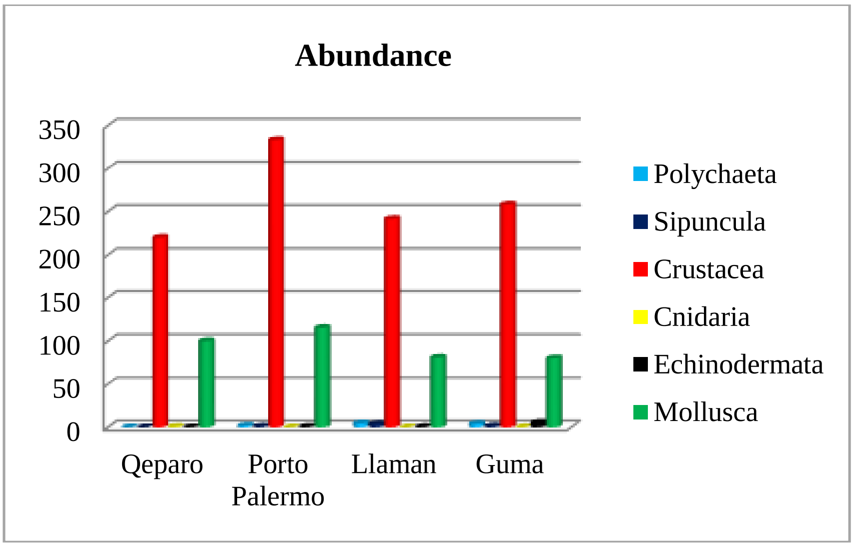

Figure 4. Abundance of benthic macroinvertebrates in each sampling site

As seen in figure 5, crustaceans have represented the highest frequency, which is almost the same in all sampling sites. For Molluscs the highest frequency was recorded in Qeparo, and it was almost the same in the other three sampling sites. It is also noted a high frequency ofCnidarians in Qeparo, compared to Porto Palermo, Llaman and Guma. The frequency of the other taxonomic groups was very low in the four sampling sites.

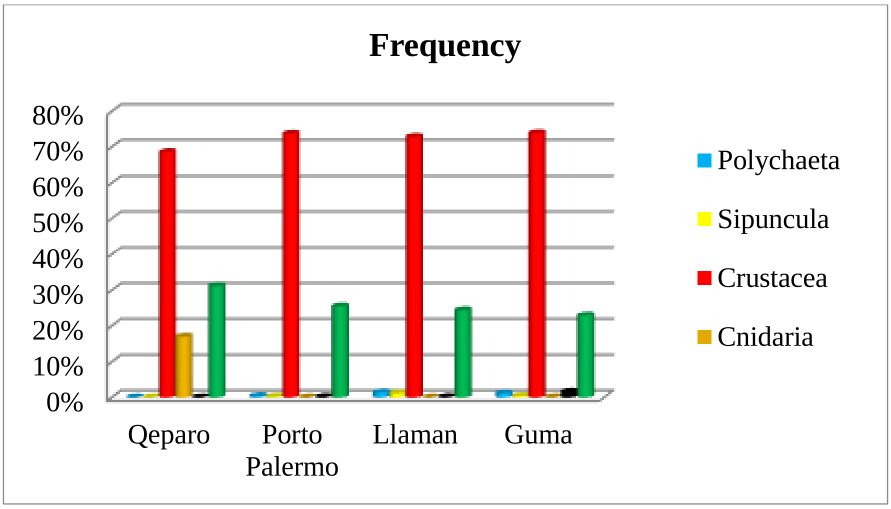

Figure 5.Frequency of benthic macroinvertebrates in each sampling site

Diversity of microhabitats, exposure degree of the coastline, macroalgal cover, and environmental impacts mainly from tourism activities, seem to be the main factors that influence the species diversity and abundance of benthic invertebrates in the Himara area.

Continuation of this study, and its integration with the assessment of water physicalchemical parameters, will give a more comprehensive understanding of the benthic community and its environmental impacts in this study area.

ABSTRACT

A fertilizer is a material derived from natural or synthetic origin that is mostly applied to soil or to plant tissues to supply plant nutrients. With increasing concerns about environmental pollution and human health, trust in synthetic fertilizers has decreased and the tendency to use natural fertilizers has increased. One of the organic fertilizers is vermicompost. This fertilizer is obtained due to worms processing in the soil, or the nutrients presented to them, and has been included in many scientific studies. Most of these studies are on the Solanaceae family members, which are considered as vegetables and medicinal-aromatic-ornamental plants. While most of these studies were conducted on plant productivity, some were carried out to determine whether it protects the plant against biotic or abiotic problems. The studies on plant productivity measure and evaluate factors such as yield, plant height, flowering, fruit set, root, stem, tuber, and leaf development. In terms of plant health, besides biotic factors, the effects of edaphic factors such as salinity and nutrient deficiency, environmental factors such as drought, undesirable cold or hot climate conditions, and their interaction with vermicompost fertilizers have been investigated. In this review study, the data on abiotic stress interactions with vermicompost usage regarding the forms, times and results of applications on Solanaceae family cultivars such as tomato, pepper, eggplant, potato, and petunia were focused and compiled.

Keywords: Abiotic Stress, Plant Protection, Vermicompost, Organic Fertilizer, Solanaceae, Vegetable, Ornamental Plants

INTRODUCTION

Solanaceae family contains approximately 100 genera and 2500 species, and the species mostly occur on all temperate and tropical continents (D’Arcy, 1991; Olmstead & Bohs, 2007; Olmstead et al., 2008). The family includes wild and most important agricultural cultivated species, which have economic importance in human nutrition, and medicinal-aromatic-ornamental plant sectors. In the cultivation steps, fertilization is one of the most common tasks a producer does. Farmers mostly use this fertilization process to improve yield. However, as a result of the studies and observations, it has been observed and demonstrated that effective fertilization overcomes abiotic problems such as drought, soil salinity, and adverse weather conditions in addition to macro and microorganism-related biotic problems. For this reason, although many types of fertilizers are used and have the potential to be used, organic fertilizers have begun to come to the fore in terms of environmental pollution and human health. One of the organic fertilizers that has been produced in businesses that have made significant investments in recent years is vermicompost. This fertilizer, which is obtained as a result of worms processing the soil or the nutrients given to them, has been included in many scientific studies. Some of the studies were on the growth effect on fruits (Pawar et al., 2020; Geiklooi & Shirmohammadi, 2013), vegetables (Espinosa-Palomeque et al., 2020; Ali & Kashem, 2018), field crops (Prajapati et al., 2018; Ding et al., 2021) and on ornamental plants (Esringü et al., 2022; Kumar et al., 2022). Some studies about growth and yield have shown that vermicompost and inorganic fertilizers are successful when applied together (Ali & Kashem, 2018; Prajapati et al., 2018). In some studies, liquid vermicompost was applied to obtain an effect on growth and yield (Elumalai et al., 2013; Awadhpersad et al., 2021).

In this study, the studies reviewed that have been carried out on dealing with adverse growing conditions that are problems in plants by using vermicompost as abiotic factors. For this aim the data from the studies obtained regarding the forms, times and results of vermicompost applications on cultivated Solanaceae family plants such as tomato, pepper, eggplant, potato, and ornamental plants such as petunia were focused and compiled.

THE STUDIES ON ABIOTIC STRESS-VERMICOMPOST INTERACTION IN SOLANACEAE

Salinity-Vermicompost

Undoubtedly, salinity has become a major problem in agricultural lands. The physiological stressor can reduce water availability (Cavusoglu, 2023) and can cause the absorption of toxic ions while causing a decrease of absorption of essential elements (Acosta-Motos et al., 2017).

Tomato (*Solanum lycopersicum* L.) is one of the most known and consumed species of vegetables worldwide in Solanaceae which is a glycophytic species and is affected by salt stress in different degrees of salt concentration. In a study on the preventive effect of vermicompost against salt stress in tomatoes, vermicompost leachate was applied to a cultivar of fifteen-day-old tomato seedlings in aerated hydroponic culture in a growth chamber under 16 hours photoperiod. In this study, which aimed to show the effect of vermicompost applications before and concomitantly of 150 mM NaCl stress with nutrient solution, the application of before salt stress was found more effective than the second application time. According to the data, in the tomato, vermicompost leachate application abolished the harmful effect of salt stress on growth via decreasing Na^+ accumulation partly (Benazzouk et al., 2018).

Potato is one of the top ten major crops around the world. The plant is grown nearly in all countries and some of the fields face abiotic problems such as organic matter deficiency, drought, and salinity. A study was conducted with vermicompost and vermiwash to obtain their effect on potato growth under salinity stress. For this purpose, vermicompost and vermiwash were applied at three doses each and salinity at 15, 20, and 25 mM NaCl levels. The study showed that vermicompost and vermiwash have ameliorative effects on the growth of tuber, plant habitus, and tuber characteristics under saline conditions (Pérez-Gómez et al., 2017).

In a study about seedling substrates and salt stress, three different substrates, including 100% vermicompost and %50 vermicompost with peat, and only peat were used in the first step of obtaining pepper (*Capsicum annuum* L.) seedlings. Salt stress was applied to the seedling at the second step which was at the transplanting site. Briefly, the study showed that vermicompost and its mixture with peat are the best media in the nursery period. In the second step, transplanted seedlings from the two substrates showed better results under saline conditions than other used peat substrate (Kaciu et al., 2011).

Drought-Vermicompost

Drought is another environmental abiotic stress factor that threatens crop production at unexpected times and in unexpected ways. Drought causes significant yield losses worldwide in areas where irrigation water is limited.

Ebrahimi et al. (2021) used vermicompost in two levels (0 and 1500 g/m^2), pistachio and date palm biochar (0, 500 g/m^2 each) alone or in combination to find out the effect of them on irrigation water deficiency at three levels (50, 75 and 100% of plant water requirement) in eggplant (*Solanum melongena*) under the field condition. Four months after planting; chlorophyll a and b, antioxidant capacity, malondialdehyde and antioxidant enzyme activity, plant nutrients in the plant tissue, yield components, and water use efficiency were determined. The results showed that vermicompost and biochar have positive effects on eggplant growth and yield. Their usage increased N, P, K, Fe, and Mn in plant leaves. Their usage at 50% plant water requirement increased water use efficiency. The results are important especially in arid and semi-arid conditions.

Petunia is a Solanaceous, spring and summer plant that sometimes has to be planted under soil conditions such as rainless, infertent and limited-irrigation in gardens. A study was conducted with vermicompost and two other organic fertilizers to find out the effect of them on the petunia under drought conditions. The used drought rates were 100%, 50%, 25% field capacity of water. The results of the study showed that the effects of the vermicompost treatments on some parameters that are important for petunia growth can be improved under different irrigation regimes via improving water holding capacity (Goldani & Kamali, 2016).

Plant Nutrient Deficiency-Vermicompost

Plant nutrition is a key component in agricultural plant production. Nutrient deficiency effects lots of physiological steps on the road to yield. For this reason, organic or inorganic fertilization is done.

In a study conducted on the effect of vermicompost application in increasing doses to pepper (*Capsicum annuum* L.) and eggplant (*Solanum melongena* L.) P and K contents, vermicompost quantities (0, 3, 5, and 7%) were applied to the soil under the controlled laboratory condition at viol. The P and K levels of the 40-day-old test plant were analyzed after drying at 65°C in the oven. The results showed that both elements increased in both plant species with increasing vermicompost levels (Bellitürk et al., 2017).

Petunia spp. is a pot or garden flower, included in the Solanaceae family. Petunia hybrids are marketed and grown fondly around the world. The ornamental plants sometimes have to be planted on infertile soils in the garden or pots. A study was carried out with vermicompost, inorganic NPK fertilizer, *Azospirillum* sp., and phosphate solubilizing bacterium added to soil with low nutrient content. The vermicompost and others that are used in this study were applied singly or in combination. As a result of the study, when the infertile soil (control) group and other applications were evaluated together, it was seen that the highest growth values were reached when inorganic and two bio-fertilizers were added to vermicompost (Moghadam & Shoor, 2013).

It is a known fact that fertilization is required in most cases when growing tomatoes in the fields because of poor soil conditions. In a study, vermicompost was applied to the soil at rates of 0/1, 1/1, ½, 1/3, ¼ and 1/5 (v/v) under a greenhouse condition. A hundred days after planting, measurement showed that plant height, marketable tomato yield and titratable acidity were found as the best at higher vermicompost rates. The results indicate that soils need enrichment and vermicompost may be a good option for this (Gutiérrez-Miceli et al., 2007).

Temperature-Vermicompost

Unexpected high, low, and unwanted changes in temperature affect the plant's health and yield. As the plant moves away from the optimum temperature, it reduces its physiological function and yield. Studies, besides Solanaceae, are showing that these temperature-related negative reactions can be reduced with vermicompost.

Because it originated from tropical and mild-temperate regions, most Solanaceous plants sensitive to too cold and hot. In a study (Chinsamy et al., 2014), tomato seedlings treated with vermicompost leachate (1:10 v/v) under different temperatures (10, 15, 20, 25, and 30°C) at perlite substrate enriched with Hoagland's solution were used. It has been revealed that vermicompost has positive contributions to leaf number, stem thickness, plant leaf area, chlorophyll b, proline, and total sugar properties at both the lowest (10°C) and the highest (30°C) temperature. The study clearly emphasized that vermicompost leachate has growth-enhancing effects on tomato seedlings under non-optimal temperatures.

Since studies on vermicompost focus on other stress factors such as nutrient deficiency and salinity, few studies could be revealed on temperature differences in solanaceous plants.

CONCLUSION

The fertilizers applied to the rooting media or upper part of the plant not only have plant nutrition properties but also have the function of alleviating the effects of abiotic factors that begin to disturb the plant by moving away from the optimum. When evaluated from this perspective, vermicompost, whether in solid or liquid form, appears to be an environmentally friendly, relatively cheaper, easy-to-use, and suitable option for organic agriculture in Solanaceae plants. The latest studies showed that vermicompost was effective in eliminating abiotic stress factors that may occur in Solanaceae plants. But many other stress factors in plants that may occur in different places and at different times still need to be studied.

ABSTRACT

In this survey conducted by Trakya University İpsala Vocational School Laboratory Technology Program students with 199 university students, 7 survey questions were asked and the participants were asked about their corn consumption preferences. Among the corn consumption types presented, the participants preferred popcorn the most with a rate of 35.2%, followed by corn chips with 22.6%. 42.7% of the participants stated that they consume corn monthly, while 35.2% stated that they consume it weekly. In the question asked about the value of corn in terms of human nutrition, 50.3% stated that they did not have any information, and the closest rate to this was 39.7%, which indicated that it was a healthy food as far as they followed from the media. When purchasing any corn product, 40.2% of the participants stated that they cared about the information about the production method or processing of the product, and the closest to this was their brand preference with 25.1%. 72.4% of the participants wanted the corn product they consumed to contain no additives. In the question about the future situation of corn, 49.2% of the participants stated that they preferred that the interest in corn would increase, while 19.1% of the participants thought that production would decrease due to the risk of drought. Again, in the question about the consumption rate of corn oil in the future, 43.6% of the participants stated that consumption would increase if its price was lower than sunflower oil.

Keywords: Corn, Consumption Preference, University Students

INTRODUCTION

The corn plant is still one of the six grains that feed the world's population. Corn, which has the largest cultivation area after wheat and barley among grains in our country, is successfully produced as the main product and second product. After the 1980s, significant increases were recorded in corn production in Turkey. The reason for the increase in corn yield is that the state encourages corn production, producers implement modern corn production techniques, expand the use of hybrid seeds, shift corn production to irrigated areas and ensure the use of fertilizers at certain levels. Although the production reached 5.95 million tons in 2014 in our country, the ratio of production to consumption was 90%. 78% of the corn produced in our country is used in the feed industry and 15% is used in the starch sector. In recent years, corn cultivation for silage purposes has become quite widespread, especially as a second crop

Corn has a very important place in the world agricultural products market in terms of both production and demand and foreign trade. In addition to being largely used as animal feed, its use for human nutrition further increases its importance. In Turkey, corn is the product that is very common in production and has the highest production share after wheat and barley in the grain group (Akkurt and Demirbaş, 2021)

The corn plant is divided into seven varieties. The most important varieties of corn, dent and hard corn, are used intensively in human and animal nutrition. In addition, special corn types such as popcorn (Zea mays L. everta), sweet corn (Zea mays L. saccharata sturt.) and waxy corn (Zea mays ceratina) can be used as a snack by popping, boiled or canned. Popcorn, a traditional snack food in our country, has been grown on approximately 9000-10,000 hectares of land in recent years and is especially enjoyed by children. Sweet corn is consumed boiled and canned, especially in coastal regions, especially in the Mediterranean and Aegean regions. The demand for waxy corn is also increasing day by day throughout the country.

The main areas of use of corn are human food and industrial raw material. Corn stalks and leaves are used as animal feed, especially in the form of silage, and the stalks and leaves are also used in the industry for paper production and small-scale wicker crafts. In addition to its main areas of use, corn is also consumed as a snack in special variety groups. Corn's special areas of use include the oil and sweetener sector and biofuel-bioethanol production.

Popcorn is used specifically as a snack, its difference from other snack foods is that it contains low calories and fat, and high carbohydrates (Hansen, 2012). Özkan (2007) stated that one of the reasons popcorn is preferred in nutrition is the vitamins and minerals it contains.
It has been reported that it is a good diet product due to its ability to keep you full and absorb stomach acid (Ülger, 1998). When the energy value of popcorn is examined, it is reported to be equivalent to two eggs on average. Nguyen et al. (2012) reported in a study they conducted that popcorn provides a feeling of satiety due to its low calorie value and the energy it provides from whole grain corn, and that it can be an important choice in body weight control thanks to this feature.

Popcorn has a special place among other corn variety groups with its popping feature and its ability to be used as a snack by turning it into popcorn and its rich nutritional content. The demand for popcorn is increasing in our country, especially because it is consumed with pleasure by children and preferred as a snack by moviegoers. Sweet corn is among the special corn types and its production and consumption are increasing rapidly due to its nutritional content, flavor and different areas of use. Purple waxy corn, whose consumption trend is rapidly increasing for modern consumers in the world due to its health benefits, is also increasing rapidly in our country (Öztürk et al., 2019).

MATERIALS AND METHODS

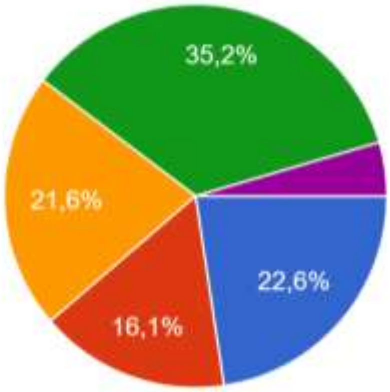
In this study conducted by Trakya University İpsala Vocational School Laboratory Technology program students with students from different universities in Turkey, random sampling method was used and 7 survey questions were directed to 199 students studying at different faculties and vocational schools and the participants were asked questions about their corn consumption preferences. In this study conducted with face-to-face survey method, the students were asked about their corn consumption preferences, corn consumption frequency, whether they have knowledge in terms of human nutrition, their perspective on corn additives and whether they have knowledge about corn production techniques.

.

RESULTS AND DISCUSSION

In this research conducted by Trakya University İpsala Vocational School Laboratory Technology program students using a face-to-face survey method, the first question asked to the students was corn consumption preferences. The participants' answers are shown in Fig.1 below.

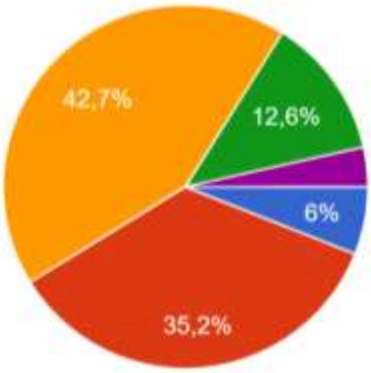
Fig.1. Corn consumption preferences of students from different universities in Turkey



According to the table in Figure 1, popcorn ranks first in students' corn consumption preferences with a rate of 35.2%. This is followed by corn chips with a close gap of 22.6% and corn cobs with a rate of 21.6%. Corn flakes were also preferred by 16.1%. The rest of the students said that they did not consume corn. In general, it was observed that there was no significant difference between the students' corn consumption preferences due to the closeness of the rates.

The second question asked to the students was the frequency of corn consumption. The participants' answers are shown in Figure 2.

Fig. 2. Frequency of corn consumption of students from different universities in Turkey



According to Fig.2, the frequency of students' corn consumption was determined as 42.7% once a month. This was followed by 35.2% once a week, 12.6% annual consumption and 6% daily consumption.

The answers given by the students to the third question, which asked about the value of corn in terms of human nutrition, are shown in Fig.3.

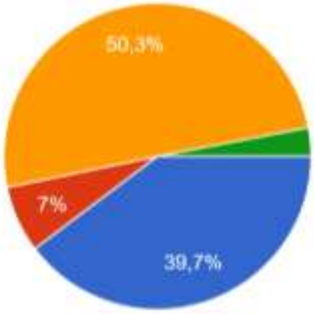


Fig.3. Knowing the value of corn in human nutrition

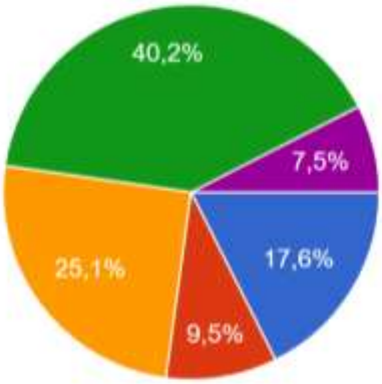
According to Fig.3, 50.3% of the students stated that they had no information about the value of corn in human nutrition. 39.7% of the students said that they believed that corn had an important place in human nutrition, while 7% said that they thought it was likely to be harmful. The answers of the students to the question asking about the factors they pay attention to when buying any corn product are shown in Fig.4.

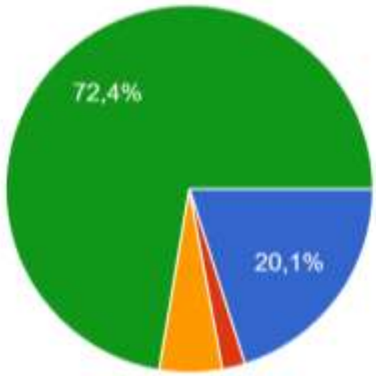
Fig.4. Factors they pay attention to when buying corn products



Students stated that they pay attention to whether the corn variety they desire is GMO at a rate of 40.2%, make a brand preference at a rate of 25.1%, care about nutritional value at 17.6%, and calorie content at 9.5%.

The 5th question asked to students attempted to learn which additives in corn products would be acceptable to them. The students' answers to this question are shown in Fig. 5.

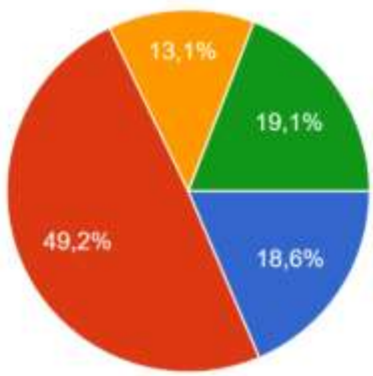
Fig.5. Which additives in corn products are acceptable?



When looking at Fig.5, the vast majority of the students participating in the survey, 72.4%, did not want any additives and wanted to consume the product completely natural. 20.12% of the students thought that preservatives would be acceptable in corn products. Colorants and sweeteners, which were among the other options asked, were the substances preferred by the students in very small proportions.

The response rates given by the students to the 6th question, which asked about the future role of corn, are shown in Fig.6.

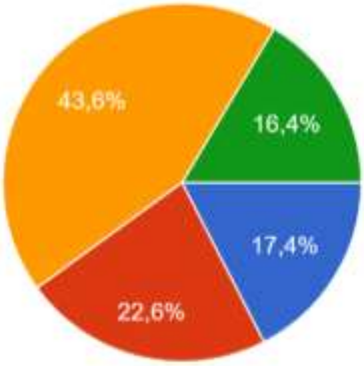
Fig.6. The future role of corn



49.2% of the students who participated in the survey thought that corn oil would be consumed much more in the future, 19.1% thought that corn production would decrease significantly, 18.6% thought that corn would grow only in the oil industry and 13.1% thought that it would be used only for silage.

The situation of these two vegetable oil sources in the future was asked in Question 7, as corn oil is considered to be a competitor to sunflower oil by the students who prepared the survey. The answers of the students who participated in the survey are given in Fig.7.

Fig.7. Comparison of the future situations of sunflower oil and corn oil



43.6% of the students stated that corn oil would be preferred more than sunflower oil if its price was lower, 22.6% thought that sunflower oil would always be preferred more, 17.4% believed that corn oil would be preferred more, and 16.4% stated that sunflower would always be preferred more than other oil types.

CONCLUSIONS

In this study conducted by students of Trakya University İpsala Vocational School Laboratory Technology program with students from different universities in Turkey, it was tried to understand the students' opinions about corn consumption. It was stated that although the students did not have much knowledge about corn cultivation, they were informed about GMO products and generally followed them on social media. Students who are aware of the importance of consuming healthy products stated that they prefer to consume popcorn especially when they socialize, even if occasionally.

Although it is preferred for consumption as a snack, the students thought that corn oil would be preferred if it is more economical than sunflower oil.

ABSTRACT

Konya Domestic Wastewater Treatment Plant produces approximately 150 tons/day of stabilized domestic treatment sludge. Disposal of the existing treatment sludge is a problem. In this study, the effect of sewage sludge in terms of soil organic matter, pH, salinity, aggregate formation, erosion prevention and soil improvement on eroded, weak and degraded pasture soils in Karapınar was investigated. For this purpose, sewage sludge containing 80% dry matter was applied to the plots at 0 (Control), 1, 2, 4 and 8 tons/da (DM) by two different methods as raking into the 0-5 cm layer of the soil and sprinkling on the soil surface. Then, soil samples were taken from the treatment plots for 3 years. According to the data obtained at the end of the experiment, it was determined that the treatments increased the soil organic matter especially in the 0-5 cm soil depth and this increase became more effective as time passed. The effect of the treatments on soil salinity partially increased over time. The average value of 0.23 mmhos/cm before the application in the first year was 0.34 mmhos/cm at the end of the fourth year. The average values of water saturation, stability index and mechanical stability index showed significant increases compared to the first sampling year. It was observed that sewage sludge applications increased soil organic matter, increased structural stability, may be effective in preventing sediment transport and consequently increased erosion resistance and resistance of soils to erosion. In the study, it was concluded that 1 ton/da can be applied in eroded weak pasture soils with a rainfall of at least 250 mm, in accordance with the regulation on the use of sewage sludge in soil, once every three years for the ecological conditions in this region, by mixing it into the soil to a depth of 0-5 cm.

Keywords: Erosion, Sewage Sludge (Biosolids), Aggregate, Karapinar, Degraded Pasture Lands.

INTRODUCTION

Due to the growth of cities and the increase in population, there is a significant increase in the amount of sewage sludge(SS) generated from wastewater treatment plants. Among the disposal methods of SS, the most cost-effective method is land disposal. However, land disposal of SS can cause serious problems due to salinity and heavy metals in the sludge. Although the content of SS (biosolids) varies from region to region and depending on the type of treatment, it can be introduced into the soil in a controlled manner because it is generally rich in organic matter, nitrogen and phosphorus (Hakerler, 1980). Biosolids are used in severely damaged marginal areas to restore the soil to a productive state or to establish vegetation to prevent soil erosion. Soil losses due to erosion decrease as the amount of biosolids applied increases. This effect is explained by the positive effect of biosolids on soil aggregation and infiltration as well as water retention and surface roughness (Bilgin et al., 2002). Sewage sludge added to loosely textured sandy soils increases the water holding capacity of these soils (Ayvaz, 2000), allows nutrient exchange and retention, increases the number and activity of soil microorganisms (EPA, 1994). In areas that are severely affected by erosion and where soil depth is low, biosolids application prevents erosion with its physical effect and then increases the emergence and development of seeds in the environment and can rapidly provide the formation of natural vegetation (İşçi, 2006).

The physical, chemical properties and biological productivity of sandy loam textured soils exposed to wind erosion in semi-arid areas are low. What should be done to improve such areas is to increase the organic matter content in the soil. Due to the organic matter content of SS, if it is used in areas exposed to erosion in arid areas, it will have the effect of improving the population of pasture plants as well as improving the soil. Therefore, due to its soil covering and erosion prevention effect, it was aimed to carry out this study and to determine the optimum application dose of SS.

MATERIALS AND METHODS

Material

Research location: The research is located in Karapınar district of Konya province in Turkey, which has 465.913 hectares of land dune with mild to very severe wind erosion problems. In Karapınar Desertification and Erosion Research Center, the study was conducted in the “No. 1 eroded, weak, fragile, degraded Yenice Pasture area” shown in Figure 1. This area constitutes 22.1% of the wind erosion area at the country level.

Figure 1. Location image of the trial site

The climate of the region is described as semi-arid continental, with dry and hot summers and cold and rainy winters. The average precipitation is 275 mm, 40% of which falls in the winter months and the average precipitation from July to September is 15 mm (Şimşekli, 2012).

In the project area, the high temperature in the summer months and the low humidity in the soil profile throughout the year reduce the amount of organic matter in the soil. As a result, it has a negative impact on the physical and chemical quality of the soils(Bot and Benites, 2005). These reductions in vegetation due to the temperature difference cause a decrease in the organic matter cycle in the soil. This plays an effective role in increasing desertification and wind erosion. The soils in Karapınar are generally of alluvial origin formed on old lake deposits. The soil series in Karapınar are presented in Figure 2. In our study, the soils of the area where SS was applied were of sandy loam texture.

Figure 2. Soil series in Karapinar (Groneman, 1968; Akça, 2001)

Characteristics of the Sewage Sludge Used in the Study: Sewage sludge (biosolids) from Konya domestic wastewater treatment plant is dewatered after digestion in airless environment. In 2011, a total of 47.728 tons of sludge (24.23% dry matter(DM)) was dewatered and removed from the system. Samples taken from these dewatered stabilized sewage sludges are regularly analyzed every month at TÜBİTAK-MAM ÇE Research Laboratory. The SS used in the project was also analyzed in the same laboratory and the analysis results were found to be in compliance with the Regulation on the Use of Treatment Sludge in Soil dated 03.08.2010 (Table 1). Bio-sludge sample number 2, whose analysis results are shown in Table 1, was selected to be used in the study.

Preparation and application of sewage sludge (biosolids): In the study, stabilized SS from the sludge dewatering unit of Konya Domestic Wastewater Treatment Plant (on 15.08.2014) was spread as a thin layer in the surrounded U-shaped concrete lagoons. The stabilized domestic SS pile, which was in compliance with the directive as a result of the analysis procedures, was turned upside down with a mixer bucket machine and crushed with a roller in certain periods and dried in an open pile in the sun for 2 months. In this way by drying method, the dry matter content of the sludge was increased from 25% DM to 80% DM by drying method. Afterwards, the SS was grinded/shredded with a rotatiller machine and sieved with a 10 mm sieve and ready-to-use biosolids piles were formed. In November 2014, the moisture content of the SS was carried out at 100% dry matter (DM) as specified in the trial plan.

The doses of SS were applied as 0 (Control), 1, 2, 4 and 8 tons/da (DM) in two treatments (mixing with rake into the 0-5 cm layer of the soil (D main subject) and spreading on the soil surface (S main subject)). The experiment was carried out in 2 main subjects, 4 replications, 5 doses of SS in a total of 40 plots. Trial plot dimensions were 8 m*10 m = 80 m^2 and each plot was side by side with a gap of 1.5 m and the gap between the blocks was set as 2.5 m. The treatments were carried out according to the randomized block split-plot experimental design.

Figure 3. Experimental design

D: Mixing sewage sludge (biosolids) into the soil at a depth of 0-5 cm with a rake
S: The process of spreading sewage sludge (biosolids) on the soil surface

Sewage sludge was applied at a single application in November 2014. Subsequently, the effects of SS on soil and plants were observed for 3 years after application (in June 2015, 2016 and 2017). Therefore, biosolids were not applied every year.

Method

In the study, soil samples were taken and analyzed before the application of SS (biosolid) in October 2014 and after the application in June 2015, 2016, and 2017. Samples were taken from 0-5 cm, 5-10 cm, 10-20 cm from the trial plots and then organic matter, electrical conductivity, pH and calcium carbonate analyzes were performed on the soil samples taken (Tüzüner, 1990; Kacar, 1972). Dry aggregate percentages of erosion parameters were analyzed with the help of Rotary sieve (Chepil, 1962). As it is known, Mechanical Stability Percentage, which shows the resistance of soils against wind erosion, is also an expression of the resistance of aggregates against friction. Mechanical stability values lower than 50% indicate that these soils are not resistant to erosion. As the mechanical stability increases in terms of wind erosion, the resistance to erosion increases in that soil. As the amount of organic matter in the soil decreases, mechanical stability decreases and the ability of the soil to be eroded will increase (Okur et al 2008). Using Chepil's "Rotar sieve", the mechanical stability percentages and stability indices of the soils were calculated according to the following formula.

Mechanical Stability, % = (W_1 / W) x 100

Where; W = Amount of particles larger than 0.840 mm obtained at the end of the first sieving, %

W_1 = Amount of particles larger than 0.840 mm obtained at the end of the second sieving, %

The Stability Index, which shows the erodibility (resistance to erosion) of the soils, in terms of the erosion status of the soils, those with a stability index less than 1.5 are classified as weak and those with a stability index greater than 1.5 are classified as resistant (Çelebi 1981). Statistical analyses of the obtained data were performed using Minitab 18 package program.

RESULTS AND DISCUSSION

Organic matter: When the organic matter contents of the soil samples taken for 3 years SS applications were examined, compared to the organic matter content before the first application (2014), organic matter content increased with increasing SS application doses in both spreading and mixing treatments ($p<0.01$) (Table 2, Figure 4, 5). The highest increase values are in the 8 ton SS/da application. When the difference between the years was examined, the highest increase in organic matter was observed in the second year of the SS application (2016). While there was no difference in the organic matter content of different soil depths with the applications, significant differences were observed between SS application doses and soil depth ($P<0.01$). While the amount of organic matter increased in the first and second years of the open application, it was observed that there was a slight decrease in the third year. It is thought that this situation is due to the decomposition of organic matter in the soil over time. While the organic matter content was 0.56% on average before the SS application, it increased to 1.17% on average three years after the application.

Table 2. Effect of different doses of sewage sludge applications on the average values of soil organic matter (%) according to years ($p <0.01$)

Depth(cm)	Organic Matter(%)			
	2014	2015	2016	2017
0-5	0.61 a	1.54 a	2.12 a	2.22 a
5-10	0.49 b	0.63 b	0.84 b	0.64 b
10-20	0.58 ab	0.65 b	0.88 b	0.66 b

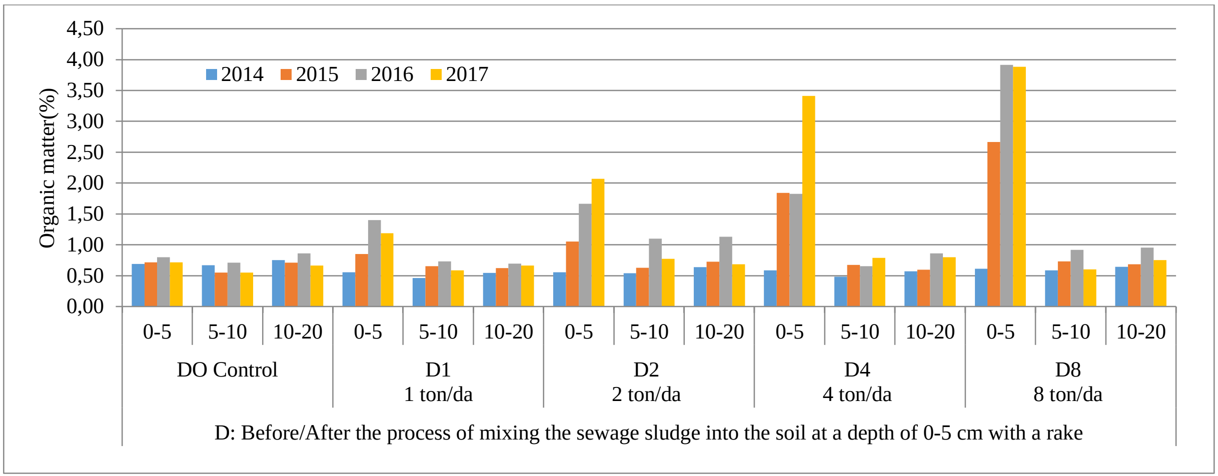

Figure 4. Effect of different doses of sewage sludge applications (D) on the average values of soil organic matter (%) content

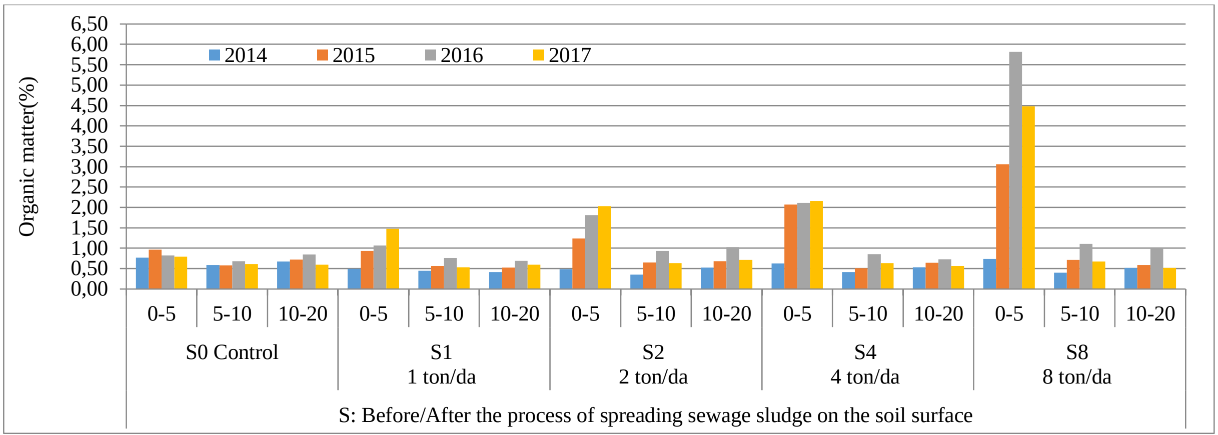

Figure 5. Effect of different doses of sewage sludge applications (S) on the average values of soil organic matter (%) content

Salinity (EC): In the experiment, there was a significant difference ($P<0.01$) in the EC values of the soil between the SS application doses. However, there was no difference between the of spreading and mixing application methods. There was also a significant difference ($P<0.01$) between the effect of SS applications and EC soil depth. Accordingly, the highest EC values were measured at 0-5 cm soil depth, while EC values decreased at 5-10 and 10-20 cm depths. In all years, EC values were below the limit value of 4 dS/m (Richards. 1954). According to the years, EC values increased approximately two times at 0-5 cm depth compared to 2014 when there was no first application (Table 3, Figure 6, 7).

Table 3. Effect of different doses of sewage sludge applications on the average values of soil EC (mmhos/cm) according to years (p <0.01)

Depth (cm)	EC*(mmhos/cm)			
	2014	2015	2016	2017
0-5	0.25 a	0.65 a	0.58 a	0.41 a
5-10	0.21 b	0.42 b	0.37 b	0.28 c
10-20	0.23 ab	0.48 b	0.43 b	0.33 b

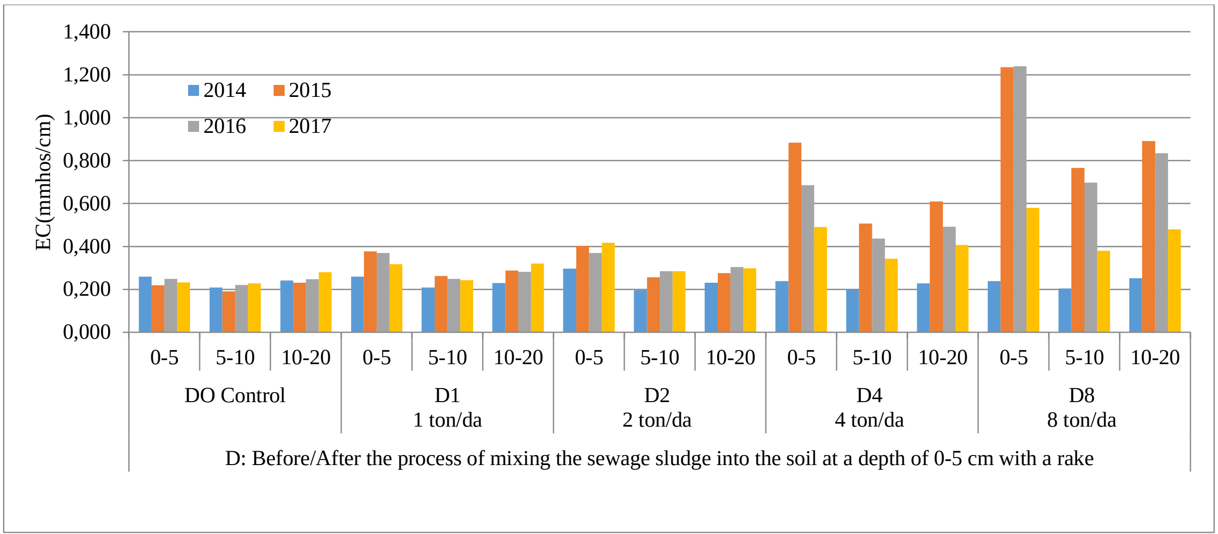

Figure 6. Effect of different doses of sewage sludge applications (D) on the average values of soil EC (mmhos/cm)

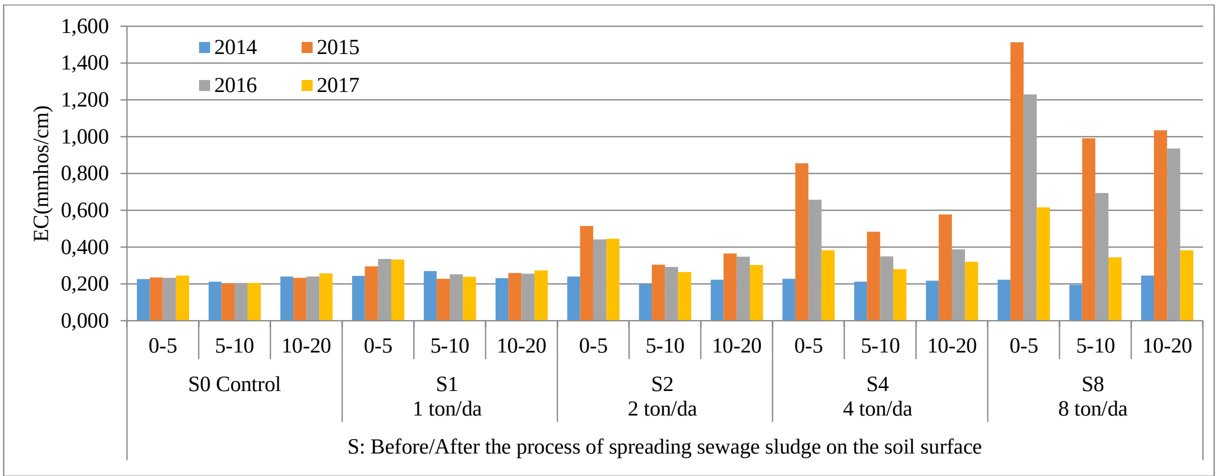

Figure 7. Effect of different doses of sewage sludge applications (S) on the average values of soil EC (mmhos/cm)

Calcium Carbonate(%): The calcium carbonate(%) content differed significantly with the SS application methods, application doses and soil depth. In 2015 and 2016 compared to 0-5 cm soil depth, lime content increased slightly at 5-10 cm depth and decreased at 10-20 cm depth (Table 4, Figure 8, 9).

Table 4. Effect of different doses of sewage sludge applications on the average values of soil $CaCO_3$ (%) according to years ($p < 0.01$)

Depth(cm)	Calcium Carbonate (%)			
	2014	2015	2016	2017
0-5	61.37 a	60.83 b	58.37 b	61.78 a
5-10	60.73 a	62.52 a	60.83 a	59.75 b
10-20	58.47 b	59.60 c	58.94 b	59.39 b

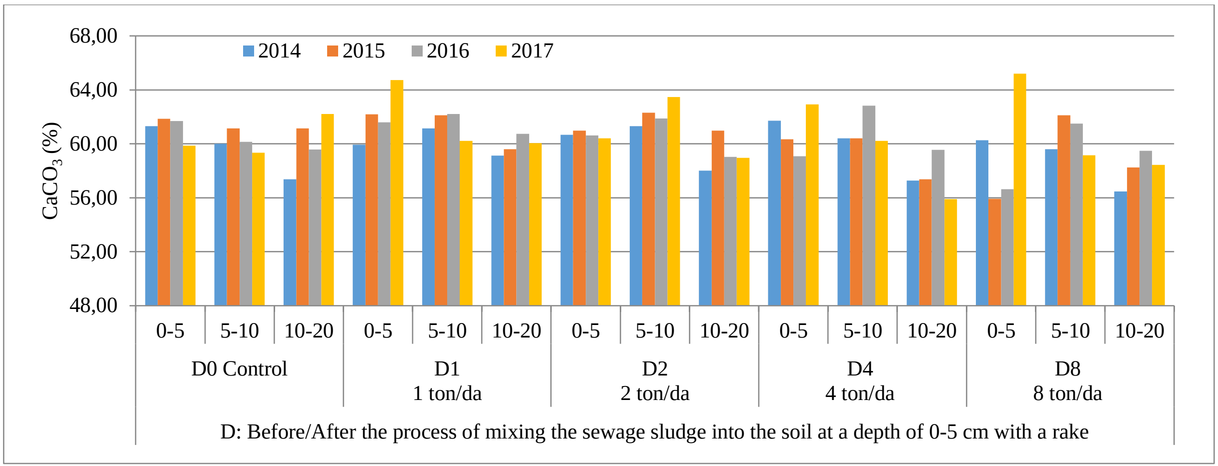

Figure 8. Effect of different doses of sewage sludge applications (D) on the average values of soil $CaCO_3$(%) content

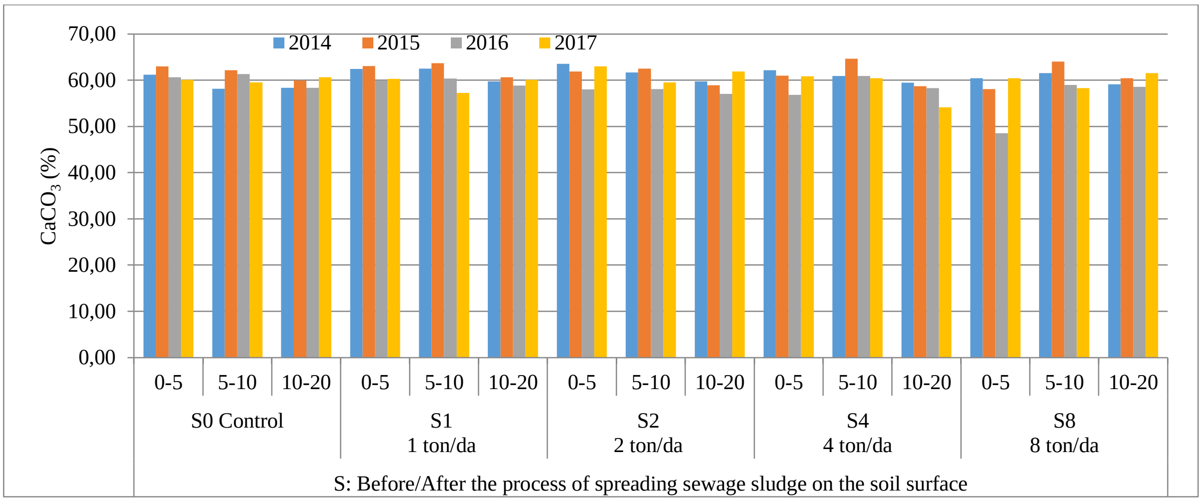

Figure 9. Effect of different doses of sewage sludge applications (S) on the average values of soil $CaCO_3$(%) content

Soil pH: When the pH values of soil samples taken for 3 years after sewage sludge (SS) applications were examined, it was not observed statistically significant difference, when compared to before the first application (2014) (Figure 10,11). Soil pH average values varied between 7.28 - 7.90.

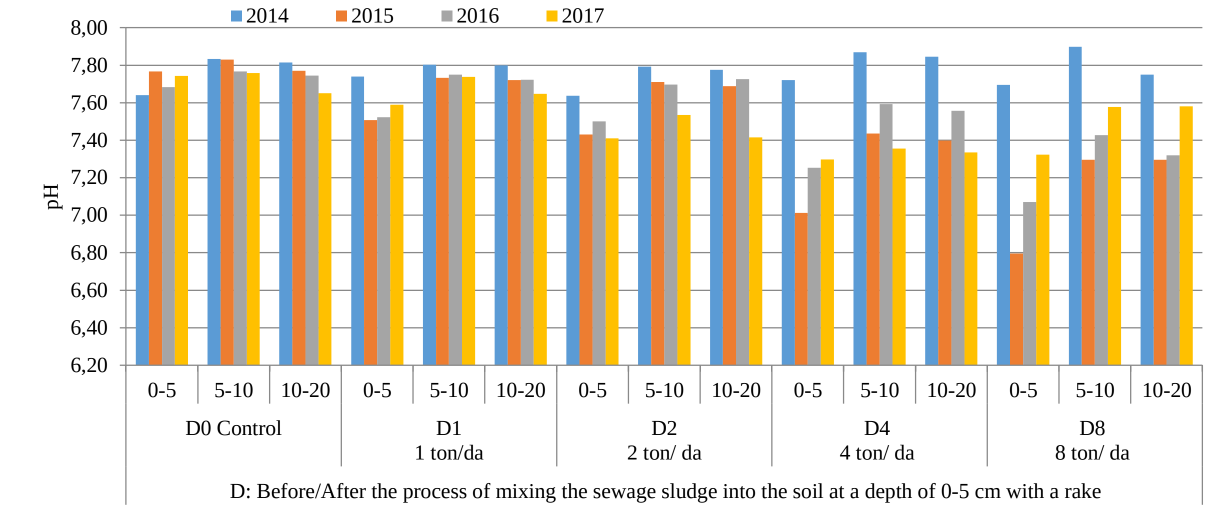

Figure 10. Effect of different doses of sewage sludge applications (D) on the average values of soil pH

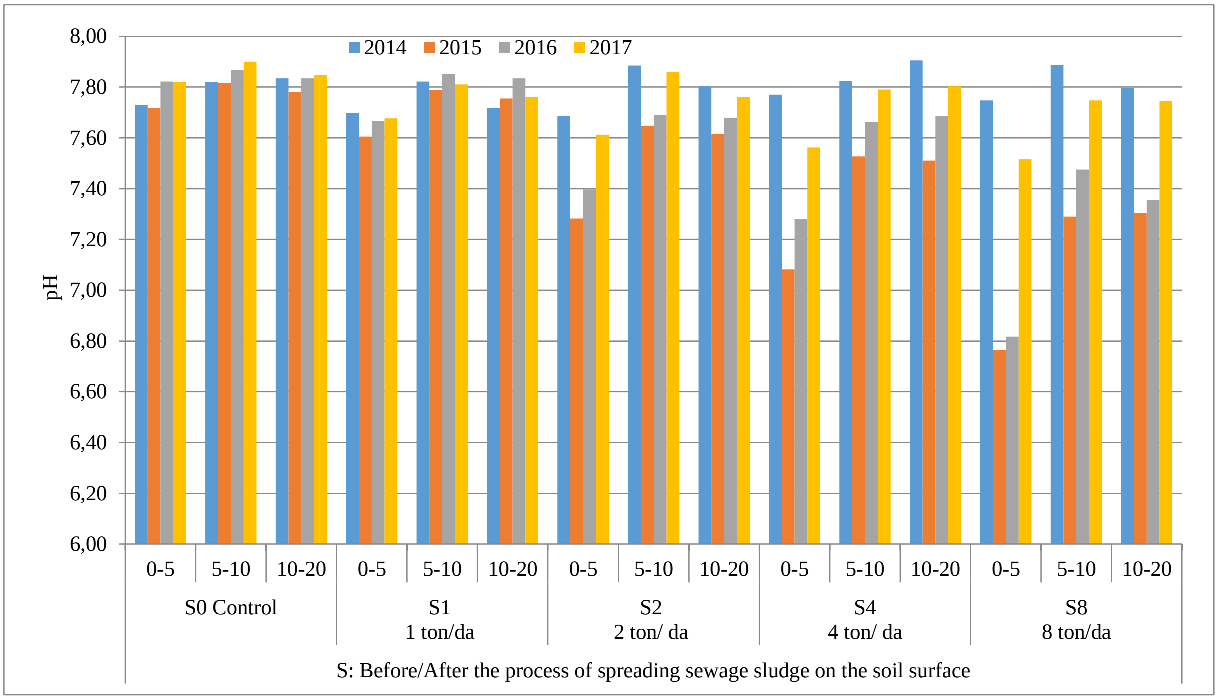

Figure 11. Effect of different doses of sewage sludge applications (S) on the average values of soil pH

Stability Index: If the stability index values obtained in the experiment are examined in detail, the stability index values of the soil samples taken from 0-5 cm depth before SS application (2014) vary between 0.61 and 0.81. This situation is an indication that the aggregate structures are not resistant to erosion. As a result of mixing SS into the soil, stability index values increased in all treatments compared to the control when the 2015 data were analyzed. The highest increase was obtained as 4.66 in 4 tons/da application. The stability index value obtained at 8 tons/da application dose was 4.17. This shows that intensive sewage sludge application is not effective in the formation of durable aggregates above a certain dose. When the stability index values obtained in 2016 and 2017 are analyzed, it is seen that a significant decrease occurred compared to the values obtained in 2015. This situation shows that this application was significantly effective in the first year. but its effectiveness gradually decreased in the following years. When the data of 2015 were analyzed after the application of SS as spreading on the soil surface, an increase was observed in the stability index values in parallel with the amount of dose applied to the soil surface. While this value was determined as 1.41 in the control application, this value was determined as 5.14 in the highest dose application of 8 tons/da. In 2016, this value decreased, and it was determined that durable aggregate structures were observed only in 4 tons/da and 8 tons/da applications. In 2017, it was determined that all of these applications on the soil lost their effect in terms of stability index value. In short, it is seen that SS mixing or spreading applications at a depth of 0-5 cm maintained their effectiveness in terms of stability index value for 1 year and these activities decreased in the following years (Figure 12, 13).

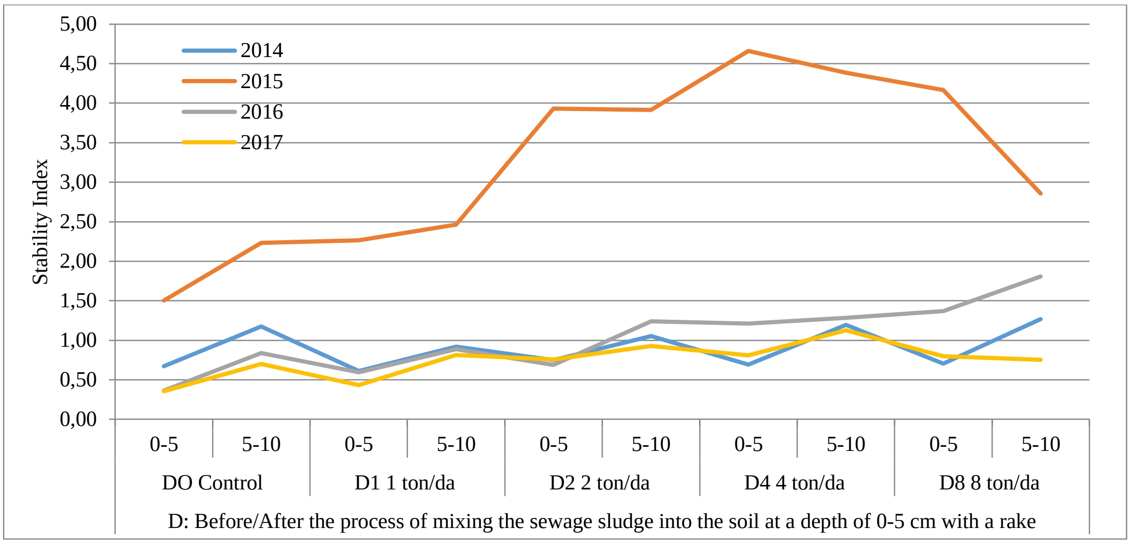

Figure 12. Effect of different doses of sewage sludge applications (D) on the average values of Stability Index

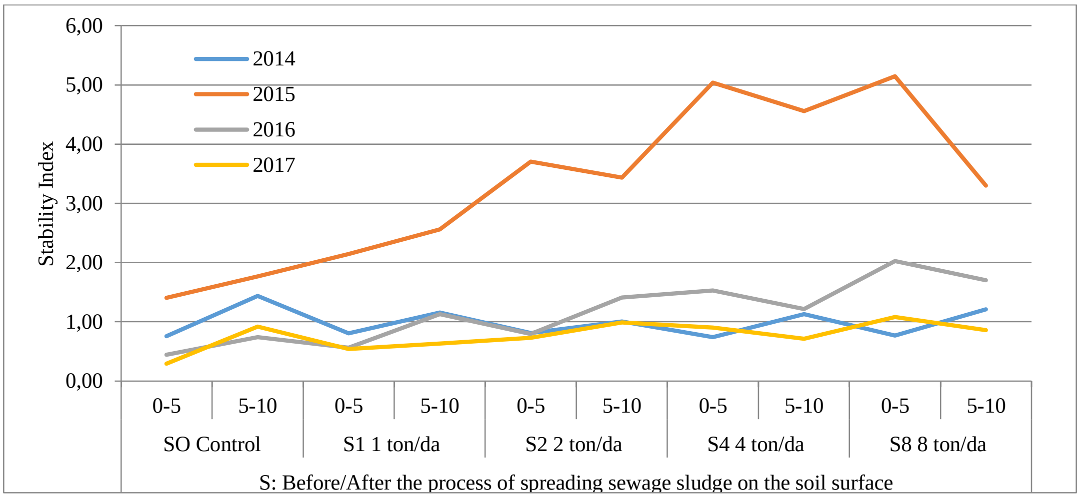

Figure 13. Effect of different doses of sewage sludge applications (S) on the average values of Stability Index

The stability index values determined in the soil samples taken from 5-10 cm depth before SS application (2014) vary between 0.92 and 1.43. Stability index values below 1.5 indicate that these soil samples taken from 5-10 cm depth have aggregate structures that are not resistant to erosion. When the data obtained in 2015 in the treatment of SS applied as soil mixing were examined, stability index values were obtained above 1.5 in all application doses except control. The highest stability index value was 4.39 in 4 tons/da application. In the 8 ton/da application, while an increase was observed compared to the control, the stability index value was less than the value obtained in the 4 ton/da application. SS applied as spreading to the soil was quite effective in terms of stability index in 2015 compared to the control. The highest stability index value was obtained as 4.56 in 4 tons/da application. The value obtained in the 8 tons/da application was close to the 2 tons/da application.

Mechanical Stability: If the mechanical stability values obtained in the study are examined in detail, the mechanical stability values of soil samples taken from 0-5 cm depth before SS application (2014) vary between 43.30 and 51.08%. This is an indication that the resistance of the soils against wind erosion is quite low. After the mixing of SS with the soil with a rake, mechanical stability values increased in all applications compared to the control when the 2015 data were analyzed. The highest increase was obtained as 79% in 8 tons/da application. When the mechanical stability values obtained in 2016 and 2017 are analyzed, it is seen that a significant decrease occurred compared to the values obtained in 2015. This shows that this application was significantly effective in the first year, but its effectiveness gradually decreased in the following years. When the data of 2015 after the application of SS as spreading on the soil surface were analyzed, an increase in mechanical stability values was observed in parallel with the amount of dose applied to the soil surface. While this value was determined as 58.63% in the control application, it was determined as 80.76% in the highest dose application of 8 tons/da. In 2016, this value decreased, and it was determined that aggregate structures resistant to erosion against wind erosion were observed only in 4 tons/da and 8 tons/da applications. In 2017, it is seen that these applications gradually lost their meaning in terms of mechanical stability value (Figure 14, 15).

In short, it was determined that the applications as mixing or spreading of the SS made at a depth of 0-5 cm with a rake to the soil increased and maintained their effectiveness in terms of mechanical stability value for 1 year, but gradually decreased in mechanical stability values in the following years.

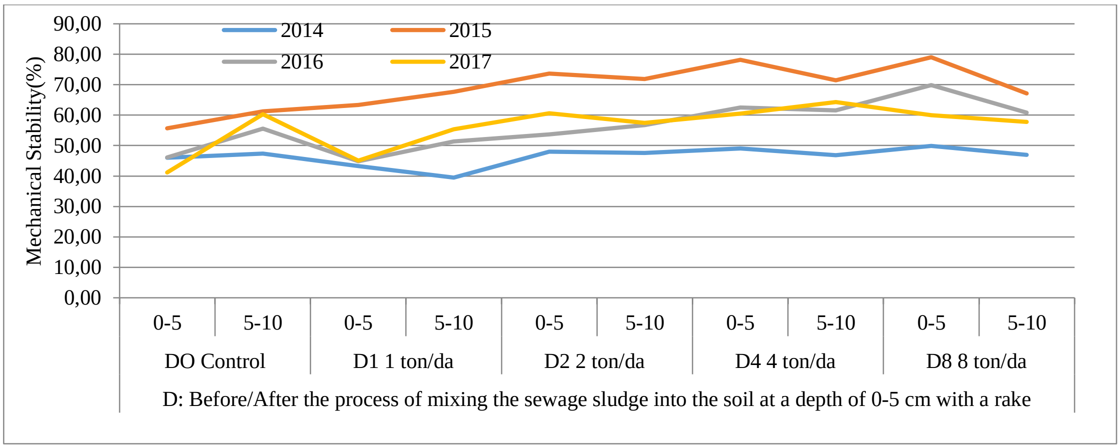

Figure 14. Effect of different doses of sewage sludge applications (D) on the average values of mechanical stability (%)

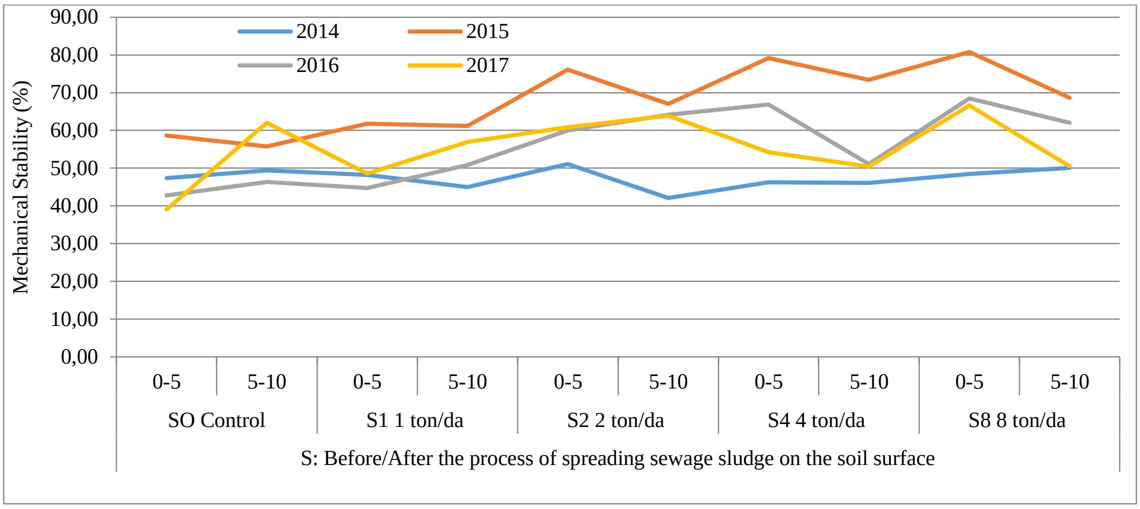

Figure 15. Effect of different doses of sewage sludge applications (S) on the average values of mechanical stability (%)

The mechanical stability values determined in soil samples taken from 5-10 cm depth before the application of sewage sludge (2014) vary between 39.48 and 50.08%. Mechanical stability values below 50% indicate that these soil samples taken from 5-10 cm depth have aggregate structures that are not resistant to erosion. When the mechanical stability values obtained in 2015 in the treatment of sewage sludge applied to the soil by mixing with a rake were examined. mechanical stability values were above 50% in all application doses except control. The highest mechanical stability value was determined as 71.85% and 71.43% at 2 and 4 tons/da of SS applications. respectively. At 8 tons/da of SS application. the mechanical stability value was determined as 67.13%. Treatment SS applied as spreading to the soil was quite effective in terms of mechanical stability in 2015 compared to the control. The highest mechanical stability value was 73.40% at 4 tons/da of SS application. The value obtained at 8 tons/da of SS application was 68.68%.

CONCLUSION

In the study, in eroded poor pasture soils with at least 250 mm of rainfall, the organic matter content at 0-5 cm depth increased from 0.61% before sewage sludge application to 2.22% three years after the application. However, there was no significant difference in other soil depths at the end of three years. This is thought to be due to the decomposition of organic matter in the soil over time. According to the years, EC values increased approximately twice as much at 0-5 cm depth compared to 2014, the first year without application. But EC values were below the limit value of 4 dS/m in the measurement data of all three years. Lime content and pH values did not show any difference between SS applications and years. Considering the erosion parameters, sewage sludge applied to the soils by mixing with rake or spreading was very effective in the formation of resistant aggregates at both soil depths against wind erosion and it is obvious that its effect on soil and water conservation will increase with regular application. In addition, the importance of the application dose was also revealed in this study. At doses above 4 tons/da, it was observed that decreases in durable aggregate formation could be observed. However, when other parameters such as heavy metal enrichment factors examined in this study are taken into consideration, it is concluded that the application dose of sewage sludge can be 1 ton/da once every 3 years by mixing it into the soil at a depth of 0-5 cm. The study is valid for the ecological conditions of the region where the experiment was conducted. This research, which is a pioneering study, can contribute to the literature by making sewage sludge applications in different soil structures.

ABSTRACT

Increasing cancer cases in recent years have cause to the use of antineoplastic (anticancer) drugs in high doses and in more combinations. Due to the inadequacy of traditional treatment facilities, antineoplastics can reach the environment from different sources and contaminate different parts of the environment such as soil, groundwater or surface water. 5-Fluorouracil (5-Fu) is a cytotoxic chemotherapy agent widely used in the treatment of various cancers. In this research, some morphological, biochemical and physiological changes in rice plants exposed to 5-Fu were investigated. In addition, the effects of melatonin and jasmonic acid applied to the plants on these changes were determined.

Keywords: 5-Fluorouracil, melatonin, jasmonic acid

INTRODUCTION

Pharmaceutical drugs are compounds used in the prevention, diagnosis and treatment of various diseases in humans and animals. These drugs are biologically active substances and are designed to have specific effects. Pharmaceutical drugs are classified according to their application areas as analgesic/anti-inflammatory drugs, antibiotics, anticonvulsants, heart drugs, cholesterol drugs and chemotherapy drugs, birth control and hormonal drugs and other drugs (stomach, sugar, etc.) (Savcı, 2010; Ustun Odabas, vd, 2020). The primary sources of pharmaceutical drugs in the environment are wastewater from hospitals and other healthcare facilities, domestic wastewater, pharmaceutical industry wastewater, and leaks from storage areas. Since pharmaceutical compounds that enter the environment through various means generally have long half-lives, they can accumulate in groundwater, surface water and soil and harm the plants and animals in the environment (Güler ve Can, 2017; Turhan, 2021; Kaya, 2023).

5-Fluorouracil (5-Fu) is a cytotoxic chemotherapy agent widely used in the treatment of various cancers (Misik ve ark. 2019). This chemotherapy agent is present in both surface water and wastewater. Therefore, it has a strong potential to contaminate agricultural areas. However, there is a huge gap in the literature regarding how this drug affects crop plants.

Plants develop various morphological, physiological and molecular responses to cope with environmental stresses. In addition, exogenous application of some compounds which are naturally synthesized in plants increases the stress tolerance of plants. Melatonin (N-acetyl-5-methoxytryptamine) and jasmonic acid (JA) are two compounds often used to increase stress tolerance of plants exposed to stress conditions. JA is a phytohormone associated with plant growth processes and also plays an important role as a signaling molecule in the formation of plant stress responses. (Wasternack, 2013). Melatonin is a compound that plays a role in the regulation of various physiological processes in both plants and animals and is also an important antioxidant molecule (Surendran et al., 2012; Kaya and Doğanlar, 2019).

In this study, the phytotoxic effects of 5-Fu were investigated using rice (*Oryza sativa*) as a model plant. Additionally, the effects of JA and melatonin on the phytotoxicity of 5-Fu were determined.

MATERIAL AND METHOD

Rice (*Oryza sativa* L.) seedlings were grown from certified seeds of the Luna variety. Rice seeds were sterilized with NaClO and then kept in distilled water for 6 hours. Then, seeds were sown in pots containing peat and perlite (3:1) and the pots were kept in the climate chamber. 8-day-old seedlings were divided into 4 groups and the treatments were done as follows:

Table 1. Experimental design

Groups	Treatments
Control	Distilled water
S	5-Fu (124 ng/L)
S+Mel	5-Fu (124 ng/L) + Foliar Mel (150 μM)
S+JA	5-Fu (124 ng/L) + Foliar JA (45 μM)

Treatments are made every other day for 7 days. After 7 days the plants were harvested. Root length and plant height were determined using fresh plants. The remaining plant samples were frozen at -80 °C for physiological and biochemical analyses.
Chlorophyll and carotenoid contents were determined according to De Kok ve Graham (1980) and Lichtenthaler ve Welburn (1983). MDA content analyzed according to Heath ve Packer (1968). For enzyme analyses, leaves were extracted according to Andrews et al. (2005) and measured activities of ascorbate peroxidase (Cakmak, 1994) and catalase (Luck, 1963).
Statistical analyses were performed using the IBM SPSS 20.0 package program. Differences between the means of different application groups were determined according to the Tukey test.

RESULTS AND DISCUSSION

Root Length and Plant Height

5-Fu decreased root length in rice. However, exogenous Mel and JA applications increased root length. Root length of plants treated with both JA and Mel was found to be higher than the control (Fig 1) ($P<0,05$).
Plant height decreased in plants exposed to 5-Fu. However, Mel and JA applications ameliorated this decrease. JA showed a stronger curative effect on plant height than Mel ($P<0,05$) (Fig. 1)

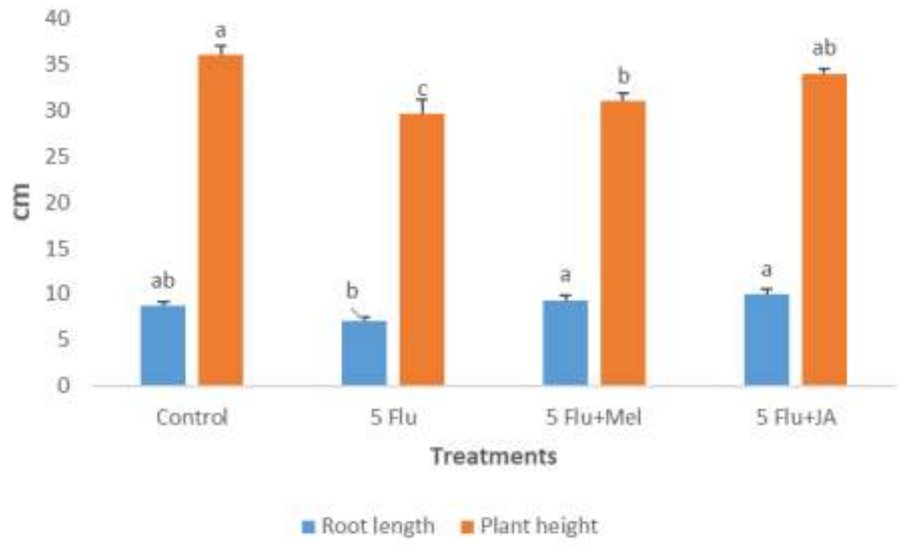

Fig 1. Changes in root length and plant height in plants treated with 5-Fu, Mel and JA.

Chlorophyll and carotenoids Contents
5-Fu application decreased the chlorophyll content in plants. Foliar Mel and JA applications increased the total chlorophyll content back to control level. Similar to chlorophyll content, carotenoid contents decreased as a result of 5-Fu application. However, Mel and JA applications had no significant effect on carotenoid content (*P<0,05*) (Fig 2).

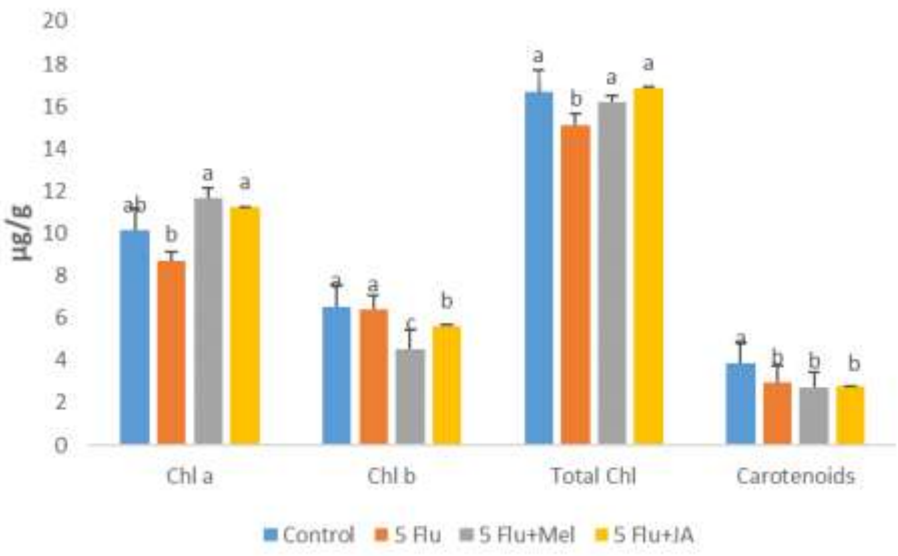

Fig 2. Changes in contents of chlorophyll and carotenoid in plants treated with 5-Fu, Mel and JA

MDA content
5-Fu application significantly increased the MDA content in rice leaves. Exogenous Mel and JA applications reduced the MDA accumulation in plant tissues, but the lowest MDA content was found in the control group (*P<0,05*) (Fig 3).

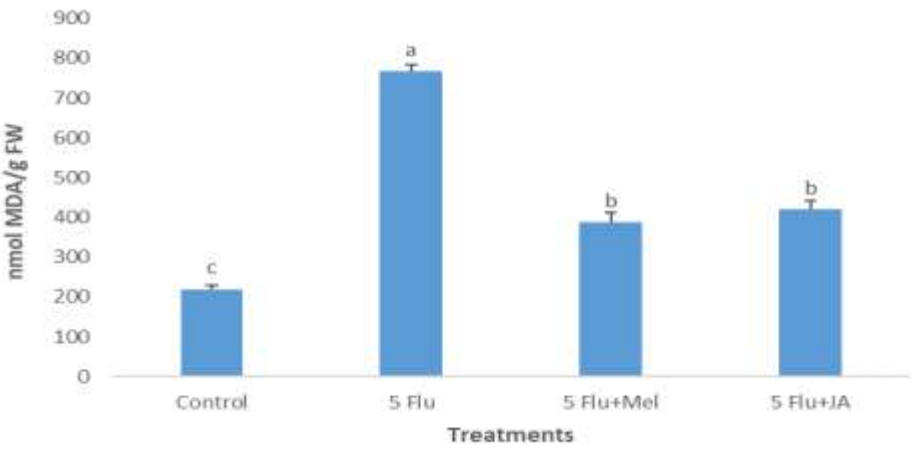

Fig 3. Changes in MDA contents of plants treated with 5-Fu, Mel and JA

Activities of ascorbate peroxidase (APX) and catalase (CAT)

5-Fu application decreased APX activity in all plants compared to control. Foliar JA and Mel applications did not cause any significant change in APX activity of plants exposed to 5-Fu (*P<0,05*) (Fig 4).

CAT activity increased all plants exposed to 5-Fu. Foliar Mel application increased CAT activity, whereas JA application did not cause any significant change in CAT activity (*P<0,05*) (Fig 4).

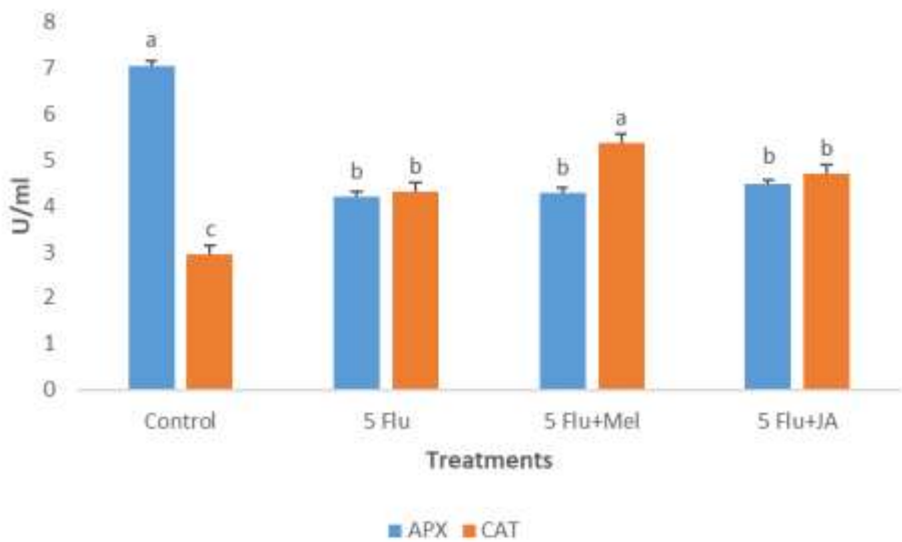

Fig. 4. Changes in activities of ascorbate peroxidase and catalase of plants treated with 5-Fu, Mel and JA

As a result, 5-Fu application decreased plant height, root length, total chlorophyll and carotenoid content and APX activity, and increased CAT activity and MDA content. Additionally, foliar Mel and JA applications alleviated the phytotoxic effects of 5-Fu by increasing plant height, root length, chlorophyll content and decreasing MDA content. However, both compounds did not alter APX activity, while only foliar Mel application increased CAT activity.

ABSTRACT

For many years, pesticides have been used in agricultural production areas to control pests. However, restrictions on pesticide use have been increasingly imposed due to the understanding of their toxic effects on non-target organisms in recent years. This has highlighted other methods of pest control. In this context, Entomopathogenic nematodes (EPNs), widely used in biological control, have come to the forefront. Effective utilization of EPNs in agricultural fields depends significantly on environmental factors. Recently, global warming has been notably affecting agricultural areas, particularly causing concerns about drought and high temperatures, which are anticipated to negatively impact EPNs already in use or planned for use. Therefore, developing EPN isolates adapted to our country's conditions, resilient to high temperatures and drought, becomes crucial for future biological pest control strategies in agricultural areas.

Keywords: Biological control, Entomopathogenic Nematodes, Drought, Global warming

INTRODUCTION

There are numerous factors causing yield losses in agricultural production areas. One of the most significant factors contributing to these losses is known as pests. For many years, chemical pesticides have been employed in the control of pests (Baker et al., 2020; Veres et al., 2020; Şahin et al., 2023; Susurluk & Bütüner, 2024; Bütüner et al., 2024a). However, recent studies have revealed the unintended toxic effects of pesticides on non-target organisms. Consequently, the European Union has imposed restrictions on pesticide use in agricultural production areas (Robin & Marchand et al., 2019; Dede et al., 2022; Marchand, 2023; Gensch et al., 2024). This development has brought alternative methods of pest control to the forefront, with biological control emerging as one of the most important and widely used among them (Van Lenteren et al., 2020; Agboka et al., 2024; Bütüner et al., 2024b).

One of the most commonly used organisms in biological control is Entomopathogenic Nematodes (EPNs). EPNs belong to the Secernentea class, Rhabditida order, and families Heterorhabditidae and Steinernematidae. These organisms are known as obligate endoparasites because they require a host organism to complete their life cycle (Boemare et al., 1996; Ehlers, 2001; Koppenhöfer et al., 2007). Generally, their life cycle consists of egg, Juvenile 1, Juvenile 2, Juvenile 3 (Infective Juvenile or IJ), Juvenile 4, and adult stages. These organisms actively seek and infect their hosts only during the Infective Juvenile (IJ) stage (Stock et al., 2002; Lewis et al., 2006; Susurluk & Ehlers, 2008; Bütüner et al., 2023). When IJs encounter their hosts, they enter the host tissue through natural openings (mouth, anus) or pre-existing wounds. Once inside the host tissue, they release gram-negative bacteria belonging to the Enterobacteriaceae family, with which they live in a symbiotic relationship (Dix et al., 1992; Stock, 1998; Shapiro-

Ilan & Gaugler, 2002). These gram-negative bacteria are specialized at the family level in EPNs. Symbiotic bacteria associated with the Heterorhabditidae family are known as *Photorhabdus* spp. whereas those associated with the Steinernematidae family are known as *Xenorhabdus* spp. (Boemare et al., 1996; Ehlers, 2001; Susurluk et al., 2001; Ciche et al., 2006; Susurluk, 2008; Ulu & Susurluk, 2024).

Entomopathogenic nematodes are utilized for potential control of various pests, especially in field conditions and greenhouses such as *Frankliniella occidentalis* (Thysanoptera: Thripidae) (Dlamini et al., 2020; Zhang et al., 2021; Dede et al., 2022; Yüksel et al., 2022; Bütüner et al., 2024b). However, several factors significantly influence their activity on hosts and their survival conditions. Among these factors, temperature and soil moisture (drought conditions) are paramount (Ulu & Susurluk, 2014; Lillis et al., 2022; Bütüner et al., 2023; Ulu & Erdoğan, 2023; Susurluk & Bütüner, 2024). Increases in temperature can enhance the metabolism and infectivity of EPNs, thereby shortening their development periods. Conversely, excessively high temperatures can negatively impact their activity and survival. Similarly, low temperatures can reduce their activity and slow EPN development (Aryal et al., 2022; Bütüner & Susurluk, 2023; Dzięgielewska et al., 2023).

Temperature tolerance varies among EPN species and is often associated with their geographic distribution. Some species thrive in warmer climates, while others are better adapted to cooler regions. This adaptability allows EPNs to achieve greater success both in natural habitats and agricultural environments (Susurluk & Ulu, 2015; Lee et al., 2016; El Khoury et al., 2018; Bütüner & Susurluk, 2023).

In recent years, assessing the potential impact of global warming and consequent droughts on EPNs widely used in biological control in agricultural production areas, both globally and in our country, is of utmost importance (Susurluk & Ulu, 2015; Aryal et al., 2022; Dzięgielewska et al., 2023). Determining the effect of these conditions is believed to pave the way for more effective utilization of EPNs. Additionally, it is thought that developing isolates resistant to high temperatures and drought could enable EPNs to be used more effectively under adverse conditions. This understanding is crucial for optimizing the efficacy of EPNs in agricultural practices amidst changing environmental conditions.

THE EFFECT OF DROUGHT ON EPNs

Entomopathogenic Nematodes exhibit distinct behaviours and capabilities in soils characterized by heavy, clayey texture and compact particle structures. Particularly, it is known that in soils with sandy-loamy texture, EPNs can more easily access their hosts and have greater mobility, whereas such environments severely restrict the host-seeking potential of IJ (Susurluk & Ehlers, 2008; Yadav & Lalramliana, 2012; Ulu & Susurluk, 2014; Susurluk & Ulu, 2015). However, studies have indicated variability in the impact of soil moisture level on different EPN species, hybrid strains, and isolates (Brown & Gaugler, 1997; Radová & Trnková, 2010; Frankenstein et al., 2024). Susurluk & Bütüner (2024) examined the efficacy of *Heterorhabditis bacteriophora* HBH hybrid strain, *Steinernema carpocapsae* TUR-S4, *Steinernema feltiae* TUR-S3, and S-Bilecik isolates on *Tenebrio molitor* (Coleoptera: Tenebrionidae) larvae under different doses and soil moisture conditions. They found that EPNs adapted to local conditions, such as the *H. bacteriophora* HBH hybrid strain, exhibited effective control over hosts even at low soil moisture levels. Soil moisture level not only influences the efficacy of EPNs on hosts but also affects their physiological characteristics, such as reproductive capacity, both positively and negatively. Nevertheless, comprehensive studies regarding the effects of soil moisture on different life stages of EPNs are still lacking (Nouh, 2022; Bütüner & Susurluk, 2023; Susurluk & Bütüner, 2024).

THE EFFECT OF TEMPERATURE ON EPNs

High temperatures are widely recognized as one of the most significant abiotic factors that adversely affect EPNs, notably by significantly shortening their lifespan. While some isolates are known to tolerate high temperatures to a certain extent, studies have identified the duration of exposure to high temperatures as a critical determinant (Kung et al., 1991; Lee et al., 2016; Lillis et al., 2022; Susurluk & Bütüner, 2024). Recent research has also shown that high temperatures can increase the efficacy of certain EPN isolates on their hosts while simultaneously reducing their lifespan. Conversely, very low temperatures have been found to diminish the effectiveness of EPNs on hosts and slow their development (Radová & Trnková, 2010; Nouh, 2022; Devi, 2024). Furthermore, studies have indicated that prolonged exposure to high temperatures negatively affects physiological traits such as reproductive capacity in EPNs. In a study by Bütüner et al. (2023), various EPN isolates were exposed to high temperatures over a prolonged period of three weeks. The findings revealed that increased temperature and duration negatively impacted the efficacy of EPNs on hosts, with a significant portion of the EPNs exposed to high temperatures dying during the exposure period. Similarly, in a study conducted by Susurluk & Bütüner (2024), prolonged exposure of the *H. bacteriophora* HBH hybrid strain to high temperatures resulted in changes in reproductive capacity, hermaphrodite length, and egg size. The results indicated that reproductive capacity and hermaphrodite length were adversely affected with increasing temperature and duration of exposure. These findings underscore the critical importance of temperature management in optimizing the efficacy of EPNs in biological control strategies, highlighting the need for further research into the specific impacts of temperature on different stages and traits of EPNs.

CONCLUSIONS

Entomopathogenic nematodes are recognized for their highly effective use in biological control against pests. However, there are still many aspects of EPNs that remain not fully understood, such as their mechanisms for locating hosts and whether they follow each other while searching for hosts (Erdogan et al., 2021; Trejo-Meléndez et al., 2024). Among these uncertainties, their biological and physiological responses to high temperatures and drought are particularly significant. Research on the effects of high temperatures and drought has often been limited to their efficacy on hosts (Nouh, 2022; Bütüner & Susurluk, 2023; Bütüner et al., 2023; Susurluk & Bütüner, 2024; Matuska-Łyżwa et al., 2024). Studies investigating the physiological traits that may differ in new generations after EPNs infect hosts are relatively scarce. Therefore, studies focusing on adverse conditions, especially concerning EPN species and isolates used in our country, are considered essential (Ulu & Susurluk, 2014; Susurluk & Ulu, 2015). Such research is expected to enhance the effective utilization of EPNs in agricultural production areas, particularly in the face of potential temperature increases and drought due to global warming in the coming years. In this context, active research is being conducted at the Nematology Laboratory, Plant Protection Department, Faculty of Agriculture, Bursa Uludağ University, aimed at developing isolates that are resistant to high temperatures and drought.

ABSTRACT

This study aims to prove that growth and biochemical quality of *Moringa oleifera* the miraculous tree able to grow under different culture conditions, were optimized by nitrogen fertilization of soil. In our case, three-aged seedlings were grown under control condition (without fertiliser) or in presence of NH_4NO_3 as fertilizer. Leaves and flowers numbers, stem diameter and height, relative growth rate (RGR), net assimilation rate (NAR), relative leaf area expansion rate (RGRA) and relative growth rate of the principal stem in height (RGRh) were enhanced by nitrogen fertilizer presence. The high growth level seemed to be the result of increase of chlorophyll a fluorescence parameters principally the maximum quantum efficiency of PSII photochemistry (Fv/Fm). More that, when Moringa reached the most pronounced degree of growth (August, 2023), biochemical measures were realized. At that time of phonologic cycle in which they were generated, a rise in the contents of total phenolic compounds, total flavonoids, condensed tannins, soluble sugars, proline and proteins was observed. Compared to in control trees, dramatic tenor's rise of all secondary metabolites, osmolytes and proteins was shown in fertilezed plants. Recording to our goals, data demonstrated the importance of soil fertilization in Moringa improvement of bioactive compounds richness improving there healthy benefits.

Keywords: Bioactive compounds, Nitrogen fertilizer, Fluorescence, *Moringa oleifera,*

INTRODUCTION

The constraint of low soil fertility in soil is largely associated with welp productivity of crop. For this reason, many manure of fertilization (compost, crop residue…) were applied as optimization approach in order to maximize crop productivity and support species to increase biomass production, especially, under the climatic changes. Several studies (Nalivata et al., 2022; Ouattara et al., 2022; Warttman et al., 2022; Kayouki et al., 2022) prove that small or no fertilization due to financial or socio-economic factors.

Moringa oleifera is widely esteemed for its therapeutic characteristics and nutritional advantages (Padayachee et al., 2020). Hence, this plant has great economic significance. Several efforts have been made to promote its culture extensively in various regions around the globe. However, Moringa culture encounters some challenges as salinity and drought (Sadak et al., 2020; Azeem et al., 2023). So, fertilization was used to enhance plant growth and propagation. Different types of fertilizers were used to enhance plant growth (Ndagi et al., 2023). Inorganic fertilizers increased growth of Moringa and enhance leaf yield (Ngwenya et al, 2022). Recently, Ndagi et al. 2023 showed that organic fertilizer (poultry dropping) gave the best result for Moringa farming. In other environmental conditions, Cobalt and organic fertilization made a promising strategy to improve moringa plant productivity (Gad et al., 2019). Despite the importance of these results, additional investigation is required to determine the effect of these fertilizers on the biochemical properties of this plant, from which its commercial value is derived. The phytocomplex found in Moringa leaves has been extensively linked to a range of advantageous effects on human health such as antioxidant (Sreelatha et al., 2019). Several studies showed that abiotic stress induced antioxidant metabolites and potential in Moringa oleifera (Azeem et al., 2023; Zanella et al., 2019). Studies showed too, that the administration of inorganic fertilizer increased the accumulation of secondary metabolites (Mutua et al, 2021). Conversely, nitrogen fertilization reduced secondary metabolites in *Rosmarinus officinalis* (Bustamante et al., 2020).

In light of Moringa's economic significance, research efforts should be concentrated on enhancing its growth and mitigating environmental stresses, all the while monitoring its active constituents to safeguard its medicinal properties. Hence, the purpose of this study was to determine the effect of ammonium nitrate fertilizer on growth and biochemical components of *Moringa oleifera* seedlings.

MATERIAL AND METHOD

Experimental site description and growth conditions. The experiment was carried out at the research area of National Institute of Research in Rural Engineering, Waters and Forests (INRGREF) of Tunis (Tunisia). Three years-aged *Moringa oleifera* trees previously planted under Tunisian climate conditions (Table 1) were used to realize this study. In November 2022, plants showing a total leaf fall were transferred in pots containing 10Kg of soil to grow under control condition (without fertiliser) or in presence of NH_4NO_3 (250g/pot) as nitrogen fertilizer. The experiment was conducted for 13 months (November, 2022 to December, 2023) for four replicates.

Table 1. Different temperature and rainfall levels during experimental period

	November 2022	June 2023	July 2023	August 2023	Sptember 2023	October 2023	November 2023	December 2023
Temperature (°C)	18,3	25,6	32,5	28,4	27,4	24,9	19,9	15,5
Rainfall	8,3	5,3	0	9	1	0	5,7	6,3

Morphological and growth parameters. Growth and morphological parameters measures have been taken at the first time at November, 2022 (t_0), and later every 30 days during 07 months (June-December, 2023). Leaves and flowers numbers, the principal stem height and diameter were determined at the different times in plants grown in absence of fertilizer (control) or in presence of nitrogen fertilizer (NH_4NO_3).

At August month (2023), total leaves fresh and dry weights were determined. Also, a planimeter (model CI-202, USA) had been used to measure the several leaves parameters (area, length, width, and perimeter).

Relative growth rate (RGR mg. g^{-1}. d^{-1}), net assimilation rate, (NAR g. m^{-2}. d^{-1}), relative leaf area expansion rate, (RGRA mm^{-2}.d^{-1}) and relative growth rate of the principal stem in height (RGRh, cm. cm^{-1}. d^{-1}) were determined according to the following equations respectively

$(lnw_9-lnw_0)/(t_9-t_0);(w_9-w_0)/dt*(lnA_9-lnA_0)/(A_9-A_0);(lnLA_9-lnLA_0)/(t_9-t_0)$ and (lnh_9-lnh_0/t_9-t_0)

W (shoot weight); A (leaf area); DW (increment in leaves biomass); LA (total plant leaves area); h (stem height); t_0 is the time at the beginning (November, 2022) and t_9 at August month (2023) when all growth parameters showed the major values.

Fluorescence measurement and photosynthetic pigments determination. The measurement of fluorescence is carried out on plants previously adapted to darkness for 30min. Following the application of a pulse of saturating light, the fluorescence increases from the ground state Fo (All reaction centers are open) towards a maximum level F_m (all reaction canters are closed). In this case plastoquinone QA, the first electron acceptor emitted by PSII, is completely reduced. This situation allows us to determine the maximum efficiency of PSII in converting light energy into chemical energy. Fluorescence measurements at the beginning (November, 2022) and at August month (2023) were measured by modulated chlorophyll fluorometer (OS1p- Opti-Sciences, USA).

Contents of Chla, Chl tot and carotenoids determination from extracted leaves samples were determined spectrophotometricaly with PG instrument (T60 UV-V /UK) according to Arnon et al. (1956).

Determination of proline and soluble sugars contents. Leaves samples collected at the beginning (November 2022) and at August 2023 were extracted in order to determine proline contents in accordance with Bates (1973) method. Results were expressed as µmol. g^{-1} DW. Dubois et al. (1956) developed method was adopted to determine total soluble sugars, which was defined as µmol. g^{-1} DW.

Proteins and nitrogen crude determination. As described by Pearson (1976), proteins contents of leaves samples collected at the beginning (November 2022) and at August 2023, were determined. Also, according to the equations below, the nitrogen amount and crude protein were respectively estimated:

$$N\ \% = [(V \text{ x } n \text{ x } 0.014)/M] \times 100$$

$$\text{Crude protein } \% = \%\ N \times 6.25. \text{ (N: Nitrogen).}$$

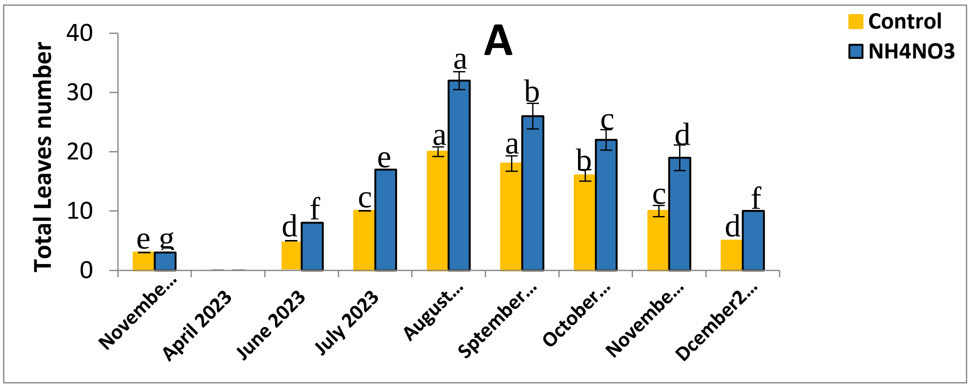
(V: volume of hydrochloric acid used in the titration. n: normality of hydrochloric acid and M: mass of the sample in grams).

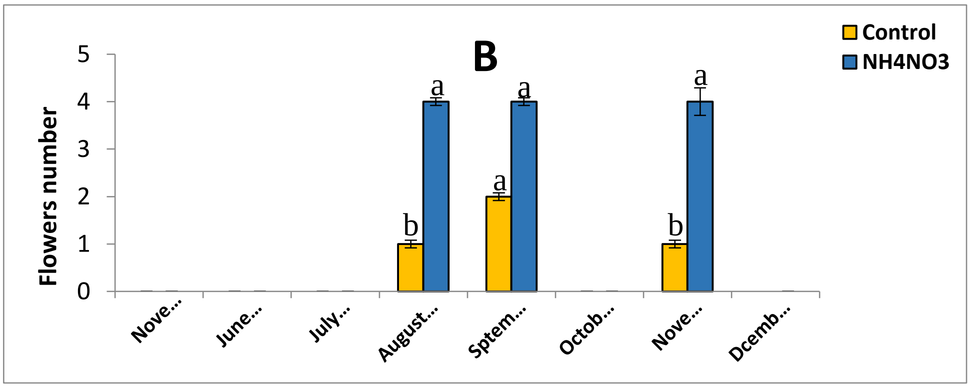
Total phenolic compounds, total flavonoids and condensed tannins contents quantification. To do, leaves samples collected at the beginning (November 2022) and at August 2023 were used. Total phenolic compounds were quantified in accordance with the Folin–Ciocalteu method of Li et al., (2004). To calculate the total phenolic compounds, Gallic acid was used (mg GAE.g^{-1}). Dehpeur et al. (2009) method was adopted to carried out total flavonoid content. Which is expressed in mg quercetin equivalent per gram of dry weight (mg Qu. g^{-1}). To estimate total condensed tannins Ba et al. (2010) method was followed. Total condensed tannins Contents of total condensed tannins were defined in mg catechol equivalent/g dry weight (mg cat. g^{-1}).

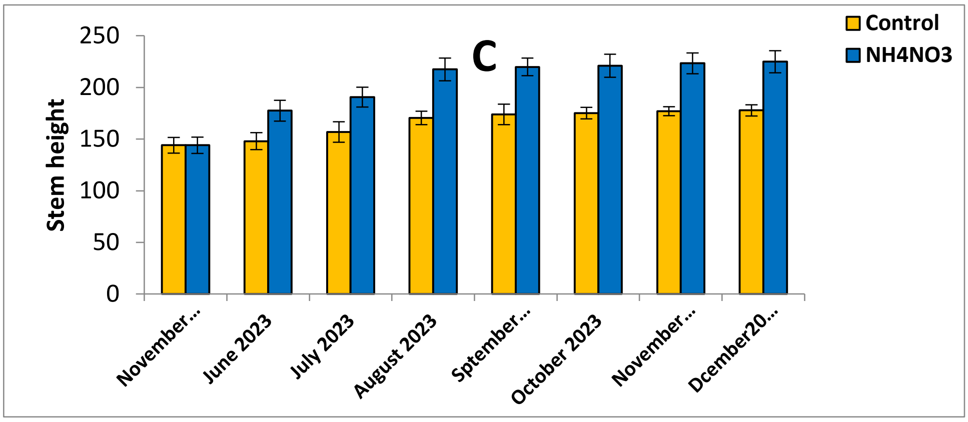
Statistical analysis. Data are means of six replicates. All data were statistically analysed and subjected to a one-way ANOVA analysis based on Tukey's HSD test (IBM SPSS Statistics 23). Correlation was designed by Pearson test at probability levels of 0.01 and 0.05. Letter used to indicate significant differences between treatment means.

RESULTS AND DISCUSSION

Extensive distribution of *Moringa oleifera L.* occurs across the globe areas. It is utilized globally as a multipurpose herbal plant for human consumption and as an alternative medicinal plant. This tree's foliage is rich in antioxidants, including flavonoids, carotenoids, phenolics, and ascorbic acid (Vongsak et al., 2014). Due to its economic importance, numerous studies have been devoted to enhancing the medicinal properties and agricultural practices of this plant (Razis et al., 2014). Our data showed that, at August 2023, M. *oleifera* trees acquired the highest leaf number in both control and fertilized plants (Figure 1A). The leaf number increase is preceded by a temperature peak (28,4°C) dtected in July 2023 (Table1). The increment in leaves number is more significant in fertilized plants (32 leaves) compared to control plants (20 leaves). More that and as shown by Figure 1B, floral blossoming reached a maximum of 4 flowers at August 2023 in fertilized plants. Whereas, in control plants, the maximum of flowers (2) is observed at September 2023 month. After failure and ablotion of these flowers news one in order of 1 and 4 in control and fertilzed trees respecteively, were observed. In fact, it is widely known that the Moringa tree is a miraculous species that grows in several environmental and soil conditions (Karin et al., 2020), but we cannot ignorate the effects of climate change crossing the world and which is resulting in nutriments poor soil. This is why the reconstitution of soils through fertilization appears fundamental to increase soil fertility on the one hand and increase crop yields on the other (Mason et al., 2015; Ouattara, 2017). Accordingly, we can understand the morphological and growth responses of Moringa trees grown on medium added with fertilizer. In addition, results showed that soil nitrogen fertilization improved shoot part growth through improvement of stem growth (Figure 1C, D). In another way, total leaves weights, area, lengh and perimeter were increased when soil was enriched by ammonia nitrate (Table 2).







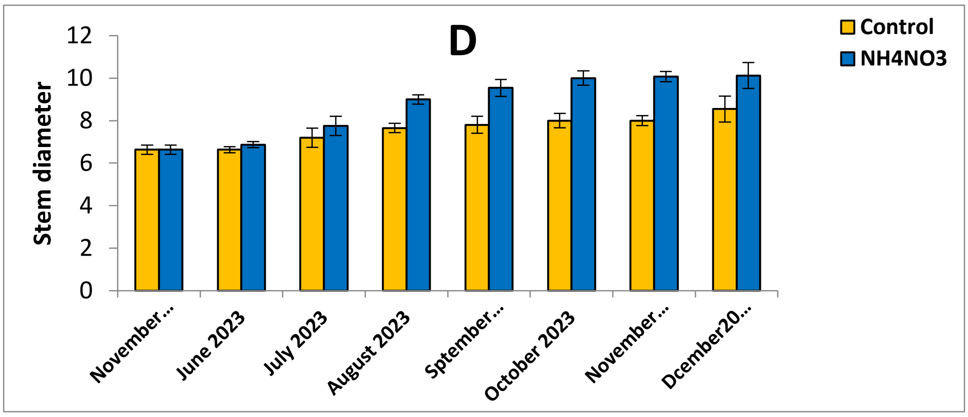


Figure 1. Variation of leaves number (A), flowers number (B), stem height (C) and stem diameter (D) in *Moringa oleifera* grown on different nutritive media (control and NH_4NO_3 fertilisation).

Table 2. Leaves morphological parameters in *Moringa oleifera* grown under different nutritive media (control and NH_4NO_3 fertilisation). (t0: time zero; tf: final time)

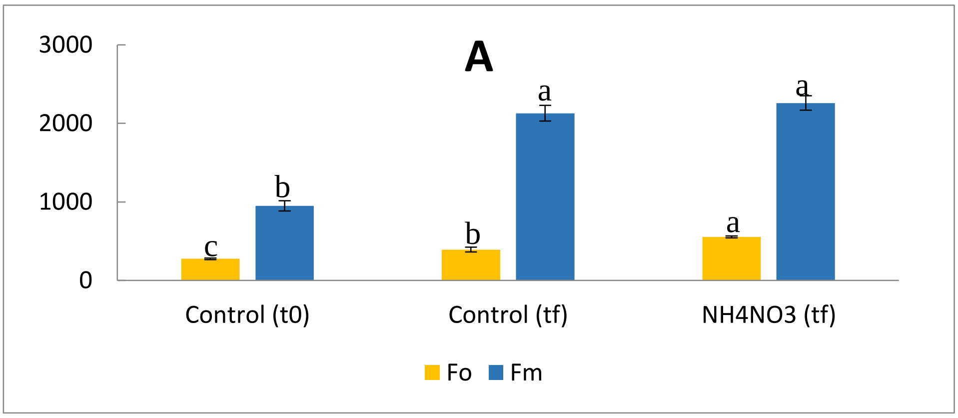
	Total leaves fresh weight (g)	Total leaves dry weight (g)	Total leaves area (cm^2)	Total leaves length (cm)	Total leaves width (cm)	Total leaves perimeter (cm)
Control (t0)	4,2347±0.142^c	0,445±0.022^c	267,94±2.013^c	66,11±4.092^c	28,68±1.28^c	671,36±30.301^c
Control (tf)	16,402±1.01^b	1,286±0.084^b	651,449±22.22^b	132,29±8.086^b	97.609±60.607^b	1438,336±30.05^b
NH_4NO_3 (tf)	38,635±2.35^a	4,117±0.233^a	1171,315±10.102^a	258,27±6.631^a	112,65±9.974^a	2884,32±10.414^a

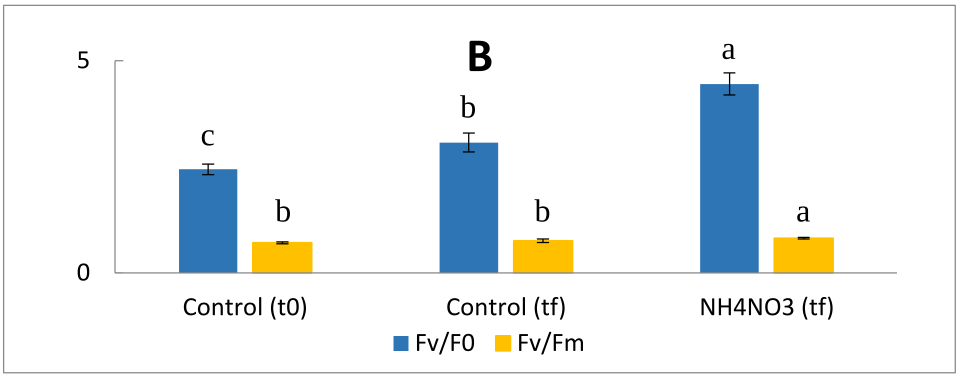
More, relative growth rate (RGR) relative leaf area expansion rate (RGRA) and net assimilation rate (NAR), were remarkably improved in fertilezed Moringa plants (Table 3).

Table 3: Variation of relative growth rate (RGR), relative leaf area expansion rate (RGRA), relative growth rate of principal stem (RGRh) and net assimilation rate (NAR) in *Moringa oleifera* under different nutritive media (control and NH_4NO_3 fertilisation).

Growth parameters	Relative growth rate: **RGR** ($mg.g^{-1}.d^{-1}$)	Relative leaf area expansion rate **RGRA** ($mm^{-2}.d^{-1}$)	Net assimilation Rate **NAR** ($g.m^{-2}.d^{-1}$)	Relative growth rate of principal stem in height **RGRh** ($cm.cm^{-1}.d^{-1}$)
Control	$3.428078\ .10^{-3}$	$2.249205.10^{-3}$	1.314698748	$0.516778.10^{-3}$
NH_4NO_3	$5.597079.10^{-3}$	$3.734479.10^{-3}$	5.056261034	$1.120942.10^{-3}$

Our data were opposit to Ndagi et al, (2023) suggestions, which reported that inorganic fertilizer (NPK) had no significant effect on leaf number and leaf area in *Moringa oleifera*. Whereas, many other resaerchers (Zhang et al., 2019; Amin, 2020; Ngwenya et al., 2022, Phinehas et al., 2022; Hafeez et al., 2023; Huang et al., 2024) have confirmed that inorganic fertilizers application enhanced leaves yield in sevral species such as Camelia, Moringa chick pea, pepper, tomato... Khalaj and Noroozisharaf (2020) proved that an appropriate ammonium nitrate ratio as fertilezer improved plant production in vegetative and in reproductive stages by increasing flowers number. However, ammonia nitrate had a key role in nutrient uptake, plant growth and fruit quality (Pedersen et al, 2019; Yan et al, 2019; Zhang et al, 2019). More precisely work specifed that optimal plant yields and fruit quality were dependent to N fertilization rates (Souza et al., 2020). Also, primary (stem height) and secondary growth (stem diameter) also than stem relative growth in height were rised in Moringa plants grown on added soil by ammonia nitrate. Logically and as described by Jianbo et al. (2020), the first effect of nitrogen fertilization is associated to change of soil properties through cycle of soil nutrient and avilability of nutrients. More that, according to many other researchers (Liu et al., 2013; Kitonyo et al., 2018; Hafeez et al., 2023), nitrogen fertilizer rise significantly soil water content, soil water retention capacity and soil aggregate components amounts. More, at plant level, fertilizer affects its physiology through stimulation of photosynthesis apparatus based on enhacement of photosynthetic pigments (Chlorophylls) accumulation. According to theses ideas, our results (Figure 2A and B) demonstrated an increase of both maximum primary yield of PSII photochemistry (Fv/F_0) and the maximum/potential quantum efficiency of PSII (Fv/Fm) in fertilzed plants showing the high level of growth.





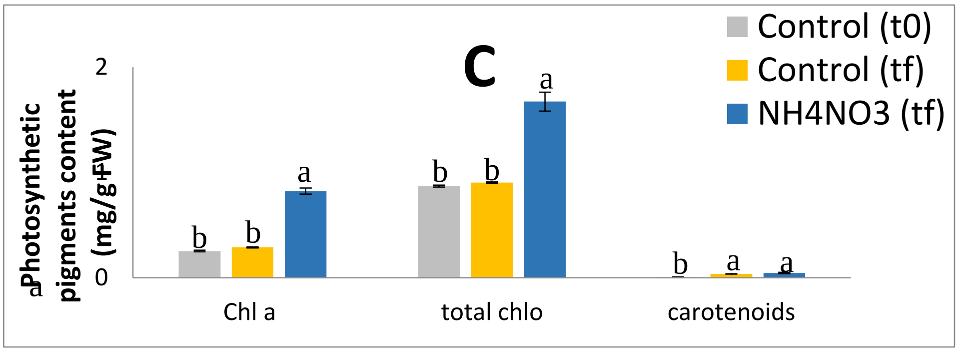


Figure 2: The chlorophyll fluorescence parameters Fo, Fm, (A), Fv/F0 and Fv/Fm (B) and photosynthtetic pigments contents (C) in *Moringa oleifera* grown on different nutritive media (control and NH_4NO_3 fertilisation). (t0: time zero; tf: final time).

Recently, Song et al, (2019) reported that nitrogen application improved chlorophyll fluorescence processes of oat plants. Likewise, Nasraoui and Gouia (2014), and Ullah et al, (2020) reported that nitrogen fertilezer application affects largely photosynthesis pocess. In fact, photosynthesis enhancement was directly linked to photosynthetic pigments tenors in leaves tissues. Figure 2C demonstareted thet referring to control, fertilization resulted in a greater than 80% increase in total chloropyll. The photosynthetic pigments amounts in leaves were closely related to nitrogen fertilizer (Zebarth et al., 2002), therefore, availability of chlorophylls enhance photosynthesis resulting in plant growth (Yuan, 2017; Rodrigo et al., 2019; Peng, Zhang et al., 2019; Chen et al., 2021; Gitelson et al., 2003).

Far from, and because there is no doubt that nitrogen disponibility to plants is one of the major factors affecting plant growth and thier richness in bioactives compounds crucial to cover vital humain needs (Yadav et al., 2017; Fathi and Zeidali, 2021; Amin, 2022). Furthermore, the observed rise in crude protein content could potentially be attributed to rise in crude protein content that seemed a result of availability of nitrogen stimulating its uptake and distribution in different plant organs (Ngwenya et al., 2022). Regarding organic compounds, Figure 3 displayed rise of proline and soluble sugars contents under ammonium nitrate fertilization condition. Similar results were published by Li et al, (2012), Zahra et al, (2021) and Amin (2022).

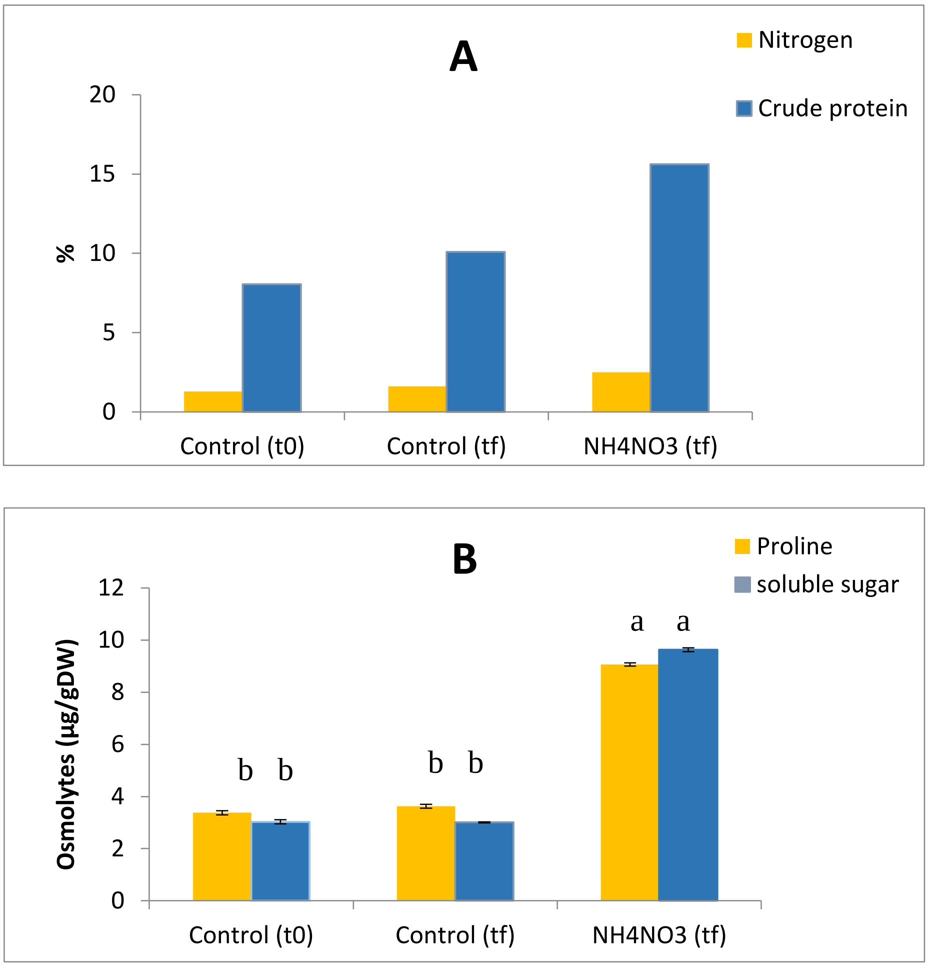

Figure 3: Variation of nitrogen and crude proteins (A), and osmolytes level (B) in *Moringa oleifera* grown on different nutritive media (control and NH_4NO_3 fertilisation). (t0: time zero; tf: final time).

Coming back to the reality that *Moringa oleifera* has immense value and is remarkably versatile in medicinal and pharmaceutical applications, we must remember that all these characteristics are in relationship with its richness in secondary metabolites (Mohammed et al., 2015). About it, our data (Figure 3) demonstrated how foliar tenor in total phenolic compounds, flavonoids, and condensed tannins were significantly elevated by ammonium nitrate fertilizer application. In fact, in control plants, the level of total polyphenols, flavonoids and tannins increased with plant age from November 2022 (t0) to December 2023 with about 10%, 16% and 13%. With plant fertilization, the levels of total polyphenols, flavonoids, and tannins increased by over two folds in comparison to the control group (Figure 4).

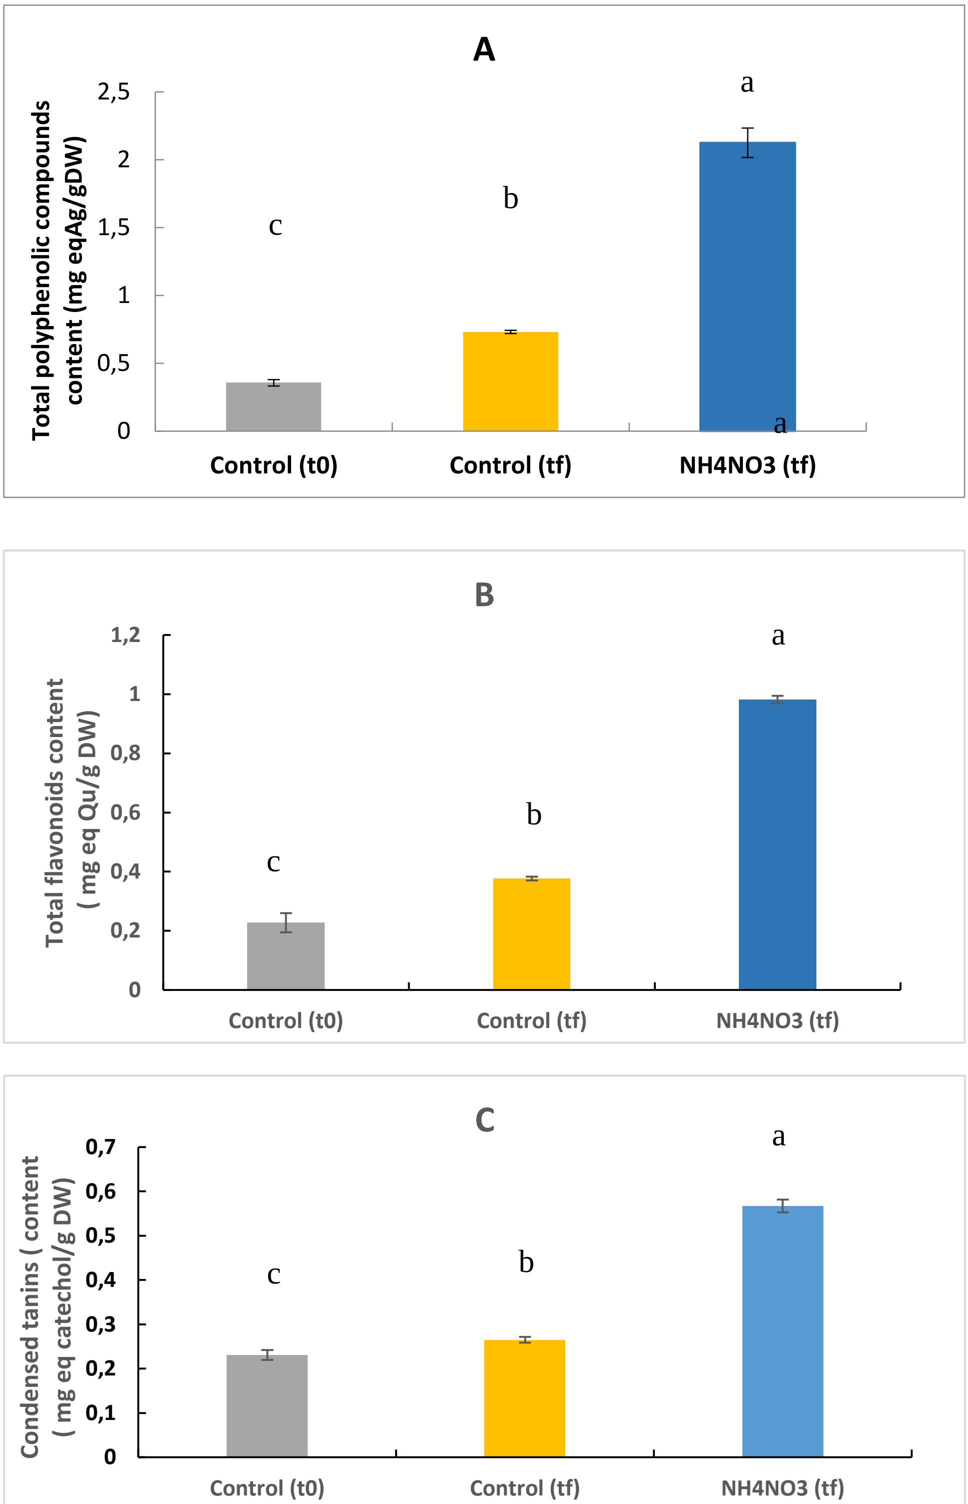

Figure 4: Variation of total polyphenolic compounds (A) total flavonoids (B) and condensed tanins (C) in *Moringa oleifera* grown on different nutritive media (control and NH_4NO_3 fertilisation). (t0: time zero; tf: final time).

However, positive correlations were observed between proteins and secondary metabolites (including flavonoids and tannins) contents in Moringa leaves (Table 4). In accordance with Litvaak et al, (1996) and Mutua et al, (2021), increased nutrient concentration in leaves may lead to enhanced carbon fixation and protein synthesis, resulting in raised production of secondary metabolites. In contrast to this context, Bustamante et al, (2020), reported a negative correlation between N fertilization and secondary metabolites in *Rosmarinus officinalis*.

Positive correlation (r= 0.944) observed between Fv/Fm and ssoluble sugars (Table 4) which are products of photosynthesis and reflecting the rate of carbohydrate metabolism. In fact, availability of high nitrogen level which influences soluble sugar production is significantly pronounced in fertilized Moringa in which carbon assimilation was more pronounced than in control ones (Jianbo et al., 2020).

Highlights in our study demonstrated that nitrogen fertilizer plays a crucial role in *Moringa oleifera* growth. Improving fertility of soil by its amendment by nitrogen fertilizer (NH_4NO_3) corresponds to an effective key strategy for improving biochemical quality of *Moringa oleifera* biomass.

Table 4: Pearson's correlation coefficients of morphological parameters changes and biochemical measures in nitrogen- fertilized *M. oleifera leaves*

CONCLUSIONS

In conclusion, ammonium nitrate fertilizer contributes significantly in the growth improvement of Moringa oleifera and its biochemical quality amelioration. Inorganic fertilizer (NH_4NO_3) application regulates chlorophyll fluorescence intensity, thereby strengthens and promotes photosynthesis process. There for, it stimulates carbohydrate metabolism, which is fundamental process ensuring energy supply to living cells. The mineral nitrogen fertilizer addition promotes foliar content in crucial bioactive molecules keys of *Moringa oleifera* leaves values.

STRAIN EFFECT ON HOLE-CONFINED PHONON SCATTERING RATES IN $Al_{0.25}Ga_{0.75}As/GaAs/Al_{0.25}Ga_{0.75}As$ QUANTUM WELLS

ABSTRACT

This study presents a theoretical investigation of hole-confined polar optical phonon scattering rates in symmetric $Al_{0.25}Ga_{0.75}As/GaAs/Al_{0.25}Ga_{0.75}As$ quantum wells. We compute intrasubband heavy hole-confined phonon scattering rates in the quantum well using Fermi's Golden Rule in conjunction with the dielectric continuum model. Numerical results demonstrate that these scattering rates are reduced by strain via tensile hydrostatic strain and tensile biaxial strain. We compare scattering rates for quantum wells grown along the [001] and [011] directions. Our findings show increased scattering rates for the [011] growth direction compared to the [001] orientation.

Keywords: Quantum Well, Confined Phonon, Semiconductor, Strain

INTRODUCTION

Strain in semiconductor physics is an important tool to alter the band structure and, consequently, modify the electronic and optical properties of materials. Strain can improve optoelectronic devices such as quantum well lasers. Strain can be caused by phonons or induced by a mismatched lattice in heterostructures, as well as by external application (Sun, et al., 2007).

In this work, we study the interaction of holes with confined phonons in a symmetric quantum well, $Al_{0.25}Ga_{0.75}As/GaAs/Al_{0.25}Ga_{0.75}As$, as well as the effect of stress on this interaction, considering both hydrostatic tensile and biaxial tensile strain (Ehrhardt. Et al., 2014). Moreover, we calculate scattering rates for two quantum well growth directions, [001] and [011], respectively. Finally, we study the effect of valence band anisotropy on scattering rates, concluding with a summary.

MATERIAL AND METHOD

Using the empirical band structure method, we calculate the valence band structure, employing Bloch states as basis functions for the Schrödinger equation. The 6×6 Luttinger-Kohn Hamiltonian is implemented via the k·p method, incorporating heavy holes, light holes, and split-off subbands while accounting for spin-orbit interaction (Willatzen, et al. , 2009; Boumaza et al. 2014)

Fermi's golden rule is used to determine the scattering rate of a hole from a state with in-plane wave vector k_i in subband i to all possible hole states in subband f with wave vector k_f . The rule can be expressed as (Ridley 1997; Boumaza et al., 2022)

$$\gamma_{i\to f} = \frac{2\pi}{\hbar}\int |M(f,i)|^2\,\delta\left(E_f \pm \hbar\omega - E_i\right)dN_f \qquad (1)$$

In this case, the number of final hole states is denoted by N_f , the initial and final hole state energies are E_i and E_f, respectively. The matrix element that connects the hole states engaged in the scattering process is denoted by $M(i, f)$. Equation (1) gives us

$$\gamma_{i\to f} = \frac{1}{2\pi\hbar}\frac{k_f}{\frac{\partial E_f}{\partial k}}\left(N_q + \frac{1}{2} \pm \frac{1}{2}\right)\Gamma_{if} \qquad (2)$$

Where Nq is the phonon occupation number and the function Γ_{if} is the overlap integral of the hole wave function and the phonon potential, which is given by

$$\Gamma_{if} = \sum_m \int \left|\int \langle f, k_f | e\Phi_m(z) | i, k_i \rangle dz\right|^2 d\theta \qquad (3)$$

Here, e represents the electron charge. Equation (3) is calculated numerically, taking into account the conservation of energy and momentum. The notation for the phonon potential is as follows (Mori et al., 1989).

$$\Phi_m(z) = A_C cos(\frac{m\pi z}{L}) \qquad m=1,3,5,.. \qquad (4)$$

$$\Phi_m(z) = A_C \sin(\frac{m\pi z}{L}) \qquad m=2,4,6,.. \qquad (5)$$

Here, L is the quantum well width, and AC is the normalization constant.

Table 1. Parameters used in this work (Boyer-Richard et al., 2011; Vurgaftman et al., 2001; Adachi 1985)

Parameter	Unit	GaAs	AlAs
γ_1		6.85	3.69
γ_2		2.1	0.79
γ_3		2.9	1.4
Δ	eV	0.341	0.28
E_g	eV	1.424	2.671
a_v	eV	-1.16	-2.47
$\hbar\omega_{LO}$	eV	0.03625	0.05009

RESULTS AND DISCUSSION

Figure 1 shows the structure of the valence band of heavy holes as a function of the wave vector *k* in the (xy) plane for a quantum well with a width of 30 Å in a $Al_{0.25}Ga_{0.75}As/GaAs/Al_{0.25}Ga_{0.75}As$ system, where we clearly observe an anisotropy that becomes more pronounced as we move away from the center of the Brillouin zone.

Figure 2 shows the scattering rates for intrasubband heavy hole absorption of confined phonon, both without strain and with hydrostatic tensile and biaxial tensile strain. We observe that the scattering rates decrease rapidly with increasing hole energy, from a maximum value of $0.57x10^{12}$ s^{-1} to $0.43x10^{12}$ s^{-1}. After this point, the variation with hole energy becomes weaker. The effect of strain induces a reduction in scattering rates, particularly for low-energy heavy holes. However, for tensile biaxial strain, the reduction is more significant, reaching up to 25 %.

Despite the dependence of scattering rates on the variation of the density of states and the integral overlap, the behavior of the scattering rate is greatly influenced by the variation in the overlap integral, as shown in Figure 3. When warping in the subband structure is fully taken into account, Figure 4 displays the intrasubband scattering rate due to the confined phonon as a function of the initial 2D wave vector, where we can clearly observe a strong anisotropy at high energies of heavy holes. This anisotropy originates from the anisotropy in the band structure of heavy holes.

In Figure 5, we calculate the intrasubband scattering rates for confined holes in two growth directions, [001] and [011]. Our results show an increase in scattering rates for the [011] direction, which is attributed to the higher density of states and the increased overlap integral.

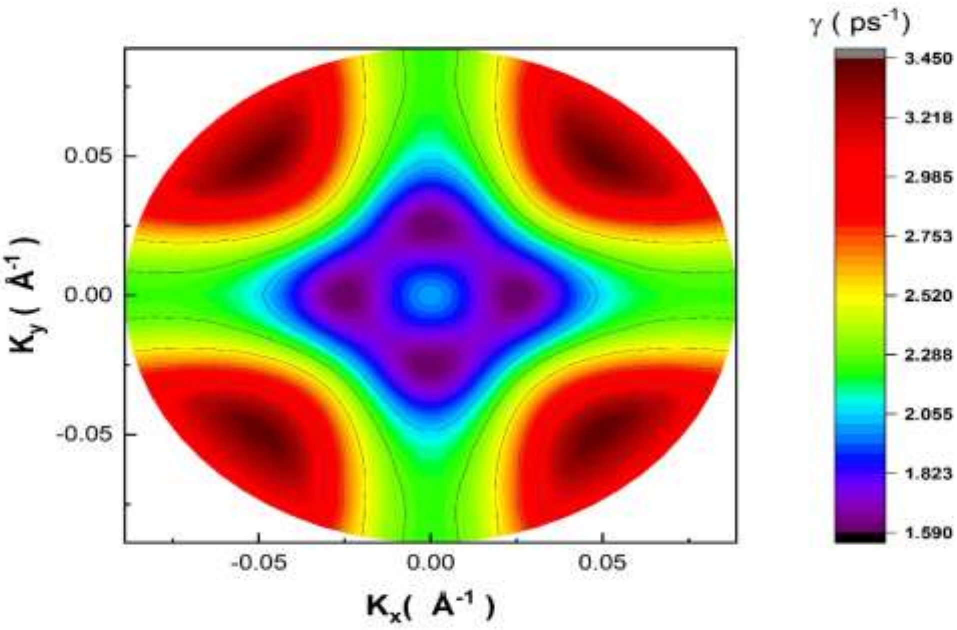

Figure 4. Intrasubband scattering rates with confined phonon absorption as a function of the hole wave vector k in polar coordinates and for L = 30 Å.

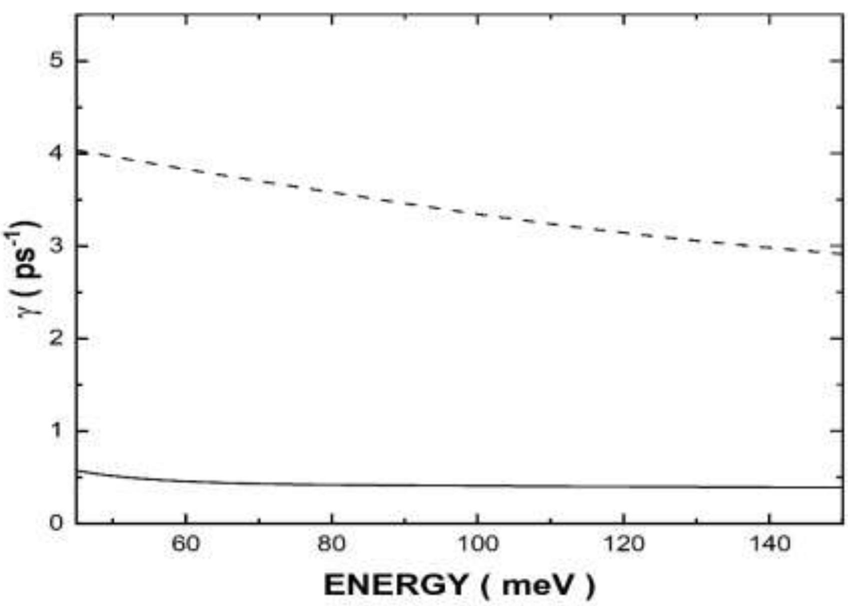

Figure 5. Intrasubband scattering rates as a function of hole energies, where the solid lines represent the case when the growth direction is [001], and the dashed lines correspond to the [011] growth direction.

CONCLUSIONS

This study provides a comprehensive analysis of hole-confined phonon scattering rates in $Al_{0.25}Ga_{0.75}As/GaAs/Al_{0.25}Ga_{0.75}As$ quantum wells, considering the effects of strain on these interactions. Our results demonstrate that tensile hydrostatic and biaxial strains significantly reduce scattering rates, especially at lower hole energies, contributing to enhanced hole mobilities. We also observe that the scattering rates increase along the [011] growth direction compared to the [001] orientation, primarily due to the increased density of states and the overlap integral. Additionally, the strong anisotropy in the valence band structure and its impact on scattering rates were highlighted. These findings contribute to a deeper understanding of strain effects on hole-phonon interactions in quantum wells, offering valuable insights for the design and optimization of advanced semiconductor devices.

ABSTRACT

One of the important complications of diabetes is diabetic foot infections accompanied by neuropathy and vascular problems. These infections, especially caused by resistant bacteria, are among the most important etiological causes of foot amputations. *Pseudomonas aeruginosa* is the most common cause of diabetic foot infections in our country. The widespread and multidrug resistance seen in this bacterium poses a global threat. In this study, the antibiotic resistance profile of 100 *Pseudomonas aeruginosa* strains isolated from diabetic foot infections was determined by E-test method. **Materials and Methods:** In our study, a total of 100 *Pseudomonas aeruginosa* strains isolated from diabetic foot infections were used. The susceptibilities of different antibiotics (piperacillin, piperacillin+tazobactam, ceftazidime, meropenem, ticarcillin+clavulanate, cefepime, cefpirome, aztreonam, imipinem, amikacin, ciprofloxacin and tigecycline) in *Pseudomonas aeruginosa* isolates were determined using the E-test method**. Results:** While two of the *Pseudomonas aeruginosa* strains isolated from diabetic foot infections were resistant to all the tested antibiotics, all the isolates except one of the isolate were found to be intermediate or resistant to at least one antibiotic. The most common resistance rate among *Pseudomonas aeruginosa* strains evaluated within the scope of our study was Ticarcillin-Clavulanate (60%), followed by Ciprofloxacin (48%), Aztreonam (45%), Piperacillin (30%), Piperacillin-Tazobactam (28%), Ceftazidime. (22%), Imipenem and Meropenem (15%), Amikacin (13%). The least resistance was found against Cefepime (4%). Since there is no breakpoint value in the CLSI data of tigecycline and cefpirome, the resistance rate could not be determined. **Discussion and Conclusion:** *Pseudomonas aeruginosa*, which has multidrug resistance, is being isolated at increasing rates from diabetic foot infections in our country. According to previous studies, although the resistance situation was generally similar, it was observed that sensitivity to carbapenems was higher and the resistance to cefepime was very low. Monitoring sensitivity to antibiotics according to isolation locations is important in directing empirical treatments.

INTRODUCTION

Diabetes is a significant public health issue, and the number of people affected by the disease is increasing daily (Jneid et al., 2017). Diabetes can lead to various complications such as kidney failure, heart attack, blindness, stroke, and lower extremity amputations. Diabetic foot ulcers are a major global health concern and are one of the most common conditions among diabetic patients. Diabetic foot ulcer is a primary reason for the hospitalization of diabetic patients. Approximately 25% of infected wounds do not heal, which can result in the amputation of the lower leg (Iraj et al., 2013).

Recent studies indicate that the causative agents of diabetic foot infections (DFIs) vary by country and geographic location (Hatipoğlu et al., 2014). In Europe, Gram-positive bacteria such as *Staphylococcus aureus* are predominantly isolated from diabetic foot ulcers. In temperate climate regions, including our country, as well as Asia and Africa, *Pseudomonas aeruginosa* is the most frequently encountered pathogen in these infections (Ertuğrul et al., 2017). For example, in a large case series study from India covering data from 1991 to 2008, Gram-negative agents accounted for 57.1% (with *P. aeruginosa* at 16.9%, being the most frequently detected agent), while Gram-positive agents were found at 40.6% (Ramakant et al., 2011). Similarly, a study from Kuwait reported a Gram-negative/positive ratio of 51%/32%, with *P. aeruginosa* at a high rate of 17.4% (Al Benwan et al., 2012). Studies conducted in our country also show that *P. aeruginosa* constitutes a high proportion of DFI agents, ranging from 15% to 20% (Ertuğrul et al., 2008; Ertuğrul et al., 2012; Ertuğrul et al., 2017). The most significant challenge in treating infections caused by this agent is antibiotic resistance. Another study from our country indicates that the treatment failure rate for DFIs caused by resistant agents is five times higher, amputation rates are increased, hospital stays are prolonged, and treatment costs are approximately twice as high compared to infections caused by susceptible agents (Ertuğrul et al., 2012).

As with most microorganisms, antibiotic resistance in *Pseudomonas aeruginosa* is increasing day by day. It is thought that inadequate infection control measures and inappropriate antibiotic use contribute to the rising antibiotic resistance rates in *Pseudomonas spp*.; this acquired antimicrobial resistance limits treatment options and complicates the management of infections. In the antimicrobial treatment of pseudomonal infections; aminoglycosides, antipseudomal cephalosporins, carbapenems, fluoroquinolones, beta-lactam/beta-lactamase inhibitors, monobactams, phosphonic acids, polymyxins are used (Magiorakos et al.,2012). Resistance of *P.aeruginosa* to antimicrobials may vary depending on time period, country, different geographical regions, hospitals and clinics of the same country (Avcıoğlu et al.2019, Çakmaklıoğulları ve Kuru, 2019, Shortridge et. al.,2019, Erdoğan et. al.,2021).

In this study, the antibiotic resistance profile of 100 Pseudomonas aeruginosa strains isolated from diabetic wound sites was examined according to CLSI criteria using the E-test method.

MATERIALS AND METHODS

Isolates Used:

A total of 100 *P. aeruginosa* isolates of diabetic foot ulcers origin from the collection of the Nazlı-Selim Eren Chronic Wound and Chronic Wound Infection Treatment Unit at Aydın Adnan Menderes University Hospital were used in the study.

E-Test Procedure:

P. aeruginosa isolates were cultured in Tryptic Soy Broth (TSB) and incubated at 37ºC for 18-24 hours. The density of the bacteria to be tested was adjusted to 0.5 McFarland. For this purpose, 100 µl from an overnight culture was suspended in 10 ml of 0.9% sterile saline solution (FTS), and the bacteria adjusted to a 0.5 McFarland density were spread on the surface of

Mueller-Hinton agar using a sterile swab. The plates were left to dry in an incubator at 37ºC for 10-15 minutes. Following this, E-test strips containing a specific antibiotic gradient (piperacillin, piperacillin + tazobactam, ceftazidime, meropenem, ticarcillin + clavulanic acid, cefepime, aztreonam, cefpirome, imipenem, amikacin, ciprofloxacin, and tigecycline) were placed on the agar surface with sterile forceps, with two different strips per plate. The plates were incubated at 37ºC for 18-24 hours. The next day, the Minimum Inhibitory Concentration (MIC) values were determined. The MIC value was considered the point where the inhibition ellipse intersected with the scale on the strip (Joyce et al., 1992).

RESULTS

E-test strips were used in determining the antibiotic sensitivities of *Pseudomonas aeruginosa* isolates in accordance with the manufacturer's instructions. MIC results of all tested antibiotics were obtained as examples shown in the picture (Figure 1). Critical values of antibiotics whose MIC values were determined by E-test according to CLSI 2023 are given in Table 1, and the E-test results performed with 100 *P. aeruginosa* are given in Table 2.

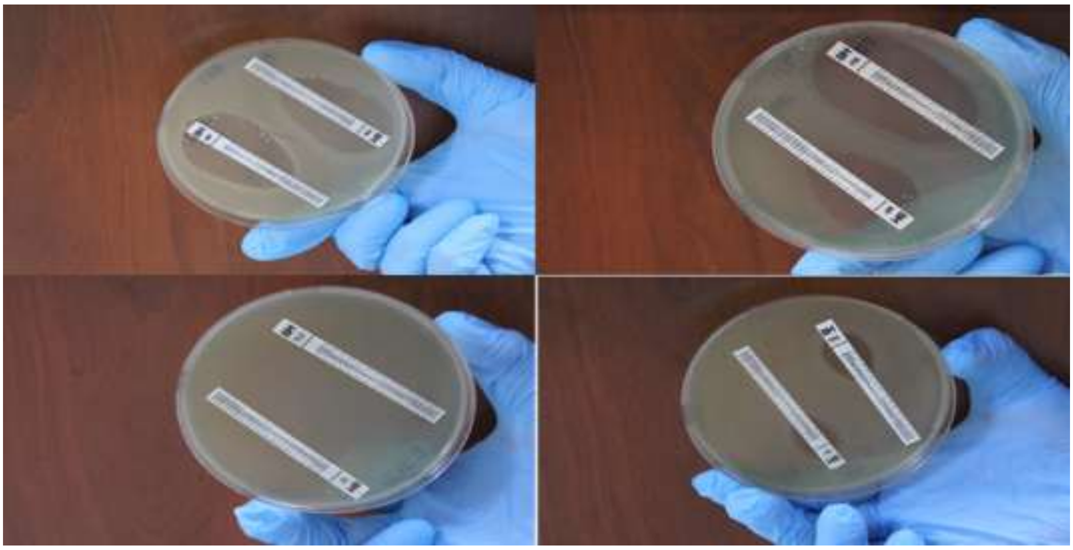

Figure 1. MIC values determined by E-test strips of different antibiotics

Table 1. Antibiotics used and their critical values (S: Sensitive, I: Intermediated R: Resistance)

Abbreviation	Antibiotic	Critical values
(TZ)	Ceftazidime	**S**≤8 **I**:16 **R**≥32
(AT)	Aztreonam	**S**≤8 **I**:16 **R**≥32
(MP)	Meropenem	**S**≤ 2 **I**:4 **R**≥8
(TGC)	Tigecycline	*There are no breakpoint values for P. aeruginosa.*
(TLC)	Ticarcillin + clavulanic acid	**S**≤16 **I**:32-64 **R**>64
(TPZ)	Piperacillin + tazobactam	**S**≤16 **I**:32-64 **R**>64
(AK)	Amikacin	**S**≤16 **I**:32 **R**≥64
(IMI)	Imipenem	**S**≤2 **I**:4 **R**≥8
(PP)	Piperacillin	**S**≤16 **I**:32-64 **R**>64
(PM)	Cefepime	**S**≤8 **I**:16 **R**≥32
(CL)	Ciprofloxacin	**S**≤0,5 **I**:1 **R**≥2
(CR)	Cefpirome	*There are no breakpoint values for P. aeruginosa..*

While two of the *Pseudomonas aeruginosa* strains isolated from diabetic foot infections were resistant to all tested antibiotics, all isolates except one were found to be intermediate or resistant to at least one antibiotic. The highest resistance rates among *P. aeruginosa* isolates were, Ticarcillin and Clavulanic acid (60%) respectively, It was determined as Ciprofloxacin (48%) and Aztreonam (45%). The highest sensitivity rates were found for the antibiotics cefepime (96%), meropenem (83%) and amikacin (81%), respectively (Table 3). Table 4 shows the MIC50, MIC90, range values of the antibiotics evaluated in our study (Table 4).

Table 3. Antibiotic sensitivity/resistance rates according to MIC results

DISCUSSION

Diabetes, with its rising prevalence and incidence, is considered as a global health problem, currently affecting around 171 million people worldwide and projected to reach 366 million by 2030 (Pedras et al.,2016). Diabetic patients have a higher rate of developing foot wound infections than non-diabetic individuals due to reasons such as deterioration of microvascular circulation, neuropathy, deterioration in immune capacity and anatomical changes. Therefore, one of the important complications of diabetes mellitus is diabetic foot ulcers (Abdulrazak et al.,2005). Diabetic neuropathy and peripheral arterial disease (PAD) play an important role in the development of foot ulcers complicated by infection and are also considered a strong indicator of amputation. Additionally, the high recurrence rate of diabetic foot ulcers, due to immune suppression and treatment costs ranging from $900 to $4,595 per episode in different countries, not only hampers the quality of life but also imposes a significant financial burden on patients (Mairghani et al.,2019).

It has been reported that over 50% of people with diabetic foot ulcers become infected by various types of microorganisms due to the damage to the protective skin layer. (Lipsky et al.,2012). Potential causative organisms of diabetic foot ulcers (DFUs) are believed to include *Staphylococcus, Streptococcus, Proteobacteria, Pseudomonas aeruginosa,* and coliform bacteria (Lipsky et al.,2015). Numerous studies have shown that *Staphylococcus aureus* is the predominant pathogen of diabetic foot ulcers in Western countries, while *Pseudomonas* is more common in Asian and African countries (Kwon and Armstrong,2018). Empiric antibiotic therapy is a crucial aspect of managing diabetic foot ulcers (DFUs). In recent years, the use of antimicrobial agents has become challenging due to the emergence of multi-drug resistant (MDR) bacteria, making the selection of appropriate antibiotics difficult. Antibiotic resistance rates have been increasing at an alarming rate in low- and middle-income countries. The rate of diabetic foot ulcers is increasing in developing countries due to inadequate knowledge about foot care among diabetic patients, an inefficient primary health care system, and low socio-economic status (Al-Rubeaan et al., 2015, Sharoni et al., 2017)

Aminoglycosides have a concentration-dependent bactericidal effect and are among the oldest antibiotics used in the treatment of infections caused by Gram-negative and some Gram-positive bacteria. While the amikacin resistance rate in *P. aeruginosa* varies between 0-29.5% in national studies, this rate is between 13.5-57% in international studies (-Kara et al.,2014, Du

et al.,2022, Öner et al.,2022, Makeri et al.,2023)-. The 13% resistance rate we obtained in our study is within the Türkiye and world average.
Ceftazidime, a third-generation cephalosporin, and cefepime, a fourth-generation cephalosporin, are antimicrobials with antipseudomal activity. In national studies, the cefepime resistance rate was reported as 24.2-42.3% and the ceftazidime resistance rate was reported as 11- 58,3 % -(Aykan and Çiftçi, 2015, Avcıoğlu et al.,2019, Erdoğan et al.,2021). When *the P. aeruginosa* resistance data of the SENTRY antimicrobial surveillance program, which includes the Asia-Pacific region, Europe, Latin America and North America, was evaluated between 1997 and 2016, the cefepime resistance rate was reported as 20.7% and the ceftazidime resistance rate was reported as 22.5% (Shortridge et al.,2021). In the meta-analysis study conducted by Du et al. in China, the ceftazidime resistance rate was 33.9%, the cefepime resistance rate was 20% (Du et al., 2022). In meta-analysis studies conducted in Africa, resistance rates were found to be 48.48% for ceftazidime and 22% for cefepime (Makeri et al., 2023, Wada et al., 2023). Cefpirome, a broad-spectrum cephalosporin tested in our study, does not have a breakpoint value for *Pseudomonas aeruginosa* in CLSI data. *Pseudomonas aeruginosa* can develop resistance mechanisms to various antibiotics, especially to broad-spectrum cephalosporins such as cefpirome.

Ciprofloxacin, a member of the fluoroquinolone class of antibiotics, has been used successfully to treat a wide range of bacterial infections since 1987 and is included in the World Health Organization's list of essential medicines (Rehman et al.2018). Ciprofloxacin allows oral or intravenously, and recently an inhalable treatment of many infections that require parenteral treatment due to its bioavailability, good penetration into tissue, and low side effects (Şenol,2002, Kłodzińska et al.,2016). In national studies, the ciprofloxacin resistance rate has been reported as 7-48% (Gönüllü et. al., 2003, Gültekin et al.,2004). According to the results of meta-analysis conducted in China, Africa and Iran, ciprofloxacin resistance in *Pseudomonas aeruginosa* was determined as 37.5%, 24.58% and 19.6%, respectively. (Shahrakh et al.,2021, Du et al.,2022, Wada et al.,2023). In our study, the ciprofloxacin resistance rate was found to be 48%. The resistance rate was higher than those mentioned studies.
The increasing level of carbapenem (imipenem/meropenem) resistance in *Pseudomonas aeruginosa* is an important public health problem. Resistance significantly limits treatment options. Significant differences are observed in the percentages of carbapenem-resistant *P. aeruginosa* across the WHO European Region. While resistance development of 5% or less was detected in only two of the countries where Central Asian and European Surveillance of Antimicrobial Resistance data were obtained, carbapenem resistance was found to be over 50% in 14 countries. Again, according to these data, the carbapenem resistance rate in Turkey is between 25-50% (WEB1, 2024). In our study, the carbapenem resistance rate was found to be 15% for both imipenem and meropenem, which showed lower percentage of resistance in comparison to other studies in Turkey and in many other countries.
Piperacillin extends the spectrum of activity of ampicillin to include most strains of *Pseudomonas aeruginosa*, *Enterobacteriaceae* (non-β-lactamase producing), many *Bacteroides* species, and *Escherichia faecalis*. (Pasifici,2023). In a study conducted in our country, the resistance rate to piperacillin was reported as 42.8%. According to the results of the meta-analysis conducted in China, piperacillin resistance rate was found to be 23,1% (Du et al., 2022).
The production of β-lactamases is the most common mechanism by which Gram-negative bacteria develop resistance to β-lactam antibiotics. A successful method to circumvent the threat of plasmid-encoded β-lactamases is to combine penicillin with inhibitors of these enzymes. Ticarcillin-clavulanate and piperacillin-tazobactam have the broadest spectra of activity, including effectiveness against *Pseudomonas aeruginosa*. Although ticarcillin-

clavulanate and piperacillin-tazobactam have similar spectra of activity, they exhibit many differences. (Lister, 2000). In various studies conducted in our country, the resistance rate to ticarcillin clavulanate and piperacillin tazobactam in *Pseudomonas aeruginosa* was found to be approximately 38%. According to the results of the meta-analysis conducted in China, piperacillin resistance rate was found to be 15,4% (Du et al., 2022) Piperacillin/tazobactam, which is formed when combined with the β-lactamase inhibitor tazobactam, has a much broader antibacterial spectrum (Pasifici,2023).) In a study covering Western Europe, the piperacillin-tazobactam resistance rate was found to be 25,2%. In the same study, this resistance rate was found to be 88.9% in *Pseudomonas aeruginosa* with multidrug resistance (Karlowsky et al., 2023). In our study, the ticarcillin clavulanate resistance rate was found to be 60% and the piperacillin/tazobactam resistance rate was 28%. In our study, the resistance rate developing in piperacillin tazobactam was at a level similar to the studies conducted in Turkey and the world, while the resistance rate in ticarcillin clavulanate was found to be quite high.

Aztreonam is the first monobactam drug to enter antibacterial therapy. It is completely synthetic. It has a relatively narrow spectrum. It can be used instead of aminoglycosides in Gram (-) bacterial infections. It is an antibiotic that has not been used in the treatment of *Pseudomonas aeruginosa* in our country in recent years. The *Pseudomonas aeruginosa* aztreonam resistance rate in our country was found to be 49.6%. In a study covering France, Germany, Italy, Portugal, Spain and the United Kingdom, aztreonam resistance was found to be 19.1%, and in the examination of *Pseudomonas* with multidrug resistance in the same countries, the resistance rate was found to be 73.1% (Karlowsky et al., 2023). In meta-analysis studies conducted in China, the aztreonam resistance rate in *Pseudomonas* was found to be 45.2% (Du et. al.,2022). The 45% resistance rate we found in our study is within the Türkiye average. It is thought that the reason why aztreonam resistance is so common may be due to other antibiotic groups that can induce the synthesis of plasmid-controlled extended-spectrum β-lactamase (ESBL) and chromosomal inducible β-lactamase (IBL) seen in *Pseudomonas* species and are in active use in treatment (Baddal et.al.,2021).

Studies have shown that the majority of *Pseudomonas aeruginosa* strains exhibit natural resistance to tigecycline, making its use as a monotherapy in treating *Pseudomonas* infections limited (Zhanel et al., 2008). In another study conducted by Biedenbach and colleagues, the activity of tigecycline against pathogens isolated from patients with skin infections was examined, and it was found that *Pseudomonas aeruginosa* isolates exhibited high resistance to tigecycline (Biedenbach et al.,2005). In our study, evaluation could not be performed for tigecycline against *Pseudomonas aeruginosa* isolates due to the absence of a breakpoint value in the CLSI data. Among the 100 isolates evaluated, a MIC value of 256 or higher was detected in 52 isolates.

The resistance rates we observed in our study are generally consistent with those found in other similar studies conducted in our country. However, contrary to the general situation, we found a higher sensitivity to carbapenems and a significantly lower resistance to cefepime. Differences in antibiotic susceptibility results among hospitals vary depending on antibiotic use policies, the clinic where the patients from whom the strains were isolated were hospitalized, and the patients' underlying diseases. The observed differences in antibiotic resistance patterns highlight the need for ongoing surveillance and collection of localized resistance data to guide effective treatment strategies.

The objective of this study was to chemically characterise and evaluate the antimicrobial activity of essential oils (EOs) from red oregano (*Origanum vulgare* L. subsp. *vulgare)* and thyme (*Thymus capitatus)* grown in the wild in Albania against foodborne pathogens and key spoilage microorganisms. The antimicrobial activity was tested against five bacteria (*Escherichia coli*, *Salmonella enteritidis*, *Pseudomonas aeruginosa*, *Micrococcus luteus, Stenotrophomonas maltophilia)* and one yeast *(Candida albicans),* all sourced from the American Type Collection Cultures (ATTC). Plants were collected in the wild in 2 different geographic locations in Albania, subsequently air-dried, and their essential oils were extracted by hydrodistillation method. EO yields (% v/w) were 0.25% for oregano and 0.75% for thyme. The chemical compositions of the EOs were determined using Gas Chromatography-Mass Spectrometry (GC-MS). GS-MS analysis revealed that red oregano and thyme main components were gremacrene D (15.2%), carvacrol (12%), β-Caryophyllene (13.8%) and carvacrol (76.74%), p-cymene (6.4%), γ-terpinene (4.5%) respectively. The antimicrobial activity was performed evaluating the Minimal Inhibitory Concentration (MIC). Thyme EO was effective against all tested microorganisms, whereas red oregano did not show activity against *Salmonella enteritidis and Pseudomonas aeruginosa.* Both EOs were equally effective against *Micrococcus luteus and Candida albicans*, however, thyme EO showed stronger activity towards *Escherichia coli* and *Stenotrophomonas maltophilia.*

Keywords: *Origanum vulgare* L. subsp. *vulgare, Thymus capitatus, antimicrobial, MIC*

1. INTRODUCTION

A major global concern facing humanity today is the resistance of microbes, mostly clinically significant bacteria, to antimicrobials, especially antibiotics essential to human treatment. (McEwen, S.A. et al. 2018). Pathogenic bacteria that represent a serious threat to human health, which spread also through food, include those from the Enterobacteriaceae and Pseudomonadaceae families which are immune to most of antibiotics recommended for treatment (Chaudhary, A.S. 2016). On the other hand, although oxidation is essential to the life cycle of cells, oxidative stress is the primary factor in the genesis of numerous human diseases, including cancer, Alzheimer's disease, atherosclerosis, arthritis, and cardiovascular disorders (Es-safi, I. et al. 2009). In the meantime, artificial antioxidants that stabilize food, including butylated hydroxytoluene (BHT), have been linked to cancer (Ito, N. 1986). One of the most attractive strategies in addressing these issues is the utilization of medicinal plants, many of which are well known for their antibacterial and antioxidant effects.

Essential oils (EOs) are becoming more and more popular because of their therapeutic qualities, which are postive for human health and because they are generally regarded as safe (GRAS) by the US Agency for Food and Drug Products (Fancello, F. 2016). The volatile secondary metabolites that constitute the EOs are naturally occurring compounds. Their complex mixture, which includes hydrocarbons of monoterpenes and sesquiterpenes, their oxygenated derivatives (such as alcohols, aldehydes, ketones, and ethers), several derivatives of phenyl propane, phenols, and various volatile organic compounds, is what gives them their distinctive aroma (Viuda-Martos, M. et al. 2010, Hammer, K.A. et al. 2010). It is known that EOs exhibit a variety of biological properties, including insecticidal, antifungal, and antibacterial properties (Celiktas, O.Y. et al. 2007). EOs of some medicinal plants have been shown in several studies to possess antioxidant and antibacterial properties (Es-safi, I. etal 2021, Bouhaddouda, R. et al. 2016, El Bouzidi, L. 2013). As a result, differences in the chemical composition can affect the antibacterial and antioxidant properties of EOs (Gachkar, L. et al. 2003, Hazzit, M. et al. 2009). Therefore, to validate the use of EOs as preservatives in the food, pharmaceutical, and cosmetic industries, analysis of their chemical composition and assessment of their biological activity are required.

Origanum vulgare L. subsp. *vulgare* and *Thymus capitatus* (L.) Hoffmanns. & Link, both belonging to the Lamiaceae family, are two medicinal and aromatic plants that are extensively found in the wild across Albania. These species are commonly utilized for both medicinal and culinary purposes.

Red oregano (*Origanum vulgare* L. subsp. *vulgare*), one of the two subspecies of *Origanum vulgare* L. present in Albania, alongside White oregano (*Origanum vulgare* L. subsp. *hirtum*), is particularly noteworthy. In northern Albania, where it grows naturally on mountain slopes, red oregano is locally referred to as "Mountain Tea." This subspecies is especially prevalent in the central and northern regions of the country, thriving in a range of environments at altitudes between 400 and 1300 meters above sea level (Kadiasi et al., 2024).

Compared to the *hirtum* subspecies, red oregano is characterized by a lower essential oil content, with concentrations reaching up to 2%. This lower essential oil content makes red oregano particularly suitable for use in herbal teas, which are traditionally employed in the treatment of colds and sore throats (Pieroni, 2008).

The genus *Thymus* is considered to be one of the eight most important genera in the Lamiaceae family comprising around 215 species, which are native to the Mediterranean basin (Pirbalouti, A.G. et al. 2015). Thyme’s medicinal and aromatic properties have made it one of the most popular genera in the world. Besides, its essential oils are widely used to flavour and preserve several food products. Several studies linked *Thymus* EO chemical composition to its antimicrobial and antioxidant activities (Ballester-Costa, C. et al. 2017). *T. capitatus*, known also as *Thymbra capitata* (L.) Cav. or *Satureja capitata* (L.) Cav., is an endemic Mediterranean plant (Figueiredo, A. et al. 2008). In Albania it is predominantly found in the south of the country were often it is referred locally as “wild oregano”, due to the similar with the commonly used white oregano, probably because both have the same main components, carvacrol and thymol (Ibraliu A. et al. 2011).

The present study aimed to investigate the chemical composition and the antimicrobial activity of the EOs of two endemic plant species growing in Albania: *Origanum vulgare* subsp. *vulgare* and *Thymus capitatus* (L.) Hoffmanns. & Link.

2. MATERIALS AND METHODS

2.1 Plant material

Both plants were collected in July 2023. *Origanum vulgare* subsp. *vulgare* population was collected at the Mountain of Balgjajt, near Kurdari village, Albania, at coordinates 41°35'27" latitude (N); 20°08'35" longitude (E). *Thymus capitatus* (L.) Hoffmanns. & Link. was collected above Livadh beach, Himara, Albania at coordinates 40°06'38"latitude (N) 19°43'50" longitude (E). The species identification for each population was carried out by, and also herbarium specimen vouchers were deposited in, the Genetics and Plant Breeding Laboratory, Agricultural University of Tirana, Albania. The plant materials were dried in a well–ventilated, shaded area, at room temperature about 25 °C and relative humidity around 50%.

2.2 EO extraction

The essential oils were extracted by hydrodistillation using a Clevenger apparatus. One hundred grams of dried plant material, including of flowers, stems, and leaves, were minced finely and put into a one-liter flask with half a liter of distilled water. The distillation process was carried out over a period of three hours, with a steady distillation rate of three milliliters per minute. The essential oil yield was calculated as a percentage of volume by weight (% v/w) relative to the dry weight of the plant material. The obtained EOs were stored at 4 °C prior to analysis.

2.3 Microbial strains

The bacterial and fungal ATCC strains (American type culture collection strain (ATCC) *Salmonella enteritidis* (ATCC:49223), *Escherichia coli* (ATCC:10535), *Pseudomonas aeruginosa* (ATCC:9027), *Stenotrophomonas maltophilia* (ATCC:13637). *Micrococcus luteus* (ATCC:10240), along with one fungal isolate *Candida albicans* (ATCC:10231)) were procured from Microbiologics , Inc., (Minnesota United States). 96-well plates were secured from Corning Inc. (New York, United States).

Blood agar medium and Muller Hinton Broth were procured from Remel Inc, (California, United States) ,0.5 Polymer McFarland Standard from Thermo Fisher Scientific (Massachusetts, United States) and Dimethylsulfoxide (DMSO) from Sigma-Aldrich (Missouri, United States).

2.4 Gas Chromatography-Mass Spectrometry

Gas Chromatography-Mass Spectrometry Essential oil analyses were performed on a Shimadzu GC-2010-GCMSQP2010 system operating at 70 eV. The temperature program was from 60 ^{o}C to 250 ^{o}C, at a rate of 5 ^{o}C/min. Helium was used as a carrier gas at a flow rate of 1.0 ml/min. Injection volume of each sample was 1 μL. Retention indices for all compounds were determined according to Van den Dool and Kratz, 1963, using n-alkanes as standards. The identification of the components was based on comparison of their mass spectra with those of

NIST21 and NIST107, Massada, 1976 and by comparison of their retention indices with literature data Adams, 2007. Component relative concentrations were calculated based on GC peak areas without using correction factors. Essential oils were often subjected to co-chromatography with authentic compounds (Fluka, Sigma).

2.5 Evaluation of antimicrobial activity by Micro-dilution Broth Experiment

Microbial strains and growth conditions: The Essential Oil (EO) antimicrobial activities were investigated against different clinical and food-borne pathogens using standard American type culture collection strain, five bacteria along with one fungal isolate. The bacterial and fungal ATCC strains were stored at 4°C and sub-cultured for the experimental setup. Prior to the inoculation of the strains with EOs, the microorganisms were grown at 28 or 37 °C (for fungus and for bacteria) for 18-20 h on blood agar medium.
Evaluation of MIC: The MIC (Minimum Inhibitory Concentration) of each EO was determined using a broth microdilution method in 96-well plate in accordance with the Clinical & Laboratory Standards Institute (CLSI) protocols (M100 Ed34, 2024). In brief, bacterial suspensions were adjusted to a final concentration of 10^5 CFU/mL cells standardized by 0.5 McFarland in Muller Hinton Broth (MHB) media. EO stock concentration of 100mg/ml was prepared by dissolving in DMSO. From this stock, a working concentration of 5mg/ml was prepared (in MHB media) to be used in plate susceptibility testing, ensuring DMSO conc. less than 5%. This resulted in EO's concentration range of 5mg/ml to 0.0097 mg/ml on the plate. One hundred microliters of bacterial suspension were finally added to each well. The plate setup included the 11^{th} column as the media control (negative control), and the 12th column containing bacteria and media (positive control). Additionally, rows D and E were designated for solvent controls, with row D with only EO (solvent control) and row E for DMSO (conc. used to dissolve EO) and bacteria served as DMSO control. The plates were incubated at 37 °C for 24 h. MIC was determined using Tecan I-control software (Infinite M Plex TECAN) to measure the OD (600nm) compared with positive control. Everything was kept constant for determining antifungal activity except incubation was done for 45-48h, with OD determined at 530nm. MIC was determined as the lowest concentration of EO that inhibited visible growth of the tested microorganism (Puškárová A et al. 2017).

3. RESULTS AND DISCUSSION

3.1 EO extraction

The essential oil of *Origanum vulgare* subsp. *vulgare* had a pale yellow color with a yield of 0.25% (v/w). This result is in line with another study of Albanian Red oregano where Kadiasi et al. (2024) reported that from 15 individuals from seven different red oregano accessions collected from various Albanian locations had an EO yield ranging from 0.05% to 1.3%. Similar results were reported for this species from other countries: 0.12% in serbia (Aćimović M. et al. 2020), 0-7-1.2% in Montenegro (Stešević, D. et al. 2018), 0.108% and 0.249% from Moldova (Vazirian, M. et al. 2014), 0.35 to 0.87% in Poland (Kosakowska, O. et al. 2018) and

0.08% in Türkiye (Sezik, E. et al. 1993). From this the population in study is positioned as with medium yield of EO.
The EO extracted from *Thymus* resulted in pale-yellow colour, with a yield of 0.21 % (v/w). The authors did not find any existing reports on the EO yield of *Thymus capitatus* from Albania. However, when compared with unpublished data, this particular population demonstrates a relatively low yield. In contrast, other populations of *T. capitatus* have been reported to yield approximately 1% EO.

3.1 Quantitative and qualitative analysis of the EO

GC-MS analysis of the *Origanum vulgare* subsp. *vulgare* EO (Fig. I) identified in total 20 different components, counting for 83% of the EO. The most abundant compounds in were gremacrene D (15.2%), β-Caryophyllene (13.8%), carvacrol (12%) and several other compounds like Eucalyptol, Terpinen-4-ol, γ-Eudesmol, p-Cymene, α-Farnesene ect (Table 1). This results are in line with other reports from Albania (Kadiasi, N. et al. 2018, Kadiasi, N. et al. 2024). Studies from other countries show a high variation of the main compounds where depending on environmental factors Sabinene, p-Cymene, 1,8-Cineole, γ -Terpinene, Linalool, Linalyl Acetate, Thymol, Carvacrol, α-Terpineol, β-Citronellol, Linalyl Acetate, Thymol, Carvacrol, β -Caryophyllene, Germacrene D, Caryophyllene Oxide interchange as principal components (Aćimović M. et al. 2020).

Table 1. Composition of the essential oil from *Origanum vulgare* L. subsp.*vulgare*

Compounds [a]	**AI [b]**	**%**	**ID [c]**
α-Pinene	935	0.6	AI, MS, Co-GC
Sabinene	976	2.1	AI, MS
α-Phellandrene	1007	0.8	AI, MS
α-Terpinene	1019	0.6	AI, MS
p-Cymene	1028	2.6	AI, MS, Co-GC
Eucalyptol	1034	9.1	AI, MS
γ-Terpinene	1062	1.2	AI, MS, Co-GC
Bornyl acetate	1075	1.2	AI, MS
Terpinen-4-ol	1186	8.2	AI, MS, Co-GC
Thymol	1298	0.7	AI, MS, Co-GC
Carvacrol	1309	**12.0**	AI, MS
β-Caryophyllene	1419	**13.8**	AI, MS, Co-GC
γ -Muurolene	1487	1.9	AI, MS, Co-GC
α-Farnesene	1489	2.6	AI, MS
Vividiflorol	1495	2.3	AI, MS
γ-Cadinene	1514	1.4	AI, MS
δ -Cadinene	1524	1.7	AI, MS
Germacene D	1587	**15.2**	AI, MS, Co-GC
Caryophyllene oxide	1589	1.5	AI, MS, Co-GC
γ-Eudesmol	1610	3.5	AI, MS
Total (%)		**83**	

[a]Compounds listed in order of elution from an HP-5 MS capillary column; [b]AI: Arithmetic indices as determined on a HP-5 MS capillary column using a homologous series of n-alkanes (C9-C23); [c]Identification method: AI=Arithmetic Index, MS=mass spectrum, Co-GC=Coinjection with authentic compound.

GC-MS analysis of the *Thymus capitatus* EO (Fig. 2) identified in total 18 different components, counting for 96.14% of the EO. The most abundant compounds in were carvacrol (76.74%), p-cymene (6.4%), γ-terpinene (4.5%). The results were in line with other reports where Ibraliu at al. (2011) reported 4 different populations of *T. capitatus* from Albania with a mean of 71.3% carvacrol, 6.6% p-cymene and 3.5% γ-terpinene (Table 2). Also other reports from the mediterranean area showed the same main compounds (Gitsopoulos T.K. et al. 2013; Tagnaout I. et al. 2022; Russo, M. et al 2013). This population can be classified as carvacrol chemotype (Ćavar Zeljković, S. et al. 2015).

[a]Compounds listed in order of elution from an HP-5 MS capillary column; [b]AI: Arithmetic indices as determined on a HP-5 MS capillary column using a homologous series of n-alkanes (C9-C23); [c]Identification method: AI=Arithmetic Index, MS=mass spectrum, Co-GC=Coinjection with authentic compound.

3.3 Antimicrobial activity

Table 3 shows the antibacterial activity of essential oils from *Origanum vulgare* L. subsp. *vulgare* and *Thymus capitatus* as Minimum Inhibitory Concentration. Red oregano EO did not show any activity against *Salmonella enteritidis, Pseudomonas aeruginosa,* at the maximum tested concentration (5 mg/ml). It inhibited the growth of *E. coli* at 5 mg/ml, *Stenotrophomonas maltophilia* at 2.5 mg/ml, *Micrococcus luteus* at 1.25, and was most effective against the fungal strain *Candida albicans* with a MIC of 0.32 mg/ml.

Meanwhile *Thymus capitatus* EO was in general much more effective against the tested strains, showing antimicrobial activity against all of them. The lower effect was on *Pseudomonas aeruginosa* with a MIC of 2.5 mg/ml, and the highest effect against *Stenotrophomonas maltophilia* (MIC=0.15 mg/ml). MICs for *E. coli*, *Salmonella enteritidis, Micrococcus luteus* and *Candida albicans* were 0.31, 0.625, 1.25 and 0.31 mg/ml respectively.

The weak antibacterial activity of *O. vulgare* subsp. *vulgare* EO could be attributed to low concentrations of bioactive compounds and their inability to exhibit activity (Aćimović M. et al. 2020). *Thymus capitatus* was much more effective because its main compound, carvacrol is well reported for its remarkable antimicrobial properties (Baser K.H. 2008).

To our knowledge this is the first report that shows the antibacterial activity of essential oil from *Origanum vulgare* L. subsp. *vulgare* and *Thymus capitatus* EOs on *S. maltophilia*.

Table 3. Minimum Inhibitory Concentration of essential oil from *Origanum vulgare L. subsp.vulgare* and *Thymus capitatus* EOs.

Microorganism	**Minimum Inhibitory Concentration**	
	Origanum vulgare L. subsp.vulgare EO	*Thymus capitatus EO*
E. coli ATCC 10535	5 mg/ml	0.31 mg/ml
S. enteritidis ATCC 49223	NO MIC	0.625 mg/ml
P. aeruginosa ATCC 9027	NO MIC	2.5 mg/ml
M. luteus ATCC 10240	1.25 mg/ml	1.25 mg/ml
S. maltophilia ATCC 13637	2.5 mg/ml	0.15 mg/ml
C. albicans ATCC 10231	0.31 mg/ml	0.31 mg/ml

4. CONCLUSIONS

The purpose of this study was to analyze the chemical composition and antibacterial properties of the essential oils (EOs) derived from two populations of *Origanum vulgare* L. subsp. *vulgare* and *Thymus capitatus*, both of which are extensively used for culinary and medicinal purposes and grow wild in Albania.

Our findings corroborate a limited number of previous reports on the primary constituents of the EOs from these plants collected in Albania. Notably, while both EOs exhibited comparable efficacy against *Candida albicans*, *Thymus capitatus* demonstrated superior antimicrobial activity.

In conclusion, as the demand for new, natural, and safe antimicrobial agents grows across various sectors, the examination of the chemical profile and evaluation of the antibacterial activity of these species indicates their potential as valuable sources of natural agents. The outcomes of this investigation suggest that *Thymus capitatus* essential oil, in particular, could be effectively applied in the development of functional foods and as a pharmaceutical ingredient to enhance well-being.

a

ABSTRACT

Mulberry is a berry known worldwide for its over 150 species, commonly represented by *Morus alba* L. (white mulberry), *Morus nigra* L. (black mulberry), and *Morus rubra* L. (red mulberry). The mulberry plant has a wide cultivation area, growing in both the northern hemisphere and tropical and subtropical climates. Mulberries are consumed in various forms depending on traditional methods, including fresh, dried, juice, concentrate, molasses, and fruit leather.
Mulberries offer numerous health benefits. They can used medicinally as anthelmintic, anti-anemic, anti-diabetic, odontalgic, expectorant, laxative, emetic, hypoglycemic, and for treating dysentery and oral lesions. Additionally, mulberry seed oil is rich in δ-tocopherol, providing high antioxidant capacity, and can be added to other edible vegetable oils to enhance nutritional value in dietary food products. The significant amounts of tocopherols and sterols in mulberry seed oil serve as antioxidants in diets and supplements. The essential oils in mulberry seeds are mainly composed of monoterpenes, alkanes, and aldehydes. With its L-limonene content, mulberry seeds are also utilized as by-products in the juice and wine industries. The oil content of mulberry seed is similar to that of high-oil sesame. Obtaining bioactive substances from seed waste in mulberry processing facilities is natural, low-cost, and straightforward. These mulberry wastes can be converted into high-value compounds for the production of food, pharmaceuticals, cosmetics, and other industrial products. This study aims to investigate the chemical properties of mulberry seed oil in detail and highlight its potential applications in the food and pharmaceutical industries. Mulberry seed oil is notable for its high antioxidant capacity and rich tocopherol content, making it valuable component in dietary supplements and food products. Furthermore, the using of mulberry seed oil in phytotherapeutic applications is significant for its health benefits. Converting the waste produced in mulberry seed processing facilities into bioactive substances at a low cost enables the production of high-value products for food, pharmaceuticals, cosmetics, and other industries. In this context, the study aims to demonstrate the multifaceted industrial and health potential of mulberry seed oil.

Keywords: Mulberry, mulberry seed, mulberry seed oil, fatty acids, tocopherols

INTRODUCTION

Mulberry, botanically classified under the *Morus* genus within the Moraceae family, comprises flowering plants. It is known that there are 68 species in the *Morus* genus, with hundreds of varieties under a single subspecies. However, most botanists generally recognize only 10 to 16 species (Das and Mukherjee, 1986; Liang et al., 2012). The most well-known mulberry species include *M. alba* L. (white mulberry), *M. nigra* L. (black mulberry), and *M. rubra* L. (red

mulberry). *M. alba* L. produces white and purple fruits that are sweet and low in acid, *M. nigra* L. yields very dark fruits that are sweet with a slight tartness, and *M. rubra* L. offers dark fruits that are sweet with a high dry matter content and low acidity (Özgen et al., 2009). Due to their tolerance to various climatic conditions, mulberry plants are widely cultivated in temperate, tropical, or subtropical regions across the Northern and Southern Hemispheres (Abbas et al., 2014; Abbas et al., 2016). The seeds are oval-shaped, with a micropillar and nearly flat surface, appearing in yellow or brown. The seed coat consists of two layers: a hard and brittle outer layer called the testa, and a thin, papery, slightly brownish inner layer known as the tegmen. Inside the seed coat, there is a kernel containing an outer endosperm and an inner embryo. The embryo comprises a primary axis (plumule and radicle) and two cotyledons. Mulberry seeds contain 25-35% yellow pigment oil (Barnes, 2008; Biasiolo, 2004; Vijayan et al., 2011).
Recent studies have increasingly focused on the oil content of various plant seeds due to their significance in nutrition and human health. Research has demonstrated that plant seeds are rich in fatty acids and possess strong antioxidant activity. Consequently, research on plant seed oils is rapidly expanding (Sbihi et al., 2018; Chrysochou et al., 2022). In this context, different plant seed oils, particularly those rich in linoleic acid and linolenic acid, are of particular interest due to their monounsaturated and polyunsaturated fatty acid content. Linoleic acid, an "essential fatty acid," cannot be synthesized by the human body and is considered an anti-carcinogenic substance. Symptoms of linoleic acid deficiency may include dry skin, hair loss, and poor wound healing (Argon et al., 2019). Due to these reasons, the oil content of seeds from various fruit types is of significant interest. For instance, mulberry seed oil is claimed to be a valuable dietary source rich in linoleic acid. However, it is relatively poor in linolenic acid. Low levels of linolenic acid are preferred in edible oils because high levels can lead to undesirable odours and tastes in the oil. Additionally, linolenic acid can easily oxidize due to its three double bonds in the hydrocarbon chain, reducing the stability and shelf life of oils rich in linolenic acid. Mulberry seed oil offers significant advantages in terms of human health and oil shelf life due to its low linolenic acid content (Yao et al., 2020). In this regard, several studies have been conducted on mulberry seed oils. Gecgel et al. (2011) examined the composition of black mulberry seed oil and identified that it is rich in fatty acids such as oleic acid, linoleic acid, palmitic acid, and linolenic acid. They reported that the average linoleic acid content exceeds 73%, indicating that mulberry seed oil is a good source of essential fatty acids. A subsequent study revealed that mulberry seed oil contains high levels of δ-tocopherol, thus possessing high antioxidant capacity (Yılmaz and Durmaz, 2015). Both Gecgel et al. (2011) and Yılmaz and Durmaz (2015) investigated the composition of mulberry seed oil and reported its strong antioxidant activity. Additionally, Chang et al. (2018) found that mulberry seed oils were preserved in an oil-water emulsion system using acid-hydrolyzed egg albumin. Li et al. (2020) prepared a lipid consisting of n-6/n-3 polyunsaturated fatty acids in a microfluidic enzyme reactor using mulberry seed oil and linolenic acid. However, they noted that further detailed research is needed to clarify the composition and properties of mulberry seed oils.
In a study conducted in China, various mulberry varieties (Nongsang 12, Nongsang 14, Qiangsang 1, Qiangsang 2, Fengtian, Guisang, and Dongsheng) were analyzed for their seeds' physical and biochemical properties. The study reported the total oil, phenolic and flavonoid acids, and antioxidant power of mulberry seeds, which were derived from 2,2-diphenyl-1-picrylhydrazyl (DPPH) radical scavenging activity. Dongsheng, Fengtian, and Guisang varieties exhibited the highest antioxidant activities (FRAP, DPPH), and it was suggested that these varieties could produce high-quality oil for health care or functional food components (Yao et al., 2020).
A study conducted in Korea examined the oil content, fatty acids, phytosterols, and tocopherol compositions of *Morus alba* and *Cudrania tricuspidata* seeds. The study also assessed the polyphenolic compounds and biological activities of defatted seed residues. The oil contents of

Morus alba and *Cudrania tricuspidata* seeds were found to be 29.36% and 16.69%, respectively, while the methanol (MeOH) extracts of defatted *Morus alba* and *Cudrania tricuspidata* seed residues were 5.10% and 6.22%, respectively. The compositions of the seed oils for these two species were 81.4% and 74.37% linoleic acid, 5.75% and 11.39% oleic acid, 8.40% and 10.18% palmitic acid, 3.52% and 3.0% stearic acid, and trace amounts of linolenic and arachidic acids. *Morus alba* seeds were noted for their higher phytosterol (507.59 mg/100 g oil), tocopherol (99.64 mg/100 g oil), and total flavonoid (106.50 mg/100 g seed) contents compared to *Cudrania tricuspidata* seeds, which had a higher total polyphenol content. The MeOH extract of *Morus alba* seed residues showed higher antioxidant, anti-diabetic, and anti-melanogenic activities compared to *Cudrania tricuspidata* seed residues. The main polyphenolic components in the MeOH extract of *Morus alba* seed residues were identified as trans-resveratrol (9.62 mg/100 g), quercetin (54.83 mg/100 g), and 4-prenylmoracin (48.70 mg/100 g). These results indicate that *Morus alba* seeds are a better source of essential nutrients with antioxidant, anti-diabetic, and anti-melanogenic activities compared to *Cudrania tricuspidata* seeds (Kim et al., 2010).

Gecgel et al. (2011) investigated the physicochemical properties of mulberry (*Morus nigra* L.) seeds and seed oil obtained from domestic black mulberry in 2008 and 2009. They found that the seeds contained 27.5-33% crude oil, 20.2-22.5% crude protein, 3.5-6% ash, 42.4-46.6% carbohydrates, and 112.2-152.0 mg of total phenolic compounds per 100 grams. Additionally, they noted that mulberry seeds contain 20 different fatty acids, with proportions ranging from 0.02% myristic acid (C14:0) to 78.7% linoleic acid (C18:2). Gas chromatography (GC) analysis of the methyl esters of fatty acids in *Morus nigra* seeds revealed linoleic acid (C18:2), followed by palmitic acid (C16:0), oleic acid (C18:1), and stearic acid (C18:0), which together constituted approximately 97% of the total fatty acids identified. According to this study, the high C18:2 content (average 73.7%) indicates that black mulberry seed oil is a significant source of the essential fatty acid linoleic acid. Conversely, *Morus nigra* seeds contained relatively lower amounts of linolenic acid (C18:3) (0.3-0.5%), and 0.17 to 0.20 mg of α-tocopherol per 100 grams of *Morus nigra* seed oil. Major sterols in *Morus nigra* seed oil included β-sitosterol, D5-avenasterol, D5,23-stigmastadienol, clerosterol, sitosterol, and D5,24-stigmastadienol. The study concluded that black mulberry seed oil could be a highly valuable dietary substance.

Yılmaz and Durmaz (2015) examined the oil contents of different mulberry seed varieties, analyzing radical scavenging capacity, tocopherol, and total phenolic content. They observed that the oil content of mulberry seeds varied between 1645 and 2587 mg/kg, with differing δ-tocopherol levels. The second most common tocopherol homolog was γ-tocopherol, found in concentrations ranging from 299 to 854 mg/kg. The oil was found to contain 2,2-diphenyl-1-picrylhydrazyl (DPPH) radical scavenging activity, with α-tocopherol equivalent (α-TE) ranging from 1013 to 1743 mg/kg, and very high antioxidant capacity in freeze-dried samples with 2,2′-azino-bis (3-ethylbenzothiazoline-6-sulfonic acid) (FD-ABTS) radical cation tests showing 2574 to 4522 mg α-TE/kg. The study concluded that mulberry seed oil has higher antioxidant capacity and total phenolic content compared to mulberry pomace oil, with linoleic acid being the predominant fatty acid (66-80%).

Overall, defatted mulberry seeds contain approximately 30% protein, with 28.69% of this being essential amino acids. Although there are some challenges in the development and use of plant proteins, defatted mulberry seed protein is considered to have significant untapped potential compared to other fruits (Yao et al., 2020). Therefore, defatted mulberry seed proteins are suggested as a viable raw material source for producing edible antioxidant peptides. Expanding the application areas of mulberry seed protein and increasing protein extraction efficiency are crucial. Traditional extraction methods have disadvantages such as low yield, time-consuming processes, low energy efficiency, high cost, and low peptide yield. In contrast, ultrasonic-

assisted extraction is a low-cost, high-efficiency, and environmentally friendly method often used to extract active components like essential oils, proteins, and bioactive compounds from animal and plant sources (Sicaire et al., 2016; Sanwal et al., 2022; Pan et al., 2022).
Additionally, a study conducted in Bangladesh analyzed the physicochemical properties, glycerides, lipids, and fatty acid composition of mulberry seed oil. It was observed that the oil from mulberry seeds is orange-yellow and contains 31.41% oil. The triglyceride content ranged from 90.08% to 91.05%, while diglycerides ranged from 3.25% to 4.10%, and monoglycerides from 1.47% to 2.05%. Saturated and unsaturated fatty acids in mulberry seed oil varied between 15.04% and 16.28%, and 74.29% and 75.86%, respectively. The oil was found to contain a high percentage of linoleic acid (74.29%), followed by palmitic acid (10.60%), stearic acid (5.61%), and a very small amount of myristic acid (0.07%) (Rahman et al., 2014).

USING OF MULBERRY SEEDS IN THE FOOD INDUSTRY

The oil extracted from mulberry seeds contains a high proportion of unsaturated fatty acids, making it suitable for use in food products. Particularly, its high oleic acid content provides health benefits and allows for its use in various food products, including as a cooking oil or in salad dressings and margarine. As a protein source, mulberry seeds are valuable due to their high protein content (approximately 25-40%). This protein content can be utilized in the food industry for high-protein dietary supplements, sports nutrition products, and various processed foods. Additionally, peptides derived from mulberry seeds can be used in functional food products. These peptides may exhibit antioxidant, antimicrobial, and other biological activities, making them suitable for use in health-beneficial functional food products. Furthermore, they can contribute to various food products through their flavouring and aroma-enhancing properties. Moreover, components derived from mulberry seeds can be used as food additives. For instance, mulberry seed extracts rich in polyphenols can be employed to extend the shelf life of food products and prevent oxidative deterioration. Mulberry seeds, with their high fibre content, can be used as a fibre supplement in food products. Fibre supports digestive health and can be added to various processed foods. The utilization of waste generated during the processing of mulberry seeds can enhance environmental sustainability. These wastes can be used as animal feed or for environmental applications such as composting. Mulberry seeds also have potential applications in various biotechnological processes. For example, some active components can be involved in the production of probiotic products and other food products that enhance biological activities. The potential of mulberry seeds in the food industry is significant not only in terms of nutritional value but also for its health benefits and environmental sustainability. Therefore, research and development efforts focused on mulberry seeds could offer innovative and valuable applications across various sectors of the food industry (Orhan et al., 2020; Merz et al., 2020; Gómez-Mejía et al., 2021; Sanwal et al., 2022).
Fresh foods, particularly meat products, produce ammonia and volatile gases during storage, causing pH changes (Zhang et al., 2019). This has led to a growing need for natural pH-sensitive pigments derived from plants in packaging materials due to the potential health hazards associated with synthetic chemical dyes (Wang et al., 2019). In this context, various sources of anthocyanins, such as black rice bran (Ge et al., 2020), carrots (Goodarzi et al., 2020), jambolan (*Syzygium cumini*) fruits (Merz et al., 2020), purple sweet potatoes (Chen et al., 2020), and hibiscus (roselle) (Zhang et al., 2019), are being explored for pH indicator-based materials for packaging to monitor and preserve food quality.
Mulberry pomace, which constitutes approximately 40% of the total fruit weight as a byproduct of mulberry juice processing, is a rich source of anthocyanins (Garg et al., 2019; Liu et al., 2019). Evaluating mulberry pomace extract as a film-forming component helps reduce food waste and contributes to the development of advanced functional natural food packaging

materials. Zhang et al. (2021) conducted a study using free and microencapsulated mulberry pomace extracts combined with psyllium seed gum to develop active and pH-sensitive food packaging films. They proposed that natural pH indicator-based smart packaging films, derived from enriched psyllium seed gum and microencapsulated mulberry pomace extracts, could be healthier and more promising alternatives compared to synthetic films.

Lee et al. (2011) examined the antioxidant activities and contents of polyphenolic compounds isolated from the methanolic extracts of defatted mulberry seeds from three mulberry varieties ('Daesungppong', 'Iksuppong', and 'Cheongilppong') using a range of column chromatographic methods, including silica gel, Sephadex LH-20, and ODS-A. They found that eleven polyphenolic compounds exhibited antioxidant activities, with rutin (IC50 = 20.2 μM), isorhamnetin (IC50 = 22.5 μM), quercetin (IC50 = 24.6 μM), quercetin (IC50 = 27.8 μM), (+)-dihydroquercetin (IC50 = 28.9 μM), and chlorogenic acid (IC50 = 30.6 μM) showing stronger antioxidant activities compared to L-ascorbic acid (IC50 = 31.5 μM) and α-tocopherol (IC50 = 52.3 μM). However, protocatechuic acid (IC50 = 68.2 μM) showed lower activity, while (+)-dihydrokaempferol (IC50 = 33.8 μM), trans-resveratrol (IC50 = 36.2 μM), morin (IC50 = 47.6 μM), and 4-prenyl morin (IC50 = 48.2 μM) exhibited moderate antioxidant activities. The levels of these eleven polyphenolic compounds in mulberry seeds varied among the three varieties: rutin (31.1–60.0 mg/100 g) > quercetin (7.2–34.2 mg/100 g) > (+)-dihydroquercetin (13.2–33.1 mg/100 g) > quercetin (15.8–19.5 mg/100 g) > 4-prenylmorin (10.5–43.3 mg/100 g) > isorhamnetin (5.8–15.4 mg/100 g) > chlorogenic acid (0.0–15.3 mg/100 g) > morin (4.7–7.2 mg/100 g) > procatechuic acid (0.0–11.6 mg/100 g) > (+)-dihydrokaempferol and trans-resveratrol (<0.1 mg/100 g). The 'Daesungppong' variety showed higher flavonoid content, particularly rutin and quercetin derivatives, while the 'Iksuppong' variety had the highest levels of phenolic acids and morin derivatives. The 'Cheongilppong' variety contained fewer polyphenolic compounds compared to the other two varieties. These results suggest that mulberry seeds with antioxidant polyphenolic compounds could be used as potential anti-diabetic, anti-hypertensive, and anti-aging agents in functional foods and cosmetics.

Furthermore, due to its high oleic acid content, mulberry seed oil is suggested for use in the industry for products such as soap, cosmetics, body massage oil, and dye preparation, as well as for artificial feed production for poultry, fish, and cattle (Gecgel et al., 2011). Additionally, the utilization of seed waste from wine and mulberry processing offers a simple, natural, and cost-effective alternative for obtaining bioactive compounds, which can be converted into high-value products for food, pharmaceutical, cosmetic, and other industries. The total market value of products derived from fruit and grape food waste in Europe and North America is expected to exceed 4 billion dollars by 2020 (Ghate et al., 2019).

Moreover, the health benefits of mulberry and grape seed wastes, particularly their antioxidant-rich components, and their potential to support a circular economy through waste valorization are crucial aspects of sustainable strategies to reduce waste in the current food industry. The potential use of mulberry extracts, for instance, as preservatives to extend the shelf life of food products or as health agents in the pharmaceutical sector, underscores the importance of effectively and sustainably utilizing these by-products. This approach aids in making mulberry juice and wine production more cost-effective and sustainable while generating strategies for the recovery of valuable compounds from these residues (Gómez-Mejía et al., 2021).

China, one of the leading producers of mulberries, has a total annual mulberry production of approximately 6.5 million tons, with this amount expected to increase further. Additionally, in China, mulberry seeds are used in large quantities at low cost as by-products in the juice and wine industries. Mulberry seeds have high nutritional value (Oh et al., 2013). The oil content of mulberry seeds is 30-40%, which is comparable to that of high-oil crops like sesame. Furthermore, mulberry seed oil is dominated by unsaturated fatty acids (UFAs), constituting 87.5% of total fatty acids, with linoleic acid (LA) making up approximately 80% of this proportion, which is higher than that of general edible oils. However, the content of alpha-linolenic acid (ALA) in mulberry seed oil is relatively low (McCusker and Grant-Kels, 2010). The need to explore effective energy-saving technologies due to resource and energy scarcity highlights the urgency of finding new ways to utilize mulberry seeds efficiently (Lonnie et al., 2020).

SIGNIFICANT OF MULBERRY SEEDS FOR HUMAN HEALTH

Studies indicate that mulberry seeds contain high levels of antioxidant components, particularly polyphenols and flavonoids. These compounds are known to combat free radicals, reduce oxidative stress, and slow down cellular ageing. Antioxidants play a significant role in reducing the risk of chronic diseases such as cardiovascular diseases and cancer. In this context, mulberry seeds contain healthy fatty acids, especially oleic acid, which supports cardiovascular health. Unsaturated fatty acids help regulate cholesterol levels, lower blood pressure and reduce the risk of heart diseases. Components in mulberry seeds also exhibit anti-inflammatory properties. Chronic inflammation is associated with numerous health issues, and thus mulberry seeds are reported to improve overall health by reducing inflammation. The high fibre content of mulberry seeds supports the digestive system, with fibre regulating bowel movements, preventing constipation, and enhancing digestive health. Mulberry seeds, as a low glycemic index food, may assist in regulating blood sugar levels. Additionally, some studies have indicated that mulberry seed extracts show protective effects against diabetes. Mulberry seeds contain vitamins (e.g., vitamin E) and minerals (e.g., zinc) that support skin health. These nutrients can improve skin elasticity, reduce signs of ageing, and address skin issues. Vitamins and minerals in mulberry seeds contribute to a strengthened immune system, with components such as vitamin C and zinc enhancing immune responses and protecting the body against infections. Due to its high fibre content, mulberry seeds may increase satiety and aid in weight management. Fibre slows digestion and helps maintain a feeling of fullness for longer periods. Mulberry seeds also contain omega-3 fatty acids and antioxidants that support brain health, potentially improving brain function and reducing the risk of neurological diseases. Due to these health benefits, mulberry seeds are a valuable addition to the diet but should be consumed as part of a balanced diet with a variety of foods to achieve the best nutritional outcomes (Kadam et al. 2019; Yao et al. 2020; Gómez-Mejía et al. 2021; Rahman and Islam 2021; Maqsood et al. 2022).

Mulberry seed oil is obtained by pressing the seeds. Research indicates that over 70% of the oil content in mulberry seeds is composed of linoleic acid. Since linoleic acid is highly beneficial for human health and can be used as a potential functional lipid source, its preservation is crucial. However, due to the high levels of polyunsaturated fatty acids in mulberry seed oil, it is prone to oxidation. To prevent this, researchers have explored the use of acidolysis as an alternative method for effective emulsification and antioxidant purposes. This method involves using moderately asidolized egg albumin, which has been reported to enhance protein activity. However, enzymatic hydrolysis, although a method for increasing target protein activity, is limited by the cost, activity, and stability of the enzymes used (Chang et al. 2018).

Lectins play a role as recognition molecules in many biological processes, including the regulation of glycoprotein intracellular trafficking, the attachment of infectious agents to host cells, the recruitment of leukocytes to inflamed areas, metastasis, and cell interactions in the immune system. Understanding how lectins bind to carbohydrates at the molecular level could facilitate the design and production of drugs for combating infections, inflammation, and cancer (Harmankaya et al. 2014). In this context, lectins purified from mulberry seeds, despite similarities to sugars in content, differ significantly in terms of molecular mass, subunit structure, neutral sugar content, and sugar composition compared to most lectins purified from other sources. Mulberry seed lectins have been found to exhibit toxic properties similar to those of lectins extracted from *Abrus precatorius*, *Ricinus communis*, and *mistletoe* (Yeasmin et al. 2001). Consequently, research is ongoing into their potential use in the development of carbohydrate-binding and anti-cancer drugs.

Lectins isolated from mulberry seeds using ConA Sepharose affinity chromatography were purified to obtain a mannose/glucose-specific lectin. This lectin was found to be monomeric, with a molecular weight of 22,000 as determined by SDS-PAGE. The lectin obtained from mulberry seeds is a glycoprotein with a neutral sugar content of 28.57%, identified as mannose and glucose. The lectin agglutinated rat red blood cells, and D-mannose and D-glucose were found to be inhibitors in hapten inhibition tests. Additionally, the lectin exhibited cytotoxic effects in the saltwater shrimp lethality bioassay, with N-terminal sequences identified up to residue 45, excluding positions 21, 39, 42, and 44. It is noted that the production of monomeric mannose-specific lectins from mulberry seeds is significant due to the carbohydrate (38%), fat (32%), and protein (15%) content, highlighting their importance as a source for lectin production (Absar et al. 2005).

Influenza viruses have become a significant infectious disease in recent years, causing seasonal outbreaks and pandemics, which pose severe threats to human health and the global economy. Alongside vaccines, various strategies are employed to combat this pathogen, with recent studies highlighting plant-derived anti-influenza components. Among these components are polyphenols, such as quercetin-3-gallate, cardiotonic glycosides from *Adenium obesum*, teaflavin derivatives, catechins, resveratrol, chlorogenic acid, and dendrobin (Thapa et al. 2012; Li et al. 2017). *Morus alba*, belonging to the *Moraceae* family, contains 1-deoxynojirimycin, which has antiviral effects against hepatitis B and C viruses (Jacob, et al. 2007). Research has indicated that *Morus alba* fruit juice and seeds possess antiviral properties against foodborne viral analogues (Oh et al. 2013; Lee et al. 2014). However, the antiviral activities of *Morus alba* fruit juice and seeds against influenza viruses have not been previously investigated. Studies have explored the antiviral effects of *Morus alba* fruit juice and seeds against influenza virus strains A/Brisbane/59/2007(H1N1) (BR59), pandemic A/Korea/01/2009(H1N1) (KR01), A/Brisbane/10/2007(H3N2) (BR10), and B/Florida/4/2006 (FL04). *Morus alba* fruit juice showed dose-dependent significant antiviral effects against BR59, KR01, and FL04 strains and exhibited noteworthy antioxidant activity (Kim and Chung, 2018). *Morus alba* juice demonstrated 0.2 log inhibitory effects against BR59 and KR01 at a 1% concentration, and 0.8 log inhibitory effects against FL04, a type B virus, at the same concentration. At 2% and 4% concentrations, it showed over 1.3 log inhibition against FL04, while displaying 0.5 and 0.4 log inhibition against BR59 and KR01, respectively, at 4% concentration. For *Morus alba* seeds, 0-0.4 log inhibition was observed at 50 μg/mL and 0.2-0.6 log inhibition at 100 μg/mL against BR59, KR01, BR10, and FL04. Particularly, *Morus alba* juice exhibited strong inhibitory effects against FL04 with 1.1 and 1.3 log reductions at 2% and 4% concentrations, respectively, whereas *Morus alba* seeds showed no antiviral activity against influenza viruses under similar treatment conditions (Kim and Chung, 2018).

Numerous studies have investigated the potential applications of mulberry seed extract in both food and health contexts. Noroviruses are among the most common causes of foodborne viral gastroenteritis, responsible for approximately 90% of non-bacterial outbreaks globally. The antiviral effects of mulberry seed extract (MAS) against foodborne viral analogues, namely feline calicivirus-F9 (FCV-F9) and murine norovirus-1 (MNV-1), were assessed using plaque assays and reverse transcription polymerase chain reaction (RT-PCR). Polyphenol compound analysis conducted via liquid chromatography-mass spectrometry identified caffeic acid, 3,4-dihydroxybenzoic acid, rutin, and cyanidin-3-rutinoside as the primary components of MAS, in decreasing order of abundance. The fraction with a molecular weight below 1 kDa (MAS-F1), except for caffeic acid, was found to have a similar but minor composition. When FCV-

F9 and MNV-1 were added to cells and simultaneously incubated with MAS or MAS-F1, the maximum antiviral effect was achieved in studies conducted on rats. MAS-F1 also showed a dose-dependent significant reduction in the expression of MNV-1 or FCV-F9 polymerase genes, with cyanidin-3-rutinoside found to be effective in reducing MNV-1 polymerase gene expression among the polyphenols. MAS or MAS-F1 inhibited viral infection on foodborne viral analogues, demonstrating effectiveness at the initial stage of viral replication. Therefore, mulberry seed extract has been reported as a potential candidate for antiviral food substances and for its anti-noroviral activity (Oh et al., 2013).

Grape and mulberry extracts are known to have high content of organic acids, particularly oxalic and quinic acids, whereas mulberry seeds are richer in tocopherols, primarily γ-tocopherol. Phenolic compounds are predominant in grape seed residues, mostly existing as catechin trimers and dimers. These phenolic compounds have also been detected in lower concentrations in mulberry seeds, indicating that both types of waste are readily available sources of catechins and their conjugates. Additionally, mulberry seeds contain significant amounts of ellagic acid derivatives, which are likely to play a crucial role in inhibiting lipid peroxides and hydroperoxides and in antimicrobial activity. Regarding bioactivities, antioxidant activity tests have shown that mulberry seed extract is more effective in inhibiting the formation of thiobarbituric acid reactive substances (TBARS) and erythrocyte membrane hemolysis. Studies have also identified similar antimicrobial activity in grape and mulberry extracts, with effectiveness against methicillin-resistant *Staphylococcus aureus* (MRSA). Furthermore, no cytotoxic effects were observed against tumour and normal cells at a concentration of 400 µg/mL, demonstrating that these extracts are not effective for cytotoxic purposes (Gómez-Mejía et al., 2021). Among the primary bioactive compounds of mulberry are alkaloids, flavonoids, polyphenols, and polysaccharides (Hao et al., 2022). Among polyhydroxylated alkaloids, 18 alkaloid derivatives isolated from mulberries have been identified, with over 72% of the total alkaloid content being 1-deoxynojirimycin (DNJ) (Asano et al., 2001). 1-Deoxynojirimycin (DNJ) is a polyhydroxy piperidine alkaloid with a D-glucose-like structure that competitively inhibits α-glucosidase activity (Butt et al., 2008) and exhibits anti-diabetic (Kimura et al., 2007), anti-viral (Warfield et al., 2017), and anti-tumour (Lou et al., 2010) effects. In nature, DNJ is predominantly found in the mulberry plant and, though at very low concentrations, also in *Streptomyces* and some *Bacillus* species. The yield of DNJ isolated from dried mulberry material has been reported as 1.650 mg/g from roots, 0.840 mg/g from fruits, 0.690 mg/g from leaves (Asano et al., 2001), and 6.015 mg/g from seeds (Yin et al., 2018). However, the DNJ content in mulberries varies not only between different tissues but also among different varieties (Lou et al., 2010).

Mulberry (*Morus alba* L.) plants are rich in 1-deoxynojirimycin (DNJ), a potential α-glucosidase inhibitor with various physiological activities (Hao et al., 2022). Compared to other tissues, *Morus alba* L. seeds have the highest content of 1-deoxynojirimycin; however, the biosynthesis mechanisms of DNJ remain unclear. Xin et al. (2024), conducted a study on DNJ biosynthesis in seeds from 27 mulberry varieties and found that variety MS02 had the highest DNJ level (22.28 mg/g), while variety MS15 had the lowest DNJ level (0.37 mg/g). Their study identified four key enzymes involved in DNJ biosynthesis: polyphenol oxidase, tyrosine aminotransferase, aromatic-L-amino-acid decarboxylase, and tropinone reductase. They concluded that DNJ biosynthesis in mulberry seeds occurs through the upregulation of these enzymes. The findings from these studies are crucial for further research on the biosynthesis of this important medicinal compound.

Mulberry seeds contain significant amounts of protein (25% to 40% fat) and essential amino acids (28.69% of total amino acids). Enhancing the bioavailability of these proteins could reveal the economic value of mulberry seeds. Nutritionists are concerned about the quality and functionality of protein-rich plants and are striving to extract proteins from these plants to increase their potential applications (Kumar et al., 2021; Lonnie et al., 2020). Bian et al. (2022), conducted a study on the production of biologically active sweet-flavoured peptides from mulberry seed protein using multifrequency countercurrent ultrasonic technology. They demonstrated that the protein yield from mulberry seeds is high and that the multifrequency ultrasonic method is an effective way to prepare sweet-flavoured peptides from mulberry seed meal. The study also suggested that these peptides could be good candidates for use as natural flavour enhancers in functional food products due to their activity and their inhibitory effects on the growth of HepG2 cells in vitro. However, the relationship between the biological activities and flavour characteristics of these peptides is not yet fully understood, indicating that further research on mulberry seed peptides is necessary.

CONCLUSION AND RECOMMENDATIONS

Mulberry seeds, which are rich in protein (25-40%) and contain high levels of essential amino acids, have significant potential for use in the food industry. The oil derived from mulberry seeds is also notable for its high content of unsaturated fatty acids (UFAs), particularly oleic acid, making it beneficial for health and suitable for use in cooking oils, salad dressings, and margarine. Additionally, mulberry seeds are a valuable source of peptides with antioxidant, antimicrobial, and other biological activities, which can be utilized in functional food products and as natural flavor enhancers. The seeds are also high in polyphenols, which can extend the shelf life of food products and prevent oxidative spoilage. Furthermore, mulberry seeds contain dietary fibre that supports digestive health and can be used as a supplement in processed foods. The processing of mulberry seed waste for use in animal feed or compost contributes to environmental sustainability. Overall, mulberry seeds have significant potential in various biotechnological processes, including the production of probiotic products and other biologically active food items, highlighting their importance not only for their nutritional value but also for their health benefits and environmental impact.

In this study, it is recommended that a more comprehensive analysis of the phytochemical components of mulberry seed oil be conducted. Specifically, comparing the phytochemical profiles of oils obtained from various *Morus* spp. could aid in identifying components that might optimize specific health benefits. Further detailed research is needed to explore the potential applications of mulberry seed oil in the food industry. Notably, studies should continue on its use as a food additive, its potential as a natural preservative, and its impact on flavour and texture improvement in different food products. Clinical trials are required to evaluate the effects of mulberry seed oil on human health. Research involving human subjects is crucial for validating the antioxidant, anti-inflammatory, and other health benefits of this oil. Additionally, it is important to investigate how to utilize the waste generated during the production of mulberry seed oil and how these wastes can contribute to environmental sustainability. Studies could focus on the use of waste materials in composting or as animal feed. The development of new technologies and methods for extracting and processing mulberry seed oil is recommended. Specifically, the advancement of cost-effective and energy-efficient methods could enhance the widespread applicability of this oil. Educating consumers about the health benefits and potential applications of mulberry seed oil in the food industry could facilitate broader adoption. These recommendations could provide a significant foundation for better understanding and optimizing the potential of mulberry seed oil in both the health and food industries.

ABSTRACT

Environmental pollution is a significant global issue, especially in areas exposed to metal pollution. Remediation techniques for such areas often incur high costs. An alternative and highly effective method involves using biological molecules rather than physical and chemical methods to remove metals from industrial waste. Applications of biological molecules for metal removal include biosorption, adsorption, and phytoremediation methods. Biosorption is the process of metal ion uptake from aqueous environments by biomass. The dissolved substances on the surface of the biosorbent biomass must pass through the film of its surrounding liquid solvent. Optimal conditions are required for the biosorption process, including factors such as the type of metal ion, the amount and type of biomass, concentration, temperature, and pH of the solution, all of which influence the biosorption method.

Keywords: Remediation, Biological molecules, Biosorption, Biomass

INTRODUCTION

As technological advancements continue to evolve, so do the requirements for raw materials. Strategic raw materials (SRMs), such as those found in smartphones, electric vehicles, magnets, and low-carbon technologies like wind turbines and solar panels, play a crucial role in modern technologies and economic development (Ferro and Bonollo, 2019). The shift towards green technologies, crucial for attaining net-zero emissions, heavily relies on strategically important raw materials (SRMs) integrated into these technologies. Nations prioritizing this transition are embracing circular economy strategies to manage energy consumption and enhance recycling rates of SRMs (Alliance, 2021). In Turkey, the proliferation of policy frameworks for renewable and low-carbon technologies indicates a steep rise in demand and criticality of SRMs (Balcilar et al., 2023). The heightened demand for these materials raises issues such as supply risk and economic significance (Martins and Castro, 2019).

The term "criticality" refers to the combination of high economic importance and a high risk of supply disruption (Buijs et al., 2012). Assessing the raw materials on which countries heavily depend, particularly those with limited reserves, is essential for development.

The demand for strategic raw materials (SRMs) continues to rise with the increasing activities in advanced technology sectors. However, there are concerns about potential supply interruptions for certain raw materials like silver, antimony, and gold in the coming years (Zanoletti et al., 2021).

SRMs hold a pivotal position across diverse industries and national economies owing to their economic significance, indispensable applications, innovative capabilities, and vulnerability in terms of supply. They are integral components in sectors ranging from electronics and renewable energy systems to defense equipment, material recycling, CO2 capture and utilization, sustainable biomaterials, and agricultural production.

Metals such as lithium, cobalt, manganese, nickel, aluminum, and copper have gained considerable attention for their essential roles in enabling cleaner energy technologies and sustainable practices (Han et al., 2023). Biosorption, an often overlooked method in wastewater treatment, offers a cost-effective approach for removing strategic raw materials (SRMs) from wastewater. This method requires less processing cost, energy, and chemicals, and it also boasts shorter processing times compared to traditional techniques (Olawale, 2019). Biosorption involves the use of living or non-living biomass to effectively remove contaminants from wastewater.

Indeed, biosorption is a rapid and reversible process in which ions from aqueous solutions bind to various functional groups present on the surface of biomass. This mechanism allows for efficient removal of contaminants from water, making biosorption an effective technique in wastewater treatment and environmental remediation processes. Unlike some other methods, biosorption doesn't depend on cellular metabolism and can be effective for removing various types of metals (Davis et al., 2003). Environmental sustainability, cost-effectiveness, and abundance of biomass have indeed made biosorption an attractive option for various applications. This method offers a promising approach for removing contaminants from aqueous solutions while minimizing costs and environmental impact, making it a valuable tool in wastewater treatment and pollution remediation efforts (Lee and Park, 2012).

According to Ibrahim et al., (2012), Various biomass sources, including byproducts from industries like rice, wheat, corn, and wood, as well as living organisms such as microorganisms have been considered suitable biosorbent materials (Ibrahim et al., 2018). Biosorption processes typically involve ion exchange, microprecipitation events, complexation and adsorption, are fast and reversible.

Overall, biosorption is recognized as a cost-effective biotechnological method for treating low-concentration, high-volume wastewater containing metals, utilizing biomaterials like bacteria, crab shells, fungi, and algae. It involves the accumulation of biological and waste materials in aqueous solutions on or inside the cell surface.

Biosorption of strategical raw materials

One of the physicochemical processes in which specific biological substances passively bind pollutants to their cellular structures is Biosorption. The biomaterial that operates through this mechanism is actually a biological environment that enables the binding of ions from aqueous solutions to functional structures on the biomass surface. The rapid development of this process is characterized by its reversibility. Microorganisms used for biosorption are mostly plant-derived materials and are produced from waste products, biopolymers and environmentally friendly materials. It consists of materials obtained from various easily available sources.

Multiple interactions that enable ions to bind to functional groups on the surface of the biosorbent occur through biosorption. This means the accumulation of strategic raw materials. Since this method is carried out with simple processes without the need for additional nutrients and energy, its cost is also low. According to the definition in Razzak et al. (2022), bioadsorption is another term used for the removal of undesirable elements with the help of microorganisms and is a very effective method for removing SRMs from the waste environment with minimal chemical or biological wastewater treatment.

The mechanism of SRM pollutant removal through biosorption occurs in a step-by-step manner, and it offers an affordable option that can be completed in a very short time. Additionally, bioadsorbents are recyclable, and there are various types available that can be tailored for specific metals of interest.

Factors Affecting Biosorption

The kinetics of biosorption in SRM recovery are influenced by various factors. Optimal conditions must be established for the biosorption process to occur effectively. Initially, dissolved substances targeted for retention on the biosorbent surface must pass through the surrounding solvent liquid film, a process known as film diffusion. Following this, the substances must undergo pore diffusion to enter the inner parts of the pores in the biosorbent material. The final stage involves the binding of the dissolved substance to the biosorbent material.

The amount of element bound to biomass in biosorption methods is affected not only by the type of biomass but also by physicochemical factors such as concentration, temperature, amount of biomass, and solution pH (Volesky, 2004). These factors play crucial roles in determining the efficiency and effectiveness of the biosorption process for SRM recovery.

Effect of pH

According to Deniz and Karabulut (2017), pH is an important parameter in affecting the biosorption of SRMs as it affects the surface charge of the solvent and also affects its mobility. High hydrogen ion concentration in the solvent inhibits the binding activity of metal cations to the adsorbent material at low pH levels. Lee and Park (2012) also explain the effect of pH during biosorption in more detail. According to them, lower pH levels cause functional groups in the biomass to be protonated with more hydrogen ions, and as a result, the negative charge density decreases and the electrostatic attraction of metal ions decreases. Considering the opposite of this situation, increasing pH values causes deprotonation of hydrogen ions attached to functional groups, and as a result of this situation, biosorption of SRM cations becomes easi

Another factor that affects the biosorbent material and the load of adsorbate molecules is the pH of the wastewater. Fluctuations in pH affect the speciation and solubility of some pollutants as well as electrostatic forces. Optimizing pH settings means increasing the adsorption properties of certain adsorbate types. In addition, another impressive critical factor is the contact time between the biosorbent and the wastewater. Sufficient contact time paves the way for mass transfer and spreading of adsorbate molecules onto the biosorbent surface. One of the critical conditions of this situation is that excessive contact time may not always lead to high adsorption, which may negatively affect the overall efficiency of the purification process (Sarma et al., 2019).

Effect of Temperature

The effect of temperature on adsorption is inevitable. It is known that high temperatures generally lead to increased adsorption rates. Therefore, temperature also affects the concentration of adsorbate molecules and the binding ability between the adsorbate and the biosorbent. The negative effect of this situation may vary depending on the specific adsorbate and biosorbent system. Additionally, degradation and competition in wastewater is an important variable that may compete for adsorption sites rather than the intended adsorbate. Interference from competing ions, dissolved organic matter, or other contaminants also inhibits adsorption ability or selectivity. As a result of this situation, understanding the wastewater content and potential degradation is also very important for designing optimum biosorbents.

The amount or dosage of biosorbent used in the current treatment system also has a significant impact on the adsorption efficiency. While insufficient amounts of biosorbent lead to the removal of the pollutant at low efficiencies, high doses may be uneconomic (Chen et al., 2020). As a result of this situation, some experimental studies or process modeling should be preferred in order to determine the optimum amount of biosorbent for effective treatment efficiency.

Turbulence and flow velocity

Turbulence and flow rate are important in continuous flow systems where agitation can affect contact time and mixing of biosorbents. Optimum flow rates and agitation are required to ensure the interaction between adsorbent and biosorbent while minimizing the risk of inadequate mass transfer. It is necessary to carefully examine and optimize these factors according to the characteristics of the target pollutants in the wastewater that need to be eliminated and the selection of biosorbent materials. A detailed characterization study and column studies provide significant insight into adsorption behavior and lead to the development of efficient wastewater treatment technologies.

Effect of biomass dosage

According to their research in Sarada et al., (2017), the amount of biomass is essential in determining the presence of surface area of biosorbents and binding sites for SRM ions. Increasing the biomass dosage typically allows the affinity between the algal cell wall and SRM ions to strengthen (Ibrahim et al., 2018). However, there may be a saturation point where the removal percentage stabilizes or decreases due to the aggregation of biosorption sites, leading to a reduction in the available surface area for SRM ions to bind (Kayalvizhi et al., 2022).

Accoding to Ibrahim et al. (2018), contact time is indeed a critical factor in determining biosorption capacity Many experiments have been carried out to establish the optimal contact time necessary for biomass to reach equilibrium with SRM solutions.

Effect of SRM concentration on biosorption.

The initial concentration of SRM ions can indeed have a significant impact on the removal percentage. Moreover, temperature plays a crucial role in the biosorption process. Temperature increases can promote chemical absorption. In this case, physical intervention cannot be neglected. Fluctuations due to increases in temperatures are associated with thermodynamic processes occurring between metals and biomass. This may bring to mind that biosorption is an endothermic reaction (Lucaci et al., 2020). We can summarize the temperature dependence of adsorption as increasing temperature, which can activate more regions on the biomass surface and expand the pores on the biosorbent material, leading to a higher reaction rate. According to Kayalvizhi et al. (2022), this underlines the importance of temperature in increasing the efficiency of biomass as a biosorbent (Ciobanu et al., 2023).

Adsorption isotherms

Biomass analysis is crucial for understanding its properties related to biosorption and its affinity to metals, including surface characteristics. Adsorption isotherm studies provide valuable insights into the biosorption behavior of biomass. Various studies have utilized Langmuir, Freundlich, and Temkin isotherm models to analyze the adsorption efficiency of metals such as As, Zn, Cr, and Pb by biomass, yielding information about adsorbed metals and aqueous concentration at equilibrium (qe and Ce, respectively) (DeMessie et al., 2022).

The Langmuir isotherm model elucidates sorption characteristics on homogeneous solid surfaces through monolayer adsorption, describing the adsorption rate and sites occupied by the adsorbate. It effectively explains the homogeneity of binding sites and the uniformity of energy used for sorption on active sites (Alavi et al., 2018). AlHazmi et al. (2022) further detailed the Langmuir model and concluded that the adsorption balance on the adsorbent surface is dynamic and the adsorbed substances do not come into direct contact.

Proctor and Toro-Vazquez, (1996) conducted that, the Freundlich isotherm, characterized by nonlinear sorption, elucidates the heterogeneous surface characteristics of the adsorbent biomass, explaining the exponential distribution between energy used for sorption and sorption sites. This reversible equilibrium adsorption occurs rapidly at a fixed temperature conditions.

The temkin isotherm model examines the interaction between the adsorbates and adsorbents to be adsorbed and is also related to the free energy of sorption according to the surface coverage. It indicates how the heat of adsorption of whole adsorbates or related molecules decreases linearly as the coverage area of the adsorbent surface increases. According to Piccin et al. (2011), the adsorption process is expressed as a consistent distribution of binding energies until the maximum binding energy is reached. This developed and mentioned model also follows an effective process in determining the linear decrease in the adsorption heat and the uniform distribution of the binding energy up to the maximum energy level (Inyinbor et al., 2016).

Adsorption kinetics

The data regarding biosorption kinetics offer valuable insights into the rate at which SRMs are adsorbed onto the surface of biomass, providing crucial information for optimizing the biosorption process. Understanding these kinetics allows for the identification of optimal conditions for efficient SRM removal. The movement of solute particles from the concentrated solution to the surface of the adsorbent through various mechanisms such as intra-particle transport and adsorption on the inner surface of the pores according to the liquid film diffusion law represents the biosorption process. (Shakir et al., 2010). In this mechanism of action, the adsorbent is formed rapidly and significantly in the interior of the biomass, in the capillary spaces and pores. As a result, this contributes to the overall efficiency of the process.

The kinetics of biosorption is affected by the mass transport rate of the particles as well as the chemical and physical properties of the biomass used for adsorption. These factors play a crucial role in determining the effectiveness of SRM removal. Additionally, biomass undergoes significant changes in its surface morphology and characteristics after biosorption, further highlighting the dynamic nature of the process (Shakir et al., 2010). Overall, biosorption kinetics provide essential insights into the mechanisms and efficiency of SRM removal, guiding the development of effective wastewater treatment strategies.

RESULTS AND DISCUSSION

Recent studies have highlighted the significant biosorption capacity of lichens. For instance, Uluozlu et al. (2008) investigated the biosorption of Pb(II) and Cr(III) from aqueous solutions using the lichen species Parmelina tiliaceae. Ekmekyapar et al. (2006) studied the biosorption of copper(II) from the non-living biomass of Cladonia rangiformis. Sari et al. (2007) examined the biosorption of Pb(II) and Ni(II) from aqueous solutions using the lichen species Cladonia furcata. Bingöl et al. (2009) explored the biosorption of chromate ions from aqueous solutions using the lichen species Cladonia rangiformis. Yalcin et al. (2010) investigated the biosorption of Cu^{2+} and Zn^{2+} by the lichen species Rocella phycopsis.

Uluözlü et al. (2010) focused on the biosorption of antimony (III) using the lichen species Physcia tribacia.

Biosorption, also known as the removal of metal ions using dead biomass in a solution, occurs because the surfaces of organisms are negatively charged, enabling them to adsorb positively charged metal ions (Volesky, 2004). Microorganisms can take up metals both actively (through acclimated cells) and passively (via biosorption). Research indicates that passive uptake is more prevalent in biosorption methods compared to active uptake, as living systems (active uptake) require frequent addition of additional nutrients, thereby increasing the chemical oxygen demand or biological oxygen demand or at the reaction outlet (Hussein et al., 2004).

CONCLUSION

Absolutely, biosorption indeed stands out as a promising technology for environmental remediation. Its remarkable adsorption capacity for various pollutants, coupled with its versatility in targeting a broad spectrum of contaminants, makes it a valuable tool in the ongoing effort to address environmental pollution. Harnessing the power of biological substances such as algae, fungi, or bacteria, biosorption offers an effective means of removing pollutants from water or air. Moreover, its cost-effectiveness, especially in scenarios involving low to moderate levels of contamination, further enhances its appeal as an environmentally friendly solution. Overall, biosorption holds significant potential in safeguarding ecosystems and human health while contributing to sustainable environmental management.

ABSTRACT

This study intends to provide a comprehensive account of the species of Short-Horned Grasshoppers belonging to the family Acrididae (Orthoptera) that may be discovered in the various habitats of the Vlora region, which is located in the southern part of Albania. A well-defined seasonal pattern that includes a cold and rainy winter and a warm and arid summer is characteristic of the climate in this region, which shows some characteristics that are typical of the Mediterranean climate. On a worldwide scale, this region represents a discovery that is both extraordinarily valuable and one of a kind. Following an examination of the data, it has been determined that the genera *Calliptamus*, *Chorthippus*, and *Oedipoda* are known to exist, with two species belonging to each of these genera. It is estimated that 13.33% of each species is present. For the purpose of establishing whether or not these species are present in this region, the Llogara and Armen National Parks were both investigated. According to the conclusions of the study, these parks, which each include six species and have a species frequency of forty percent, offer the best possible environment for the species in question.

Keywords: Orthoptera, Acrididae, Habitat, Biodiversity, Vlora, Southwestern Albania

INTRODUCTION

The Acrididae family, is a diversified group within the Orthoptera order. These grasshoppers are generally referred to as short-horned grasshoppers (Memon et al. 2021). According to (Riffat, 2015; Shaikh et al. 2018), the agricultural crops that they infest are considered to be pests if they occur. In addition to wetland environments, they may be discovered in a wide variety of habitats, including as grasslands, shrublands, herbaceous regions, and woods. (Dempster, 1963; Uvarov, 1966; Shaikh et al. 2018) all came to the conclusion that the majority of the species that belong to the Acrididae family are herbivorous insects.
The findings of the study conducted by (Akwanjoh, 2020) suggest that they have the potential to function as helpful bio-indicators for identifying changes in the environment. According to (Song et al. 2018), the family Acrididae is comprised of a wide variety of species that fall within the order Orthoptera and the suborder Caelifera.
Each and every member of the Acridiea family contains a pair of antennae that are extremely small and very thin. In contrast to the tympanum, which is situated on the lateral sides of the first abdominal segment, the tarsi are composed of three segments. The research conducted by

(Smith et al. 2014) revealed that certain adult species have wings, whereas others either do not have wings at all or have wings that are severely reduced. In this paper, we provide the results of our taxonomic investigation into the species belonging to the Acrididae family that were found in the Vlora region.

MATERIALS AND METHODS

During the years 2022 and 2023, the species were gathered from a variety of locations within the Vlora region, including National Park Llogara, Armen, and Selenica. The different species were gathered by the utilization of aerial entomological nets (NET). In order to maintain the color, the species were placed in tubes that contained ether (Colas, 2000; Halimi et al., 2023). Each tube was then labeled with the appropriate information, which included the date, location, coordinates, and altitude from the data collection. Notes were recorded in a journal regarding the vegetation, as well as any particular traits that were considered to be unique to particular species. For the taxonomic identification, the species were observed with a stereomicroscope (Perfex Sciences), and the keys from the publications for the countries bordering Albania, which offer similar climatic conditions and habitats to our study area, were used (Eades et al., 2014; Willemse et al. al., 2018; Willemes, 1985) as well as previous publications on the Order Orthopetra of Albania (Csiki, 1922; Ebner, 1910; Lemonnier – Darcemont & Darcemont, 2015; Subashaj, 2024).

RESULTS AND DISCUSSIONS

This study presents the species of the Acrididae family, which are listed in Table 1 according to the stations (Llogara, Armen, and Sevaster National Parks) in the habitats of the Vlora area, which is situated in the southwestern part of Albania, across the Ionian Sea, and in the southern Adriatic Sea. The Vlora area is located in the southern Adriatic Sea.

Table 1. List of species of the Acrididae family

No.	Specie	Llogara National Park	Armen	Sevaster
1	**Genus Chorthippus**			
1	*Chorthippus mollis mollis* Charpentier, 1825	+		
2	*Chorthippus bornhalmi* Harz, 1971	+		
2	**Genus Oedipoda**			
3	*Oedipoda caerulescens* Linnaeus, 1758	+	+	+
4	*Oedipoda germanica* Latreille, 1804	+		
3	**Genus Pezotetix**			
5	*Pezotettix giornae* Rossi, 1794	+		
4	**Genus Euchorthippus**			
6	*Euchorthippus declivus* Brisout, 1848	+		
5	**Genus Sphingonotus**			
7	*Sphingonotus caerulans* Linnaeus, 1767		+	
6	**Genus Pseudochorthippus**			
8	*Pseudochorthippus parallelus tenuis* Zetterstedt, 1821		+	
7	**Genus Paracaloptenus**			
9	*Paracaloptenus caloptenoides* Brunner von Wattenwyl, 1861		+	
8	**Genus Acrotylus**			
10	*Acrotylus patruelis* Herrich-Schaffer, 1838		+	
9	**Genus Acryptera**			
11	*Arcyptera sp* Serville, 1839		+	
10	**Genus Calliptamus**			
12	*Calliptamus sp* Serville, 1831			+
13	*Calliptamus italicus* Linnaeus, 1758			+
11	**Genus Oedaleus**			
14	*Oedaleus decorus* Germar, 1825			+
12	**Genus Acrida**			
15	*Acrida ungarica mediterranea* Herbest, 1786			+

Twelve genera and fifteen species are included in the collection of species belonging to the Acrididae family that was collected from three different sites (Table 2, Figure 1).

Table 2. Species and genus enlisted

Genus	Species number	Species frequency
Acrida	1	6.66%
Acrotylus	1	6.66%
Acryptera	1	6.66%
Calliptamus	2	13.33
Chorthippus	2	13.33
Euchorthippus	1	6.66%
Oedaleus	1	6.66%
Oedipoda	2	13.33
Paracaloptenus	1	6.66%
Pezotetix	1	6.66%
Pseudochorthippus	1	6.66%
Sphingonotus	1	6.66%

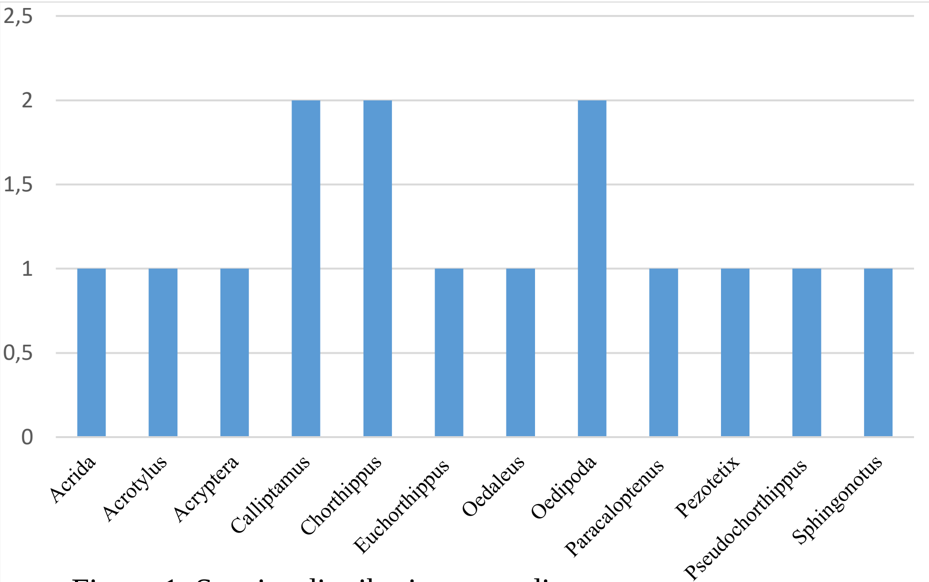

Figure 1. Species distribution according to genus

Based on the data, it can be deduced that the genera *Calliptamus*, *Chorthippus*, and *Oedipoda* are responsible for two species out of the total number of species. Thirteen point three percent of the total number of species in the entire collection is accounted for by these genera. The genera *Acrida, Acrotylus, Acryptera, Euchorthippus, Oedaleus, Paracaloptenus, Pezotetix, Pseudochorthippus*, and *Sphingonotus* are the ones that come in close succession after them. Due to the fact that each of these genera has one species, the total number of species that may be found in each of these genera is one. The frequency of each species within each genus is found to be six point six percent.
According to the findings of the inquiry into the diversity of stations, which are shown in table 3 and figure 2, the Llogara and Armen National Park stations each include six species, which accounts for forty percent of the total number of species. These findings are presented in the

table and figure respectively. Each of the five unique species that make the Sevasteri station their home has a frequency of 33.33 percent, and the station is home to all five of these species. The stations in Llogara and Armen National Park offer the most optimal environments for species that are members of the Acrididae family. As a consequence, the amount of disturbance that is generated by human activities is reduced to the greatest extent possible.

Table 3. Species according to the surveyed stations

Station	Species number	Species frequency
Parku Kombetar Llogara	6	40 %
Armen	6	40 %
Sevaster	5	33.33 %

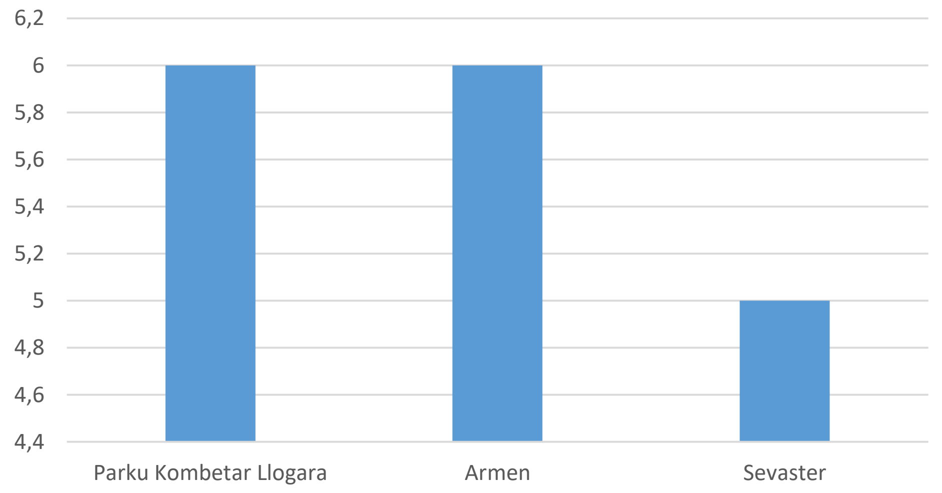

Figure 2. Species distribution according to studied

CONCLUSIONS

This research presents a complete analysis of the species that belong to the Acrididae family and are found in the ecosystems of the Vlora region. These species are found in the Vlora region. According to the parameters of this inquiry, we are discussing a total of twelve different genera and fifteen different species. A great degree of species diversity can be found within the Acrididae family, notably among the genera *Calliptamus*, *Chorthippus*, and *Oedipoda*, each of which has two different species. Acrididae is a family of insects. These three genera collectively are responsible for thirteen-point three percent of the total number of species that have ever been discovered. With a total of six species, the stations in Llogara and Armen National Park have the most species diversity of all of the stations in the park. This represents forty percent of the total species diversity count. According to the information shown here, it is possible to draw the conclusion that these stations provide the conditions that are most favorable for the species that belong to the Acrididae family.

ACKNOWLEDGMENTS

The authors wish to thank their French colleagues, M. Darcemont-Lemonnier and Ch. Darcemont, for their invaluable assistance in preparing this publication. Additionally, the University of Tirana provided support for this project through the "*UT-Search, Excellence, and Innovation—REI2023*" program.

EVALUATION OF DEVELOPMENTAL TOXICITY OF LEAD (PB) ON ZEBRAFISH (*DANIO RERIO*) EMBRYOS

Duygu Özhan TURHAN
Department of Biology, Faculty of Arts and Science, Inonu University, Malatya 44280, Turkey

duygu.turhan@inonu.edu.tr

ABSTRACT

Heavy metals are of critical importance due to their easy absorption into the food chain and bioaccumulation processes. The aim of this study was to evaluate the toxic effects of lead (Pb) in zebrafish embryos. Embryos were exposed to 4.39-50 mg L^{-1} Pb for 96 hours and the survival rates, heart rates and embryonic growth rates of these individuals were determined. According to the results of the study, the 96-hour LC_{50} value of the Pb was determined as 17.99 (16.6-20.72) mg L^{-1}. Heart rates of zebrafish embryos (48-hour) exposed to the Pb were significantly reduced at concentrations of 14.81-50 mg L^{-1}. At concentrations of 6.88 mg L^{-1} and higher, it caused significant inhibition in the length of zebrafish larvae.

Keywords: Lead, zebrafish, embryo toxicity, pollution

INTRODUCTION

Today, one of the most important threats for all living things in the ecosystem is environmental pollution. (Sökmen et al., 2018).The direct introduction of pollutants into the water system also causes the destruction of the existing ecosystem. Heavy metals, as pollutants, create a toxic effect on the living system through the food chain when they enter the water ecosystem. Heavy metals are substances that are generally found in trace amounts in natural waters, but most of them are poisonous even at very low concentrations (Şavran and Küçük, 2022; Liu et al., 2017). The term heavy metal is a general term used for metals and metalloids that have a density higher than 5 g/cm^3 and show toxic effects even at low concentrations (Jarup, 2003). Heavy metals are included in the aquatic ecosystem, especially through natural resources and human activities (Sökmen et al., 2018).

Lead, one of the heavy metals, is commonly found in the forms of oxides, sulfides, acetates, chlorates and chlorides. Nowadays, lead contamination is increasing and its toxic effects are widely reported. The element lead binds strongly to some enzymes, amino acids, DNA and RNA, thus inhibiting metabolic pathways in the organism (Nassouhi, 2018). Lead has been reported to be a metal that has adverse effects on reproduction, development and behavior of fish (Ramsdorf et al., 2009)

D. rerio is one of the widely used model organisms in aquatic toxicology due to its low cost, small size and easy laboratory maintenance (Turhan, 2021).The aim of this study was to determine the different biological responses, such as lethality, growth and development, and heart rate, of zebrafish embryos after exposure to Lead (Pb) using the Fish Embryo Acute Toxicity Test (OECD, 2013).

MATERIAL AND METHOD

Testing organisms

Zebrafish embryos were used in this study. These embryos were obtained from adult fish reared in the Zebrafish Production System of the Aquatic Vertebrate Experimental Animals Unit of the Faculty of Arts and Sciences of Inonu University. In the zebrafish system with continuous water circulation, pH was 7.30, conductivity was 720 µS/cm, temperature was 28.2 °C and photoperiod was 14 h light and 10 h dark.

Zebrafish embryos were obtained with a filtered rearing system connected to the same aquatic characteristics as the main system and water circulation directly fed by the main system. Fertilized eggs were collected within 3 h and stored in an oven at 28.5 ºC in standard embryo water.

Chemicals and exposure

For fish embryo-toxicity testing, zebrafish embryos 6-8 hours after fertilization were exposed to Lead (Pb) at seven different concentrations (4.39-50 mg L^{-1}) for 96 hours in 96-well microplates. 250 µl of Pb solution prepared at different concentrations and a zebrafish embryo were added to each well. A total of 24 embryos were used for each concentration. Mortality rates of individuals examined with a stereomicroscope every 24 hours for a 96-hour period were recorded. At the 48th hour, the heart beats per minute of the embryos were determined.

At the end of the 96th hour, the malformation rates and malformation types of the surviving individuals were determined with a stereomicroscope, while their heights were measured using Euromex Image Focus 4.0 software.

Statistical Analysis

The statistical analysis of the collected data was conducted with SPSS and GraphPad Prism 5 (SPSS Inc., USA).

The results that did not comply with the required hypotheses for parametric tests were processed with the Mann-Whitney U and Kruskal Wallis test.

Probit regression analysis was used to determine the 96h mean lethal concentration (LC_{50}) for the embryos (EPA, ver. 1.5)

RESULT AND DISCUSSION

Heavy metals are very important for human and animal health. In recent years, heavy metals have been used very intensively and are passing into the aquatic environment (Gao et al. 2018). Therefore, in recent years, the use of biological data for heavy metals has been increasingly gaining interest. The main concern regarding the toxicology of heavy metals lies mainly in their chronic accumulation in aquatic environments. In this study, changes in embryo survival rate, and body length were analyzed to evaluate the possible toxicity on embryonic development of zebrafish exposed to lead (Pb) at concentrations between 4.39-50 mg L^{-1}.

96 hour LC_{50} values in *D. rerio* embryos exposed to Pb were calculated as 17.99 (15.65-20.72) mg L^{-1}. No mortality was observed at a concentration of 4.39 mg/L Pb. Mortality was

generally not observed over 24 hours in all exposures. Singh and Ansari (2017) rported that the LC_{50} 96-h value was determined as 21.63 in embryos exposed to lead.

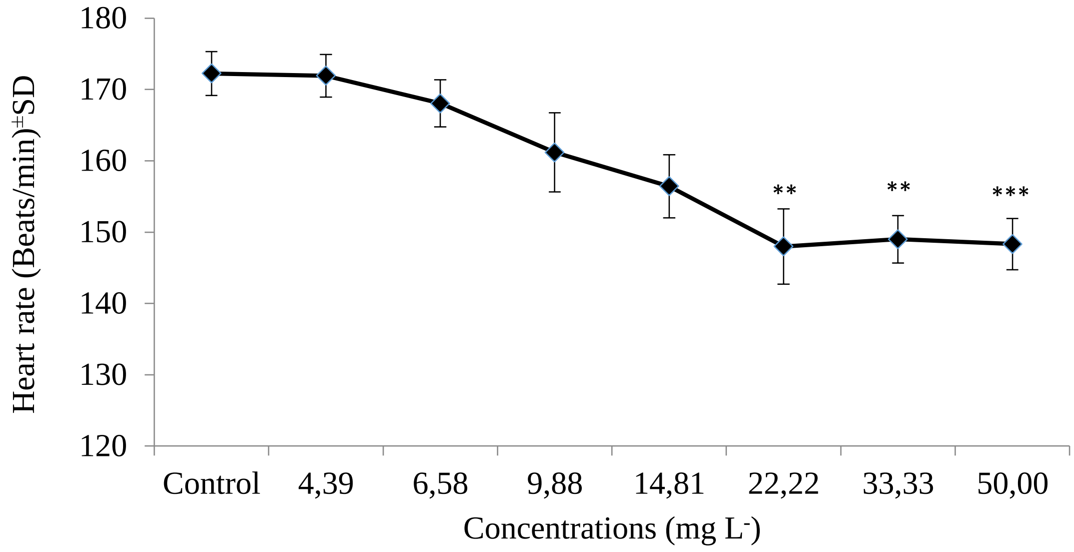

Figure 1. Heart rate in 96h *D. rerio* embryos exposed to Pb

** $p < 0.01$, *** $p < 0.001$

In this study, it was shown that zebrafish embryos exposed to Pb had a significant decrease in heart rate at 48 hours in a dose-dependent manner (Figure 1). There are many studies in the literature showing that pollution cause inhibition of heart rate in zebrafish embryos. Zhang et al. (2020) also reported that sublethal doses of pollutants can affect heart rate in zebrafish. At concentrations of 6.58 mg L^{-1} and higher, it caused significant inhibition in the length and heart rate of zebrafish larvae.

Table.1 Time-dependent mortality levels for *D. rerio* embryos exposed to different concentrations of Pb

		Σ (Mortalite)			
Consantrasyon (mg L^{-1})	n	24h	48h	72h	96h
Control	24	0	0	0	0
4.39	24	0	0	0	0
6.58	24	0	0	0	1
9.88	24	0	0	0	3
14.81	24	0	1	1	9
22.22	24	0	0	8	13
33.32	24	1	6	14	22
50.00	24	0	12	18	24

Especially at concentrations of 22.22-50 mg L^{-}heart beats per minute were significantly inhibited.

Determining body length change is an important parameter in evaluating the potential effects of pollutants on fish (Yang et al., 2018). Because the change in the length of fish significantly reflects many molecular and cellular responses that may occur in the individual depending on the effect of pollutants (Cook et al. 2005). In this study, a significant inhibition was observed in the body length of embryos exposed to Pb compared to the control group.

Table 2. Length of *D. rerio* larvae exposed to different concentrations of Pb for 96 hours

Concentrations	Pb			
	Length (mm)			
Control	3.75	±	0.06	
4.39	3.73	±	0.03	
6.58	3.71	±	0.04	
9.88	3.72	±	0.04	
14.81	3.68	±	0.05	
22.22	3.56	±	0.04	**
33.33	3.51	±	0.03	***

n: Living individual, ** $p< 0.01$, *** $p< 0.001$

Malformations were observed in all surviving individuals at concentrations of 22.22 and 33.32 mg $L^{-1.}$ Malformations such as pericardial edema (PE), yolk sac edema (YSE), tail deformation (TM) and spinal curvature (SC) were detected in zebrafish exposed to Pb. PE has been observed more frequently than other types of malformations. It has been reported that the occurrence of PE may be an indicator of abnormal cardiac development and deterioration of osmotic or metabolic functions.

CONCLUSIONS

This study showed that Pb caused dose-dependent developmental toxicity in zebrafish embryos. The effects that the potential accumulation of Pb in surface waters may cause on aquatic organisms were revealed from various aspects by this controlled experiment.

ABSTRACT

The development of drug resistance has become a worldwide problem due to the hazardous use of antimicrobials in poultry feeding. Therefore, the use of biotic or natural products such as phytobiotics (phytogenics or botanicals) as a replacement for antibiotics has received great attention. In recent years, phytobiotics or their components have been recognized as a new class of natural plants that are gaining popularity and acceptability in poultry nutrition. It has been determined that the performance of animals often increases with the addition of various phytobiotic additives to poultry feed, and that phytobiotics also show great effectiveness in protecting the normal beneficial microflora population while resisting pathogenic microorganisms in the intestine. Phytobiotics can be classified as herbs obtained from flowering, non-woody and non-permanent plants, botanicals or spices obtained from non-leaf parts such as seeds, fruits, barks or roots, essential oils and extracts and oleoresins. Many phytochemical-rich medicinal herbs are now evaluated as potential antimicrobial and growth promoter alternatives.Aromatic herbs have been successfully used in the poultry sector to increase antioxidant capacity Ginger and turmeric are among the dried plant roots used as phytobiotics in poultry feeding. In this study, we tried to give information about the studies in the last fifteen years on the use of ginger and turmeric, whose dried powdered roots are also used as tea, in the nutrition of broiler chickens.

GİRİŞ

Phytobiotics, which are phytochemical compounds obtained from plants, have been researched and widely used in animal nutrition in recent years as alternative feed additives to antibiotic growth promoters. Phytobiotics can be classified as herbs, botanicals derived from seeds, fruits, bark or roots of flowering, non-woody and non-permanent plants, or spices (having a strong odor or taste), essential oils or extracts, and oleoresins. Phytobiotics consist of natural bioactive compounds or substances of plant origin, including terpenoids, alkaloids, glycosides, and phenolics (Bote, 2004 , Shad et al., 2014). Numerous studies have been conducted to demonstrate the effect of phytobiotics as growth-promoting feed additives such as prebiotics and probiotics to improve the health conditions as well as the general performance parameters of poultry (Abd El-Ghany, 2020). Phytobiotics are also used as antimicrobial, antiparasitic, anticoccidial and immunostimulating agents in the poultry field (Hafeez et al., 2020). Phytobiotics are also called phytogenic or botanical. They are defined as natural, less toxic and residue-free plant-derived compounds used as feed additives in animal production (Wang et al., 2008). Each chemical class of phytobiotics has a mode of action. For example, phenolic compounds or flavonoids as major active ingredients are identified as potential antimicrobial and antioxidant agents. Therefore, the growth promotion results provided by phytobiotic feed additives vary depending on the phytochemical mixture used and their active chemicals and their concentrations (Rafeeq et al. 2023).

Ginger and turmeric are among the plants used as phytobiotics in poultry feeding. In this study, we tried to give information about the studies on the use of ginger and turmeric powder in broilers diets.

GINGER (*Zingiber officinale*)

Natural alternatives, such as medicinal and aromatic plants, have attracted attention due to their wide range of potential beneficial effects as alternatives to antibiotics. Ginger (Zingiber officinale) is an important crop grown mainly in Central Asia, China, India and Pakistan and exported worldwide. Ginger is widely used in traditional medicine to treat some ailments and as a spice. Ginger root contains various compounds with biological activities such as antioxidant, antimicrobial and pharmacological effects (Khan et al. 2012a). Ginger contains several active compounds including gingerol, shogaols, gingerdiol, and gingerdione. The main important compounds in ginger are gingerol, gingerdiol and gingerdione, which have the ability to stimulate digestive enzyme, influence microbial activity and have anti-oxidative activity. Ginger has been reported to have beneficial pharmacological chemicals due to its antioxidant, antibacterial, anti-inflammatory, antiseptic, anti-asiatic and immunomodulatory properties (Zhang et al. 2009, Eltazi, 2014). Ginger (Zingiber officinale) is the rhizome of the perennial plant Zingiber officinale, belonging to the Zingiberaceae family, and its root stem is widely used as a culinary spice and herbal medicine in many countries. Ginger is one of the plant-based additives used to increase the performance of poultry feed. Ginger powder has lipid-reducing effects and can also be used as a growth promoter. It has properties similar to antibiotics when included in poultry feed. These natural feed additives reduce enteric pathogen microbial loads and can increase performance by improving nutrient digestion and absorption (Abd El_Hack et al. 2020; Al-Khalaifah et al 2023). Preliminary research suggests that compounds found in ginger may bind to serotonin receptors, which may affect gastrointestinal function (Oleforuh-Okoleh et al. 2014).

The effects of using ginger powder (Zingiber officinale) in broiler diets were tried to be summarized (Table 1). Most researchers attributed the better performance of poultry fed with ginger to the improvement in the taste of this natural product, the presence of protease and lipase enzymes, and the rapid digestive effect (Irivboje et al. 2020; Abd El_Hack et al. 2020). The differences observed between studies were attributed to the different ginger types used, processing, dosage and trial period.

TURMERIC (*Curcuma longa)*

There have been grown interest in developing natural alternatives to antibiotic growth promoters in order to maintain both birds' performance and health. Turmeric has been extensively used in poultry diets. Turmeric is a natural herb of the ginger family, Zingiberaceae. Wide range medicinal properties of this plant have been advocated. In poultry feed, Turmeric has been extensively used in different concentrations, dosages and durations. Turmeric (*Curcuma longa*) is a rhizomatous herbaceous perennial plant of the ginger family, Zingiberaceae. It is native to tropical South Asia and requires temperature between 20 and 30°C and a considerable amount of annual rainfall for growth. The plant grows to a height of three to five feet and has oblong pointed leaves with funnel-shaped yellow flowers. The Curcuma longa extract is a yellow-orange poly-phenol and its usual form is a dry yellow powder that is oil-soluble in its natural state. The rhizome is the portion of the plant used medicinally (Khan et al 2012b). The active ingredients are tetrahydrocurcuminoids, curcumin, demethoxycurcumin bisdemethoxycutcumin.Curcumin (diferuloyl methane) the natural yellow pigment in the roots of Turmeric, is a poly-phenolic compound that is isolated from the rhizomes of Curcuma longa and related species (family Zingiberaceae). Curcumin, which gives yellow colour to Turmeric rhizomes, is one of the most active ingredients, responsible for the biological activity. Curcumin, which was found to have antioxidant, antibacterial activities, aflatoxin induced mutagenicity and hepatocarcinogenesis (Khan et al 2012b, Abou-Elkhair et al. 2014). Turmeric can act as an important source for an alternative to antibiotics due to its antimicrobial properties. It is less toxic, residue-free and natural compared to synthetic antibiotics or inorganic chemicals (Ali et al 2020). Studies have shown that addition of turmeric powder in broilers diets enhance their performance. However some research showed that 0.1 and 0.2% turmeric powder used as feed additive had no significant effects on the performance and carcass yield of broiler chickens (Fallah and Mirzaei, 2016).

The effects of using turmeric powder (*Curcumin longa*) in broiler diets were tried to be summarized (Table 2).

CONCLUSION

Many types of feed additives are used in broiler chicken rations to increase performance. It is quite common to use spices as additives in chicken diets. Plant active principles are chemical compounds found throughout the plant or in specific parts of the plant that provide therapeutic activity or beneficial effects. Adding spices and herbs to mixed feeds can provide many benefits to the health and performance of poultry, such as having anti-oxidative potential, antimicrobial activity, and improving digestion by stimulating endogenous enzymes. Ginger and turmeric are popular medicinal herb, which shows a wide range of pharmacological properties, such as antioxidant, antiangiogenic, antitumor, antivenom, antinflammatory, antimicrobial, antiproliferative, antiprotozoal, and antiaging. Many studies have been carried out with the inclusion of ginger and turmeric powder in the diet of broilers however the results have been quite different. The variation of results obtained in studies with ginger and turmeric in broiler performance can be explained by the variability in the amount of phytochemicals in the plants, since factors such as the age and stage of development of the plant, as well as the time when the harvest was performed, temperature, water availability, UV radiation, soil nutrients, altitude and atmospheric composition directly influence the relative proportions of these compounds in the plant. For this reason, before deciding to use medicinal aromatic plants in the nutrition of broiler chickens, the above-mentioned issues should be taken into consideration in order to obtain high efficiency from the broilers.

ABSTRACT

Increasing bacterial resistance to synthetic antibiotics and consumer awareness of health and food safety concerns have triggered restrictions or bans on the use of antibiotic growth promoters in the poultry industry. Due to the restrictions on antibiotics in poultry nutrition, the poultry industry has turned to alternatives such as plant-derived feed additives. Thus, the poultry industry, focusing on developing more sustainable feed management strategies to improve the intestinal health and growth performance of poultry, has revealed phytogenic feed additives as natural alternatives to antibiotic growth promoters and encouraged research on this issue in poultry nutrition. Phytochemicals, plant bioactive compounds in poultry diets, have gained popularity due to their potential antioxidant and antimicrobial activities. These plants improve the immune system, reduce the stress response, and positively affect health and performance. Cinnamon bark and chamomile flower are among the plants used as phytobiotics in poultry feeding. In this study, we tried to give information about the studies in the last fifteen years on the use of cinnamon, whose bark is used as tea, and chamomile, whose flowers are used, in the nutrition of broiler chickens.

Key Words: Cinnamon, broiler, feed additives, nutrition

INTRODUCTION

In recent years, significant advances have been made to improve the health and performance of poultry. Feed is a major component of the poultry industry and exposes the gastrointestinal tract to a wide range of factors that can affect intestinal health. The gastrointestinal tract is considered a highly complex and dynamic organ that plays a crucial role in intestinal health (Ali et al. 2021). Various stress factors can negatively affect the balance in the intestinal ecosystem and ultimately the health status and productivity of poultry. Stress factors such as heat stress and gastrointestinal dysbiosis are considered major threats to the poultry industry due to their effects on intestinal health and increased disease susceptibility. The intestines of healthy animals can digest and absorb nutrients efficiently in environments where these stress factors are minimized (Diaz et al. 2019). Previously, antibiotic growth promoters were used to control gastrointestinal pathogens and reduce the effects of stress factors on intestinal function. However, increasing consumer awareness of the adverse effects of antibiotics on human health and concerns about increasing bacterial resistance and food safety have led to restrictions on the use of antibiotics in poultry production. This has led researchers and industry to look for alternatives to antibiotic growth promoters, focusing on developing more sustainable dietary interventions to improve the gut microbiome and overall health of poultry. Phytogenic feed additives have emerged as alternatives to antibiotic growth promoters and have great potential in the poultry industry (Ali et al .2021).

Cinnamon bark and chamomile flower are among the plants used as phytobiotics in poultry feeding. In this study, we tried to give information about the studies on the use of cinnamon, whose bark is used as tea, and chamomile, whose flowers are used, in the nutrition of broiler chickens.

CINNAMON (*Cinnamomum cassia)*

Cinnamon possess useful biological activities, including immunomodulatory, antioxidant, antiviral, lowering blood cholesterol, antimicrobial, lipid-lowering, antihypertension, anti-inflammatory, antitumor, gastroprotective, antidiabetic, neuroprotective and blood purifying properties. Dietary supplementation with cinnamon powder has been associated with positive effects on growth, digestion, antibacterial activities and immunity in chickens, as well as enhanced shelf life and quality of meat and reduced bacterial loading in eggs. On the basis of currently available literature, dietary supplementation levels with cinnamon has been variable for broilers (Saeed et al. 2018). In recent years, cinnamon, one of the most widely used spices, has attracted the attention of researchers as a natural product with numerous health benefits for poultry. Cinnamon belongs to the genus Cinnamomum (family Lauraceae), which includes more than 250-300 aromatic evergreen shrubs and herbs. However, only a few of these species, including Cinnamomum zeylanicum (C. zeylanicum: True Sri Lankan cinnamon), C. cassia (Cassia), C. burmanni (Indonesian cinnamon), and C. loureiori, are economically important worldwide as a common spice. has importance (Vietnamese cinnamon) (Ali et al., 2021). Cinnamon to poultry feed as a natural feed additive has beneficial effects on nutrient digestibility, hypocholesterolemia, blood biochemical profile, gene expression, immunity and especially intestinal health, alleviating the impact of disease and heat stress by maintaining water and electrolytic balance and feed intake. It has been clearly demonstrated that cinnamon can be used as an alternative to antibiotics in the poultry industry, offering greater animal welfare, food safety and economic aspects of poultry production (Ali et al., 2021). The main bioactive compounds of cinnamon are cinnamaldehyde, cinnamate and cinnamic acid, all of which play vital roles in various biological activities. It has been documented that the essential oil of cinnamon consists of natural antioxidant, anti-microbial and anti-inflammatory compounds such as flavonoids, curcuminoids, coumarins, tannins, alkaloids, xanthones, terpenoids, phenolics and other compounds (Purwanti, 2021). The concentration of volatile compounds in cinnamon essential oil depends mainly on the plant parts (leaves, bark, root, trunk) from which it is extracted). About forty-one volatile compounds have been identified in the bark oil of the cinnamon tree (Geng et al., 2011). Cinnamaldehyde (55% to 78%) is the main flavor compound in CNO extracted from bark while eugenol (59–78%) is the main compound in CNO that is extracted from leaves (Hamidpour et al. 2015). The volatile oil is approximately 0.6–1% and 1–2% phlobatannins, calcium oxalate, starch, mucilage, and mannitol in the bark (Ali et al., 2021). Use of cinnamon bark powder in the diet of broiler chicken at various level had generally positive impact on the performance in terms of BW, BWG, FI and FCR, overall performance index, carcass characteristics, blood profile and net profit per birds over (Chowlu et al. 2018, Gaikwad et al. 2020). The effects of using cinnamon bark powder (*Cinnamomum cassia*) in broiler diets were tried to be summarized (Table 1).

CHAMOMILLA (*Matricaria chamomilla* L.)

Chamamile flower (Matricaria chamomilla L.) has been a subject of considerable interest as a medicine and therapeutic agent throughout the world since ancient times. Flavonoids, sezekoitrepens a-bisabolol, chamazulene, farnesene and also sis and trans isomers of N-in dicyclotera are some prominent components of chamomile. Flavonoids are also encompassing of achi jinin, loteolin, koerestin, coumarin, ciranoz and patoliterin. This plant has aromatic flora with bitter taste. Its aroma is related to the camazolen essence and the bitter taste is attributed to some glycosides like apigenin and trithdroxy flavon. Chamomile is also containing phytoesterol and flavonoids like cyranosid and patulitrin (Dada et al. 2015). Chamomile (Matricaria chamomilla L.) is classified under a plant family composites. It contains flavones apigenin and essential volatile oil such as bisabol oxide B, "-bisabolo, chamazulene and bisaboloxide A. Chamomile flowers inhibit the excessive growth of harmful intestinal Micro organisms, thus counter acting inflammation it was reported that the addition of chamomile flowers at (0.25%) level to broiler diets improved growth performance and FCR (Al-Kaisse and Khalel, 2011). Including chamomile flowers are one of the medicinal plants used in the past and contain high levels of therapeutic compounds, namely bisabolol chamaxulene, beta-trans-farnesene, and flavone glycosides. Many bioactive phytochemical components were found in chamomile flower extract, including pentadecanoic acid, a palmitic acid methyl ester with antioxidant activity and -bisabolol (monocyclic sesquiterpene alcohol), which has anti-inflammatory, anti-bacterial, and anti-fungal properties (Tenorio et al. 2017). Anti-bacterial Chamomile also has positive effects on the digestive and respiratory systems and has an important role in boosting immunity and reducing oxidative stress (Alkado et al 2022). Chamomile flowers have antimicrobial and anti-inflammatory effects on broiler chicks, furthermore, it increased egg numbers of layers while decreased serum total cholesterol and GOT levels. Moreover, chamomile flowers improved growth performance and feed conversion ratio of broilers (Ahmed et al 2015). The effects of using chamamile flower powder (*Matricaria chamomilla L*) in broiler diets were tried to be summarized (Table 2).

CONCLUSION

Leaves, barks, flowers and essential oils of medicinal and aromatic plants are added to poultry feed to increase appetite, stimulate the secretion of endocrine and digestive enzymes, and stimulate antimicrobial, anti-inflammatory, antioxidative and immune activity. In this study, we tried to summarize the effects of using cinnamon bark and chamomile flower, especially dried forms, in the mixed feeds of broiler chickens. The place where the plants were grown, the type of the plant, the characteristics of the soil in which it was grown, weather conditions, altitude, season, harvesting method, storage conditions, phenolic substance contents, physiological states of the animals, growing conditions and experimental approaches may have been effective in obtaining different results from the studies examined. Cinnamon, in particular, can be toxic when used regularly and in high amounts due to the coumarin it contains, which has strong anticoagulant properties. For this reason, before deciding to use medicinal aromatic plants in the nutrition of broiler chickens, the above-mentioned issues should be taken into consideration in order to obtain high efficiency from the broilers.

ABSTRACT

The present study aimed to diagnosis the mare's sexual activity during the breeding season. One hundred and seventy (170) of Arabian mares, aged between 04-27 years and reared in the National stud farm of Sidi Thabet, were followed during the official breeding season, from February to May 2022, while they were submitted to a natural mating (NM) service. Estrus monitoring was carried out daily through a teaser test, and if positive, the female went through an ultrasound examination starting at the 3rd day of estrus for the follow up of the follicular activity. During the estrus period, the behavioral expression in females was assessed and its intensity recorded, then the natural mating was performed every 48 hours as soon as the ovulatory follicular diameter reached 35 mm, and stopped when the corpus luteum was detected. Mares with a delay of resumption of ovarian activity or with cyclicity problems were treated with hormonal injections. The results showed that mares showing a clear estrus behaviour during the breeding season could be distributed into a typology, represented as following: i) according to their age, 78% of mares were older and 22% were young, ii) according to their status, 88% of mares were multiparous (barren and mares with foal, 41% and 47% respectively) versus the maiden ones (12%). A total of 26% of the observed mares showed a problem of resumption of ovarian activity and did not show any estral behaviour, and were thus treated with GnRH (14%) and prostaglandin F2a (12%). The average estrus and diestrus duration were 8.2 and 13.8 days, respectively. The estrus behaviour intensity varied during the breeding season and was higher during March and April, and started to decrease in May ($p<0.05$). Estrus behaviour intensity was weak in foaling estrus compared to the cyclic estrus. The results suggested that the estrus behaviour intensity depends on the mare's type estrus and tends to decrease at the end of the breeding season. The weak estrus intensity shown in mares during their foaling estrus and at the end of the breeding season leads to mare's rigorous monitoring of their follicular activity using ultrasonography in order de secure pregnancy.

Keywords: sexual activity, estrus intensity, breeding season, Arabian mares.

INTRODUCTION

Estrus behaviour intensity in mare can vary depending on the individual and the hormonal levels (Stachurka et al., 2023). Some common signs of estrus behaviour include increased vocalization, restlessness, frequent urination, tail flagging, and receptivity to stallion (McDonnel, 2000). Mares may also show signs of aggression or irritability during estrus. It is

important to horse owners and handlers to be aware of these behaviours so they can properly manage and handle the mare during this time. Additionally, it is important to monitor the mare's behaviour and consult with a veterinarian if there are any concerns about her estrus behaviour intensity.
The objective of the study aimed to diagnosis the mare's sexual activity during the breeding season.

MATERIAL AND METHODS

The study took place in the National Stud Farm of Sidi Thabet of the National Foundation of the Improvement of the Horse Breed (FNARC), in the North of Tunisia, at 24 km from Tunis. The experiment involved 170 Arabian Mares aged between 4 and 27 years, and were followed during the official breeding season, from February to May 2022, while they were submitted to a natural mating (NM) service.

Estrus' mare monitoring was carried out daily through a teaser test in the breeding courtyard, and if it was positive, the female went through an ultrasound examination starting at the 3rd day of estrus for the follow up of the follicular activity: The mare is placed in 'restraint work' to prevent possible accidents and facilitate handling. The mare is immobilised with a twisted nose in order to free the vulvo-perineal area. After emptying the rectum of faeces, transrectal palpation is carried out to get an idea of the size and consistency of the various parts of the female's genital tract and to locate the position of the ovaries. The ultrasound examination of the ovaries was carried out using an ALOKA ultrasound scanner (SSD 500) equipped with a 5 MHz linear recto-dynamic probe (model UST-587I-5) (Figure 1). The gel-lubricated probe is inserted into the mare's rectum. It is then pointed at the cervix, the uterine body, the right or the left uterine horn and finally the right or the left ovary to visualize follicular activity. If the mare is in heat, the evolution of follicular development; the diameter of the pre-ovulatory follicle is determined. If the mare is not in heat, the corpus luteum is noticed on the ovary. This shows that ovulation is completed (Haras Nationaux, 2004).
The follicular activity of mares in natural service is monitored daily until the pre-ovulatory follicle reaches 35mm in diameter. At this point, the mare is serviced every 48 hours until the corpus luteum is detected by ultrasound.

Figure 1. Ultrasound monitoring of follicular activity in mare.

During the estrus period, the behavioral expression in females was assessed and its intensity was recorded, then the natural mating was performed every 48 hours as soon as the ovulatory follicular diameter reached 35 mm, and stopped when the corpus luteum was detected. Mares with a delay of resumption of ovarian activity or with cyclicity problems were treated with hormonal injections (GnRH: Receptal® and prostaglandin F2a: Estrumate®).
Statistical analysis was carried out using SAS software (SAS Institute Inc., Cary, NC, USA). The General Linear Model (GLM) procedure was used to study the influence of the breeding season months on the estrus sign behaviour intensity in mares. The means were compared using the SNK test, and the level of signification was fixed at $p < 0.05$.

RESULTS AND DISCUSSION

The results showed that mares showing a clear estrus behaviour during the breeding season could be distributed into a typology, represented as following: According to their age (Figure 2), 78% of mares that exhibit estrus signs were older and 22% were young.

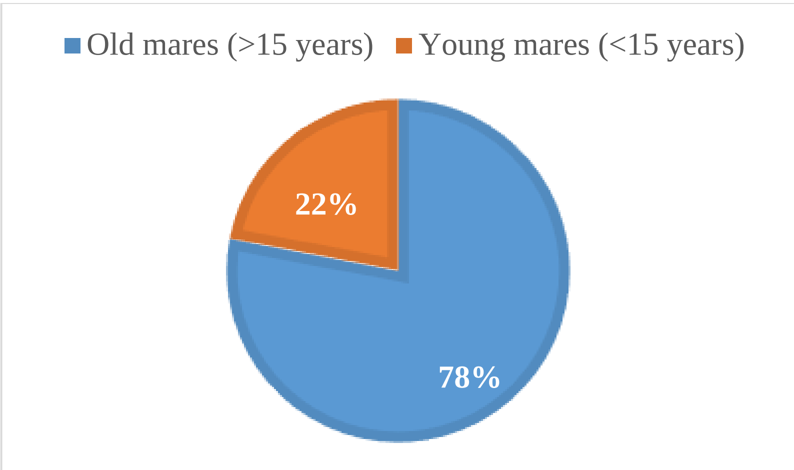

Figure 2. Variation of the percentage of mares that exhibit estrus behaviour according their age.

The intensity of estrus behaviour in mares over 15 years of age did not differ significantly ($p>0.05$) from that in mares under 15 years of age. This suggests that age does not affect the intensity of heat behaviour. This result is in line with that reported by El Ghali (2010), who proved that age has no effect on estrus behaviour in mares. However, according to Crowell-Davis (2007), young mares may exhibit an oestrus that is less attractive to the stallion than older mares.
According to their status (Figure 3), 88% of mares that exhibit estrus behaviour were multiparous (barren and mares with foal, 41% and 47% respectively) versus the maiden ones (12%).

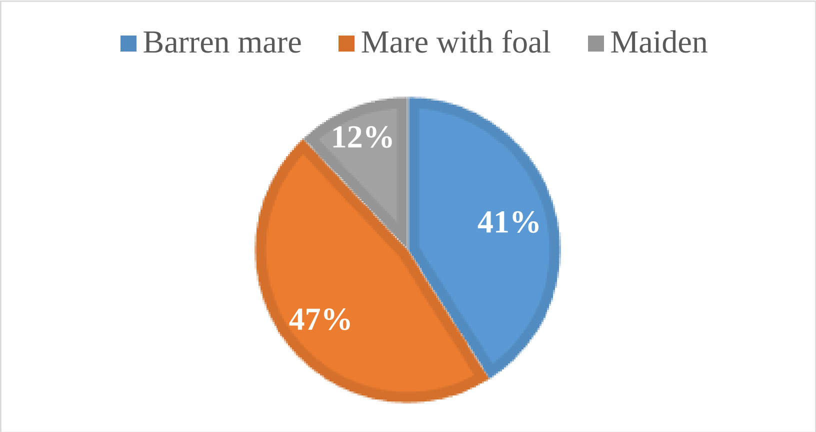

Figure 3. Variation of the percentage of mares that exhibit estrus behaviour according their status.

A total of 26% of the observed mares showed a problem of resumption of ovarian activity and did not show any estral behaviour (Table 1), and were thus treated with GnRH (14%) and prostaglandin F2a (12%).

Table 1. Percentage of mares requiring hormonal estrus induction treatment.

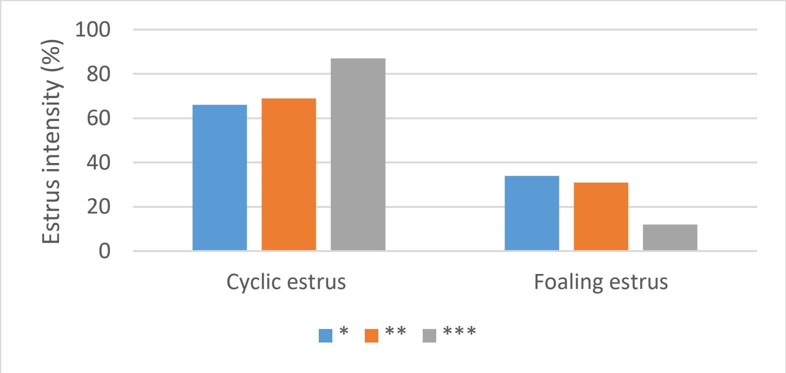
	Normal ovarian resumption (%)	Problem of ovarian resumption which involved estrus induction	
		GnRH treatment (%)	Prostaglandin F2a treatment (%)
		14	12
Total	74	26	

The average estrus and diestrus duration were 8.2 and 13.8 days, respectively, and the average estrus cycle duration and the overall mean of the ovulatory follicle were 21.8 days and 38.7 mm, respectively (Table 2).

Table 2. Variation of overall means of estrus cycle, estrus, diestrus and ovulatory follicle diameter.

	Means	Standard deviation	Min	Max
Average duration of estrous cycle (days)	21.83	3.22	17	27
Average duration of the estrus (days)	8.20	2.10	4	12
Average duration of dioestrus (days)	13.77	2.82	7	19
Overall average ovulatory follicle diameter (mm)	38.73	6.66	23	64

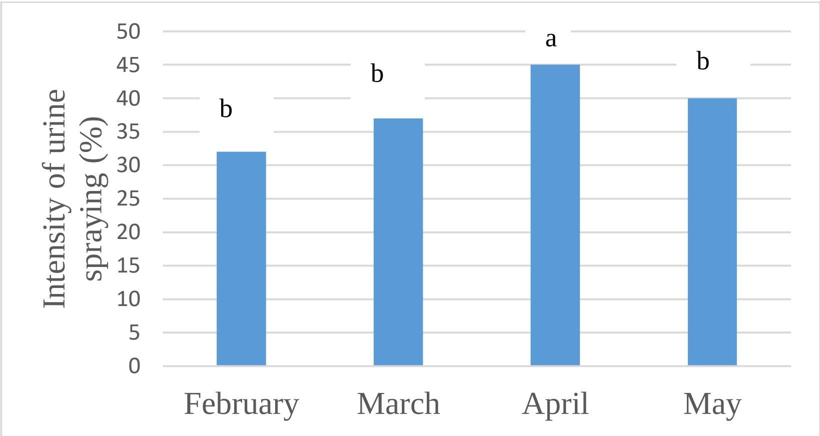
Estrus behaviour intensity was weak in foaling estrus compared to the cyclic estrus (Figure 4). The sign of estrus behaviour in the camped position was more visible and intense in mares in cyclical estrus than in those in foaling estrus. According to Meadows et al (2003) and Coleman and Powel (2004) the estrus behaviour of a mare that has foaled can be masked by her maternal behaviour.



: weak intensity of estrus, **: moderate intensity of estrus, *: strong intensity of estrus*

Figure 4. Variation the estrus behaviour intensity in the camped position in both cyclic and foaling estrus.

The estrus behaviour intensity varied during the breeding season and was higher during April, and started to decrease in May (Figure 5; $p<0.05$). The sign of urine spraying followed an ascending trend starting with a percentage of 32% in February, 37% in March and a peak in April (45%), before decreasing again in May (40%).
According to Asa (2007) oestrus behaviour in mares involves an increasing intensity of urine spraying as a function of time. This can be explained by the fact that as the mare progresses through the oestrus stage, she camps and urinates without being approached by the stallion teaser. The absence and the low levels of intensity recorded in May can be explained by the mare's seasonal sexual activity, which begins to deteriorate towards the end of the breeding season, and by the environmental conditions in Tunisia, particularly the photoperiod and the temperature.



a,b : p<0.05

Figure 5. Variation of the estrus behaviour intensity of urine spraying in both cyclic and foaling estrus.

CONCLUSIONS

The results suggested that the estrus behaviour intensity depends on the mare's type estrus and tends to decrease at the end of the breeding season. The weak estrus intensity shown in mares during their foaling estrus and at the end of the breeding season leads to mare's rigorous monitoring of their follicular activity using ultrasonography in order to secure pregnancy.

ABSTRACT

In rootstock breeding studies, examining the effects of rootstock on the growth vigor of varieties is an important stage. It is known that rootstocks are effective in resistance to soil and climatic conditions and growth vigor in fruit trees. The study was carried out in the greenhouses of the Eastern Mediterranean Transitional Zone Agricultural Research Institute. The study examined the effects of 33 selected clone rootstocks and 4 standard control rootstocks on plant development in Transvalia and Flored peach varieties. In this study, it was determined that rootstocks have significant effects on plant growth vigor in peach varieties. As rootstock scion combinations, it was determined that the highest rootstock diameter development was in Gn-22 (15.41 mm) and the lowest rootstock diameter development was in KL-26 (9.25 mm). In scion diameter developments, the highest was in Gn-22 (13.36 mm) and the lowest was in KL-4 (7.86 mm) rootstocks. The study observed that the Flored variety was stronger than the Transvalia variety in terms of growth vigor.

Key Words: Rootstock candidates, graft compatibility, seedling development, selection breeding

INTRODUCTION

Peach [Prunus persica (L.) Batsch] is the second most widely cultivated fruit species in the world after apples. In modern peach cultivation, selecting varieties and rootstocks suitable for climate and soil conditions is very important (Reig et al. 2016). In recent years, we have seen the breeding of many peach and nectarine varieties. The accelerated variety breeding efforts have led to the introduction of various new varieties, attracting increasing interest from consumers and producers. This situation necessitates accelerating rootstock breeding efforts suitable for these newly developed varieties (Iglesias, Carbo, and Bonany 2009). A few standard rootstocks are used in the newly bred peach and nectarine varieties. In fact, it would be more appropriate to use new rootstocks that are more compatible with these varieties and positively affect yield and quality according to the characteristics of the variety (Jimenez et al. 2011). Various rootstock breeding programs have been conducted to develop rootstocks with different characteristics for use in stone fruit cultivation (Moreno, Tabuenca, and Cambra 1994; Felipe et al. 1997; Beckman and Lang 2002; Loreti and Massai 2002). Rootstocks can be considered a technical tool in modern fruit growing for increasing fruit yield and quality, ensuring the plant's resistance to abiotic conditions, and controlling growth vigor to adjust planting density (Lopez-Ortega et al. 2016; Reig et al. 2018a). Therefore, selecting the right rootstock for economically efficient peach orchards in high-density plantings, high pH calcareous or sandy soils, and areas where nematode and root rot are problems becomes important (Reighard and Loreti 2008). In most Mediterranean coastal countries, peach-almond hybrids (P. amygdalus P. persica) are widely used as rootstocks for peach trees. These rootstocks, tolerant of high pH alkaline soils, are also resistant to iron chlorosis. Peach-almond hybrid rootstocks also form compatible combinations with peach varieties grafted onto them (Zarrouk et al. 2005). In recent years, new peach-almond hybrid rootstocks resistant to root-knot nematodes (Meloidogyne spp.) have also been developed (Pinochet 2009). Similarly, it has been reported that plum-derived rootstocks have been developed and marketed for peaches and other stone fruits (Moreno, Tabuenca, and Cambra 1995). Plum-derived rootstocks adapt well to very calcareous and heavy-textured soils, are tolerant to root asphyxia and iron chlorosis, and are resistant to root-knot nematodes. These rootstocks are selected for peaches for dwarf growth and high-density orchard establishment, strong graft compatibility, sustainable productive and quality fruit production (Reighard and Loreti 2008). The adoption of high-density orchards in fruit growing, obtaining higher yields per unit area, and the widespread cultivation of early peaches, including under cover, may be possible with the use of less vigorous or dwarf rootstocks. However, a satisfactory rootstock with characteristics suitable for these conditions and compatible with stone fruits has not yet been reached (Ben Yahmed, Ghrab, and Ben Mimoun 2016; Ben Yahmed et al. 2016). Studies have reported that rootstocks affect fruit yield and quality, tree health, the uptake of water and mineral substances from the soil, leaf gas exchange, flowering, formation of high-quality fruit buds, and harvest date (Font i Forcada, Gogorcena, and Moreno 2014; Ben Yahmed, Ghrab, and Ben Mimoun 2016; Reig et al. 2018a). Rootstocks also affect the mineral content of the leaves and the uptake of mineral nutrients (Zarrouk et al. 2005; Mestre et al. 2015). For the successful production of deciduous fruit species, selecting an appropriate graft combination appears to be very important. Because the interaction between rootstock and scion also affects water relations, leaf gas exchange, and plant growth vigor (Gonçalves et al. 2003). Various hypotheses have been proposed to explain the effects of rootstocks on grafted varieties. According to these hypotheses, the relationship of plant nutrients/water uptake from the soil and the interaction of hormones produced in the plant's underground and aboveground parts significantly affect the fruit yield-quality, growth form, and vigor of that tree (Sorce et al. 2002; Solari and DeJong 2006; Solari, Pernice, and DeJong 2006).

This study was planned and conducted to explain the effects of the rootstock-scion relationship on plant growth vigor in the "Transvalia" peach variety. The study was carried out in the greenhouse and field of the Eastern Mediterranean Transitional Zone Agricultural Research Institute in 2019-2020.

MATERIALS AND METHODS

The materials of the study consisted of 33 clonal rootstocks belonging to the genus Prunus obtained through selection and hybrid breeding (Table 1). The Transvalia and Flored peach varieties were grafted onto the selected and control rootstocks within the scope of the trial. In the study, the rootstock and scion diameters of these apricot varieties grafted onto selected rootstocks were measured with a caliper, and the seedling heights were measured with a meter at 15-day intervals from May to October. Statistical analysis was applied to the values at the end of the vegetation period in which the trial was conducted. Thus, the effects of rootstocks, varieties, and their interactions on rootstock diameter, scion diameter, and seedling height were tried to be observed.

The study was designed as a randomized block design, with three replications and five plants per replication. The obtained data were analyzed using analysis of variance ($P<0.05$). The comparison of means was carried out using the LSD test.

RESULTS

The rootstock diameter values for the Flored and Transvalia peach varieties grafted onto selected and control rootstocks at the end of the vegetation period of the study are presented in

Table 10. When examining this parameter, it was found that the differences among rootstocks, varieties, and the rootstock x variety interactions were statistically significant. The rootstock diameter values ranged from 9.07 mm to 15.41 mm. The highest rootstock diameter values were observed in GN-22 (15.41 mm), KL-38 (15.28 mm), and GF-677 (15.24 mm), and these rootstocks were in the same statistical group. The lowest rootstock diameter values were measured as 9.07 mm and 9.25 mm for KL-4 and KL-26, respectively. The rootstock diameter values of the varieties were close to each other, with Flored at 12.47 mm and Transvalia at 12.22 mm. The 0.25 mm difference was considered significant. Among the rootstock x variety interactions, the highest rootstock diameter values were obtained in the GN-22/Flored (15.56 mm), KL-38/Flored (15.44 mm), and GF-677/Flored (15.39 mm) combinations.

The scion diameter values for the Flored and Transvalia peach varieties grafted onto selected and control rootstocks at the end of the vegetation period of the study are presented in Table 11. It was found that the differences among the two factors examined and their interactions were statistically significant. The scion diameter values ranged from 7.86 mm to 13.36 mm. The highest scion diameter values were found in GN-22 (13.36 mm), KL-38 (13.26 mm), and GF-677 (13.22 mm), with no significant statistical differences among these rootstocks. The lowest scion diameter values were measured as 7.86 mm and 8.02 mm for KL-4 and KL-26, respectively. The effects of the varieties on scion diameter values were close to each other, with the Flored variety measuring 10.81 mm and the Transvalia variety measuring 10.60 mm. In the rootstock x scion interactions, the highest scion diameter values were obtained from the GN-22/Flored (13.50 mm), KL-38/Flored (13.39 mm), and GF-677/Flored (13.35 mm) combinations.

The seedling height values for the Flored and Transvalia peach varieties grafted onto selected and control rootstocks at the end of the vegetation period of the study are provided in Table 12. It was found that the differences among the two factors investigated and their interactions were statistically significant. The seedling height values were observed to be similar to the rootstock and scion values. The highest seedling height values were measured as 138.47 cm in GN-22 rootstock. This rootstock was followed by GF-677 and KL-38 rootstocks, and these three rootstocks were in the same statistical group. The lowest seedling height was measured as 81.47 cm in KL-4 rootstock. Among the rootstocks examined in the study, 5 produced seedlings shorter than 1 meter. The seedling heights for varieties were close to each other, with Flored at 112.05 cm and Transvalia at 109.86 cm. In the rootstock x scion interactions, the highest seedling height values were observed in GN-22/Flored (139.84 cm), KL-38/Flored (138.70 cm), and GF-677/Flored (138.32 cm) combinations.

DISCUSSION AND CONCLUSION

Rootstocks influence the growth vigor of the scion varieties grafted onto them (Gravite et al. 2018). This effect is crucial for determining planting density in orchard establishment (Yordanov et al. 2015). Depending on the growth vigor in fruit trees, the amount of fruit per unit stem cross-sectional area can vary (Miloseviç, 2011). Attention to these criteria is necessary in rootstock breeding studies. When examining the seedling development of peach varieties grafted onto selected and control rootstocks, significant differences were observed both between rootstocks and varieties. Particularly, combinations of rootstocks and scions with similar origins exhibited stronger growth, while rootstocks of P. domestica origin showed more dwarf growth. Additionally, various rootstock and scion combinations with different growth vigor were formed. It was determined that the differences in growth vigor among varieties stem from the effects of rootstocks on the varieties, and these differences are a significant result of the interaction between the rootstock and scion. It is thought that the primary reason for this situation is the different origins of the rootstocks. At the end of the study, it was observed that besides strong-growing rootstocks, dwarf rootstocks also exist. These rootstocks are understood to have the potential for use in high-density planting fruit orchards in the future.

ABSTRACT

The compatibility of selected rootstocks with fruit varieties is crucial in rootstock breeding programs. A high grafting success rate ensures the commercial acceptance of the rootstock. This study was conducted in the greenhouses of the Eastern Mediterranean Transitional Zone Agricultural Research Institute Directorate during the years 2020-2021. In the study, 33 selected rootstocks and 4 control rootstocks were used. The peach varieties used were Transvalia and Flored, while the almond varieties were Feragnes and Ferraduel. The grafting studies revealed significant differences (at the 1% level) in the grafting success rates of the rootstocks with the peach varieties. The highest grafting success rates were observed in GN-22 (91.50%), FC-19 (90.66%), Rootpack-20 (90.50%), FC-22 (89.50%), and GF-677 (88.66%). The average grafting success rate across all combinations was 73.33%. Out of the 38 rootstocks, 24 had a grafting success rate of 70% or higher, which was considered a positive result. The lowest grafting success rates were found in the rootstock candidates KL-30 (56.33%) and KL-44 (56.16%). In the almond varieties, the grafting success rates ranged from 57.66% to 96.00%. The highest grafting success rates were observed in GN-22 (96.00%), GF-677 (93.83%), and FC-19 (92.66%), while the lowest grafting success rates were found in KL-1 (57.66%), KL-6 (57.83%), and KL-4 (58.83%). The average grafting success rate for the almond varieties was 73.18%, with most rootstocks having a grafting success rate above 70%, which was considered a positive outcome. The study identified a significant number of clonal rootstocks that could be used for peach and almond fruit varieties.

INTRODUCTION

Stone fruits are among the most widely cultivated fruits globally, with peaches and almonds holding significant importance. Peach is one of the most extensively bred fruits. In recent years, a considerable number of new peach and nectarine varieties have been developed, leading to an increased interest among consumers and producers. Among cultivated fruit varieties, peach shows the greatest phenological differences (Reig et al. 2016). In the Northern Hemisphere, fresh peaches and nectarines can be found in markets for six months of the year. With advances in technology, greenhouse cultivation techniques have extended this calendar even further. These characteristics necessitate the cultivation of peaches in various environments and climates. Almond cultivation is an important agricultural sector worldwide, with significant economic, nutritional, health, environmental, and cultural value. In the Mediterranean region, almonds hold historical and cultural importance. The United States alone accounts for a large portion of global almond production, followed by Spain, Iran, and Italy. Almond cultivation is essential due to its economic value and rich nutritional content, which is beneficial for health. Almonds can be grown in a variety of soil and climate conditions. Given the diverse climate and soil conditions for peach and almond cultivation, the selection of rootstocks becomes crucial. This necessitates the acceleration of breeding programs to develop suitable rootstocks for these new varieties (Iglesias, Carbo, and Bonany 2009). This study was designed and conducted to determine the graft take rates of the rootstock-scion combinations using Transvalia and Flored peach varieties. The study was conducted in the greenhouses and fields of the Eastern Mediterranean Transitional Zone Agricultural Research Institute Directorate in 2019-2020.

MATERIAL AND METHOD

The materials for the study consisted of 33 clonal rootstocks obtained through selection and hybrid breeding of the genus *Prunus* (Table 1).

Transvalia and Flored peach varieties were grafted onto selected and control rootstocks within the scope of the trial. The graft take rates of the seedlings were recorded two months after grafting. Statistical analysis was applied to the obtained values, thus revealing the compatibility of rootstocks with the varieties. The study was established in a randomized block design with three replications, each replication consisting of five plants. Variance analysis was applied to the obtained data ($P<0.05$). Comparison of means was performed using the LSD test.

RESULTS

The graft take rates of Flored and Transvalia peach varieties on selected and control rootstocks are given in Table 2. The differences in graft take rates between rootstocks, varieties, and rootstock/variety interactions were found to be statistically significant. The graft take rate of Transvalia variety was found to be 74.89%, higher than that of Flored variety (71.79%). It was determined that the rootstocks grafted with peach varieties showed statistically significant differences in graft take rates at the 1% level, with the highest graft take rates observed in GN-22 (91.50%), FC-19 (90.66%), Rootpack-20 (90.50%), FC-22 (89.50%), and GF-677 (88.66%) rootstocks among the selected and control rootstocks. In the distribution where the average graft take rate was 73.33%, it was considered positive that 24 out of 38 rootstocks had a graft take rate of 70% and above. The lowest graft take rates were found in rootstock candidates KL-30 (56.33%) and KL-44 (56.16%). It was determined that the graft take rates also showed statistically significant differences at the 1% level in rootstock/scion interactions, with these rates ranging from 54.66% to 96.33%. The highest graft take rates were calculated in GN-22/Transvalia (96.33%), GF-677/Transvalia (94.33%), FC-19/Transvalia (93.33%), and Rootpack-20/Transvalia (91.00%) combinations. It was noted that the Transvalia variety formed compatible combinations with selected and control rootstocks, and that Rootpac-20 and FC-22 rootstocks achieved high graft take rates with both peach varieties. In general, plum group rootstocks did not achieve very high graft take rates with peach. It was determined that hybrid rootstocks had higher graft take rates overall, while the KL-38/Transvalia combination had a remarkably high graft take rate of 82.00%. The lowest graft take rates were found in KL-30/Transvalia (54.66%), KL-44/Transvalia (56.00%), KL-44/Flored (56.33%), KL-30/Transvalia (58.00%), KL-1/Flored (60.00%), and KL-4/Flored (60.66%) combinations. In general, it was observed that graft take rates of 70% and above were achieved in rootstock/scion interactions.

The graft take rates of Ferragnes and Ferraduel almond varieties grafted onto selected and control rootstocks were found to be similar, with no statistically significant difference between them. The graft take rate averages of the varieties were very close, calculated as 73.26% for Ferragnes and 73.11% for Ferraduel (Table 3).

1-Different letters indicate that differences between means. In the interaction part, uppercase letters used after lowercase letters when comparing means. Rootstock means written in bold uppercase letters, variety means written in bold italic uppercase letters. 2- N.S.: Not Significant; **: p<0.01; *<0.05.3- Numbers in parentheses are arc transformation values.

The differences in graft take rates between selected and control rootstocks were found to be statistically significant at the 1% level. The graft take rates of the rootstocks ranged from 57.66% to 96.00%. The highest graft take rates were found in GN-22 (96.00%), GF-677 (93.83%), and FC-19 (92.66%) rootstocks, while the lowest graft take rates were found in KL-1 (57.66%), KL-6 (57.83%), and KL-4 (58.83%) rootstocks. In general, hybrid rootstocks showed higher graft take rates with almond varieties, possibly due to genetic proximity. In the distribution with an average graft take rate of 73.18%, it was considered positive that most rootstocks had graft take rates above 70%. It was observed from Table 29 that the combinations of both almond varieties with selected and control rootstocks showed statistically significant differences in graft take rates at the 1% level. In this distribution, graft take rates ranged from 54.33% to 96.33%, with the highest rates observed in seven combinations within the same statistical group. The highest values were found in GN-22/Ferragnes (96.33%), GN-22/Ferraduel (95.66%), and GF-677/Ferraduel (94.33%) combinations, while the lowest rates were observed in KL-44/Ferraduel (54.33%) and KL-1/Ferraduel (55.00%) combinations. In general, it was observed from Table 2 that plum group rootstocks showed lower graft take rates with almond varieties, while hybrid rootstocks achieved higher rates.

Figure 7. Observations on grafting and growing grafted buds.

Overall, the results of the grafting trials on the examined rootstocks and scions showed that graft take rates averaged above 54.66%, with the highest average reaching up to 96.00%. The study found that standard rootstocks generally had high graft take rates, with some selected rootstocks showing similarly high rates. The presence of many selected rootstock candidates with graft take rates between 75.00% and 94.66% suggests that the research conducted successfully and met its objectives. These results are promising for providing solutions to the rootstock needs of some temperate climate fruit species in Turkish horticulture. Approximately 1.5 months after grafting, the growth and development of the shoots measured and observed as shown in Figure-7.

DISCUSSION AND CONCLUSSION

Rootstocks affect the vigor of the varieties grafted onto them (Gravite et al., 2018). This effect is quite important in determining planting density in orchards (Yordanov et al., 2015). The amount of fruit per unit trunk cross-sectional area can vary depending on the vigor of the fruit trees (Milosevic, 2011). These criteria should be considered in rootstock breeding studies. When examining the growth status of peach varieties grafted onto selected and control rootstocks, significant differences observed between rootstocks and varieties. Stronger growth observed in combinations with similar origins, while more dwarf growth observed in rootstocks derived from *P. domestica*. Additionally, various combinations of rootstocks and scions exhibited different growth vigor. The overall results of the grafting trials on the examined rootstocks and scions showed that graft take rates averaged above 54.66%, with the highest average reaching up to 96.00%. The study found that standard rootstocks generally had high graft take rates, with some selected rootstocks showing similarly high rates. The presence of many selected rootstock candidates with graft take rates between 75.00% and 94.66% suggests that the research conducted successfully and met its objectives. These results are promising for providing solutions to the rootstock needs of some temperate climate fruit species in Turkish horticulture. Approximately 1.5 months after grafting, the growth and development of the shoots were measured and observed as shown in Figure-7. It has been determined that the differences in growth vigor are due to the effects of the rootstock on the variety and that these differences are a significant result of the interaction between the rootstock and the scion. This situation is thought to be primarily due to the different origins of the rootstocks. At the end of the study, it was observed that, in addition to rootstocks showing strong growth, there are also dwarf rootstocks. It was understood that these rootstocks might have the potential to be used in high-density fruit orchards in the future.

USAGE OF PLANT ESSENTIAL OILS IN THE CONTROL OF PATULIN PRODUCING *Penicillium* SPECIES

ABSTRACT

Patulin is a toxin produced by some toxigenic species of fungi belonging to the *Penicillium*, *Aspergillus* and *Byssochlamys* genera. It is a type of enteropathogenic mycotoxin, it is rapidly absorbed by the intestines and can have toxic, mutagenic and cytotoxic effects in many living things. Patulin can be found especially in apples and apple products, and rarely in peaches, grapes, tomatoes, oranges and products derived from them. The most common patulin-producing fungus is *Penicillium expansum*. The main method to prevent and control the spread of patulin in food products is to prevent the development and production of patulin-producing fungi before and after harvest. Chemical and physical methods used to prevent patulin formation in apple fruits and derivatives, where patulin formation is most commonly observed, are expensive and may negatively affect product quality. Chemical applications require a thorough understanding of whether reaction products are toxic. In addition, some of these chemicals can seriously reduce the quality of the product by destroying its nutritional content and taste. Today, biological methods, such as the direct degradation of patulin by an antagonist microorganism or more natural factors such as plant extracts, stand out as the healthiest practices today. When the studies on the effects of some plant extracts on *Penicillium expansum*, the most important patulin producer, and patulin production are examined, *Ocimum basilicum* (basil), *Foeniculum sativum* (fennel), *Lavandula officinalis* (lavender), *Origanum majorana* (bridegroom), *Oreganum vulgare* (thyme), *Satureja montana* (winterwort), *Mentha arvensis* (mint), *Rosmarinus officinalis* (rosemary), *Salvia officinalis* (sage), *Thymus vulgaris* (thyme) essential oils were investigated. Studies have yielded promising results for plant essential oils.

Key words: Essential oil, *Penicillium*, patulin, apple

INTRODUCTION

Mycotoxins are natural toxins with low molecular weight and a wide variety of chemical structures, formed as a result of the secondary metabolism of fungi such as *Aspergillus, Penicillium, Fusarium, Alternaria* and *Claviceps*. They have strong and diverse toxic effects on human and animal health (Steyn and Stander, 1999). Patulin (PAT) is a toxic metabolite produced by various *Penicillium, Aspergillus* and *Byssochlamys* species (Harrison, 1989).

It usually contaminates cereals, vegetables, fruits and their derivatives, especially apples and derivatives. Patulin can easily enter and accumulate in the processing of final products due to its water-soluble and heat-resistant properties (Moake et al., 2005). Patulin also contaminates many other foods such as apples, dried figs and corn. Currently, patulin is considered a global toxin and many countries monitor its residues in foods (Zhao et al., 2018). Patulin can be seen in highly acidic fruits, vegetables and products such as apples, apple juice and concentrate, apple jam and candied fruit, pears, apricots, oranges, peaches, and tomatoes (Tunail, 2000). Among mycotoxins, patulin (4-hydroxy-4H-furo[3,2-c] pyran-2(6H)-one) is a polyketide lactone with a molar mass of 154.12 g/mol and a melting point of 110℃. It is soluble in water, stable under acidic conditions and heat, and cannot be thermally denatured (Saleh and Göktepe 2019a; Zheng et al., 2020).

Patulin was first isolated from *Penicillium griseofulvumin* by Harold Raistrick in 1943 (Saleh and Göktepe, 2019a). Shortly after its identification, patulin was investigated as an antimicrobial agent against some gram-positive and gram-negative bacteria under the name of "tercinin" at the British Medical Research Center. However, it did not take long for researchers at the center to detect its toxic effects in 1944 (Saleh and Göktepe, 2019b). Its activity as an antimicrobial was seen to be very promising, as it proved to be up to ten times more effective in the treatment of infections caused by *Bacillus* ssp. At that time, the substance was selected from *Penicillium patulum* (later named *Penicillium urticae* and today known as *Penicillium griseofulvum*). However, the emergence of its toxic effects in both plants and animals between 1950 and 1960 prevented its clinical use as an antibiotic. Since the 1960s, patulin has been reclassified and is now known as a toxic secondary metabolite of fungal origin, i.e. a mycotoxin (Basso, 2019). To determine the maximum patulin production by different Penicillium species, Dombrink-Kurtzman and Blackburn (2005) compared six different culture media. 10 strains of *Penicillium expansum, Penicillium griseofulvum, Penicillium clavigerum* and *Penicillium coprobium*, which were previously identified as patulin producers, were studied. Three types of liquid media (PDB, MEB and 5-GYEP) were tested in manganese-free and 152 μmol manganese-containing forms (6 media). The flasks were incubated in a shaking incubator (240 rpm) at 25°C for 96 hours, then filtered, extracted and analyzed by HPLC. After 96 hours, P. griseofulvum isolates were determined to be the highest patulin producers (Table 1).

Table 1. Patulin-Producing Fungi

Patulin-Producing Fungi	*Penicillium expansum*	Hohler, 1998
	Penicillium patulum	
	Aspergillus terreus	
	Aspergillus giganteus	
	Aspergillus clavatus	
	Penicillium aurantiogriseum (Penicillium cyclopium)	
	Penicillium equinum (Penicillium Terrestre)	
	Penicillium melinii	
	Penicillium claviforme	
	Byssochlamys nivea	
	Byssochlamys fulva (Paelomyces variotii)	
	Penicillium roquefortii	

Thirteen *Penicillium* species can produce patulin, including *P. expansum*, a major patulin-producing species (Bokhari et al., 2009).

According to the World Health Organization, the maximum acceptable patulin level in apple juice has been determined as 50 µg/L (Saleh and Göktepe, 2019a). This value is in line with the recommendations of the Food and Drug Administration (FDA), the National Health Surveillance Agency (ANVISA) and the European Union (EU), the latter of which has limited the patulin level in solid apples to 50 µg (Basso, 2019). According to the recommendation of the European Commission and based on the determined patulin level (43 µg/kg body weight), the maximum daily patulin dose allowed temporarily has been fixed at 0.4 µg/kg body weight. This level has been adopted in most health risk assessment analyses conducted on patulin (Saleh and Göktepe, 2019a).

Due to the high prevalence of patulin, concerns have arisen regarding the toxicological effects of patulin on humans and animals through consumption. Patulin causes various chronic health effects on the genetic, immune and central nervous systems in animals, although its effects on humans are not yet clear (Sajid et al., 2018).

CONTROLING PATULIN

Physical methods include separation, high-pressure water washing of fruits, cooling, juice clarification, filtration, adsorption, pasteurization, and radiation for processing raw materials such as apples to prevent patulin contamination. Physical methods provide good results but require significant labor and material resources; they are expensive and may even affect product quality (Zheng et al., 2020). Chemical methods include ammonia and potassium permanganate, which can reduce patulin content in fruit juice by more than 99%. This technique is the most effective way to detoxify patulin, but it causes serious damage to product quality. In addition, sulfur dioxide, ascorbic acid, N-acetylcysteine, and glutathione and calcium D pantothenate can reduce the amount of patulin in fruit juice. However, the addition of these chemicals requires a thorough understanding of the reaction mechanism, that is, whether the reaction products are toxic or not. In addition, some of these chemicals can seriously reduce the quality of the product by destroying its nutritional content and flavor (Zheng et al., 2020). Biological methods, especially the direct degradation of patulin by an antagonist microorganism, have shown great promise for application in the control of patulin contamination. However, several issues need to be considered before using these microorganisms. First of all, it is necessary to investigate whether patulin is adsorbed or degraded by microorganisms. Degradation of patulin by microorganisms can prevent further overprocessing of patulin if it is converted to a less toxic or non-toxic compound. For this, patulin can be reduced through an enzymatic effect (Zheng et al., 2020).

Although physical-chemical methods have varying degrees of success, limited effectiveness and loss of important nutrients still prevent their application in food industries. Biological methods are considered a promising solution for mycotoxin decontamination and are widely investigated (Li et al., 2019).

The demand for alternative methods is rapidly increasing as consumers are less likely to prefer fruits preserved with synthetic fungicides against infections. Plant extracts are one of these alternative methods. Many plants have natural antimicrobial potential as they contain phytochemicals that exhibit antimicrobial and cytotoxic effects on microorganisms. Since they are non-toxic and environmentally and nature-friendly, they have potential as an alternative to synthetic fungicides in application to agricultural products and foods (Salhi et al., 2017; El-shahir et al., 2022).

The use of naturally obtained chemicals from plants that prevent the reproduction and development of plant pathogenic fungi will be a more realistic and ecologically reliable method in the integrated control of plant diseases and will play an important role in the development of commercial pesticides for plant protection strategies in the future (Yanar et al., 2011, Hubert et al., 2013).

Volatile oils obtained from plant materials by various extraction methods have been investigated for years in our country and in the world for their effects against plant pathogens. Today, there are many plant by-products that have antimicrobial properties against many plant pathogenic bacteria and fungi and that occur together with the main substance obtained from plants (Satish et al. 1999). The basic method to prevent and control the spread of patulin, an important mycotoxin, in apples and its products is to prevent the growth and patulin production of patulin-producing strains during the pre-harvest and post-harvest periods of apples (Moake et al., 2005).

ANTIFUNGAL EFFECTS OF ESSENTIAL OILS

In a study conducted on apple fruits, the antifungal effects of the essential oils of *Ocimum basilicum* (basil), *Foeniculum sativum* (fennel), *Lavandula officinalis* (lavender), *Origanum majorana* (oregano), *Origanum vulgare* (thyme), *Satureja montana* (zathane), *Mentha arvensis* (mint), *Rosmarinus officinalis* (rosemary), *Salvia officinalis* (sage), and *Thymus vulgaris* (thyme) were investigated against *Botrytis cinerea* and *Penicillium expansum*. As a result of the study, it was determined that *O. vulgare, S. montana* and *T. vulgaris* showed high antifungal effects in 1% emulsions. In 10% emulsions of essential oils, it caused phytotoxicity in the fruit (Lopez-Reyes et al., 2010). In studies conducted on essential oils obtained from thyme and thyme oil, the inhibitory effect of 10-500 µl/L carvacrol and thymol was tested in petri dishes containing PDA. As a result of the studies, thymol (100 µl/L) inhibited the growth of *Penicllium italicum* and *P. digitatum* by 68% and 47%, respectively (Pérez-Alfonso et al., 2012)

The antifungal effect of essential oils of 25 different plants against *Penicllium expansum, P. brevicompactum, Fusarium oxysporum, F. verticillioides, Aspergillus flavus, A. fumigatus* agents was investigated, and it was determined that *Pimenta dioica* essential oil showed the highest effect among these plants (Zabka et al., 2009)

In a study investigating the antifungal effects of essential oil components of plants growing wild in Greece such as *Salvia pomifera* subsp. *calycina, Salvia fruticosa, Satureja thymbra ve Origanum onites* against *Aspergillus niger, A. flavus, P. expansum, Phomopsis helianthi, Trichoderma viride, Cladosporium cladosporioides, Alternaria alternata*, it was determined that the essential oil with the lowest antifungal activity was sage, while the highest and broadest activity was found in the essential oils of *O. onites* and *S. thymbra* containing carvacrol. Among the tested components, it was determined that carvacrol had the highest antifungal effect and 1,8-cineole had the lowest effect (Sokovic et al., 2002).

In a study, lemon and orange essential oils were tested and it was found that patulin production by P. expansum in apples was completely inhibited with 0.2% lemon oil solution and more than 90% with 0.05% lemon oil and 0.2% orange oil solutions. Nguefack et al. (2012) reported that in addition to Ocimum gratissimum essential oil, the combination of Cymbopogon citratus, Ocimum gratissimum and Thymus vulgaris was also effective in reducing patulin levels. Other effective essential oils were tea tree, orange and lemon essential oils. In another study, it was found that the use of essential oils such as clove and cinnamon oil was effective in reducing patulin levels in apples (Sivakumar and Bautista-Baños, 2014). Similarly, it has been reported that enzymes (such as polyphenol oxidase and peroxidase) formed as a result of the use of garlic extract reduce patulin levels in fruits (Chen et al., 2023). For example, polyphenol oxidase extracted from apples has been shown to effectively reduce patulin levels in apple juice.There are many other studies on the use of essential oils against toxin producing fungi. Some of these studies are given in Table 2.

Table 2. Essential oils used against patulin-producing fungi

CONCLUSIONS

Natural toxins formed as a result of secondary metabolism of fungi such as *Penicillium, Aspergillus Fusarium, Alternaria* and *Claviceps* are called mycotoxins. Patulin produced by *Penicillium, Aspergillus* and *Byssochlamys* species poses a danger to human and animal health. Although physical methods are successful in combating, there are difficulties due to limited effectiveness and loss of nutrients. Biological methods are accepted as a promising solution in the detoxification of mycotoxins and are being researched. Some chemicals used in chemical combat are not preferred because they cause degradation of nutrients and damage to flavor. As a result, the demand for alternative methods in combat methods is rapidly increasing. Essential oils obtained from plant materials by various methods are used as a combat method and their effects are being investigated. It has been determined that essential oils containing chemicals such as thymol and carvacrol in their components have high antifungal activity in many studies. It is cheaper, applicable and does not threaten human and environmental health compared to other methods. More research is needed in this sense.

ABSTRACT

Origanum is a significant medicinal and aromatic plant belonging to the Lamiaceae family. In parallel with the developments in studies on the isolation and determination of various bioactive substances contained in *Origanum* species, it has been determined that they contain many different compounds. The main groups of these compounds are terpenoids, triterpene acids, hydroquinones, flavonoids, phenolic acids, hydrocarbons containing carvacrol, thymol, and various extracts as the main bioactive components. Studies on the effects of these different components against plant diseases have been the focus of attention of researchers in recent years. In studies on the impact of essential oils obtained from *Origanium* species on plant diseases, the effects of essential oils obtained from *Origanum vulgare, O. compactum, O. heracleoticum, O. onites, O. syriacum, O. dictamnus, O. acutidens, O. rotundifolium,* and *O. majorana* species were mostly in investigated. Essential oils obtained from *Origanum* species are used as antifungal agents against *Alternaria* spp, *Aspergillus* spp., *Penicillium* spp., *Rhizopus* spp., *Fusarium* spp., *Phytophthora* spp., *Pythium* spp., *Colletotrichum* spp., *Monilinia* spp., *Geotrichum citri-aurantii, Verticillium dahliae, Botrytis cinerea, Plasmopara viticola, Sclerotium rolfsii, Rhizoctonia solani, Macrophomina phaseolina, Sclerotinia sclerotiorum, Phoma tracheiphila, Stemphylium beticola* and *Aphanomyces euteiches.* They also have been observed to be effective as antibacterials in research on *Clavibacter* spp., *Xanthomonas* spp., *Pseudomonas spp., Erwinia spp., Ralstonia solanacearum and Pectobacterium carotovorum. The* essential oils from the *O. vulgare* plant were effective against *Zucchini yellow mosaic virus* coat protein (ZYMV-CP) and tomato leaf curl New Delhi virus (ToLCNDV) infections. Further studies are needed to evaluate the efficacy of the model products of these essential oils.

Key words: *Origanum* spp., antifungal, antibacterial, antiviral, plant diseases

INTRODUCTION

Origanum is an important medicinal and aromatic plant belonging to the Lamiaceae family. In parallel with the developments in studies on the isolation and determination of various bioactive substances contained in Origanum species, it has been determined that they contain many different compounds. The main groups of these compounds are terpenoids, triterpene acids, hydroquinones, flavonoids, phenolic acids, hydrocarbons containing carvacrol, thymol and various extracts as the main bioactive components. Studies on the effects of these different components against plant diseases have been the focus of attention of researchers in recent years.

Essential oils (EO) are aromatic oily liquids obtained from various plants, generally localized in temperate and hot countries. Essential oils, as secondary metabolites in nature, play an important role in the protection of plants as antibacterial, antiviral, antifungal and insecticide (Bakkali et al., 2008).

As observed from antifungal trials in different literature, essential oils have a great antifungal effect on many plant pathogens and have been determined to inhibit most of the plant pathogens tested in the laboratory (Omar and Kordali, 2019).

Origanum is an important medicinal and aromatic plant belonging to the Lamiaceae family. The fact that the plants of the Lamiaceae family are the source of many essential oils used in medicine and perfumery and are used both in the treatment of diseases and as spices shows the importance of this family. The effective results obtained in studies on the effects of these essential oils on plant diseases have also become the focus of agricultural research in recent years.

Thymus, Origanum, Satureja, Tymbra and Coridothymus are among the most important plants of the Lamiaceae family. The main components of the essential oils of these genera (with some exceptions) are usually carvacrol or thymol or both. One of the most important of these genera is Origanum, and 23 species of this genus grow naturally in our country. There are 41 species of this genus in the world.

EFFECT of *Origanum* spp. ESSENTIAL OILS AGAINST FUNGAL DISEASES

Guzmán-Guzmán et al. (2003) reported that the preventive effect of various concentrations of peppermint, eucalyptus, laurel, clove, sweet marjoram, rosemary, cinnamon, pepper, grapefruit and origanum spp. essential oils (1,250, 2,500 and 3,750 ppm) was possible to control *Fusarium oxysporum* f. sp. *phaseoli.* Eight substances, three of which are the main components of essential oils, from Mediterranean aromatic plants (*Verbena officinalis*, *Thymus vulgaris* and *Origanum vulgare*), were tested in vitro against some phytopathogenic fungi and postharvest fruit rot agents such as *Botrytis cinerea, Penicillium italicum, P. expansum, Phytophthora citrophthora* and *Rhizopus stolonifer*, which were previously found to be active against them. The tested compounds, β-phellandrene, β-pinene, camphene, carvacrol, citral, o-cymene, γ-terpinene and thymol exhibited fungicidal activity (Camele et al., 2012). The essential oil and various extracts obtained from *Origanum acutidens* and methanol extracts were evaluated for their antioxidative, antimicrobial and antiviral properties obtained from callus cultures (MeOH). In particular, the essential oil exhibited strong antimicrobial activity with a significant inhibitory effect against 27 of 35 bacteria (77%), 12 of 18 fungi (67%) and tested. GC and GC-MS analyses resulted in the identification of 38 components of the oil, the main component being carvacrol. MeOH Extracts obtained from plant parts showed better antioxidative activity than butylated extracts (Sökmen et al., 2004). *Origanum onites* and other essential oils were evaluated for their antibacterial and antifungal properties. The investigated oils showed antimicrobial activity and provided antifungal activity at a high concentration of 200 μg/mL. The fungi that *Origanum onites* is active against can be listed as follows; *Colletotrichum acutatum, C. fragariae and C. gloeosporioides* (Altintas et al., 2013). 83.37% carvacrol was observed as the main component in the essential oil obtained from *Origanum vulgare*. Germination of *Aspergillus flavus, A. parasiticus, A. terreus, A. ochraceus, A.*

fumigatus and *A. niger* agents was inhibited by the obtained oil (Carmo et al., 2008; Mitchell et al., 2010). *Origanum vulgare* essential oil was found to be effective against *Colletotrichum gloeosporoides, F. oxysporum, Rhizoctonia solani, P. ultimum, Botrytis cinera* (Sun et al., 2007) (Table 1).

Plant essential oils can potentially replace synthetic fungicides in the management of postharvest fruit and vegetable diseases. This study evaluated the in vitro and in vivo activities of thymol, carvacrol, linalool and trans-caryophyllene, the single components of *Origanum vulgare* essential oil, against *Monilinia laxa, M. fructigena* and *M. fructicola*, which are important phytopathogens and causative agents of brown rot in pome and stone fruits before and after harvest. Furthermore, the possible phytotoxic activities of these components were evaluated and their minimum inhibitory concentrations (MICs) were determined. In vitro experiments showed that thymol and carvacrol had the highest inhibitory concentrations. The results of in vivo experiments confirmed the potent activity of thymol and carvacrol against brown rot of peach fruits. The MIC value of thymol was found to be 0.16 lg/lL against *M. laxa* and *M. fructigena* and 0.12 lg/lL against *M. fructicola*, while for carvacrol it was found to be 0.02 lg/lL against the first two *Monilinia* species and 0.03 lg/lL against the third. The results of this study showed that thymol and carvacrol can be used after appropriate formulation to control postharvest fruit diseases caused by the examined *Monilinia* species (Elshafie et al., 2015). In addition, the oil obtained from the *Origanum compactum* plant, which contains carvacrol and thymol in its components, was found to be effective against *Alternaria alternata, Bipolaris oryzae, Fusarium graminearum, Fusarium equiseti, Fusarium verticillioides* agents (Santamarina et al., 2015) (Table 1).

It has been found to be quite successful against *Origanum majorana, Aspergillus niger, Monilinia fructicola, Penicillium expansum*. Its components include terpinen-4-ol, δ-2-carene, y-terpinene, carvacrol (Della Pepa et al., 2019). *Origanum acutidens* and its components are carvacrol, thymol, p-cymene; In vitro studies against *Alternaria alternata, A. solani, Botrytis* sp., *Fusarium acuminatum, F. culmorum, F. equiseti, F. nivale, F. oxysporum, F. sambucinum, F. semitectum, F. solani, Monilinia* sp., *Pythium ultimum, Phytophthora capsici, Rhizoctonia solani, Sclerotinia minor, Verticillium dahliae* have shown that thymol and carvacrol, which contain free hydroxyl groups in the p-cymene skeleton, are more fungitoxic than p-cymene (Kordali et al., 2008) (Table 1).

In a study, an alternative to the synthetic fungicides used was sought. *Botrytis cinerea*, a destructive fungal pathogen that causes gray mold disease in tomatoes. Antifungal activities of essential oils obtained from the aboveground parts of aromatic plants belonging to the Lamiacea family. Origanum (*Origanum syriacum* L. var. *bevanii*), lavender (*Lavandula stoechas* L. var. *stoechas)* and rosemary (*Rosmarinus officinalis* L.) were investigated against *B. cinerea*. It was found that the contact and volatile phase effects of different concentrations of essential oils inhibited the growth of *B. cinerea* in a dose-dependent manner. It was found that the volatile phase effects of essential oils were more effective on fungal growth than the contact phase effect. It was found that the volatile vapor of Origanum oil in air at 0.2 μg/ml completely inhibited the growth of *B. cinerea* (Soylu et al., 2010).

Plasmopara viticola is the most important pathogen in vine cultivation. Alternatives to reduce fungicides are needed to ensure a fully sustainable vineyard ecosystem, consumer health and public acceptance. Essential oils are among the most promising natural plant protection alternatives and have demonstrated antibacterial, antiviral and antifungal properties in various products. In the study, grape leaves were infected with *P. viticola* and then continuously fumigated. *Origanum vulgare* essential oil was proven to be sufficient to reduce the development of the pathogen by 95% 24 hours after infection during the steam treatment (Rienth et al., 2019) (Table 1).

Legumes products such as chickpeas, lentils and dry peas are widely grown for human and animal consumption. It is quite difficult to control pathogens that cause yield losses. Alternative methods should be resorted to due to the negative effects of fungicides used on human and environmental health. Safe and environmentally friendly plant-derived essential oils have been reported to be effective against some pathogenic fungi. Growth in essential oil supplemented growth media and inverted petri plate assay were used to determine the effects of 38 oils and their volatiles on mycelial growth and spore germination of important pathogenic fungi: *Aphanomyces euteiches, Botrytis cinerea, Colletotrichum lentis, Didymella pisi, D. rabiei, D. lentis, Fusarium avenaceum, Stemphylium beticola, Sclerotinia sclerotiorum* and *Pythium sylvaticum.* Addition of palmarosa, thyme, clove, cinnamon, lemongrass, citronella and oregano oils to the media inhibited the mycelial growth of all pathogens by 100% at 1:1,000 to 1:4,000 dilutions (Parikh et al., 2021) (Table 1).

The antioxidant and antimicrobial activities of methanol or dichloromethane extracts obtained from wild and organic culture samples of *Origanum dictamnus* were determined. Rancimate and malondialdehyde (MDA) were used to measure the antioxidant activity by HPLC methods in comparison with common commercial antioxidants butylated hydroxytoluene (BHT) and α-tocopherol. Extracts showing high antioxidant activity were encapsulated in liposomes and their antioxidant activity was estimated again by differential scanning calorimetry (DSC). Thermal-oxidative decomposition of samples (pure liposomes and encapsulated extracts) and modification of the main transition temperature for lipid mixture and splitting of the calorimetric peak in the presence of antioxidants were also investigated by DSC method. All extracts showed antioxidant and antimicrobial activities. Their effects were proved to be superior to α-tocopherol. Methanol extract (240 ppm) of organically grown *O. dictamnus* showed higher activity than butylated hydroxytoluene. After encapsulation in liposomes, antioxidant and antimicrobial activities were proven to be higher than the same extracts in pure form (Gortzi et al., 2007) (Table 1).

In the study, in vitro antifungal activities of essential oils and their main components (carvacrol, trans-etol and 1,8-cineole) obtained from taxonomically different medicinal plants such as thyme (*Origanum syriacum* L.), fennel (*Foeniculum vulgare* Mill.) and laurel (*Laurus nobilis* L.) growing naturally in different regions of Hatay province were investigated. The effectiveness of essential oils investigated against soil-borne fungal disease agents of bean plants, *Sclerotium rolfsii, Rhizoctonia solani* and *Macrophomina phaseolina,* has been determined to be quite high (Türkölmez and Soylu, 2014) (Table 1).

EFFECT of *Origanum* spp. ESSENTIAL OILS AGAINST BACTERIAL DISEASES

Origanum heracleoticum, whose main component is carvacrol, has been found to be effective against fungal agents such as *Aspergillus niger*, *Botrytis cinerea*, *Monilinia fructicola*, *Penicillium expansum* and bacterial agents such as *Clavibacter michiganensis, Xanthomonas campestris, Pseudomonas fluorescens, Pseudomonas syringae* pv. *phaseolicola* (Della Pepa et al., 2019). *Clavibacter michiganensis* subsp. *michiganensis* (Smith) Davis et al. (Cmm) and *Ralstonia solanacearum* Yabuuchi et al. (Smith) (Rs) are important seed-borne bacterial pathogens of tomato (Solanum lycopersicum) listed as A2 pests in the EPPO (European and Mediterranean Plant Protection Organization) region. Currently, there are few strategies to control these pathogens and seed control with eco-compatible approaches is widely promoted. In this study, essential oils (EOs) of oregano (*Origanum vulgare*), garlic (*Allium sativum*), basil

(*Ocimum basilicum*), cinnamon (*Cinnamomum zeylanicum*), clove buds (*Syzygium aromaticum*), thyme (*Thymus vulgaris)* were tested in vitro for their antimicrobial activities against Cmm and Rs. The tested essential oils caused significant inhibition of bacterial growth with very promising MBC (minimum bactericidal concentration) and MIC90 (minimum inhibitory concentration that causes 90% growth inhibition) values. Furthermore, in vivo germination test showed that there was no significant reduction in seed germination when the substances were applied as seed treatments. To test the antimicrobial activity of thyme and cinnamon oil in seed treatment in vivo, a rapid molecular screening method was developed for the specific quantification of Cmm in the presence of a plant matrix by real-time PCR without resorting to time- and space-consuming whole plant experiments (Orzali et al., 2020) (Table 1).

Hydrodistilled essential oils from *Origanum acutidens, O. rotundifolium* and *O. vulgare*. showed a broad spectrum of antibacterial activity on *Xanthomonas axonopodis*. At the same time, other main components such as carvacrol, thymol and terpinen-4-ol and linalool were found to have antimicrobial activity (Dadaşoğlu et al. 2011) (Table 1).

In vitro activity of *Origanum heracleoticum* L. essential oil compounds was tested against *Verticillium dahliae, Fusarium oxysporum, Phoma tracheiphila, Phytophthora cactorum* and *Botrytis cinerea* using four different concentrations (1×104 to 1×10-2 µg.ml-1) by well diffusion method. Carvacrol and plain essential oil showed inhibitory effect against all tested pathogens at higher concentrations (Salomone et al., 2008). In this study, essential oils of four aromatic plants were tested. The compositions and antimicrobial effects of the essential oils of cinnamon (*Cinnamomum zeylanicum*), thyme (*Thymus vulgaris*), oregano (*Origanum vulgare*) and clove (*Syzygium aromaticum*) were investigated against plant pathogenic bacteria (*Pectobacterium* spp. and *Pseudomonas* spp.). Both are commonly associated with diseased fruit trees. As a result, it was concluded that some essential oils can be used for the control of postharvest bacterial pathogens. The findings of the present study showed that essential oils have the potential to be used as antibacteial agents (Božik et al., 2017) (Table 1).

Erwinia amylovora was found to be susceptible to essential oils obtained from *Melissa officinalis, Mentha arvensis, Origanum compactum, O. vulgare, Thymus vulgaris, Eugenia caryophyllata, Mentha pulegium* plants (Kokoškova and Pavela, 2007) (Table 1).

EFFECT OF *Origanum* spp. ESSENTIAL OILS AGAINST VIRAL DISEASES

A study aimed to evaluate the antiphytoviral activity of applications with three essential oils obtained from *Origanum vulgare, Thymus vulgaris* and *Rosmarinus officinalis* and their corresponding hydrosols on *Zucchini Yellow Mosaic Virus* and *Tomato Leaf Curl New Delhi Virus* infected squash plants. Applications were applied after or simultaneously with virus inoculation to detect an inhibition or curative activity, respectively. Symptoms were observed and weekly samplings were done. Virus titer and expression levels of phenylalanine ammonia lyase gene (PAL) were measured in treated and untreated infected plants by real-time PCR. PAL gene plays an important role in plant defense response as it is involved in tolerance/resistance to phytopathogens. A significant inhibition was observed with *O. vulgare* essential oil and hydrosol, resulting in a 10-4 fold reduction in virus titer after 3 weeks of treatment (Taglienti et al., 2022) (Table 1).

CONCLUSIONS

In recent years, interest in the biological activities of natural compounds has been increasing due to the increasing use of fungicides that pose a risk to human and environmental health. In plant protection, essential oils are reported to exhibit antiviral, antifungal and antibacterial activities and are considered promising for the formulation of safe antimicrobial agents. Essential oils are considered as an alternative method due to their low cost and availability, and further research is required to make their use widespread.

ABSTRACT

It is necessary to extend the period of supply of fresh products and raw materials for processing, which is related to the adaptation of sowing and planting periods of vegetable crops to the changed environmental situation.
Green beans are an important vegetable crop essential for nutritional balance and solving the protein problem for many peoples of the world.
The main reason for the development of this paper is the establishment and popularization of up-to-date scientific information on the phenological and morphological development of garden beans, with a view to expanding the range of varieties in this vegetable crop.
The experiments were carried out in the period 2021-2022, in the area of the village of Ezero, Nova Zagora municipality, with an altitude of 131 m, located in the Thracian valley. Four varieties of green beans were used. The experimental design was based on the block method. A total of 15 variants were tested, which were a combination of each variety and the three sowing dates.
The results show that late sowing (May) contributes to the formation of better biometric indicators, supporting better vegetative development of plants and the establishment of an actively photosynthesizing leaf apparatus. By sowing at the beginning of May, the plants develop under conditions closer to their biological requirements and a better synchronization between vegetative development, flowering and fruiting is achieved.

Keywords: garden beans, *Phaseolus vulgaris*, development, growth

INTRODUCTION

Green beans are an important vegetable crop, essential for nutritional balance and solving the protein problem for many peoples of the world. In the context of a healthy and rational diet for the population, there is a growing need to extend the period for the supply of fresh produce and raw material for processing, which is linked to adapting the sowing and planting times of vegetable crops to the changed environmental condition.

A detailed description of all stages of plant growth and development was made by Shaban (2014). The author defines two main phases of the bean life cycle: vegetative and reproductive. The vegetative phase lasts from seed germination until the first flower bud appears. During this phase, the stem and branches form nodes with lateral buds from which vegetative and generative organs later develop.

The reproductive phase begins with the appearance of the first flower and continues until physiological maturity. In determinate forms, growth ends with the differentiation of the apical flower bud, while in indeterminate forms it continues through the reproductive phase. The two phases are divided into 10 periods, the beginning and end of which are determined by easily identifiable physiological events that occur in all plants, regardless of their habit and the influence of external conditions. The first five periods (germination, emergence, first true leaf, first triple leaf) belong to the vegetative phase and the remaining periods (budding, flowering, bean growth, grain growth and maturity) to the reproductive phase.

The duration of periods is affected differently by genotype and environment and their interaction. Under the same conditions, the periods of germination, emergence, simple leaves hardly differ among varieties. However, they are subject to considerable variability depending on changes in environmental conditions. Recently, studies in this country have shown that the length of the collection period from germination to flowering decreases when sowing is delayed from mid-April to the end of May and increases when sowing is further delayed until mid-July. A decrease in the length of the period coincides with an increase in the mean daily temperature and a decrease in the relative humidity and, conversely, a lengthening of the growing season coincides with a decrease in temperature and an increase in the relative humidity. The total length of the flowering to maturity periods is equally influenced by environmental conditions, and with a delay in sowing from early May to mid-July, it becomes longer, coinciding with a decrease in temperature, an increase in relative humidity and a decrease in day length (Shaban, 2014).

The need to optimize sowing dates and determine their influence on the growth performance of different garden bean varieties is a subject of scientific interest by scientists worldwide. The effects of cultivar and growing season on growth development and fruit yield of garden beans were analyzed in a two-year experiment in Spain by Pérez-Barbeito et al. (2008). The effects of seed size and sowing dates on green bean growth and yield were the subject of experiments conducted by Nosser and Behnan (2011). Elhag and Hussein (2014) studied the effect of sowing date on plant development and yield. Mashiqa et al. (2019) investigated the growth performance of different genotypes of garden bean depending on sowing date.

Similar research has been conducted with other vegetable crops such as Haque et al (2013) - potato; Dhaliwal et al. (2017) - pepper, Prosanta et al. (2013) - okra, Yaser et al. (2016) - garlic.

The main aim of this publication is to comparatively evaluate the phenological development and vegetative performance of garden bean varieties at different sowing dates.

MATERIAL AND METHOD

The research was carried out in the period 2021-2022, in the land of the village of Ezero, Nova Zagora municipality, with an altitude of 131 m., located in the Thracian valley, near the Mountain Sredna Gora from the north and the Iliyskite hills in the southeast.

The prevailing topography is flat, the river Blatnitsa runs through the land. The soil is black earth, heavy, clayey, difficult to warm. Climatic conditions. Snow cover is very rare. Precipitation during the year is insufficient. Summers are relatively hot and droughts are frequent. In recent years there has been an almost constant summer dry spell.

The experiment was designed using the block method in four replications with an experimental plot size of 10 m^2 and a treatment plot size of 8 m^2.

For the purpose of the experiment the varieties 'Capitano', 'Gina', 'Ebro', 'Playa' 'Bergold' were used. All varieties are determinate, with a bush habitus, suitable for fresh consumption and for processing.

A total of 15 variants were tested, which were a combination of each variety and the three sowing dates. Seeds of the five varieties were sown on three different sowing dates, 10 days apart, during the period from the middle of April to the first ten days of May (13.04; 24.04; 03.05, respectively).

The plants were grown according to the technology adopted for southern Bulgaria for growing garden beans (Cholakov, 2009). The cultivation scheme was 60 x 20 cm. Irrigation was done by drip irrigation system. For the optimal development of the plants, the necessary agronomic practices, based on the applied technology, were carried out during the growing season. Harvesting was done manually when the fruits reached consumption maturity (Mihov et al., 2014).

Phenological observations were made to determine the phases mass: germination (in days after sowing), appearance of: first true leaf, first triple leaf, budding, flowering, fruit formation, fruiting. The mass occurrence of the respective phase was recorded in 70% of the plants.

At mass flowering and mass fruiting stage, morphological characterization of plants including: stem height (cm); stem weight (g); number of leaves; leaf weight (g); number of blossoms, number of fruits, weight of fruits was determinate on 5 plants of each replicate;

RESULTS AND DISCUSSION

Different sowing dates of garden beans (Table 1) affect seed germination. Seeds sown at the earliest sowing date take the longest time to germinate, ranging from 16 to 21 days, with little variation between varieties. When sown in the middle of April, the vegetative development of the plants is slow, as illustrated by the time taken for the first leaves to form on the first true leaf. This varies from 31 to 39 days for different varieties. The generative organs are laid down approximately one and a half months after the plants emerge. The earliest buds appear in the Capitano variety and the latest in the Playa variety. Mass flowering in the varieties tested occurs between the 51st and 70th day after germination, following the trend of the previous phase. Mass fruiting occurs from day 69 for the variety Gina to day 91 for the variety Playa. There is little difference in the onset of fruiting in the varieties Gina, Capitano and Ebro. The difference with the other two varieties is 12 and 22 days respectively. The discrepancy in the onset of mass fruiting creates favorable conditions for regular harvesting (Shaban, 2014).

Table 1. Length of interphase periods at first sowing date (13.04) /days after sowing/

variety	germination	first true leaf	first triple leaf	budding	flowering	Fruit formation	fruiting
Capitano	16	22	31	38	51	61	70
Gina	17	24	32	42	53	62	69
Ebro	20	26	33	43	54	63	74
Bergold	18	25	36	46	65	74	81
Playa	21	27	39	49	70	81	91

As temperature conditions improved under field conditions, seeds from the second date germinated, between days 11 and 15, respectively (Table 2). The first generative organs set between 45-59 days after germination. Mass fruiting also occurs without significant differences in the Capitano, Gina and Ebro varieties. The Bergold and Playa varieties come into fruit at 70 and 80 days after germination respectively.

Table 2. Length of interphase periods at second sowing date (24.04) /days after sowing/

variety	germination	first true leaf	first triple leaf	budding	flowering	Fruit formation	fruiting
Capitano	11	17	26	30	45	55	64
Gina	12	19	27	37	48	59	66
Ebro	17	23	30	34	45	56	67
Bergold	13	20	29	35	54	63	70
Playa	15	23	30	38	59	70	80

A similar trend in the progression of interphase periods was observed for sowing in the beginning of May (Table 3).

Table 3. Length of interphase periods at third sowing date (03.05) /days after sowing/

variety	germination	first true leaf	first triple leaf	budding	flowering	Fruit formation	fruiting
Capitano		15	24	28	41	51	60
Gina	10	17	25	35	46	55	62
Ebro	14	20	27	31	42	51	62
Bergold	10	17	26	32	51	60	67
Playa	13	19	26	34	55	66	76

The results obtained show a harmonious progress of the interphase periods without abrupt deviations from normal plant development. They are in line with the development process of garden bean described by Shaban (2014). The length of the harvest period from emergence to flowering decreases when sowing is delayed from the middle of April to the end of May. Decrease in period length coincides with increase in mean daily temperature and decrease in relative humidity and conversely, increase in growing season length coincides with decrease in temperature and increase in relative humidity.

Biometric measurements to investigate the vegetative development of the plants were carried out twice during the vegetation in the mass flowering phase (Table 4) and in the mass fruiting phase (Table 5).

The first biometric measurement of the plants showed small differences in stem height at the three sowing dates. The same trend is also observed in the formation of flowers and setting of the first fruits.

Table 4. Biometric parameters of garden bean plants at mass flowering stage

variety	stem height (cm)	stem weight (g)	numbe r of leaves	leaf weigh t (g)	number of blossoms	number of fruits	weight of fruits (g)
first sowing date (13.04)							
Capitano	9.1	14.1	9	20.1	35	6	41.5
Gina	9.9	11.8	14	18.6	30	5	27.5
Ebro	8.8	6.0	8	16.3	12	4	23.8
Bergold	4.8	9.1	12	19.7	28	4	25.9
Playa	7.5	9.3	15	20.4	19	6	29.8
second sowing date (24.04)							
Capitano	8.9	13.8	10	19.8	34	4	35
Gina	9.7	12.6	13	17.6	33	3	26
Ebro	8.5	6.4	8	15.4	10	3	25
Bergold	5.0	8.9	12	18.3	27	3	23
Playa	7.9	9.2	15	21.2	20	4	26
third sowing date (03.05)							
Capitano	9,4	14,3	11,2	21,8	36	6	48,1
Gina	10,1	12,8	15,1	19,7	35	5	39,4
Ebro	9,3	6,4	9,7	17,9	13	3	21,3
Bergold	4,5	9,4	13,8	21,1	29	4	27,6
Playa	8	9,4	14,4	22,3	21	5	17,4

Within 30 days, until the next biometric measurements, there was a slight increase in stem growth, an increase in the number of leaves and in the fresh mass of the plants. A steady flower set and fruit formation was observed (Table 5).

Table 5: Biometric parameters of garden bean plants in mass fruiting phase

variety	stem height (cm)	stem weight (g)		number of leaves	leaf weight (g)	number of blossoms	number of fruits	weight of fruits (g)
	first sowing date (13.04)							
Capitano	41.3	16.5		28	104.8	68	58	350.2
Gina	36.5	15.4		24	94.3	39	51	264.4
Ebro	32.8	9.3		19	68.9	31	20	240.0
Bergold	28.0	13.8		25	90.2	37	36	190.4
Playa	32.6	12.6		21	57.2	25	23	161.0
	second sowing date (24.04)							
Capitano	42.6	18.6		28	103.3	68	54	348.7

Ebro	34.3	10.9		17	64.6	30	20	140.4
Bergold	28.0	14.2		25	86.1	36	38	202.54
Playa	33.2	14.8		20	52.4	21	23	162.38
	third sowing date (03.05)							
Capitano	43.7	19.9		27	101.1	64	53	320.4
Gina	38.4	17.9		23	90.4	36	52	290.3
Ebro	35.3	11.8		16	58.6	29	15	180.4
Bergold	28.6	14.5		23	83.1	35	38	201.7
Playa	34.9	15.3		18	49.6	19	21	147.5

Good plant foliation is a precondition for the formation of a developed and active assimilation apparatus, providing an active photosynthetic surface for the normal course of physiological processes in the plant organism. It is necessary to note that in this period there are formed mass formation of fruits, which is the visible expression of the vegetative growth deceleration and the gradual transition of plants into the reproductive phase of their development (Alemu et al., 2017).

CONCLUSIONS

Late sowing (in May) contributes to the formation of better biometric indicators, justifying better vegetative development of plants and the establishment of an actively photosynthesizing leaf apparatus.
Sowing at the beginning of May results in the plants developing under conditions closer to their biological requirements and in better synchronisation between vegetative development, flowering and fruiting.

ABSTRACT

Green beans are a vegetable crop with a very high nutritional value. Research on appropriate sowing dates and varietal structure of garden beans is topical and has been investigated by various scientists. It is topical to renew the cultivar structure of garden beans in order to expand the variety of this vegetable crop and to extend the period of fresh production on the Bulgarian market. The objective of this paper is to comparatively evaluate the cultivar characters of green bean at different sowing dates by observing the yield and fruit quality.
The experiments were carried out in the period 2021-2022, in the area of the village of Ezero, Nova Zagora municipality, with an altitude of 131 m, located in the Thracian valley. Four varieties of green beans were used. The experimental design was based on the block method. A total of 15 variants were tested, which were a combination of each variety and the three sowing dates.
The results show that higher yield was obtained from plants sown in early May. The difference with the yield from the second sowing date varies between 11 and 14%, with small differences for the different varieties. The same plants also yielded 57% to 22% higher than the first harvest. The results of the economic productivity of the plants and the quality characteristics of the fruit give us reason to conclude that the cultivars Capitano, Gina, Ebro and Playa can be recommended for cultivation with a view to enriching the cultivar range with new varieties of green beans.

Keywords: garden beans, *Phaseolus vulgaris*, cultivars, growth, yield

INTRODUCTION

Green beans are a vegetable crop with a very high nutritional and value. biological value (Cholakov, 2009; Shaban, 2014).

Asia and especially India and China are the largest producers of green beans with approximately 50% of the total area in the world, closely followed by the U.S. (FAO, 2010). In European Union countries, green bean yields are high. They are highest in Poland at 20 000 kg/ha, Spain at 14 576 kg/ha, Portugal at 13 076.9 kg/ha, Cyprus at 11 796.1 kg/ha, Austria at 11 255.7 kg/ha and Belgium at 11 494.25 kg/ha (FAO, 2010). According to the Agrostatistics Department of the Ministry of Agriculture, the area harvested in 2022 with green beans is 184 ha, average yields are 9046 kg/ha, total production amounts to 6522 tonnes (Ministry of Agriculture, 2022).

Ensuring optimal conditions for plant growth and development during the growing season are the basis for the expression of their maximum productive potential and an important prerequisite for increasing the profitability of vegetable production. In this regard, optimizing agronomic factors to manage the productivity of vegetable crops is of primary importance.

At this time, research on the appropriate sowing dates and cultivar structure of garden beans is current and is the subject of research in various countries.

Research has shown that the highest yields are obtained when sowing in late April and the lowest when sowing from 20 May to 5 June. However, over the last decade, varieties with reduced sensitivity to high temperatures have entered production, and conditions have been created for industrial crops that reduce the detrimental effects of adverse climatic factors (Kenneth, 2012).

Sowing date has significant effect on yield and yield attributes is the argument of Pandey et al. (2012). According to them, early sowing of garden bean has a positive effect on early initiation of flowering and formation of taller plants with the largest fruits The early sowing date also recorded the highest yield compared to the other two, averaging 35.35 t/ha.

Sharma et al. (2013) stated that optimum sowing time and correct cultivar selection are essential to achieve potential biological yield for garden bean.

To investigate the effect of different planting dates on yield and yield components of two garden bean varieties Mirzaienasab and Mojaddam (2014) conducted a research study over two years. They found the highest percentage of yield and yield components at the earliest sowing date and the lowest results were recorded at the latest sowing date.

The results of Rao (2022) showed that sowing dates have significant effect on total yield, fresh weight of beans fruits, length of bean fruits and total soluble solids. Higher market and non-market yields, as well as greater pod length and soluble solids, in all three varieties, were more pronounced at midle and late sowing dates.

The quality of green beans is also dependent on changes in climatic conditions, which are summarized in the different sowing dates. In all varieties, the tasting score decreases in a regular manner starting from the sowing in the middle of April until the sowing in the end of May and then starts to increase, equaling the score at the first sowing date in the middle of July (Shaban, 2014). This thesis is confirmed by Spravoli et al. (2015).

An important aspect in the light of which research on optimizing sowing times can be argued is the climate change that is occurring. Last but not least, the need to renew the cultivars composition of garden beans in order to expand the range of this vegetable crop and extend the period of fresh production on the Bulgarian market should also be noted.

The main aim of this paper is to comparatively evaluate the cultivar characters of green bean at different sowing dates by observing the yield and fruit quality.

MATERIAL AND METHOD

The research was carried out in the period 2021-2022, in the land of the village of Ezero, Nova Zagora municipality, with an altitude of 131 m., located in the Thracian valley, near the Mountain Sredna Gora from the north and the Iliyskite hills in the southeast.

The prevailing topography is flat, the river Blatnitsa runs through the land. The soil is black earth, heavy, clayey, difficult to warm. Climatic conditions. Snow cover is very rare. Precipitation during the year is insufficient. Summers are relatively hot and droughts are frequent. In recent years there has been an almost constant summer dry spell.

The experiment was designed using the block method in four replications with an experimental plot size of 10 m^2 and a treatment plot size of 8 m^2.

For the purpose of the experiment the varieties 'Capitano', 'Gina', 'Ebro', 'Playa' 'Bergold' were used. All varieties are determinate, with a bush habitus, suitable for fresh consumption and for processing.

A total of 15 variants were tested, which were a combination of each variety and the three sowing dates. Seeds of the five varieties were sown on three different sowing dates, 10 days apart, during the period from the middle of April to the first ten days of May (13.04; 24.04; 03.05, respectively).

The plants were grown according to the technology adopted for southern Bulgaria for growing garden beans (Cholakov, 2009). The cultivation scheme was 60 x 20 cm. Irrigation was done by drip irrigation system. For the optimal development of the plants, the necessary agronomic practices, based on the applied technology, were carried out during the growing season. Harvesting was done manually when the fruits reached consumption maturity (Mihov et al., 2014).

The yield was determined on the basis of three harvests carried out at the consumption stage of the fruit.

Morphological characteristics of the fruit were determined using an average sample of 20 fruit from each variant. Observations and measurements were carried out to determine: - color of the beans; - fruit length (cm); - fruit diameter (cm); - fruit weight (g);

A sensory evaluation of the fruit was carried out on average samples of each variant by interviewing 20 consumers. The evaluation was carried out on the following characteristics: size; color; texture; presence of lyco; texture; consumer preference.

RESULTS AND DISCUSSION

The results showed that the third sowing date (03.05) had the greatest positive effect on the yield of all garden bean cultivars (Table 1). For the Capitano cultivar, the increase compared to the first sowing date was 21.69% and compared to the second date - 11.25%. The yield of Gina cultivar was higher by 25.08% compared to the first date and by 14.36% compared to the second date. The increase for the Ebro cultivar was 43.31% and 14.00%, respectively, compared to the first and second sowing dates.

Table 1 Total yield and fruiting dynamics of garden bean cultivars

cultivar	First harvest kg/dka	Second harvest kg/dka	Third harvest kg/dka	Total yield kg/dka
first sowing date (13.04)				
Capitano	73.75	109.91	220.35	404.01
Gina	68.08	91.45	190.24	349.77
Ebro	42.56	37.82	120.22	200.60
Bergold	35.61	30.42	139.43	205.46
Playa	25.99	27.30	98.46	151.75
second sowing date (24.04)				
Capitano	80.60	120.79	240.34	441.73
Gina	72.14	103.49	206.90	382.53
Ebro	44.99	75.78	131.40	252.17
Bergold	39.40	97.98	151.97	289.35
Playa	30.60	73.94	109.10	213.64
third sowing date (03.05)				
Capitano	91.66	133.33	266.66	491.65
Gina	79.16	116.66	241.66	437.48
Ebro	49.99	87.50	149.99	287.48
Bergold	44.99	109.99	168.33	323.31
Playa	33.34	81.66	123.33	238.33

Sowing the Bergold cultivar in the beginning May resulted in a 57.36% higher yield compared to sowing in middle of April. For the same variety, the yield was 11.73% higher compared to that obtained from plants sown on the third tenth day of April. The differences in yields of the cultivar Playa are: an increase of 57.05% compared to the first sowing date and 11.56% compared to the yield of the second sowing date.

The increase in yield with the sowing date in the beginning of May may be due to the availability of favorable environmental conditions for appropriate timing of flowering and subsequent transformation into fruit to achieve optimum yield (Topliceanu et al., 2018).

Lower yields at early sowing dates may be associated with reduced concentrations of reducing sugars in flower buds and flowers, which may lead to pollination inefficiency and cause flower and panicle drop under sub-optimal temperature conditions for bean flowering (De Ron et al., 2016; Rao, 2022).

Alemu et al (2017) defined yield as a complex quantitative trait that is controlled by several yield-related elements, and thus information on the nature and degree of association among traits contributing to yield is useful for indirect selection to improve yield. They summarized the experiments of different researchers and reported a positive correlation between number of pods per plant and green pod yield, and reported a positive correlation between green pod length and green pod yield.

Our results are in full agreement with the conclusions of the authors, who substantiate these plant responses with more suitable environmental conditions during flowering and fruiting.

Garden bean varieties of ssp. nanos, to which those involved in the experiment belong, are characterized by amicable fruit formation resulting in three successive harvests. At each successive harvest, the quantity of fruit picked increased. The cultivars can be ranked, in descending order, as follows: Capitano, Gina, Bergold, Ebro, Playa. Capitano is the highest yielding cultivar. Playa is the lowest yielding cultivar (Table 1).

The marketability of garden beans for fresh consumption depends on the appearance of the beans and their uniformity. In this regard, measurements were carried out to determine the morphological characteristics of the fruits of the cultivars studied (Table 2).

Table 2. Morphological characteristics of beans fruits

Cultivar	Color	fruit length (cm)	fruit diameter (cm)	fruit weight (g)
Capitano	Yellow	14	1.9	7.03
Gina	Green	16	1.8	6.84
Ebro	Green	15	1.6	7.02
Bergold	Yellow	13	0.8	5.33
Playa	Green	15	1.4	7.06

Two of the cultivars have yellow colour of bean fruits and the other three have green color of beans fruits. Of all the cultivars, only the Bergold variety has cylindrical shape of fruits. The length of the fruit varies from 13 to 16 cm for different cultivars. Fruit diameter varies from 0.8 to 1.9 cm. Bergold is relatively smaller. For the other cultivars, there is little variation in weight. When the general appearance of the fruit is assessed visually, there are no sharp deviations from the varietal characteristics.

In the sensory evaluation, the fruits of the five garden bean varieties were evaluated for the characteristics relevant to their suitability for fresh consumption (Table 3).

Table 3. Average sensory evaluations of garden bean cultivars

cultivar	texture	lyco	consistency	Preferences of consumers
Capitano	juicy	no	medium delicate	yes
Gina	Medium juicy	no	firm fruit	yes
Ebro	Medium juicy	no	firm fruit	yes
Bergold	Less juicy	no	firm fruit	no
Playa	Medium juicy	no	firm fruit	yes

Reference values for sensory qualities of vegetable crops are not given in the scientific literature. Currently, there is also no unified standard for evaluation (Paschova, 2021). Therefore, the sensory studies conducted are mainly based on the subjective opinion of evaluating consumers. Considering the combination of attractive bean appearance, texture and consistency, the most preferred varieties are Capitano and Gina. Other varieties are less favored, with the Bergold variety being the least desirable.

CONCLUSIONS

Higher yields were obtained from plants sown in the beginning of May. The difference with the yield from the second sowing date varied between 11 and 14%, with small differences between cultivars. The same plants also yielded 57% to 22% higher than the first harvest.
The results of the economic productivity of the plants and the morphological characteristics of the fruit give us reason to believe that the cultivars Capitano, Gina, Ebro and Playa can be recommended for cultivation with a view to enriching the cultivar range with new varieties of garden beans.

ABSTRACT

The American grapevine leafhopper is a primary vector of the *Flavescence dorée* phytoplasma, posing a significant threat to vineyards worldwide. After the first record of leafhopper in the Kosovo vineyards in 2022, a comprehensive monitoring study was conducted during the year 2023 in order to assess the presence of first nymph and adult population dynamics of *Scaphoideus titanus* Ball (Hemiptera: Cicadellidae) in the grape-growing region of Rahovec, Kosovo. The monitoring program was carried out in four localities within the Rahovec region. Mainly wine varieties were the dominant population in all inspected vineyards. In order to study the first appearance of the nymph, the first and oldest leaves of the grapevine were inspected from the middle of May to the end of June 2023. While the adults were investigated and monitored from late June to early October 2023. Yellow sticky traps method was used across multiple vineyard sites throughout the growing season. Results indicated fluctuating population levels, with peak activity observed in mid-summer. The data collected provides essential insights for local viticulturists and can aid in developing targeted control measures to mitigate the impact of this pest and safeguard the viticulture industry in Rahovec.

Key words: *Scaphoideus titanus*, monitoring, grapevine, Kosovo

INTRODUCTION

The leafhopper *Scaphoideus titanus* Ball (Hemiptera, Cicadellidae) is a phloem-feeding Nearctic leafhopper originated from northeastern America, then it was first reported in Europe in the late 1950s (Bonfils & Schvester 1960). After its initial introduction in Europe, it spread from southwestern France to Italy, later to the Balkan countries and subsequently to Spain and Portugal (EFSA, 2020). The North American grapevine leafhopper years earlier was also identified in neighboring countries of Kosovo, in Serbia was first reported in 2004 (Magud and Toševski 2004) and in Montenegro was found in August 2008 (Radonjić et al., 2008). Recently, *Scaphoideus titanus* Ball has also been reported in Kosovo (Gjinovci et al., 2022). *Scaphoideus titanus* Ball is primarily ampelophagous, feeds on the lower surface of the leaves and completing its life cycle on *Vitis* species, including both European grapevines (*Vitis vinifera* L.) and American grapevines. In Europe, it has predominantly been reported on *Vitis vinifera*, although it is also known to thrive in abandoned vineyards and on wild grapevines (Rossi et al., 2019). However, it has recently been reported on other plant species as well (Alma et al. 2019). The leafhopper *Scaphoideus titanus* Ball serves as the main vector for *'Flavescence dorée'* (FD) phytoplasmas (Ripamonti et al., 2022). *'Flavescence dorée'* (FD) is an obligate bacterial pathogen that primarily reside in the phloem tissue of plants. When sap-sucking insects, such as *Scaphoideus titanus*, feed on infected plants, they can inadvertently acquire these pathogens and subsequently transmit them to healthy plants. Recent studies revealed that nymphs can acquire *'Flavescence dorée'* (FD) phytoplasmas by feeding on infected plants. After a latency period of 4–5 weeks, during which they mature into adults, they become vectors capable of transmitting the phytoplasmas to other plants (Belli et al., 2010; Ottati et al., 2020).

MATERİALS AND METHODS

The aim of this study was to detect the first appearance of the nymph emergence that was carried out by visually examining the underside of the oldest grapevine leaves from mid-May to late June 2023. Furthermore, adults were monitored from late June to early October 2023 using yellow sticky traps (Insect trap Aria® 10×25 cm) placed across different vineyard sites throughout the growing season. The monitoring survey was carried out during 2023 across four localities within the Rahovec region (Rahovec, Deshkidov, Hamovc and Opterush) (Fig. 1), where the dominant grapevine variety was the black variety Vranac.

Figure 1. *Map of Kosovo with particular focus in the region of Rahovec (Source: Wikipedia).*

To detect the presence of nymphs, three parcels from each locality were inspected. Nymphs collected from each surveyed locality were brought to the lab for morphological identification using a stereomicroscope (Olympus SZX16 Tokyo, Japan). In addition, adults were monitored weekly by directly counting individuals from grapevine plants using yellow sticky traps. The collected adults were preserved in 75% ethanol for later identification. The identification of adult specimens was conducted using the EFSA Pest Survey Card (2020) as the primary identification key. This card provides a systematic approach for accurately identifying nymph and adult specimens based on established morphological and diagnostic criteria.

RESULTS AND DİSCUSSİONS

During the 2023 survey, the initial inspection revealed the presence of both nymphs and adults of *Scaphoideus titanus* in four surveyed localities (Rahovec, Deshkidov, Hamovc and Opterush). Following a detailed visual inspection, the initial presence of first nymphal instars was documented at the beginning of June 2023 in the locality of Hamovc, within the Rahovec region. These nymphal instars were predominantly observed on the lower surface of the oldest grapevine leaves, which were situated closest to the bark of the grapevine plants (Fig. 2). During visual inspections, larval skins were also observed on the lower surface of grapevine leaves. According to Aldini et al. (2003), examining the lower surface of the leaves is more effective for identifying the immature stages of *Scaphoideus titanus*.

Figure 2. *Scaphoideus titanus nymph: left – first instar; right – fifth instar.*

Based on the observed number of nymphs and the sporadic presence of larval skins, the population density of *Scaphoideus titanus* was classified as low. Specifically, there were 3-5 nymphs detected on grapevine leaves per vineyard. Through continuous monitoring over the subsequent months, the initial presence of adult specimens was recorded at the beginning of July 2023 in the locality of Hamovc, within the Rahovec region (Fig. 3). The population density showed a consistent low level over two decades of July 2023, with adult individuals captured fluctuating between 1 and 10 specimens. In contrast, during the last decade of July 2023 and the first decade of August 2023, the capture increased to between 10 and 40 specimens (Figure 4). This observation suggests a rapid dispersal and establishment of *S. titanus* across all inspected sites within a short timeframe. The findings underscore the need for continuous monitoring and implementation of management strategies to mitigate the spread and potential impact of this pest on local viticulture.

Figure 3. *S. titanus adult*

Figure 4. *Collecting adults using yellow sticky traps*

CONCLUSIONS

The data indicates that *Scaphoideus titanus* Ball is an established pest in the Rahovec region, the largest grapevine-growing area in Kosovo. Although the population density of this leafhopper was categorized as low in 2022, consistent with previous years, its recurrent detection in the Hamovc locality signifies its adaptation to the agroecological conditions of this viticultural area. Consequently, there exists a tangible risk of *S. titanus* progressively invading the entire region. The established presence and potential dissemination of *S. titanus* could pose a significant threat due to the possible occurrence of *Flavescence dorée* (FD) phytoplasmas.

ABSTRACT

The aim of this paper is to present the effects of the applied regimes of fertilization and irrigation on the physical characteristics of white strawberry fruits. A two factors experiment was conducted during 2024 in unheated greenhouse in the Chelopechene experimental field, Sofia, Bulgaria with drip irrigated and fertigated strawberry variety (*Fragaria x Ananassa „Snow White"*). The irrigation and the fertilization factors were applied in two rates: I1 - 75% (ETc) I2 - 50% (ETc), F1: optimal fertilization $N_{8.09}P_{12.76}K_{15.62}$; F2 – suboptimal fertilization - 75% (F1). Five treatments were tested: control: I0F0:100% (ETc) without fertigation; I1F1; I1F2; I2F1; I2F2. The highest percent (26.02%) "Extra" Class fruits were obtained from I1F1 treatment and the highest average fruit weight in "Extra" Class was obtained from I1F2 treatment – 7.91 g.
It was found that the method of cultivation and irrigation affects the instrumentally measured physical parameters of fruit firmness and color ($p<0.05$). The applied agricultural techniques influenced the measured parameters of firmness and adhesion only for the fruits grown with 75% irrigation and 75% fertilization, as well as for the adhesion parameter in fruits grown with 50% irrigation and 75% fertilization. For the remaining fruits studied in the planned experiment variants, the method of cultivation did not affect the values of the mentioned parameters ($p>0.05$).
The color parameters—brightness, yellow hue, color saturation, and color difference—did not influence the quality of the fruits across all analyzed cultivation variants ($p>0.05$). The best qualitative and quantitative color parameters, including measured red hue, saturation, and shade of color, were observed in the fruits of the control group with 100% irrigation, followed by the fruits grown with 50% irrigation and 75% fertilization. For the other fruits from the studied cultivation variants, no effect on the measured color parameter values was found after statistical data processing ($p>0.05$).

INTRODUCTION

Fragaria Ananassa berries are an important source of vitamins, minerals and fibers and widely consumed fruit. They are produced by open-field cultivation, by greenhouse cultivation (Ivanova et al., 2024), by hydroponic cultivation (Balan et al., 2024), under mulch (Taparauskiene and Miseckaite. 2014) and other cultivation practices, technologies and mechanization techniques. At the same time strawberry is one of the most drought sensitive plants. Soil moisture deficit has a negative impact on strawberry growth, development, yield, berry size, persistency in winter time (Taparauskiene, 2006).

The physical parameters of strawberry fruits - diameter (Akhijahcmi and Khodaei, 2011), weight (Birania et al., 2022) can range vary widely based on cultivar and environmental conditions.

Strawberries with white fruits have long history of cultivation no shorter then red varieties. White strawberry has cultivated for hundreds of years in Chile and has grown in two botanical forms - wild *Fragaria chiloensis ssp. chiloensis f. patagonica* and cultivated *Fragaria chiloensis ssp. chiloensis f. chiloensis* (Grez et al., 2020). It was brought to Europe in the 18th century. „Snow White" cultivar has been selected in 2010 out from *Fragaria x ananassa "Weisse Ananas"* and *Fragaria chiloensis f. Chiloensis* (Olbricht et al., 2013). White strawberries are distinguished by their white or pale pink flesh and unique pineapple-like flavor.

Research on white strawberries is still limited and with current studies focusing on their genetic diversity (Lu et al., 2021), cultivation requirements (Whitaker, 2023), potential health benefits (Lin et al., 2018), sugar content (Seki et al., 2021), chemical composition and biological activities (Fierascu et al., 2020). This indicates that there is substantial scope for further research in this area.

This research investigates the effects of drip irrigation and fertigation on white strawberries' physical characteristics.

MATERIAL AND METHOD

✓ Experimental layout

The second year two-factor experiment was conducted on drip irrigated strawberry plants in a tunnel greenhouse in 2024 in the Chelopechene experimental field (latitude 42°44′22.8″N, longitude 23°28′3.7″E and altitude 550 m above sea level) of the Institute of soil science, agrotechnologies and plant protection "Nikola Poushkarov" in Sofia, Bulgaria. Sofia field falls into temperate continental climate subzone. The greenhouse was unheated with area 420 m^2 (7.9 m x 53 m) covered with a five-layer UV+EVA+IR+AD+dif -150 μm polyethylene film. The soil could be defined as moderate to strong water-permeable with an average filtration capacity. The soil was *Chromic Luvisol* with bulk density 1.47 g cm^{-3}, field capacity 22% and wilting point 10% for 0-50 cm layer. To further reduce water losses, mulching with silver-black UV polyethylene mulch with a thickness of 30 μm was applied.

The object of the study was white strawberry cultivar (*Fragaria × ananassa "Snow White"*). The experimental treatments were arranged according to the method of long plots with three replications. Each plot has 23.2 m^2 area and consisted of twin rows of strawberries. Healthy bare-root frigo plants were planted in scheme of 90 + 30/30 cm on 22 March 2023. According to the white strawberries cultivation technology in each of the experimental plots were provided the appropriate amount of red fruit plants (4: 1 ratio) to ensure better pollination. The irrigation factor was applied in two rates: I1 – deficit irrigation - 75% (ETc); I2 - deficit irrigation - 50% (ETc). The fertilization factor was applied in two rates: F1: optimal fertilization $N_{8.09}P_{12.76}K_{15.62}$; F2 – suboptimal fertilization - 75% (F1) - $N_{6.07}P_{9.57}K_{11.94}$. Optimal fertilization was developed according to Haifa nutrition recommendations (Haifa Group, 2021) as follows: Haifa MAP- 25-45 kg ha^{-1} , Multi K – 80 kg ha^{-1} , Haifa MKP - 25 kg ha^{-1} , Haifa Cal - 30 kg ha^{-1} , Maguisal - 10 kg ha^{-1} , Poly-feed – 25-40 kg ha^{-1}. Five treatments were tested: control treatment I0F0: 100% (ETc) - full irrigation and without fertigation; I1F1; I1F2; I2F1; I2F2. Irrigation was applied trough drip system include NMC Junior controller for precise irrigation rate application, FertiKit Nutrigation system for precise fertigation rate application, pressure-compensated pipelines UniRam AS with 14.6 mm inside diameter, 1.2 mm wall thickness, built-in trough 20 cm drippers and flow rate 1.6 l h^{-1}.

The microclimate data (air temperature, relative humidity, solar radiation, sunshine duration and wind speed) in the greenhouse was measured at every 30 min using an automatic meteorological station located in the center of experimental area and recorded in data logger (HOBO USB Micro Data Logger, USA). FAO Penman-Monteith Equation (Allen et al., 2006a) was used for determining daily reference evapotranspiration and irrigation scheduling. Crop coefficient was 0.30, 0.80 and 0.70 respectively in initial, middle and end growing stage (Allen et al., 2006b). Fruit mass was determined through weighing with a electronic precision balance Vedia FR-H (±0.01 g). Fruit width and length was measured with a digital calliper (±0.01 mm). All the observations were carried out of 5 consecutive plants in three replications. Marketing standard strawberry classification was made according to Commission implementing regulation (EU) No 543/2011. The minimum fruit diameter for "Extra" Class - 25 mm and for Class I and Class II - 18 mm.

- ✓ **Methods**

Colour – Instrumental with colorimeter (PCE-CSM 5 portable colorimeter – measurement geometry 8°/d, Ø 8 mm, Light source D65)

The indicators are reported according to the CIE Lab system.

During the measurement 3 colour coordinates were taken: L, a и b;

- ➢ **L** – colour brightness (L=0 - black, L=100 – white);
- ➢ **a** – the positive values of the indicator characterize the amount of red color, whereas the negative ones characterizes the green color;
- ➢ **b** – positive valuescharacterize the yellow colour, whereas negative values characterize the blue color (ASTM D2244-16).
- ➢ **Saturation** – saturation characterizes the degree of dilution of the color tone with white color (white color saturation is 0).

$$C=\sqrt{(a^2+b^2)} \qquad (1)$$

- ➢ **Colour tone** It determines the position of the color in the respective quadrant and represents the ratio a/b.

A lower value of color tone implies a smaller change in color and vice versa.

- ➢ **Colour differences** between individual samples are determined by the values ΔL, Δa and Δb, and ΔE is a summary indicator of the final colour.

Colour differences ΔE is determined by the formula:

$$\Delta E=\sqrt{(\Delta L^2+\Delta a^2+\Delta b^2)}, \qquad (2)$$

where:

$\Delta L = Li – L0$

$\Delta a = ai – a0$

$\Delta b = bi – b0$

“0” – sample-variant control

“i” – sample-variant different growing

Saturation (C), colour tone (a/b) and colour differences ΔE are the parameters that characterize the color quality in the so-called physiological visual system.

Five measurements were performed on each sample. The colour coordinates of each sample represent arithmetic mean values of the measured coordinates.

The texture was analyzed using a TA.XT2 Texture Analyzer (Stable Micro Systems, Surrey, UK) in penetration mode. A cylindrical probe with a diameter of 5 mm was used for this purpose. The deformation speed was 1 mm/s, and the deformation was 5 mm. Ten replications were conducted for each cultivation variant of white strawberries. This test determined the firmness, adhesiveness, and Young's modulus (stiffness) of the white strawberry fruits. The rupture curves indicate the values of Young's modulus as the slope of the first linear section, as well as the deformation and stress at yield and at the rupture point.

The obtained data were statistically analyzed using ANOVA software, as well as Microsoft Excel and STATISTICA 8.0. Duncan's Multiple Range tests at a significance level ($p<0.05$) to measure specific differences between pairs of means was used.

RESULTS AND DISCUSSION

In 2024, an analysis of white strawberry fruits was conducted, presenting data on the impact of irrigation and fertigation on the physical characteristics of the fruits on the day of their harvest. The weight and diameter of the fruits were measured for all cultivation variants in the experimental greenhouse at the Institute of soil science, agrotechnologies and plant protection „Nikola Poushkarov", Sofia, in accordance with the quality requirements for fruits according to the general market standard for strawberry quality.

All fruits from the studied variants were healthy; intact; fresh; unwashed; practically free from visible foreign matter; undamaged by pests; free from off-flavors and odors. The fruits had a satisfactory level of ripeness and were delivered in refrigerated bags to the laboratory of the Institute of Food Preservation and Quality - Plovdiv, for conducting physical analyses, including firmness and instrumentally measured color.

The results (Table 1) showed that the highest percent (26.02%) "Extra" Class fruits were obtained from I1F1 treatment while the lowest percent (5.13%) "Extra" Class fruits were obtained from I2F2 treatment. The strawberries have a glossy appearance, with no traces of soil and no defects. Up to 5% of the number or weight of the strawberries may not meet the requirements for this class but must meet the requirements for Class I, or in exceptional cases, correspond to the permissible deviations for Class I. Of these 5%, no more than 2% may be fruits with damage.Expected, with the decrease of irrigation and fertigation rate, the fruit diameter also deceases. Reduction of the fruit diameter between the highest (I1F1) and the lowest (I2F2) values was 21.24%. Results of Duncan's Multiple Range test show that there was no significant difference between the varietal means of control treatment I0F0 and I1F1 and between the varietal means of I0F0 and I1F2. Also, there was no significant difference between the varietal means of I2F1 and I1F2. Between other pairs differences were significant at $p=0.05$.

Table 1. Marketing standard strawberry classification percentage by treatments

Treatment	"Extra" Class (%)	Class I and Class II (%)	Class III (%)
I0F0	24.15^{a}	64.76^{a}	11.09^{abc}
I1F1	26.02^{ab}	60.80^{a}	13.18^{abcd}
I1F2	21.61^{abc}	65.08^{a}	13.31^{bcd}
I2F1	14.94^{c}	64.31^{a}	20.74^{bcd}
I2F2	5.13	51.86	43.01

Values with same lowercase letter for the same parameter were not statistically different.
NS=not significant

The results (Table 1) showed that the highest percent (65.08%) Class I and Class II fruits were obtained from I1F2 treatment while the lowest percent (51.86%) were obtained from I2F2 treatment. They are of good quality, with minor defects in shape, slight pressure marks, and small white spots on the surface, free from soil and other defects that do not worsen the overall appearance, quality, or shelf life of the strawberries. Up to 10% of the number or weight of the strawberries may not meet the requirements for this class but must meet the requirements for Class II, or in exceptional cases, correspond to the permissible deviations for Class II. Of these

10%, no more than 2% may be fruits with damage. Results of Duncan's Multiple Range test show that only between I2F2 and other treatments differences were significant at p=0.05.

The results (Table 1) showed that the highest percent (43.01%) Class III fruits were obtained from I2F2 treatment while the lowest percent (11.09%) were obtained from I0F0 treatment. Results of Duncan's Multiple Range test show that there was no significant difference between the varietal means of I0F0 and I1F1. Also, there was no significant difference between the varietal means of I0F0, I1F1, I1F2 and I2F1. Between I2F2 and other treatments differences were significant at p=0.05.

With the decrease of irrigation rate and fertigation rate, the mean fruit diameter also decreases. Similar results have been reported by Bibi et al. (2016) for red variety.

The results (Table 2) showed that the highest average fruit weight in "Extra" Class was obtained from I1F2 treatment – 7.91 g. The highest average fruit weight in Class I and Class II was obtained from I1F1 treatment – 4.49 g. The highest average fruit weight in Class III was obtained from I1F2 treatment – 2.19 g. Expected, with the decrease of irrigation and fertigation rate, the fruit weight also deceases. Similar results have been reported by Kang et al. (2018), Kachwaya et al. (2015) for red variety.

Table 2.Average fruit weight according Marketing standard strawberry classification by treatments

Treatment	"Extra" Class Avg. fruit weight (g)	Class I and Class II Avg. fruit weight (g)	Class III Avg. fruit weight (g)
I0F0	7.51	4.45	2.00
I1F1	7.87	4.49	2.12
I1F2	7.91	4.46	2.19
I2F1	7.57	4.25	1.99
I2F2	6.98	3.85	1.91

The indicators of interest to consumers are visual appearance, texture/firmness, color, nutritional value, and food safety. The data from the instrumentally measured color parameters are presented in Figure 1.

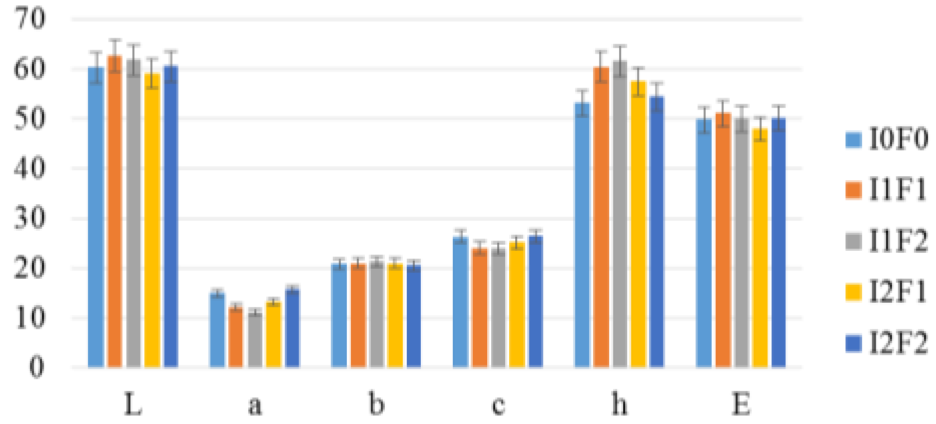

Figure 1. Color parameters of white strawberry fruits by treatments

The data from Figure 1 show that the color brightness values for all fruits from the cultivation variants do not differ statistically, and the cultivation method does not affect this color parameter ($p>0.05$) (Figure 1).

A significant difference was noted in the measured red hue of the examined fruits. Statistically distinct differences were observed in the fruits grown with 75% irrigation and 75% fertilization, with a value of 11.12, which is the lowest compared to the results reported for the other fruit variants. The cultivation method affects the red hue ($p<0.05$) (Figure 1). The highest statistically non-different red color values of 15 were recorded for the control fruits with 100% irrigation and for fruits grown with 50% irrigation and 75% fertilization, followed by the other two cultivation variants with 50% irrigation and 100% fertilization and 75% irrigation and 100% fertilization. For these last-mentioned variants, the cultivation method does not influence the reported red color values ($p>0.05$) (Figure 1).

The yellow hue of the fruits from all examined cultivation variants dominates over the red hue on the day of harvest and is around 20. The cultivation method (irrigation and fertigation) does not influence the yellow color component ($p>0.05$) (Figure 1).

Color saturation characterizes the degree of dilution of the color hue with white, with the recorded values being closer to the saturation of the white color above 23. The cultivation method (irrigation and fertigation) on the harvest day does not affect the measured color saturation ($p>0.05$) (Figure 1).

The color tone of fruits from variants with 100% irrigation and with 50% irrigation and 75% fertilization had the best values, statistically non-different from each other (above 53) ($p>0.05$) (Figure 1). Greater color changes were observed in fruits grown with 75% irrigation and 100% fertilization and with 75% irrigation and 75% fertilization (above 60), statistically non-different from each other ($p>0.05$) (Figure 1). The cultivation method (irrigation and fertigation) influences the measured color tone of the above-mentioned variants ($p<0.05$) (Figure 1).

The calculated color difference of the fruits for all studied variants showed that the irrigation and fertigation methods do not affect the color difference ($p>0.05$) (Figure 1).

Texture/firmness was assessed using destructive methods cited in the Materials and Methods section. Fresh strawberry fruits are highly susceptible to damage from mechanical handling. To prevent macro damage from external forces and to predict the evolution of damage within the internal tissues, the mechanics of texture damage to strawberry fruits and their tissues are characterized through load and unload tests at different compression speeds. The measured texture parameters include firmness, elasticity, and adhesiveness (stickiness).

The texture parameters of the studied cultivation variants for white strawberries are presented in Figures 2, 3, and 4.

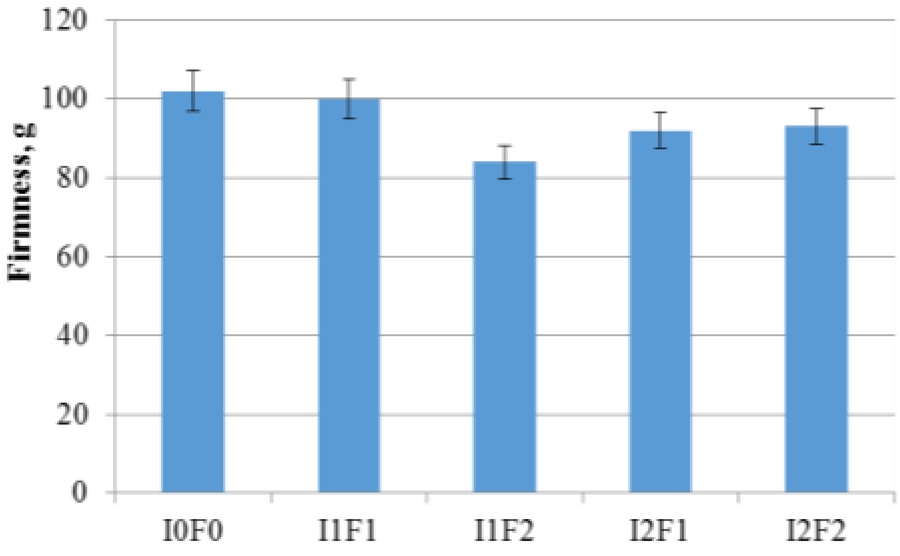

Figure 2. Firmness of white strawberry fruits by treatments

The white strawberries from the control group with 100% irrigation and those with 75% irrigation and 100% fertilization have the highest values for measured firmness, 102.1 g and 100.2 g respectively, followed by fruits grown with 50% irrigation and 100% fertilization, and 75% fertilization and 50% irrigation, which have statistically non-different values from each other ($p>0.05$). The white strawberries from the cultivation variant with equal percentages of 75% irrigation and 75% fertilization have statistically different firmness values (84 g). The cultivation method affects the firmness values of the fruits ($p<0.05$) (Figure 2).

The adhesiveness (stickiness) indicator for the examined fruits showed that the stickiness of fruits grown with 50% irrigation and 75% fertilization is the highest (-12.44 g•sec). Fruits from the control group with 100% irrigation, 75% irrigation and 100% fertilization, and 50% irrigation and 100% fertilization have statistically non-different stickiness values ($p>0.05$) (Figure 3).

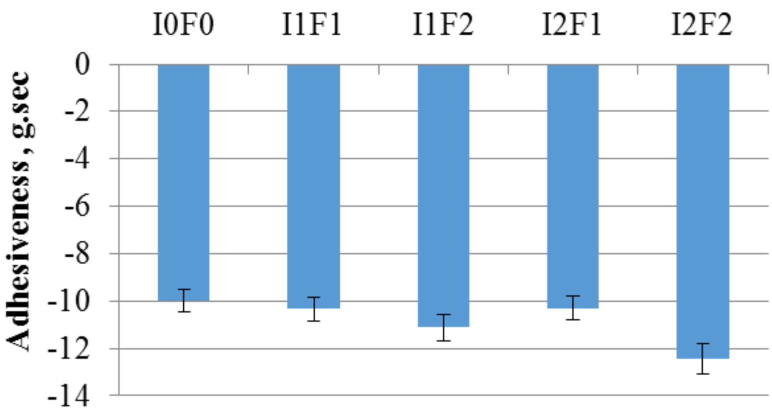

Figure 3. Adhesion (stickiness) of white strawberry fruits by treatments

The elasticity of the fruits depending on the cultivation method shows no statistically significant differences (p>0.05). All examined fruits exhibit the same degree of deformation under the applied force for structural breakdown.

The cultivation method of white strawberry fruits does not affect the elasticity parameter on the day of harvest (Figure 4).

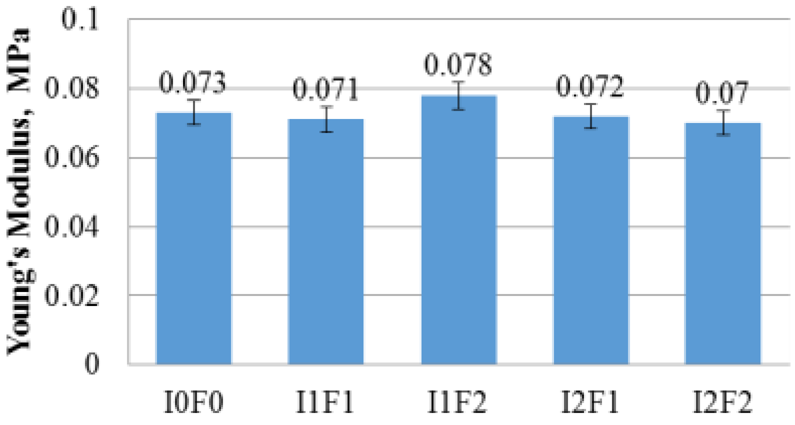

Figure 4. Elasticity of white strawberry fruits by treatments

The applied agronomic techniques affect the measured firmness and adhesion parameters only for fruits grown with 75% irrigation and 75% fertilization, as well as for the adhesion parameter of fruits grown with 50% irrigation and 75% fertilization.

No linear correlation was found between the instrumentally measured firmness parameters and the seniority assessed consistency parameter.

For the remaining examined fruits from the planned experimental variants, the cultivation method does not influence the values of the cited parameters (p>0.05).

CONCLUSIONS

The aim of this paper is to present the effects of the applied regimes of fertilization and irrigation on the physical characteristics of white strawberry *Fragaria × ananassa "Snow White"*. The highest percent (26.02%) "Extra" Class fruits were obtained from I1F1 treatment while the lowest percent (5.13%) "Extra" Class fruits were obtained from I2F2 treatment. The highest percent (65.08%) Class I and Class II fruits were obtained from I1F2 treatment while the lowest percent (51.86%) were obtained from I2F2 treatment. that the highest percent (43.01%) Class III fruits were obtained from I2F2 treatment while the lowest percent (11.09%) were obtained from I0F0 treatment. The results showed that the highest average fruit weight in "Extra" Class was obtained from I1F2 treatment – 7.91 g. The highest average fruit weight in Class I and Class II was obtained from I1F1 treatment – 4.49 g. The highest average fruit weight in Class III was obtained from I1F2 treatment – 2.19 g. The cultivation method does not affect color brightness, red hue, the yellow color, color saturation and color difference but affects the color tone. The cultivation method affects the firmness values of the fruits

The results show that water and nutrient regimes are the main factors, which affect yield, berry size and others features of strawberry development.

ACKNOWLEDGEMENTS

This research work was carried out with the financial support of the BULGARIAN NATIONAL SCIENCE FUND „Competition for financial support for basic research projects – 2022", project title "Impact of the soil and weather parameters on the irrigation management and elaboration of biological means to control phytopathogens to enhance strawberry fruit quality" (grant No КП-06-Н66/4).

The authors also want to thank *Haifa South East Europe* for providing whole range of water soluble fertilizers for conducting the experiments.

ABSTRACT

Microbial fertilisers containing various microorganisms that are in a symbiotic relationship within each other and with plant roots have positive effects on plant growth, development and flowering. They can be used in conventional, organic and sustainable agriculture systems and reduce chemical fertilizer consumption. In this study conducted under greenhouse conditions, the effects of Herasim microbial fertiliser on yield and some quality characteristics of lettuce were investigated. Caipira (*Lactuca sativa* var. *crispa*) lettuce cultivar was used as plant material. In pot trials, 70% peat + 30% perlite mixture was used as a growing medium. A total of 9 different treatments were included in the research: Control (C), 100% Chemical Fertilisation (100% CF), 50% Chemical Fertilisation + Microbial Fertilisation (50% CF + MF), 75% Chemical Fertilisation + Microbial Fertilisation (75% CF + MF), 100% Chemical Fertilisation + Microbial Fertilisation (100% CF + MF), Immersion + Chemical Fertilisation (I + CF), Microbial Fertilisation alone (MF), 50% Chemical Fertilisation + Microbial Fertilisation + Foliar Microbial Fertilisation (50% CF + MF + FMF), 75% Chemical Fertilisation + Microbial Fertilisation + Foliar Microbial Fertilisation (75% CF + MF + FMF). Head height (cm), root collar diameter (mm), number of leaves (number/plant), leaf colour (L*, a* and b*), chlorophyll (SPAD), soluble solids (%SS), pH, total and marketable yield (g/plant) criteria were examined. The total and marketable yield results obtained from 100% CF + MF, I + CF, 75% CF + MF, 75% CF + MF + FMF and 50% CF + MF + FMF treatments were the highest and very similar to that of 100% CF treatment. In addition, similar or better results were obtained fort the same treatments in terms of lettuce growth, colour, chlorophyll and SS criteria.

Key words: Bacteria, biofertiliser, chlorophyll, colour, quality

INTRODUCTION

According to data from the Turkish Statistical Institute, our country's vegetable production in 2023 is 31.8 million tons. The most produced vegetable is tomato with 13.3 million tons, followed by watermelon with 3.2 million tons and onion with 2.6 million tons. The production of leafy vegetables, including lettuce, is more than 2 million tons. Lettuce production is 577 thousand tons (TUIK 2024). Lettuce, one of the annual cool-climate vegetables whose leaves are consumed (Aćamović-Đoković et al. 2011; Colonna et al. 2016) mostly as salads and processed vegetables, are of great importance for human nutrition due to their rich vitamins, minerals, and antioxidants. Raw lettuce contains more nutrients than processed lettuce (Aćamović-Đoković et al. 2011).

One of the most significant challenges facing vegetable cultivation in our country is the relatively low yield per unit area, which varies depending on the region and on the species being cultivated (Aksoy and Altındişli, 1998). Since the beginning of the 20th century, chemical fertilizers, hormones and pesticides have been used extensively to increase yields (Aksoy 1999). In today's intensive modern agriculture, the main objective is to achieve the maximum yield. However, the potential damage to the soil and the environment caused by chemical fertilisers is often overlooked, as highlighted by Parr et al. (1994). Chemicals lead to deterioration of soil structure and biological balance in the soil. Therefore, alternative organic inputs for agriculture are being investigated to regain the lost fertility and biological balance, and to grow crops that will bring benefit to environment and human health Biofertilizers or microbial fertilizers are among these alternative products with significant potential.

Microbial fertilizers are organic products that generally contain microorganisms obtained from plant roots or root zones (Chen 2006; Gupta and Sen 2013). In other words, microbial fertilizers are products that contain different types of microorganisms that can mobilize elements in the soil that cannot be used by plants (Muraleedharan et al. 2010). Cocktail mixtures known as Effective Microorganisms consisting of lactic acid bacteria, phototrophic bacteria and yeast (Goessler and Kuehenelt, 2002) are used in plant cultivation, are physiologically compatible with each other and can coexist by working in a symbiotic relationship. There are studies on the possibility that beneficial microorganisms can increase soil quality, plant growth and yield (Kengo and Hui-lian, 2000). In addition, yeasts produce hormones and enzymes that promote plant cell and root division. Different microorganisms in cocktail mixtures complement each other and establish a symbiotic relationship with plant roots in the soil.

Plants grow extremely well in soils where effective microorganisms live (Pei-Feng et al. 2014). Plant growth promoting bacteria (PGPR) such as rhizobacteria are widely used as biofertilizers for many crops as well as vegetables (Gravel et al. 2007). Such organisms increase the availability of nutrients to the plant by reducing ethylene levels in plants or increasing the production of plant growth regulators such as indole-3-acetic acid (IAA). Physiological mechanisms also change the morphology of roots, facilitating root growth and increasing nutrient uptake (Vessey 2003; Antoun and Prévost 2005; Richardson et al. 2009). Microorganisms are also known to be capable of developing defences against both biotic and abiotic stress factors (Pieterse et al. 2014; Prasanna et al. 2014; Triveni et al. 2015). Beneficial microorganisms not only suppress soil-borne pathogens but also increase the decomposition of organic materials and the availability of plant nutrients and important organic compounds to plants (Singh et al. 2003). They have significant positive effects on improving soil fertility, plant growth, flowering, fruit development and ripening (Lévai et al. 2006). They can be used in conventional, organic and integrated farming systems to reduce the consumption of chemical fertilizers and pesticides and minimize their negative effects on the ecosystem (Molla et al. 2012). Microorganisms activate nutrients (macro and micro elements) and support plant growth (Colla et al. 2010; Wang et al. 2022).

Leafy vegetable production largely depends on the availability of NO3, which is the most important N source (Colla et al. 2011). Excessive N use can reduce leaf quality because it causes nitrate accumulation in the leaves of vegetables with a short vegetation period such as lettuce (Awaad et al. 2016). Pseudomonas, Bacillus, Lactobacillus, Paenibacillus and Pantoea bacteria are root bacteria that stimulate plant growth (Chen et al. 1996; Fálico et al. 2000; Luz 2000; Pal et al. 2000; Wall 2000). Research has focused particularly on the genera Pseudomonas and Bacillus (Compant et al. 2005). It has been reported that many Pseudomonas species promote rapid growth by affecting seed germination, growth and root development, and Bacillus megaterium helps in the solubilization of P and K in soil (Wu et al. 2012; Keshavarz Zarjani et al. 2013; Sindhu et al. 2016; Zhao et al. 2019) and promotes plant growth (Zou et al. 2010; Zhou et al. 2016; Korir et al. 2017). In one study, it was found that biofertilizers enriched with inorganic fertilizers played an important role in the growth and yield of tomatoes and reduced inorganic fertilizer costs by 50% (Haque et al. 2012). As an alternative approach, NPK fertilizers were reduced by 75% by the use of microbial fertilizers in bean cultivation (Chauhan and Bagyaraj 2015). Zhao et al. (2021) *B. megaterium*, in combination with conventional fertilization increased cucumber yield by 11.8%-15.2%. Cucumber yield and quality were not negatively affected when P and K were reduced from conventional fertilization. In another study, microorganisms significantly increased the weight of red lettuce and contributed to the highest vitamin C concentration (Stojanović et al. 2020).

This research was conducted to determine the effects of a microbial fertilizer called Herasim, which contains a cocktail of different beneficial bacteria, on the growth, quality features and yield of curly lettuce grown in pots.

MATERIALS AND METHODS

Materials

Research Area and Growing Medium

This research was carried out by growing curly lettuce in pots in a glass greenhouse located at Akdeniz University, Turkiye. Before planting the seedlings, the pots were filled with a mixture of 30% perlite and 70% peat. The salt content of the peat used is very low, the grain size is between 0-7 mm and the pH value is 6.

Plant Material

Caipira curly lettuce variety was used as plant material in the research and seedlings were purchased from a seedling company. Caipira curly lettuce variety is suitable for open fields, greenhouses, vertical farming and hydroponic systems. The head structure of Caipira, which is a curly, dark green lettuce variety, is homogeneous; the leaves are thick, juicy and crisp. The variety, which is suitable for spring and early autumn production in the open field in temperate coastal regions, is also suitable for late autumn, winter and early spring cultivation under cover. Especially in cold periods, due to the high number of leaves, it looks as if it has reached the harvest stage, which facilitates its sale. The maturity period of the variety varies between 50-60 days in hot periods and 70-90 days in cool periods. The average head weight at the harvest stage is between 750-1100 g. Caipira lettuce variety is resistant to the 16th-26th, 28th and 32nd strains of lettuce mildew, to lettuce mosaic virus and aphids.

Microbial Fertiliser Used in The Research

The microbial fertiliser used in the experiment is a product called ‘Herasim Microbial Fertiliser’ belonging to Herasim Agricultural Products Livestock and Environmental Sciences Ltd. Co. Herasim Microbial Fertiliser contains *Lactobacillus lactis*, *Lactobacillus rhamnosus*, *Lactobacillus plantarum*, *Lactobacillus acidophilus*, *Lactobacillus casei*, *Rhodopseudomonas* *palustris*, *Bacillus subtilis bacteria and Kluyveromyces lactis* and *Saccharomyces cerevisiae* yeasts. It also contains organic carob molasses and water filtered by activated carbon and sand filters. Herasim microbial fertiliser contains 1x10^7 cfu/ml total number of live microorganisms. The content of Herasim microbial fertiliser is shown in Table 1.

Table 1. Content of Herasim microbial fertiliser

Content
Lactobacillus lactis
Lactobacillus rhamnosus
Lactobacillus plantarum
Lactobacillus acidophilus
Lactobacillus casei
Rhodopseudomonas palustris
Bacillus subtilis
Kluyveromyces lactis
Saccharomyces cerevisiae
Organic carob molasses
Activated carbon
Sand-filtered water

Climatic Characteristics of The Research Area

A data logger was placed in the research greenhouse to record humidity and temperature values. After the seedlings were planted, the average humidity was recorded as 58.72% in November, 68.84% in December, and 70.42% in January. The average temperature was measured as 19.52 °C in November, 17.10 °C in December, and 15.26 °C in January. The humidity and temperature values obtained are shown in Figure 1.

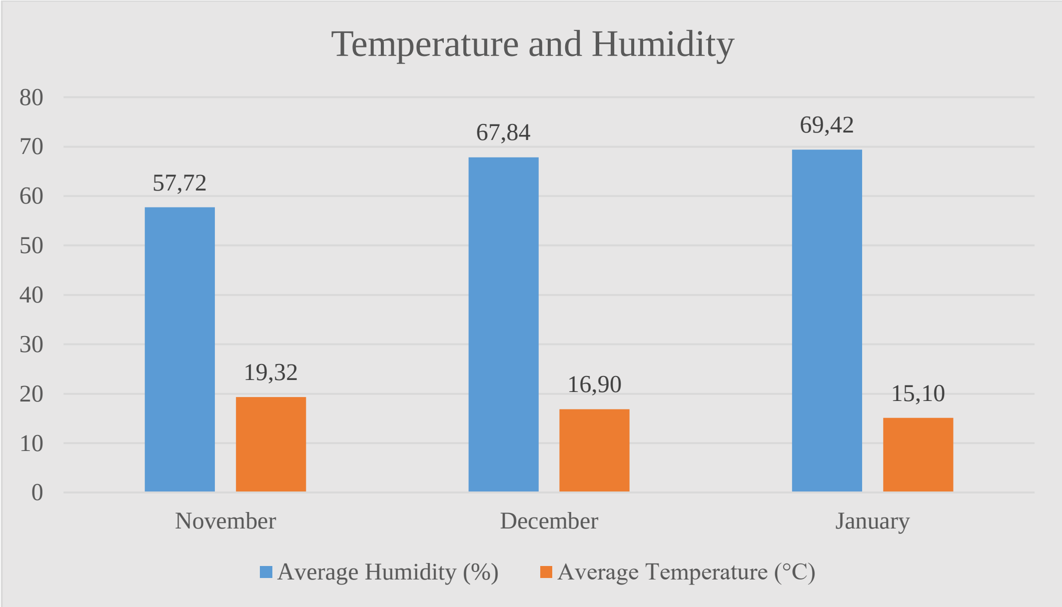

Figure 1. Humidity and temperature values recorded in the research greenhouse.

Properties of Irrigation Water Used in The Research

Well water has been used as irrigation water in the Faculty of Agriculture Research Area. Table 2 gives the pH and hardness of the irrigation water used in the research.

Table 2. Analysis of irrigation water

Parameters*	Value	Unit
pH	7.50	
EC (25 °C)	6.36	µmhos/cm
Bicarbonate (HCO_3)	5.44	meq/l
Calcium (Ca)	4.63	meq/l
Magnesium (Mg)	1.07	meq/l

*Irrigation water characteristics were used together with climate characteristics in another study conducted in the same greenhouse.

Method

Experiment Design and Treatments

Within the scope of the research, 9 different treatments were included together with the control treatment. The study was carried out according to the random plots experimental design with 3 replications. Lettuce seedlings were transplanted as one seedling for each pot on 04.11.2022. Chemical and microbial fertiliser applications were applied for lettuce plants in pots by calculating per plant. Chemical fertiliser treatments were calculated per plant in accordance with the recommended doses of 6.5 kg/da N, 2.5 kg/da P_2O_5, 6 kg/da K_2O as suggested by Aybak (2002). Chemical fertiliser was applied once a week on a certain day. Soil microbial fertiliser treatments were applied every 15 days on a certain day. Foliar microbial fertiliser treatments were applied once a week on a certain day. The treatments and their abbreviations are given in Table 3.

Table 3. Treatments and abbreviations included in the research

Treatments	Abbreviations
Control	C
100% Chemical Fertilisation	100% CF
50% Chemical Fertilisation+ Microbial Fertilisation	50% CF + MF
75% Chemical Fertilisation+ Microbial Fertilisation	75% CF + MF
100% Chemical Fertilisation+ Microbial Fertilisation	100% CF + MF
Immersion + Chemical Fertilisation	I + CF
Only Microbial Fertilisation	MF
50% Chemical Fertilisation+ Microbial Fertilisation + Foliar Microbial Fertilization	50% CF + MF + FMF
75% Chemical Fertilisation+ Microbial Fertilisation + Foliar Microbial Fertilization	75% CF + MF + FMF

Application of Microbial Fertilizer

Before lettuce seedlings were planted, a solution was prepared by mixing 1 litre of microbial fertiliser (1 L/60 L) in 60 litres of water. Except for the lettuce seedlings to be planted in the control and chemical fertiliser alone treatments, lettuce seedlings to be planted in the pots of the other treatments were planted after being immersed in the prepared solution for 30 min. After the seedlings were planted, the first irrigation was performed. One week after planting, microbial fertiliser and chemical fertiliser applications were started according to the research plan.

During the growing period, Herasim was applied with the irrigation water once every 15 days as 1 litre Herasim (1 L/60 L) per 60 litres of water. Herasim was also applied weekly by foliar spraying as 1 liter of Herasim in 120 liters of water (1 L/120 L).

Criteria Examined in Curly Lettuce

Curly lettuce plants reaching harvest maturity were harvested on 25 January 2023. The parameters measured and analysed in lettuce plants are given below. Total chlorophyll content was determined by SPAD 502 chlorophyll meter from the leaves of curly lettuce plants before harvesting. Harvested lettuce plants were crushed with a juicer and their juices were separated, and the TSS value were determined as % with a Hanna HI 96801 Model digital refractometer. Harvested lettuce plants were crushed with a juicer and their juices were extracted, and the pH of these juices was measured using a Hanna HI 2002-02 Model pH meter.

Colour measurements were taken as L, a* and b* on the third leaves from the outside of the harvested plants using the Minolta CR 400 Model colour chromameter, and the C (Chroma) and hº (hue) angle values were calculated using the *a and *b values.

C: $\sqrt{(a^2+b^2)}$

h (˚): $\tan^{-1}$ (b/a)

The L*, a* and b* colour parameters show the colour values that the human eye can perceive, and L* shows the changes in the brightness of the colour, reaching a maximum value as it approaches 100, which is called white. Of the colour values, a* shows the changes from green to red, and b* shows the changes from yellow to blue. Increasingly negative or positive values of the measured values indicate darkening of the colour, positive values of a* indicate red, negative values indicate green, and in the same way positive values of b* indicate yellow and negative values indicate blue. The hue angle calculated using the determined colour values indicates 0=red, 90=yellow, 180=green and 270=blue (Siomas et al. 2002; Madeira et al. 2003).

Statistical Analysis

The study was conducted according to the random plots trial design with 3 replications. The statistical analysis of the results was carried out with SAS 2009 Package Program and JPM Pro 17, an SAS program.

Figure 2. Lettuce plants in pot trials before harvest

RESULTS AND DISCUSSION

The effects of microbial fertiliser applications on lettuce head length (cm), root collar diameter (mm), number of leaves (number/plant), total soluble solids (TSS; %) and pH in lettuce juices are given in Table 4.

Table 4. Effects of microbial fertiliser applications on head length, root collar diameter, leaf number, TSS and pH of lettuce

Treatments	Head Length (cm)	Root Collar Diameter (mm)	Leaf Number (leaves/plant)	TSS (%)	pH
C	12.47 c*	14.92	39.00 b*	5.07 a*	6.23
100% CF	**18.33 a**	15.02	42.00 ab	4.20 b	6.21
50% CF + MF	17.03 ab	15.71	41.00 ab	4.03 b	6.22
75% CF + MF	**19.30 a**	15.43	42.00 ab	3.95 b	6.19

75% CF + MF + FMF	18.13 a	16.83	43.33 ab	3.97 b	6.25
$LSD_{\%5}$	2.7746	N.S.	5.8963	0.5836	N.S.

*Differences between values not indicated with the same letter are significant at p<0.05 level.
N.S: Not Significant

Different microbial fertilizer applications had significant effects on head length, leaf number and TSS, but no significant effects on root collar diameter and pH ($p<0.05$). The shortest plants in terms of head length were measured in the C and MF plots. The Plants in other treatments were evaluated in the same group. However, the highest values were obtained from 50% CF + MF + FMF, 75% CF + MF, 100% CF, I + CF and 75% CF + MF + FMF treatments. Root collar diameter values varied between 16.83-14.92 cm and there were no significant differences between treatments. When the number of leaves was compared in different treatments, the plants with the lowest number of leaves were obtained in the C and MF treatments, while there were no significant differences in between the other treatments, but more leaves were obtained compared to the C and MF treatments. Total soluble solids content was highest in C and all other treatments were in the same group with lower values. There were no significant differences between the measured pH values and they varied between 6.31-6.15.

Microbial fertilizer applications combined with inorganic fertilizer did not negatively affect the growth characteristics of lettuce and even showed an improving effect. These results are consistent with previous studies. For example, Demir et al. (2023) reported similar results in terms of head length, leaf number and TSS of lettuce with the use of a microbial fertilizer in combination with chemical fertilisers. In addition, contrary to this study, it was reported that it was effective on root collar diameter and pH. Miskoska-Milevska et al. (2018) found that commercial Slavol containing the microorganisms *Azotobacter chroococcum*, *Azotobacter vinelandii*, *Derxia sp.*, *B. megaterium*, *B. licheniformis* ve *B. subtilis* increased leaf length and width when sprayed on cauliflower leaves. On the contrary, Rabiei et al. (2020) reported that *Azospirillum brasilense* and *Azotobacter chroococcum* did not affect the length of coriander whose leaves were consumed. Polat et al. (2004) reported that TSS was in the range of 3.86%-4.06% in head lettuce and 4.40%-4.60% in cos type lettuce and pH was in the range of 5.99-6.06% in head lettuce and 5.89-5.94% in cos type lettuce. These values are compatible with our study. Özbay et al. (2010) found that *T. harzianum* bacteria increased the TSS of rocket by 13% and cress by 11%.

The effects of microbial fertilizer applications on L*, C and hº colour values and total chlorophyll (SPAD) content of lettuce are shown in Table 5.

Table 5. Effects of microbial fertilizer applications on L*, C and hº colour values and total chlorophyll of lettuce

Treatments	L*	C	hº	Chlorophyll
C	66.74 a*	43.26 a*	116.25 c*	24.60 ed*
100% CF	59.68 bc	40.93 cd	118.95 ab	31.47 a
50% CF + MF	58.39 cd	42.06 abc	119.24 a	26.53 cde
75% CF + MF	56.68 cd	40.61 cd	119.70 a	30.07 ab
100% CF + MF	57.53 cd	41.66 abcd	119.24 a	27.83 bcd
I + CF	59.96 bc	41.28 bcd	119.25 a	30.80 ab

75% CF + MF + FMF	55.15 d	40.16 d	119.41 a	31.07 ab
$LSD_{\%5}$	4.4066	1.7997	1.2615	3.3217

*Differences between values not indicated with the same letter are significant at p<0.05 level.
N.S: Not Significant

Statistically significant differences were found between treatments in terms of colour criteria and chlorophyll content (p<0.05). The highest L* value in lettuce leaves was measured in C and MG. The lowest L* value was determined in 75% CF + MF + FMF, 75% CF + MF, 100% CF + MF, 50% CF + MF + FMF and 50% CF + MF plots. The highest C value indicating the saturation in leaf colour was calculated in C and MG, while the lowest values were calculated in 75% CF + MF + FMF, 75% CF + MF, 100% CF and 50% CF + MF + FMF treatments. The hº angle, which expresses the changes in the colour of the leaves, was highest in 75% CF + MF, 75% CF + MF + FMF, I + CF, 50% CF + MF, 100% CF + MF and 50% CF + MF + FMF treatments. The lowest hº value was determined in K. Green colour is an important morphological trait in lettuce, the leaves of which are consumed as a vegetable. When the colour values obtained were examined from this point of view, it can be said that greener lettuce was harvested in 50% CF + MF, 75% CF + MF, 100% CF + MF, I + CF, 50% CF + MF + FMF and 75% CF + MF + FMF treatments. When the total chlorophyll content was evaluated according to the treatments, the highest values were obtained in the plants in 100% CF, 75% CF + MF + FMF, I + CF and 75% CF + MF plots. The treatments with the lowest chlorophyll content were in the MF and C plots. It was also determined that the chlorophyll contents were generally in parallel with the colour values.

Figure 3. 75% CF + MF + FMF treatment plants that have reached the harvest stage.

Ucok et al. (2019) showed in their research with different organic fertilisers that L* in curly lettuce varied between 56.23–59.43, C varied between 37.19–38.82, and hº varied between 115.56–117.61. Contrary to these, Sönmez et al. (2017) found that organic fertilisers did not affect these colour values. The colour values determined in our research are consistent with these studies. Demir et al. (2023), who investigated the effects of microbial fertilisers on lettuce, reported quite similar results to our research in terms of the lettuce colour and chlorophyll changes.

The effects of different microbial fertiliser applications on total (g/plant) and marketable (g/plant) yield of lettuce are shown in Table 5.

Table 5. Effects of different microbial fertilizer applications on total and marketable yield of curly lettuce.

Treatments	Total yield (g/plant)	Marketable yield (g/plant)
C	138.33 c*	125.00 c*
100% CF	270.00 ab	246.67 ab
50% CF + MF	253.33 b	235.00 b
75% CF + MF	280.00 ab	260.00 a

75% CF + MF + FMF	286.67 a	261.67 ab
$LSD_{\%5}$	31.622	32.43

*Differences between values not indicated with the same letter are significant at p<0.05 level.

Different treatments significantly affected total and marketable lettuce yield (p<0.05). The highest total yields were found in I + CF (296.67 g/plant), 75% CF + MF + FMF (286.67 g/plant), 100% CF + MF (281.67 g/plant), 75% CF + MF (280.00 g/plant), 50% CF + MF + FMF (278.33 g/plant) and 100% CF (270.00 g/plant) treatments. The lowest yield values were determined in C (138.33 g/plant) and MF (146.67 g/plant) treatments. The highest values in terms of marketable yield were obtained from I + CF (276.67 g/plant), 100% CF + MF (266.67 g/plant), 75% CF + MF + FMF (261.67 g/plant), 50% CF + MF + FMF (261.67 g/plant), 75% CF + MF (260.00 g/plant) and 100% CF (246.67 g/plant) treatments. Similar to the total yield, the lowest marketable yields were again determined in C (125.00 g/plant) and MF (140.00 g/plant) treatments.

When the results were evaluated in terms of yield; in the I + CF treatment, which gave the highest value in total yield, 114.5% more yield was obtained compared to C and 102.3% more yield was obtained compared to MF. When this application (I + CF) was compared to 100% CF, 9.9% more total yield was obtained. The 75% CF + MF + FMF treatment, provided the highest yield although the chemical fertilizer dose was reduced by 25%; this yield is 107.2%

higher than that of C; 95.5% higher than that of MF and 6.2% more than the yield obtained in 100% CF.

There are many studies supporting the view that microbial fertilisers increase the yield and reduce chemical fertiliser consumption. Demir et al. (2023) found the highest total yield in lettuce in the microbial fertiliser, “immersion + chemical fertilisation,” and in the “chemical fertilisation (CF) + microbial fertiliser (MF)” applications, while in the same study, the highest first class yield in cucumber was obtained in 50% CF + MF application. When the researchers compared the results obtained, they reported that savings could be achieved on chemical fertilisers by introducing accompanying microbial fertilisation. These results are similar to our research. Vejan et al. (2016) reported that yield was increased between 7% and 33% with the use of PGPR. Stojanovic et al. (2020) concluded that some microorganisms were effective on lettuce yield. There are other studies with similar results on saving on chemical fertiliser. For example, Chauhan and Bagyaraj (2015) found that NPK in beans could be reduced by microbial inoculation. Kafi et al. (2021) determined that the recommended NPK dose in cucumber could be reduced by 30% by utilizing some beneficial bacteria.

The positive and negative proportional effects related to the criteria examined within the scope of the research are shown with Pearson correlation coefficients (Table 6). Average values were used in the criteria examined.

Table 6. Pearson correlation coefficients related to the criteria examined in the study.

Parameters	L	C	hº	Chlorophyll	Total Yield	Market. Yield	Head Length	Root Collar Diam.	Leaves Num.	TSS	pH
L	1,000

*Significant at p<0.05 level; **Significant at p<0.001 level; ns: Not Significant

There was a strong positive relationship between L and C and TSS among the examined criteria, while there was a strong negative relationship between L and hº, total yield, marketable yield and head length. The negative relationship between L and chlorophyll was moderate. The significant relationships between C and other criteria were negative except for TSS (positive). Among the relationships between hº and other important criteria, only TSS was negative. There was a strong positive relationship between chlorophyll and total yield, marketable yield, head length, and a moderately significant positive relationship with the number of leaves. While there was a strong positive relationship between total yield and marketable yield, head length and number of leaves, there was a strong negative relationship with TSS. The relationships between the examined criteria can be seen in Table 6.

The principal component analysis conducted by considering the criteria examined in the research is shown in Figure 4, and the load matrices are shown in Table 7.

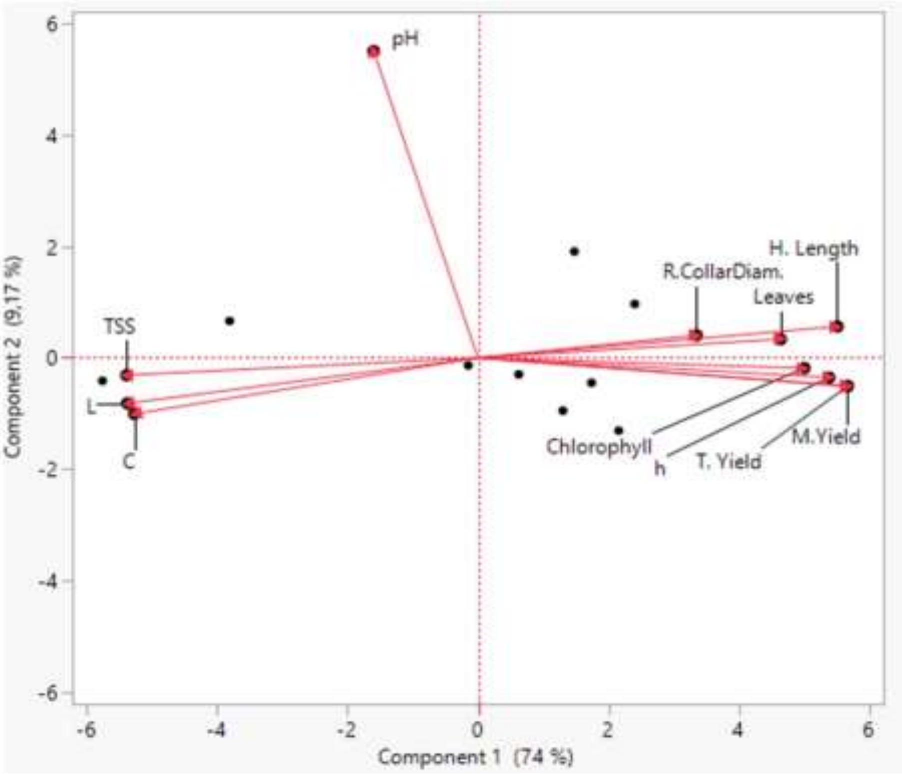

Figure 4. Principal component analysis results of the parameters examining the effects of microbial fertilizer applications.

According to the principal component analysis results, Figure 4 shows two components. The first principal component represented 74%, the second principal component 9.17% and the total variation 83.17%. All analysed components and factor loadings can be seen in Table 7.

Table 7. Load matrices of the examined criteria

Parameters	Prin1	Prin2	Prin3	Prin4	Prin5
L	-0,93390	-0,14187	-0,05527	0,28158	0,05680
C	-0,91533	-0,17470	0,15446	-0,01020	0,31765
H	0,93532	-0,06099	0,03716	-0,31904	0,05801
Chlorophyll	0,86920	-0,03195	-0,25100	0,23750	-0,33756
Total Yield	0,98398	-0,08892	-0,08128	0,04446	0,02241
Marketable Yield	0,98470	-0,08739	-0,06865	0,04093	0,07833
Head Length	0,95707	0,09793	-0,23209	-0,04192	0,12400
Root Collar Diameter	0,58232	0,07031	0,78301	0,07432	-0,19250
Leaves Number	0,80591	0,05831	0,08860	0,50667	0,28424
TSS	-0,93574	-0,05393	-0,11003	0,15663	-0,27603
pH	-0,27789	0,95777	-0,04517	0,01212	0,03662

The most important traits constituting the first main component were marketable yield, total yield, head length, TSS, h colour value, L* and C colour values, chlorophyll and leaf number according to factor loadings. In the second main component, only the most important factor loading was pH, while the third component was root collar diameter.

CONCLUSIONS

This research was carried out in pots to determine the effects of a microbial fertiliser called Herasim containing different beneficial bacteria in a cocktail form on the growth, quality and yield characteristics of lettuce. The results were obtained in the study were significant. First of all, it was determined that Herasim microbial fertiliser had no negative effects on lettuce growth characteristics, quality criteria, leaf colours and yield. It was determined that basically similar results were obtained with 100% CF in terms of the criteria examined, and even some healing effects of microbial fertilizer appeared when the chemical fertilizer dose was reduced. For example, greener lettuce leaves were harvested by applying Herasim at reduced chemical fertiliser doses.

In addition to different chemical fertiliser doses, higher yield values were obtained with microbial fertilisers applied in comparison to that of control and microbial fertiliser only applications. Despite the reduced NPK doses, it is noteworthy that similar yield results were obtained with 100% CF alone with the addition of microbial fertiliser. In this respect, 75% CF + MF and 75% CF + MF + FMF and 50% CF + MF + FMF trials are important in terms of fertiliser savings. The increase in yield by spraying microbial fertiliser on the leaves was also found to be remarkable.

We believe that it is no coincidence that the highest total yield (296.67 g/plant) and marketable yield (276.67 g/plant) were obtained in the I + %100 CF application where Herasim Microbial Fertiliser was applied only by the immersion method on lettuce before transplanting because in this treatment the microbial application was carried out at the earliest stage and directly to the roots of the plant. As a direct result of this, it should be understood that the plant could probably develop better as a result of better uptake of nutrients from the plant roots at an early stage in this treatment.

In view of the above study, we highly recommend the use of Herasim Microbial Fertiliser to save on Chemical Fertilisers.

ACKNOWLEDGEMENTS

We would like to thank Herasim Agriculture and Livestock Products Ltd. Co. for providing the Herasim Microbial Fertilizer support used in the research.

ABSTRACT

The aim of this paper is to present the effects of the time of harvesting, irrigation and fertigation on the physicochemical and biochemical indicators of white strawberry fruits during the cold storage (T= 4ºC).
The fruits were grown in 2024 as part of a two-factor experiment conducted in an experimental field at the Institute of Soil Science, Agrotechnology, and Plant Protection "Nikola Poushkarov," Chelopechene, Sofia, in an unheated greenhouse with drip irrigation and fertigation. The following irrigation and fertilization rates were applied: I1 – 75% (ETc), I2 – 50% (ETc), F1: optimal fertilization $N_{8.09}P_{12.76}K_{15.62}$, F2 – suboptimal fertilization – 75% (F1). Five variants were studied: control: I0F0: 100% (ETc) without fertilization; I1F1; I1F2; I2F1; I2F2.
The storage under refrigerated conditions (T = 4°C) and the analysis of fruit quality using standardized methods and adapted techniques over a period of 6 days were conducted in the laboratories of the "Food Technology" department at the Institute of Food Preservation and Quality – Plovdiv. The study dynamically examined the physicochemical parameters (soluble and insoluble dry matter, %; active acidity; moisture, %; water activity; chromatic parameters L*, a*, b*) and biochemical parameters (total polyphenols, mg GAE/100 g, and antioxidant activity, µmol TE/100 g) of the fruits during storage.
It was found that the time of harvest, cultivation method, and storage period under refrigerated conditions influenced the values of physicochemical parameters for all studied variants of white strawberry fruits (Fragaria x Ananassa "Snow White"), with the most significant impact on antioxidant activity and total polyphenol content ($p > 0.05$).

INTRODUCTION

Strawberries with white fruits have long history of cultivation no shorter then red varieties. White strawberry has cultivated for hundreds of years in Chile and has grown in two botanical forms - wild *Fragaria chiloensis ssp. chiloensis f. patagonica* and cultivated *Fragaria chiloensis ssp. chiloensis f. chiloensis* (Grez et al., 2020). It was brought to Europe in the 18th century. „Snow White" cultivar has been selected in 2010 out from *Fragaria x ananassa*

"Weisse Ananas" and *Fragaria chiloensis f. Chiloensis* (Olbricht et al., 2013). White strawberries are distinguished by their white or pale pink flesh and unique pineapple-like flavor.

Fragaria Ananassa berries are an important source of vitamins, minerals and fibers. The diversity of bioactive compounds, such as phenols in berry species, is reflected in a wide range of their biological activities, which have a beneficial effect on human health and disease prevention (Moyer, R, 2002). The activity of phenols is expressed in antioxidant (Cirico et al., 2006), neuroprotective (Galli et al., 2006) anticancer (Ramirez - Tortosa et al., 2001; Markovic et al., 2000), anti-inflammatory (Karakaya et al., 2004) and antimicrobial activity. The physicochemical and biochemical parameters of red variety strawberry have been widely studied (Sadik et al. 2023; Cordenunsi et al. 2003; Kumar et al. 2021; Muley et al. 2022; Wigati et al. 2024; Pinheiro et al. 2021; Balan et al., 2024), while white variety has been still limited (Ivanova et al., 2024).

This research investigates the effects of drip irrigation and fertigation on white strawberries' physical characteristics during cold storage.

MATERIAL AND METHOD

✓ Experimental layout

The second year two-factor experiment was conducted on drip irrigated strawberry plants in a tunnel greenhouse in 2023 and 2024 in the Chelopechene experimental field (latitude 42°44′22.8″N, longitude 23°28′3.7″E and altitude 550 m above sea level) of the Institute of soil science, agrotechnologies and plant protection "Nikola Poushkarov" in Sofia, Bulgaria. Sofia field falls into temperate continental climate subzone. The greenhouse was unheated with area 420 m^2 (7.9 m x 53 m) covered with a five-layer UV+EVA+IR+AD+dif -150 μm polyethylene film. The soil could be defined as moderate to strong water-permeable with an average filtration capacity. The soil was *Chromic Luvisol* with bulk density 1.47 g cm^{-3}, field capacity 22% and wilting point 10% for 0-50 cm layer. To further reduce water losses, mulching with silver-black UV polyethylene mulch with a thickness of 30 μm was applied.

The object of the study was white strawberry cultivar (*Fragaria × ananassa "Snow White"*). The experimental treatments were arranged according to the method of long plots with three replications. Each plot has 23.2 m^2 area and consisted of twin rows of strawberries. Healthy bare-root frigo plants were planted in scheme of 90 + 30/30 cm on 22 March 2023. According to the white strawberries cultivation technology in each of the experimental plots were provided the appropriate amount of red fruit plants (4: 1 ratio) to ensure better pollination. The irrigation factor was applied in two rates: I1 – deficit irrigation - 75% (ETc); I2 - deficit irrigation - 50% (ETc). The fertilization factor was applied in two rates: F1: optimal fertilization $N_{8.09}P_{12.76}K_{15.62}$; F2 – suboptimal fertilization - 75% (F1) - $N_{6.07}P_{9.57}K_{11.94}$. Optimal fertilization was developed according to Haifa nutrition recommendations (Haifa Group, 2021) as follows: Haifa MAP- 25-45 kg ha^{-1} , Multi K – 80 kg ha^{-1} , Haifa MKP - 25 kg ha^{-1} , Haifa Cal - 30 kg ha^{-1} , Maguisal - 10 kg ha^{-1} , Poly-feed – 25-40 kg ha^{-1}. Five treatments were tested: control treatment I0F0: 100% (ETc) - full irrigation and without fertigation; I1F1; I1F2; I2F1; I2F2. Irrigation was applied trough drip system include NMC Junior controller for precise irrigation rate application, FertiKit Nutrigation system for precise fertigation rate application, pressure-compensated pipelines UniRam AS with 14.6 mm inside diameter, 1.2 mm wall thickness, built-in trough 20 cm drippers and flow rate 1.6 l h^{-1}.

The microclimate data (air temperature, relative humidity, solar radiation, sunshine duration and wind speed) in the greenhouse was measured at every 30 min using an automatic meteorological station located in the center of experimental area and recorded in data logger (HOBO USB Micro Data Logger, USA). FAO Penman-Monteith Equation (Allen et al., 2006a) was used for determining daily reference evapotranspiration and irrigation scheduling. Crop coefficient was 0.30, 0.80 and 0.70 respectively in initial, middle and end growing stage (Allen et al., 2006b).

✓ **Methods**

Physicochemical parameters

- Total soluble solids by refractometer,% – BDS EN 12143-2000;
- Total soluble solids by weight, % – BDS 7133:1981;
- Moisture – BDS EN 12145:2000;
- Active acidity – BDS 11688-1993;

Biochemical indicators

- The antioxidant activity (DPPH-test) was determined according to the method of Brand- Williams et al. (1995) in the following modification: 2250 µl of DPPH solution (2.4 mg of DPPH in 100 ml of methanol) and 250 µl of sample extract.

A blank sample was similarly prepared using methanol instead of extract. After keeping the closed cuvettes in the dark for 15 min at a temperature of 20-25°C, the absorbance of the reaction mixture was measured at 515 nm.

The results obtained are presented as Trolox equivalents (GAE) per 100 g of extract.

- The content of total polyphenols in fruit and vegetable flour was determined according to the method of Singleton and Rossi (1965) with the following modification: 0.1 ml sample extract, ~7 ml distilled water, 0.5 ml Folin-Ciocalteu reagent (diluted 1:4 with distilled water) and 1.5 ml 7.5% (w/v) of aqueous sodium carbonate solution were successively dosed into a 10 ml measuring tube.

It was topped up to the mark with distilled water. After 2 hours at a temperature of 20-25°C, the absorbance of the reaction mixture was measured at 750 nm.

A blank sample was similarly prepared using distilled water instead of extract. The results are presented as gallic acid equivalents (GAE) per 100 g of extract.

The obtained data were statistically analyzed using ANOVA software, as well as Microsoft Excel and STATISTICA 8.0. Duncan's Multiple Range tests at a significance level ($p<0.05$) to measure specific differences between pairs of means was used.

RESULTS AND DISCUSSION

The results of the analyses conducted on the different growing variants of white strawberry fruits, based on harvests and storage duration, are presented in Figures 1, 2, and 3.

During the second vegetative period, the fruits from the three harvests across all irrigation and fertilization variants showed good quality results up to the 6th day of storage at 4°C.

Data from the physicochemical analyses indicate that, in terms of dry matter (refractometric), the soluble solids in the control group (I0F0 with 100% irrigation) increased to 9.13% during the second harvest, while the values for the first and third harvests were statistically indistinguishable ($p > 0.05$). The harvest factor had an effect on the control fruits ($p < 0.05$).

For the fruits from variant I1F1 (with 75% irrigation and 100% fertilization), the results were higher compared to those of the control (I0F0) only during the third harvest.

The percentage of soluble solids during the first and second harvests were statistically indistinguishable and lower than those of the control group I0F0 ($p > 0.05$). Here, the harvest factor had an effect only on the values from the third harvest ($p < 0.05$).

For the fruits from the third variant, I1F2 (with 75% irrigation and 75% fertilization), the percentage of soluble solids was the same as those in the control group, I0F0 (100% irrigation), and the second growing variant, I1F1 (75% irrigation and 100% fertilization) ($p > 0.05$). For these irrigation and fertigation variants, compared to the control I0F0 (100% irrigation), there were no statistically significant differences in soluble solids for the first harvest ($p > 0.05$). The timing of the harvests in this growing variant had a significant impact during the second and third harvests, with values being significantly lower during the second harvest (6.13%) compared to the first harvest, and increasing to 10.87% during the third harvest ($p < 0.05$).

For the fruits from the fourth (I2F1 with 50% irrigation and 100% fertilization) and fifth (I2F2 with 50% irrigation and 75% fertilization) growing variants, it was found that the percentage of soluble solids in the first harvest was lower than that of the control group, I0F0 (100% irrigation), and the above-mentioned variants, and statistically indistinguishable from each other, with values above 6% ($p > 0.05$). In this case, the growing method for the fruits from the first harvest of these two variants did not influence the measured values ($p > 0.05$). The selection of the percentage ratio of irrigation and fertilization for these two variants, compared to the control I0F0 (100% irrigation) and the variants I1F2 (with 75% irrigation and fertilization) and I1F1 (75% irrigation and 100% fertilization), had a significant impact on this parameter.

The timing of the harvests affects the second and third harvests, with dry matter content increasing gradually during the second harvest and reaching maximum values during the third harvest, at 12.5% and 11.43%, respectively, for each growing variant.

For all studied variants, depending on the harvests, the fruits from the third harvest in variant I1F1 (75% irrigation and 100% fertilization) had the highest soluble dry matter content at 12.67%, while the lowest content was 6.13% in the fruits from the first harvest of the fifth variant I2F2 (50% irrigation and 75% fertilization).

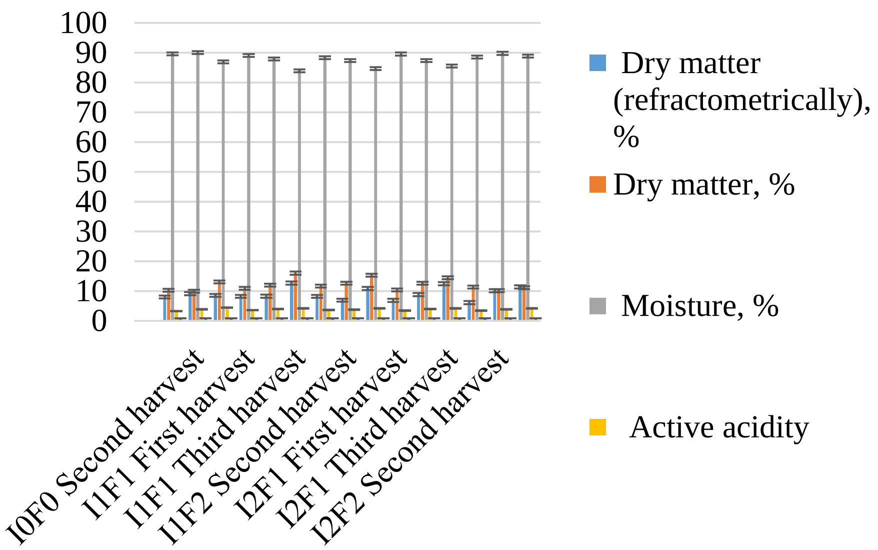

Figure 1. Physicochemical parameters of white strawberry fruits, depending on harvests and growing methods on the day of receipt

The timing and storage conditions influence the soluble dry matter values for fruits from the control group I0F0 (100% irrigation).

For the first harvest, the values are higher on the day of receipt compared to the three-day storage under refrigerated conditions, and are statistically indistinguishable from each other by the sixth day of storage ($p > 0.05$).

For fruits from the second harvest, storage conditions do not affect the percentage of measured dry matter on the day of receipt and during three-day storage ($p > 0.05$). A significant reduction is observed during six-day refrigerated storage compared to the day of receipt and the end of the storage period with other harvests, at 7.03% ($p < 0.05$).

The timing and storage conditions significantly affect soluble dry matter in fruits from the third harvest. During three-day storage, values are at their maximum for all harvests at 11%, and decrease by a factor of 1.1 by the sixth day of storage ($p < 0.05$). Only in fruits from the first harvest of the control group I0F0 (100% irrigation) is there an increase in soluble dry matter during six-day refrigerated storage compared to three-day storage.

In summary, soluble dry matter for the first harvest is statistically indistinguishable during six-day storage compared to the day of receipt, is the same for the second harvest up to the third day of storage, and decreases by the sixth day of storage, with an increase observed in fruits from the third harvest.

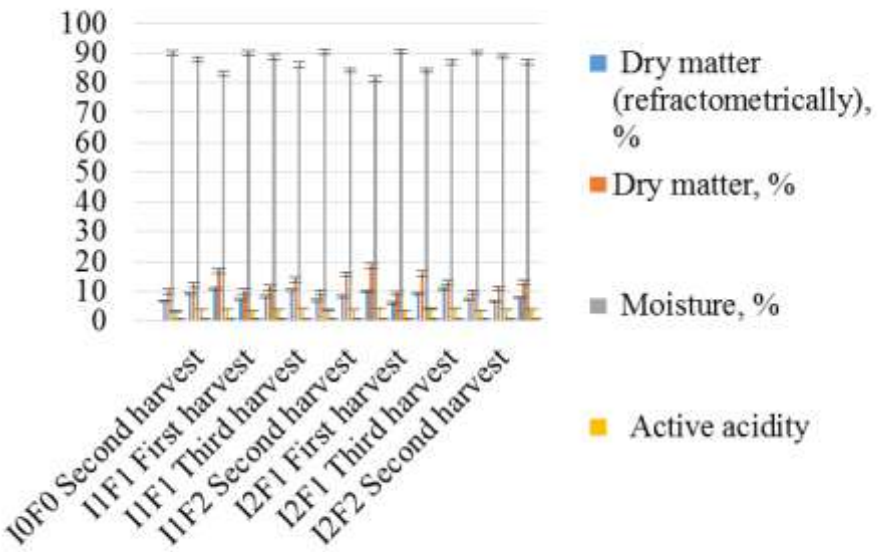

Figure 2. Physicochemical parameters of white strawberry fruits, depending on harvests and growing methods during three-day storage

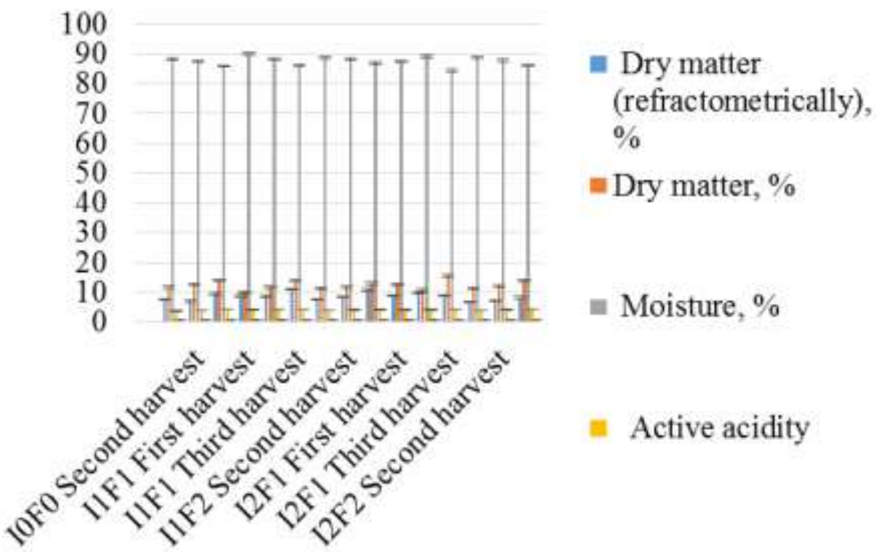

Figure 3. Physicochemical parameters of white strawberry fruits, depending on harvests and growing methods during six-day storage

Storage time affects the percentage values of soluble dry matter in fruits from the second variant I1F1 (with 75% irrigation and 100% fertilization) from the first and third harvests ($p < 0.05$). The timing of harvests and storage does not affect the values of soluble dry matter in fruits from the first and second harvests throughout the entire storage period ($p > 0.05$). The highest values are observed in fruits from the third harvest on the day of receipt at 12.67% and for the storage period at 11.07%, despite a reduction in values by a factor of 1.1.

For fruits from the third variant I1F2 (with equal irrigation and fertilization rates of 75%), harvests influence the values of soluble dry matter on the day of receipt, with the highest value recorded for fruits from the third harvest at 10.87%, which remains constant throughout the entire storage period ($p < 0.05$).

The time and storage conditions affect the first two studied harvests up to the third day of storage. For fruits from the first harvest, the percentage of dry matter decreases by a factor of 1, while for fruits from the second harvest, it increases by a factor of 1.2, reaching a value of 8.4% ($p < 0.05$). By the end of the storage period, the dry matter values (refractometric) remain unchanged for fruits from the first and third harvests ($p > 0.05$). Storage affects the values for this parameter in fruits from the second harvest ($p < 0.05$).

Harvests influence the soluble dry matter values in fruits from the fourth variant, I2F1 (50% irrigation and 100% fertilization), with the highest value on the day of receipt at 12.5%, and during three-day storage at 11% for fruits from the third harvest ($p < 0.05$). The lowest value is observed in fruits from the first harvest on the day of receipt at 6.88% and during three-day storage at 6.13%. The dry matter value remains unchanged for fruits from the second harvest at 9%. During the three-day storage, the soluble dry matter decreases by 1.5% for fruits from the first and third harvests. A significant reduction in values is measured at the end of the storage period for fruits from the third harvest, reaching 8.87%. For fruits from the first harvest, an increase in soluble dry matter is recorded at the end of the six-day refrigerated storage, similar to the increase observed for fruits from the third harvest, by a factor of 1.2. During the refrigerated storage period for this variant, regardless of the initial value on the day of harvest, the percentage of soluble dry matter for the three harvests is approximately equal at 9%.

In the last studied variant of white strawberry cultivation, I2F2 (50% irrigation and 75% fertilization), the timing of harvests affects the soluble dry matter values on the day of receipt ($p < 0.05$). The lowest value is 6.13% for fruits from the first harvest, while the highest value is 11.43% for fruits from the third harvest. During the three-day storage, only fruits from the first harvest show an increase in dry matter percentage to 7.35%, while fruits from the second and third harvests show a significant decrease, by factors of 1.6 and 1.5, respectively. At the end of the six-day storage, soluble dry matter values do not change for fruits from the second and third harvests, while for fruits from the first harvest, a decrease to 6.73% is observed.

Active acidity measured in fruits (depending on harvests and cultivation methods) on the day of receipt increases for all fruits from the third harvest and is above 4.1. The highest value is observed in fruits from the control group I0F0 (100% irrigation) from the third harvest at 4.47, while the other variants from this harvest with different irrigation and fertilization rates are statistically indistinguishable. Harvests influence this parameter, with the lowest values found in fruits from all variants of the first harvest, ranging from 3.27 in the control group I0F0 (100% irrigation) to 3.65 in fruits from the third variant I1F2 (with equal percentages of 75% irrigation and fertilization) ($p<0.05$). Cultivation method affects only the value in fruits from the control group I0F0 (100% irrigation) ($p<0.05$). Statistically indistinguishable active acidity values are found in fruits from the first harvest of variants with 75% irrigation and 100% fertilization, and 75% irrigation and 75% fertilization, as well as between variants with 50% irrigation and 100% fertilization and 50% irrigation and 75% fertilization. For these, the cultivation factor does not influence the active acidity values on the day of receipt ($p>0.05$).

Fruits from the second harvest have higher active acidity values compared to those from the first harvest, approaching 4, except for fruits from the second variant I1F2 (with 75% irrigation and 100% fertilization), whose values are not significantly different.

During the three-day refrigerated storage, the fruits from the first two harvests of all studied variants do not change their values compared to the day of receipt, and storage does not affect the investigated parameter ($p>0.05$). Harvest and storage period influence the reduction in active acidity values for fruits from the last fruiting period for variants from the control group I0F0 (100% irrigation) and I2F2 (50% irrigation and 75% fertilization) ($p<0.05$).

With minimal statistically indistinguishable values of active acidity after six-day storage (4.2), are fruits from the third harvest grown with 75% irrigation and 100% fertilization (I1F1) and 75% irrigation and 75% fertilization (I1F2) ($p>0.05$) (Figures 2 and 3). For all other cultivation variants and harvests of white strawberries, storage influences the active acidity, and values are statistically different, ranging from 3.77 in the control group I0F0 (100% irrigation) from the first harvest to 4.6 in fruits from the third harvest grown with 50% irrigation and 100% fertilization (I2F1) ($p<0.05$) (Figures 1, 2, and 3).

The summary for this parameter is that storage does not affect fruits from the third harvest, grown with 75% irrigation and 75% fertilization (I1F2) and with 75% irrigation and 100% fertilization (I1F1) ($p>0.05$). For all other variants from all harvests, storage influences the active acidity values of the fruits ($p<0.05$).

Moisture and dry matter (weight-based) in white strawberry fruits from the three harvests during storage were analyzed.

It was found that the moisture on the day of receipt for all studied cultivation variants depends on the harvests. The analyzed fruits from the first harvest have higher moisture percentages (approximately 90%) compared to other harvests, except for the I2F2 variant, which has the lowest percentages of irrigation and fertilization (50% irrigation and 75% fertilization). Statistical processing of the data showed no differences between values for fruits from the control group I0F0 (100% irrigation) and I2F1 (50% irrigation and 100% fertilization), as well as between I1F1 (75% irrigation and 100% fertilization), I1F2 (75% irrigation and 75% fertilization), and I2F2 (50% irrigation and 75% fertilization) variants for this harvest. Cultivation method does not affect this parameter ($p>0.05$).

For fruits from the second harvest, moisture values decrease by a factor of 1.1 compared to the first harvest for variants I1F1 (75% irrigation and 100% fertilization), I1F2 (75% irrigation and 75% fertilization), and I2F1 (50% irrigation and 100% fertilization), while values for variants I0F0 (100% irrigation) and I2F2 (50% irrigation and 75% fertilization) are statistically indistinguishable ($p>0.05$).

Fruits from the third harvest show a significant reduction in moisture percentage for variants I1F1 (75% irrigation and 100% fertilization), I1F2 (75% irrigation and 75% fertilization), and I2F1 (50% irrigation and 100% fertilization) (84%), with values being statistically indistinguishable from each other ($p>0.05$). The maximum moisture value is found in fruits from variant I2F2 (50% irrigation and 75% fertilization) from the third harvest (90.08%), while the minimum is in fruits from variant I1F1 (75% irrigation and 100% fertilization) from the third harvest (83.97%).

Storage influences the reduction in moisture content values for fruits grown in the control group I0F0 (100% irrigation) for all harvests, for variant I1F1 (75% irrigation and 100% fertilization) from the third harvest, I1F2 (75% irrigation and 75% fertilization) from the third harvest, and all harvests of fruits from variants I2F1 (50% irrigation and 100% fertilization) and I2F2 (50% irrigation and 75% fertilization).

For all other variants and harvests, storage does not influence the measured moisture ($p>0.05$) (Figures 1, 2, and 3). The maximum moisture percentage from all harvests and storage conditions is found in fruits grown with 75% irrigation and 100% fertilization from the first harvest (I1F1) (89.86%), while the lowest is in fruits grown with 50% irrigation and 100% fertilization (I2F1) from the third harvest (84.39%) ($p<0.05$).

Measured dry matter (weight-based) values for fruits from all harvests showed that harvests influence the recorded percentage values. Comparative analysis indicates that the highest values of insoluble dry matter are found in fruits from the third harvest, ranging from 11% for variant I2F1 (50% irrigation and 75% fertilization) to 16% for variant I1F1 (75% irrigation and 100% fertilization), compared to the first and second harvests with 10% for fruits from the control group I0F0 (100% irrigation) and I2F1 (50% irrigation and 75% fertilization) and 12.6% for fruits from I2F1 (50% irrigation and 75% fertilization) and I1F2 (75% irrigation and 75% fertilization).

Fruits from the first and second harvests for variants I0F0 (100% irrigation), I1F1 (75% irrigation and 100% fertilization), and I1F2 (75% irrigation and 75% fertilization) have no statistically significant differences, and their harvests do not affect the studied parameter. For fruits from variants I2F1 (50% irrigation and 100% fertilization), dry insoluble substances increase by a factor of 1.5, as well as for I2F2 (50% irrigation and 75% fertilization), with percentages decreasing to the same extent in the second harvest compared to the first.

Storage does not influence the values of insoluble dry matter for fruits from the control group I0F0 (100% irrigation) from the third harvest, I1F1 (75% irrigation and 100% fertilization) from the second harvest, and fruits from the first harvest of variants I1F2 (75% irrigation and 75% fertilization) and I2F2 (50% irrigation and 75% fertilization) ($p>0.05$) (Figures 1, 2, and 3).

For all other cultivation variants and harvests, storage conditions and duration influence the insoluble dry matter in fruits, with the highest average value after six-day storage being recorded for fruits from variant I2F1 (50% irrigation and 100% fertilization) from the third harvest (15.61%), and the lowest for fruits from variant I1F1 (75% irrigation and 100% fertilization) from the first harvest (10.14%) ($p<0.05$) (Figures 1, 2, and 3).

Biochemical indicators (antioxidant activity and total polyphenols) in fruits examined from all variants and harvests on the day of receipt showed that harvests have a significant impact on these indicators ($p<0.05$) (Figures 4 and 5).

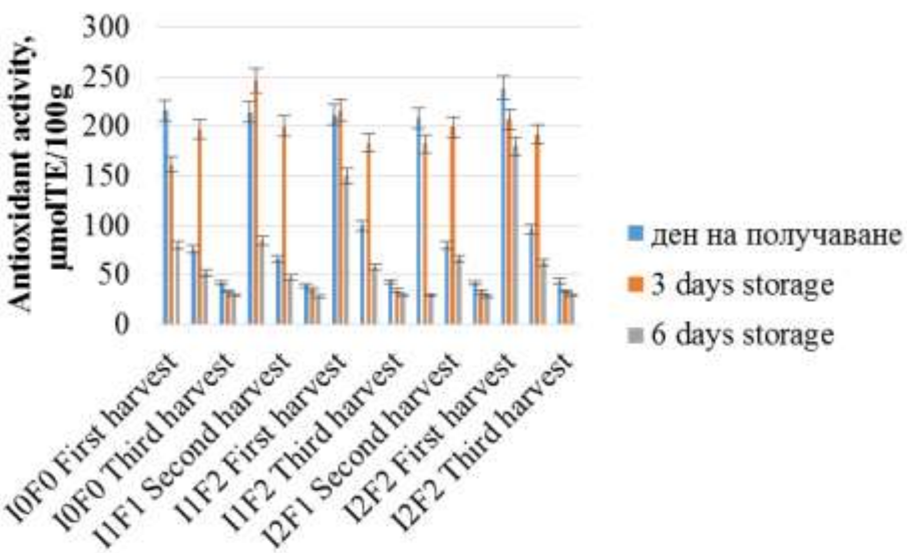

Figure 4. Antioxidant activity of white strawberry fruits depending on storage

On the day of receipt, fruits from all variants of the first harvest have significantly higher antioxidant activity values (over 200 µmolTE/100g) compared to the second harvest (over 70 µmolTE/100g) and the third harvest (over 40 µmolTE/100g) ($p<0.05$). The maximum antioxidant activity is found in fruits from the variant I2F2 (50% irrigation and 75% fertilization) from the third harvest at 238.87 µmolTE/100g, while the minimum is in fruits from the variant I1F1 (75% irrigation and 100% fertilization) from the third harvest at 39.3 µmolTE/100g (Figure 4).

It was determined that the applied agronomic conditions affect only the antioxidant activity in fruits from variant I2F2 (50% irrigation and 75% fertilization) for the first and second harvests, and in variant I1F2 (75% irrigation and 75% fertilization) for the second harvest ($p<0.05$) (Figure 4). For all other variants and harvests, the cultivation method does not influence the antioxidant activity values of the fruits ($p>0.05$) (Figure 4).

The duration and conditions of storage have a significant impact on the antioxidant activity of all fruits in the conducted test ($p<0.05$) (Figure 4).

During the three-day refrigerated storage of fruits from all variants and harvests, it was found that antioxidant activity decreases by approximately 1.5 times in fruits from the control group I0F0 (100% irrigation) from the first harvest, down to 161.3 µmolTE/100g, and by 1 order of magnitude in all fruits from the three harvests for the studied cultivation variants.

Fruits from variant I1F2 (75% irrigation and 75% fertilization) show relatively stable antioxidant activity up to this storage day, at 216.2 µmolTE/100g for the first harvest, and fruits from the same harvest of variant I2F1 (50% irrigation and 100% fertilization) at 182.5 µmolTE/100g.

At the end of the storage period, antioxidant activity significantly decreases by nearly 2-2.5 times in all examined variants compared to the day of receipt, with the lowest values in fruits from all variants of the third harvest (28.65 µmolTE/100g) for variants I1F1 (75% irrigation and 100% fertilization) and I2F1 (50% irrigation and 100% fertilization), and the highest in fruits from the first harvest of variant I2F2 (50% irrigation and 75% fertilization) at 180 µmolTE/100g.

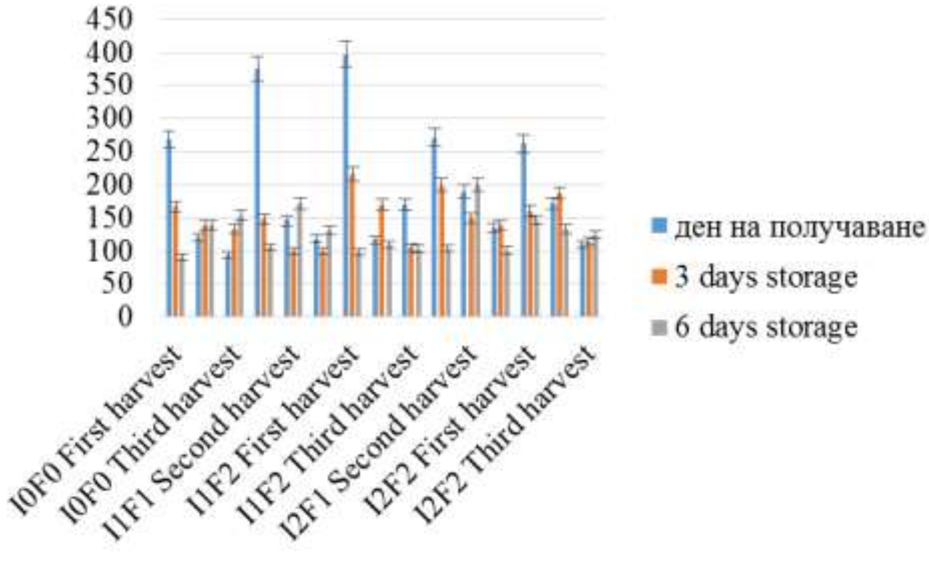

Figure 5. Total polyphenols in white strawberry fruits depending on storage

The total polyphenol content in fruits for all variants and harvests on the day of receipt showed that harvests influence the measured values ($p<0.05$) (Figure 5). Comparative analysis reveals that fruits from the first harvest for all studied variants have the highest total polyphenol values (over 260 mg GAE/100g) compared to those from the second harvest (100 mg GAE/100g) and the third harvest (90 mg GAE/100g).

The lowest values for the studied parameter are found in fruits from the third harvest, except for fruits from the variant I1F2 (75% irrigation and 75% fertilization). Statistically similar values of total polyphenols are found in fruits from the variants of the first harvest I1F1 (75% irrigation and 100% fertilization) and I1F2 (75% irrigation and 75% fertilization), as well as between I0F0 (100% irrigation), I2F1 (50% irrigation and 100% fertilization), and I2F2 (50% irrigation and 75% fertilization). For these variants, the cultivation method does not affect the total polyphenol content of the fruits ($p>0.05$) (Figure 5).

Temperature (T=4°C) and storage duration do not affect the total polyphenols in fruits from variants I2F2 (50% irrigation and 75% fertilization) and I1F1 (75% irrigation and 100% fertilization) from the third harvest, whose values at the end of the six-day storage are 124.00 mg GAE/100g and 131.00 mg GAE/100g, respectively.

For all other fruits from the studied variants and harvests, storage has an impact, with increases in total polyphenol content during storage in fruits from the control variant I0F0 (100% irrigation) for the second harvest (138.00 mg GAE/100g) and third harvest (153.00 mg GAE/100g), and in fruits from variant I1F1 (75% irrigation and 100% fertilization) for the second harvest (172.00 mg GAE/100g). In other cultivation variants and harvests, total polyphenol content decreases during storage, with the highest value at 200.00 mg GAE/100g in fruits from 50% irrigation and 100% fertilization during the second harvest, and the lowest value at 90.00 mg GAE/100g in fruits from the control variant of the first harvest. Storage duration affects the values of this parameter ($p<0.05$).

CONCLUSIONS

The impact of harvests, applied agronomic techniques, and storage time (at 4°C for 6 days) on the quality characteristics of white strawberry (Fragaria x Ananassa "Snow White") fruits has been investigated. It was found that storage affects the physicochemical and biochemical parameters of the studied fruits ($p<0.05$).

Storage time and conditions have a significant impact on the antioxidant activity of all fruits tested ($p<0.05$). At the end of the storage period, antioxidant activity significantly decreases by about 2-2.5 times in all studied variants compared to the day of receipt, with the lowest values found in fruits from all variants of the third harvest (28.65 µmolTE/100g) from variants I1F1 (75% irrigation and 100% fertilization) and I2F1 (50% irrigation and 100% fertilization), while the highest values are observed in fruits from the first harvest with variant I2F2 (50% irrigation and 75% fertilization) at 180 µmolTE/100g.

Temperature (T=4°C) and storage duration do not affect the total polyphenol content in fruits from variants I2F2 (50% irrigation and 75% fertilization) and I1F1 (75% irrigation and 100% fertilization) from the third harvest. For all other variants of the biochemical tests conducted, storage has an impact ($p<0.05$).

ACKNOWLEDGEMENTS

This research work was carried out with the financial support of the BULGARIAN NATIONAL SCIENCE FUND „Competition for financial support for basic research projects – 2022", project title "Impact of the soil and weather parameters on the irrigation management and elaboration of biological means to control phytopathogens to enhance strawberry fruit quality" (grant No KП-06-H66/4).

The authors also want to thank *Haifa South East Europe* for providing whole range of water soluble fertilizers for conducting the experiments.

ABSTRACT

This study was conducted during the 2022-2023 period in the experimental plot located at the Çukurova University Pozantı Agricultural Research and Application Center, situated at an altitude of 1200 m. The study focused on the 0900 Ziraat cherry variety grafted onto MaxMa 60 rootstock, planted at a 5x5m spacing, and pruned in a Central Leader system. The trees were five years old. In the study, %0.5 $CaCl_2$, 300 ppm Green Stim, 100 ppm Chitosan, 400 ppm Thyme oil, combinations of these treatments, and water as a control were used. The study was conducted in a randomized complete block design with 3 replications, each containing 10 plants. As a result of this study, while the control application showed a 36% cracking rate, the lowest fruit cracking rate of 2% was obtained with the Thyme Oil (400 ppm) application. Particularly, the Thyme oil application had positive effects on fruit size. The fruit weight, which was 7.39 g in the control, was determined to be 8.42 g with the Thyme oil application, indicating a positive effect on fruit weight. The best result in fruit firmness was also achieved with the Thyme oil application. While the control had a fruit firmness of 4.5 kg, the Thyme oil application resulted in a fruit firmness of 5.42 kg.

Keywords: Cherry, quality, fruit cracking, essential oil

INTRODUCTION

Cherry (Prunus avium) is a type of stone fruit from the Rosaceae family, native to Asia (Özbek, 1978; Webster et al., 1996). Fruits, which constitute an important group among the species belonging to horticultural plants, are of great importance with their production values, growing areas, nutrition and share in exports. Fruits and vegetables are a source of vitamins, minerals, dietary fiber and antioxidants in terms of nutrition. The ratio of water-soluble dry matter, skin color, hardness of the fruit flesh, fruit diameter and weight are the most important criteria affecting consumer preferences in cherry, which is a low-calorie, good source of calcium, potassium and vitamins (vitamins A, B1, B2, C and malic acid) (Wani et al., 2014).

Cherries are produced in a wide area around the world. However, they are mostly produced in Turkey, the USA, Iran and Italy in commercial terms. Turkey, which ranks first in cherry production with the changes in climate conditions and years, is also one of the countries that have a say in cherry exports. Turkey's geographical structure and climate conditions allow for high-quality cherry cultivation suitable for export. The harvest time of cherries grown in Turkey can be earlier than in many European countries, and it extends until August as they rise above sea level (Küden, 2004). Cherries are grown almost everywhere in our country. Cherry production in our country is mainly carried out in the Kemalpaşa district of İzmir, Manisa, Konya-Akşehir, Afyonkarahisar-Sultandağı, Isparta-Uluborlu, Denizli-Honaz and recently in the Konya Hadim and Taşkent regions. It is also produced in Çanakkale, Kütahya, Mersin, Antalya, Kahramanmaraş, Adana (Saimbeyli), Niğde (Ulukışla), Bursa, Amasya and Sakarya.

The area of cherry orchards in 2023 is 798,622 decares (Figure 1), export value and volume (Figure 2), the production amount is 736,792 tons (TÜİK, 2024).

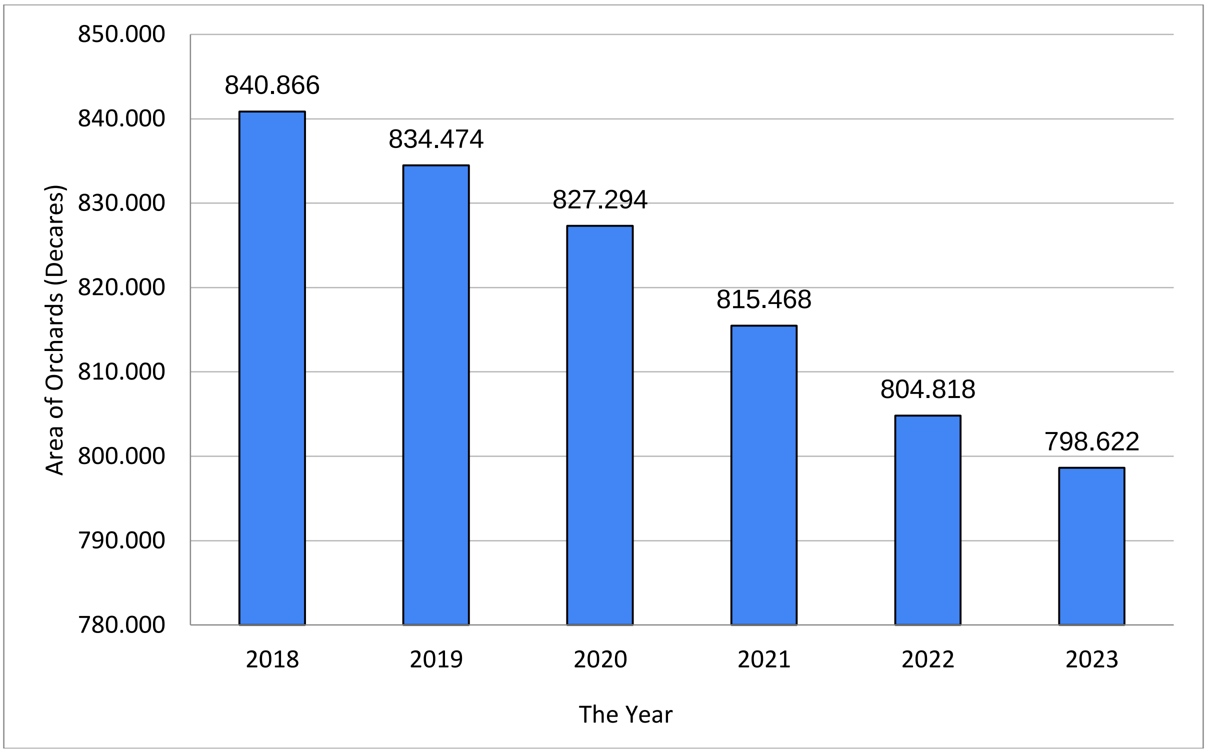

Figure 1. Turkey’s Cherry production area by years

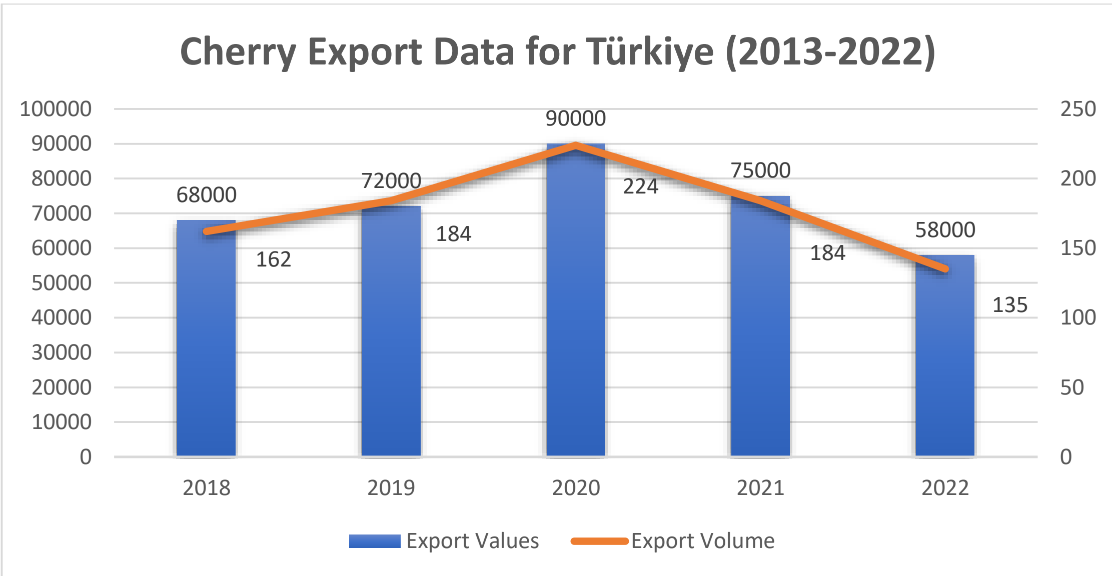

Figure 2. Turkey’s Cherry export values and volume by years

One of the most important problems arising from climatic events in cherry cultivation is fruit cracking due to excessive rainfall occurring during harvest time and close to harvest, which causes great economic losses (İmrak et al., 2018; İmrak and Küden 2023). Cracking in cherries occurs in the cuticle of the fruit and generally occurs at 3 points (stalk pit, lateral face, and fruit tip) (Peschel and Knoche, 2005). The most common cause of cracking is accepted as rainwater entering the fruit shell (Davenport, 1972). Although research on the causes of cracking began in the 1930s, this issue is still debated among scientists (Sekse, 1995). It has been accepted that many factors such as soil moisture, tree-water relations (Sekse, 1995), variety (Christensen, 1972a), fruit maturity stage (Christensen, 1973), soluble substance concentration (Christensen, 1972b), temperature (Christensen, 1972c), stomatal width and frequency (Christensen, 1972b), respiration rate (Pommier, 1989) play an important role in the cracking event.

In the study examining the susceptibility of Fermina, Regina, Lapins and ‘Brooks varieties to cracking, it was stated that Regina and Fermina varieties were more resistant than Lapins and Brooks varieties (Moing et al., 2004). It is known that Regina variety is one of the most resistant varieties to fruit cracking (İmrak et al., 2018).

The main purpose taken into consideration in the selection of chemicals applied to reduce cracking is to reduce the amount of rainwater entering the fruit surface as much as possible during and after heavy rain. In many areas, calcium-containing solutions and the use of calcium together with substances such as copper, sulfate, nitrate are used against fruit cracking, as well as antitranspirants and various surface waxes (Sekse, 1995).

In cherry cultivation, calcium-containing solutions, which are used intensively to reduce cracking, are used effectively in many areas 2-3 weeks before harvest (Brown et al., 1995). In calcium applications, calcium blocks cell wall pectins, making the cell wall resistant to pressure and cracking (Alani, 1980).

In recent years, many applications have been made to prevent cracking, and one of them is the application of 0.5 mM methyl jasmonate applied in the pre-harvest period, which is stated to have a positive effect in preventing fruit cracking by increasing tolerance to abiotic stress (Ruiz-Aracil et al., 2023)

In the research, it was aimed to prevent cracking in the fruits of 0900 Ziraat cherry variety for export, caused by excessive rainfall during harvest time, by applying Calcium Chloride ($CaCl_2$), Green Stim, Chitosan and Thyme oil, thus increasing the quantity and quality of fruit for export.

MATERIAL AND METHOD

This study was carried out on 5-year-old 0900 Ziraat cherry variety grafted onto MaxMa 60 rootstock, planted at 5x5m planting distance and pruned in the Central Leader system in the experimental area located at Çukurova University Pozantı Agricultural Research and Application Center at an altitude of 1200m in the 2022-2023 period. In the study; 0.5% $CaCl_2$, 300ppm Green Stim, 100ppm Chitosan, 400ppm Thyme oil and water were used as control. The study was carried out according to the randomized block trial design with 3 replications and 10 plants in each replication.

Plant Material

0900 Ziraat cherry variety, which is mid resistant to cracking, is known as Turkish Cherry in Europe. Fruit characteristics; colour is bright dark red and large and heart-shaped fruits are resistant to transportation and storage. It has a thin, long and green stem, and its flesh is hard, juicy and delicious; with these features, it is among the best cherries in the world (Demirtaş and Sarısu, 2011).

It is in the Bigarreau group. It ripens late. Its fruit is very large (8.15 g), wide heart-shaped and bright dark red, fruit flesh is quite hard, crisp, juicy and very delicious; quality is excellent but needs pollinator, resistant to bacterial cancer and its flowering time is quite late. Its net mesocarp ratio is 14.31 and it is resistant to transport (Anonymous 2010).

Applications to Prevent Cracking in Fruits and Increase Quality

The plant growth regulators used in the study are given below. Water application was used as a control.

1- Calcium chloride ($CaCl_2$)
2- Calcium chloride ($CaCl_2$) + Green Stim
3- Calcium chloride ($CaCl_2$) + Chitosan
4- Calcium chloride ($CaCl_2$) + Thyme oil

Calcium chloride (CaCl2)

It is an inorganic compound, a salt with the chemical formula $CaCl_2$. It is a white crystalline solid at room temperature and is quite soluble in water. It can be formed by neutralizing hydrochloric acid with calcium hydroxide. Calcium chloride is commonly found as a hydrated solid with $CaCl_2 \cdot n\ H_2O$. These compounds are mainly used for deicing and dust control. Since anhydrous salt is hydroscopic and liquid, it is used as a desiccant (Kemp and Keegan, 2000). In calcium applications, calcium makes the cell wall resistant to pressure and cracking as a result of blocking cell wall pectin's (Alani, 1980).

The main purpose taken into consideration in the selection of chemicals applied to reduce cracking is to reduce the amount of rainwater entering the fruit surface as much as possible during and after heavy rain. In many areas, calcium-containing solutions and the use of calcium together with substances such as copper, sulfate, nitrate, as well as antitranspirants and various surface waxes are used against fruit cracking (Sekse, 1995).

Green Stim

It contains natural osmotic pressure balancers (glycine, betaine) (Imrak, 2019).

Chitosan

Chitosan is obtained as a result of deacetylation of chitin in an alkaline environment. It is insoluble in water and organic-based solvents (Abdou et al., 2008). Chitosan, the most widely used polysaccharide, is an economical natural biopolymer obtained from sea shells. (Sandford, 1989).

Thyme Oil

In our country, there are many fragrant plant species known as "Thyme" belonging to the Lamiaceae family, and their essential oils especially contain carvacrol and thymol. Studies have determined that Thyme oil suppresses many fungal diseases (Baydar, 2007; Bosquez et al., 2010; Camele et al., 2012).

General Characteristics of the Research Area

The research was carried out in the experimental area of Ç.Ü. Pozantı Agricultural Research Center in Pozantı, which is 1200 meters above sea level. Coordinate: 37.480050,34.903235.

The study was conducted between 2022-2023 and was set up in a randomized plot design with 3 replications and 10 trees in each replication. All applications were made approximately 30 days before harvest when the fruits turned from yellow to pink (vein fall) with a 15-liter backpack pump to wet the entire tree. The applications and their doses are given in detail in Table 1. All spray treatments were applied when the fruit color turns from green to yellow (22.06.2022)

Table 1. Applications and doses

Applications	Doses
Control	Water
$CaCl_2$	%0.5
$CaCl_2$ + Chitosan	%0.5 $CaCl_2$ + Chitosan 100 ppm
$CaCl_2$ + Thyme Oil	%0.5 $CaCl_2$ + Thyme Oil 400 ppm
$CaCl_2$ + Green Stim	%0.5 $CaCl_2$ + Green Stim 300 ppm

Phenological Observations

Budbreak, full bloom and harvesting dates were recorded (Westwood, 1987).

Pomological Analyses

Pomological analyses were performed with 3 repetitions and on 10 fruits at harvest maturity in each repetition (Emerce, 2004; İmrak, 2019).

Average Fruit Weight (g): The fruits obtained were weighed with a scale with a sensitivity of 0.01 g and calculated by dividing the total weight by the number of fruits. Here, 30 randomly taken fruit samples that could represent the analyzed variety were divided into 3, with 10 fruits in each repetition, and these fruits were weighed individually to determine the average fruit weight of each repetition.

The fruits obtained were measured with a caliper with a sensitivity of 0.01 mm and calculated by dividing the total value by the number of fruits. fruit length (mm), fruit width (mm), fruit height (mm)

Total Soluble Solids (TSS) %: The percentage value of the samples taken from the fruit juice was measured with a hand refractometer.

Total Acidity (%): After completing 5 ml of fruit juice with distilled pure water to 100 ml, titratable 0.1 Normality NaOH (Sodium Hydroxide) will be added to 5 ml of fruit juice completed with distilled water to 100 ml with the help of a pH meter until the digital display on the pH meter reaches 8.00-8.10 and then calculated in terms of citric acid according to the formula below.

Acidity Formula = Amount of NaOH consumed x 20 x Factor (0.963) x Acid value (Acid value for citric acid, 0.0067).

Fruit Flesh Firmness (kg): The hardness of the fruits of the varieties in the trial was measured using a hand penetrometer.

Color Measurements

Color measurements made according to the C.I.E. L*a*b* system were carried out with a Minolta color measuring device. In this system, the a* value indicates the color change from green to red, and the b* value indicates the color change from blue to yellow. Positive values of a* indicate red, and negative values indicate green. Positive values of b* indicate yellow, and negative values indicate blue (İmrak et al., 2018). The data obtained from the experiment were analyzed using the JMP v.8 statistical package program and the averages were compared using the Tukey test.

Cracking Index

The cracking index will be calculated in order to determine the cracking prevention or reduction effects of the applications (Bilginer et al., 1999). In this method, cherries that reached harvest maturity were collected in the morning hours (09:00-11:00) and brought to the laboratory for analysis in the cold chain.

In order to measure the cracking resistance of cherries, 50 fruits randomly selected from the fruits located 1.5 m above the ground in the outward facing area of the trees were used. In this method, cherries that reached harvest maturity were collected before noon and brought to the laboratory for analysis in the cold chain. In order to measure the resistance of cherries to cracking, 50 randomly selected fruits were placed in 2-liter glass jars and kept in pure water at 20oC for 2-4-6 hours. At 2-hour intervals, the fruits were removed from the water and the cracked fruits were counted, and the healthy fruits were put back into the water. The same procedures were performed after 4 and 6 hours. The obtained data were calculated according to the cracking index formula used by Bilginer et al (1999) for cherries and explained below.

Cracking index = (5a + 3b + c) x 100/250

Statistical Analysis

The experiment was based on randomized blocking pattern as 3 replications and was assigned as one tree at each replication. The data were statistically analyzed using the Statistical Package for the. Means separation was determined by LSD test. Statistical analyses were carried out using JMP 5.0.1 version.

RESULTS AND DISCUSSION

It was observed that the applications made did not have any effect on the phenological stages. Phenological periods are presented in Table 2. It was determined that the dates specified in terms of phenological periods were parallel to previous studies and were found to be compatible with (İmrak and Küden, 2023).

Table 2. The effects of Applications on phenological stages in ‘0900 Ziraat’ sweet cherry variety

Variety	Dormancy Breaking	Full Bloom	Harvesting time
0900 Ziraat	15.02.2023	19.04.2023	21.06.2023

Among the applications applied to the 0900 Ziraat cherry variety included in the experiment, the highest fruit flesh hardness was determined as 5.42 kg in the Thyme oil application, while the lowest fruit flesh hardness was determined as 4.5 kg in the control application. The fruit flesh hardness obtained as a result of other applications is between these values. Thyme oil application provided the highest fruit flesh hardness and clearly distinguished itself from all other applications. Thyme oil is known to have strong antimicrobial and antifungal properties among vegetable oils and can provide a protective effect on fruit tissue. This result supports the effectiveness of thyme oil in increasing fruit quality. There are findings in the literature that thyme oil applications provide similar positive effects in other fruit species (Sivakumar and Bautista-Baños, 2014). Chitosan application also showed a significant effect on fruit flesh hardness. With 4.83 kg fruit flesh hardness, chitosan application provided a significant increase compared to the control group. Chitosan is a natural biopolymer that can prevent water loss and microbial infections by forming a protective layer on the fruit surface. This shows that chitosan is an effective agent in improving fruit quality. Similarly, chitosan applications have been reported to increase fruit flesh firmness in other fruit species (El Ghaouth et al., 1992; Bautista-Baños et al., 2006). Calcium chloride application increased fruit flesh firmness to 4.65 kg. Calcium may increase fruit firmness by contributing to the strengthening of cell walls and the increase in the water retention capacity of cells. This finding is consistent with the literature showing that calcium applications provide similar effects in other fruit species (Conway et al., 1994; Saure, 2005) (Table 3).

The lowest L* value found in color measurement was determined to be 19.61 for Thyme oil application, while the highest L* value was determined to be 26.78 for Chitosan application (Table 3). The lowest a* value was determined to be 14.03 for Thyme oil application, while the highest a* value was determined to be 23.96 for control application. In addition, the lowest b* value was determined to be 5.06 for Thyme oil application, while the highest b* value was determined to be 9.23 for control application.

Table 3. The effects of Applications on fruit frimness and colour characteristics in '0900 Ziraat' sweet cherry variety

Applications	**Fruit Frimness (kg)**	**L***	**a***	**b***
Control	4,5d	23,29ab	23,96a	7,01
$CaCl_2$	4,65c	20,44ab	17,21ab	6,06
$CaCl_2$+ Chitosan	4,83b	26,78a	17,38ab	6,47
$CaCl_2$ + Green Stim	4,53bc	24,8b	17,39ab	6,07
$CaCl_2$ + Thyme Oil	5,42a	19,61b	14,03b	5,06
$Lsd_{\%5}$	0,20	5,47	5,42	ns

Among the applications applied to the 0900 Ziraat cherry variety in the trial, the highest fruit weight was determined as 8.42 g in the Thyme Oil application, while the lowest fruit weight was determined as 7.39 g in the control. When we look at the average fruit weight data of all applications and control groups, it was determined that the average fruit weight of the Thyme Oil was higher (Table 4). The lowest SÇKM amount measurement value of the applications was measured as 14.63 in Green Stim, while the highest value was determined as 15.33 in Chitosan. In the pH value measurements of the applications in the trial, the lowest value was measured in the Calcium application as 2.88. The highest value was measured in Green Stim as 2.94. It was determined that the pH value of all applications and control groups was the highest and the lowest was in the Calcium application.

The Calcium application provided the lowest pH value (2.88) and was significantly different from all other applications and the control group. The potential of calcium to reduce fruit pH may be due to the interaction of calcium ions with cell walls and intracellular matrices and increasing acidic properties. Similar findings have been reported in the literature that calcium applications improve product quality by reducing fruit pH (Conway et al., 1994; Saure, 2005).

The control group and chitosan application showed similar results with a pH value of 2.92. Chitosan can maintain pH balance by forming a protective layer on the fruit surface with its biopolymer structure. There are findings in the literature that chitosan improves fruit quality and provides pH balance (El Ghaouth et al., 1992; Bautista-Banos et al., 2006). Oregano oil application showed a result close to other applications with a pH value of 2.93. The antimicrobial and antifungal properties of oregano oil can help maintain pH balance by reducing microbial activity on the fruit surface. Similar findings on the positive effects of oregano oil applications on fruit quality are also available in the literature (Sivakumar and Bautista-Banos, 2014) (Table 4).

Table 4. The effects of Applications on pomological characteristics in '0900 Ziraat' sweet cherry variety

Applications	Average fruit weight (g)	Total soluble solid content TSS (%)	Titrable acidity (TA) (g citric acid/100 ml)
Control	7,39b	14,93	2,92ab
$CaCl_2$	7,97ab	15,23	2,88b
$CaCl_2$+ Chitosan	7,89ab	15,33	2,92ab
$CaCl_2$ + Green Stim	7,97ab	14,63	2,94a
$CaCl_2$ + Thyme Oil	8,42a	15,17	2,93ab
$Lsd_{\%5}$	0,77	Ns	0,09

In the control group, the fruit cracking rate was determined to be the highest at 11.2%. This shows that a significant portion of the cherry fruits cracked when no application was made. 0.5% Calcium Chloride ($CaCl_2$) application reduced the fruit cracking rate to 2.4%. This shows that $CaCl_2$ significantly reduces fruit cracking. 300 ppm Green Stim application reduced the fruit cracking rate to 0.8%. This shows that Green Stim greatly reduces fruit cracking and is an effective application. 100 ppm Chitosan application also reduced the fruit cracking rate to 0.8%. This shows that chitosan is effective in reducing fruit cracking. 400 ppm Thyme Oil application achieved the lowest fruit cracking rate of 0.4%. This shows that thyme oil is the most effective application in preventing fruit cracking (Figure 3)

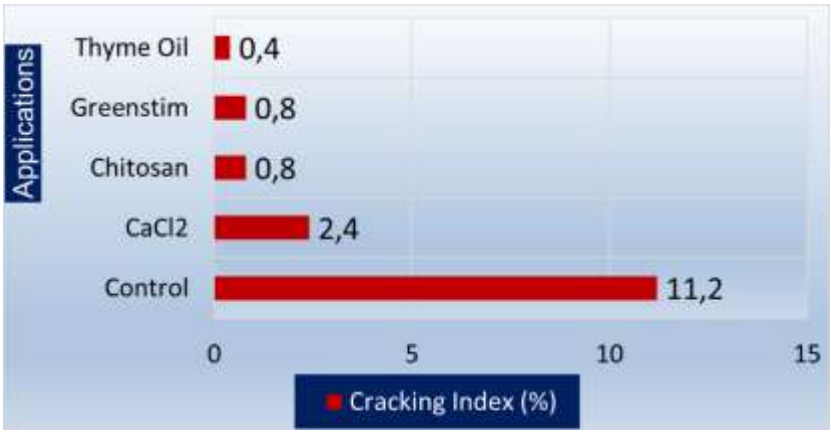

Figure 3. Effects of different treatments on 0900 Ziraat cherry fruit cracking Index

CONCLUSIONS

The results of this study have shown that all treatments significantly decreased the cracked fruit ratio compared to the control. But Thyme oil applications especially reduced the amount of 68.98 percent. In this study on 0900 Cherry, Thyme oil found to be the most effective Applications. It was followed by Green Stim, There were no detected any big differences Phenological and pomological (Except fruit weight) observations. Thus, Thyme oil gave the best result for reducing fruit cracking and Green Stim, Chitosan, $CaCl_2$ gave recommendable results compared to the control in 0900 Ziraat cherry cultivar in excessive rainfall years.

ABSTRACT

Programmed cell death (PCD) is DNA disruption in which the cell death program is rendered irreversible and facilitates the fragmentation of the nucleus. PCD is actively involved in leaf senescence, self-incompatibility and the formation of tracheary elements in many plants. PCD appears to be mainly involved in cotton fiber development and secondary wall formation. PCD, which occurs under the coordination of Ca^{2+}, hydrogen peroxide, and brassinosteroids, plays a role in the main process leading to fiber maturation following the secondary cell wall. Both developmental-regulated PCD and environmental-induced PCD are affected by several plant hormones. In this review, we have written about gland formation in cotton, its role in anther fertility under high-temperature stress and the role of PCD in the regulation of synergid death. A better understanding of the PCD network will enable us to develop future breeding strategies to improve cotton yield and quality and to increase its tolerance to biotic and abiotic stresses.

Keywords: Cotton, DNA disruption, programmed cell death, reactive oxygen species, stress.

INTRODUCTION

Programmed cell death (PCD) can occur as part of normal growth and development through specific organ-forming and morphological adaptation responses or when cell suicide pathways are activated under the influence of certain biotic and abiotic external factors. PCD can occur in events such as anther maturation during sex determination, pollen tube growth, fertilization, embryo suspension, growth, seed germination, aerenchyma formation, tracheary element and sclereid differentiation, sieve element differentiation, and leaf and flower petal senescence. Apoptosis in animals appears to occur in mycotoxin-treated plant protoplasts and during plant pathogen-induced cell death. It is also argued that apoptosis is not a universal pathway to plant death, and instead, many plant cell suicide programs depend on autophagic and autolytic mechanisms for cell death. Differentiation of xylem conduction bundles, aerenchyma formation, abscission, and senescence are the most important examples of PCDs in the vegetative period. In addition, death of synergids, degeneration of haploid megaspores, and anther dehiscence incompatible pollen tube are also involved in PCD in the generative period.

Programmed cell death (PCD) in plants is a process of cell death regulated by genetics (Buckner et al., 2000; Brodersen et al., 2002) and environmental factors during a specific developmental process (Locato and De Gara, 2018). Locato and De Gara, 2018). PCD frequently occurs during leaf senescence and is a defense mechanism in all field crops, grain formation in cereals, fiber development in cotton, the process by which the nodule provides nitrogen to the plant in leguminous crops such as soybean and aerenchyma formation in rice.

Many researchers have emphasized that multiple signals and phytohormones are involved in the PCD process (Xie et al., 2014; Cortleven et al., 2019; Li et al., 2023). Abiotic stress factors have been reported to trigger PCD (Nath and Lu, 2015; Yanık et al., 2020).

Programmed Cell Death in Cotton Fiber

The development of fibers (Figure 1), which are differentiated seed trichomes in cotton, is completed in 4 developmental stages: initiation, elongation, secondary wall deposition and maturation (Huang et al., 2021; Wen et al., 2023) under the coordination of many factors including reactive oxygen species, brassinosteroids, callose and calcium and arabinogalactans. Elongation of fiber cells, which begins with flowering, continues for about 21-26 days. Secondary cell wall synthesis begins about 16 days after anthesis (DPA), peaks at about day 24 and ends between 32 and 40 (Liu et al., 2024). A drying and ripening period of 45 to 60 DPA occurs (Ji et al., 2003; Kim and Triplett, 2001). Fibers are suggested to die by programmed cell death (PCD) sometime after 40 DPA (Jareczek et al., 2023).

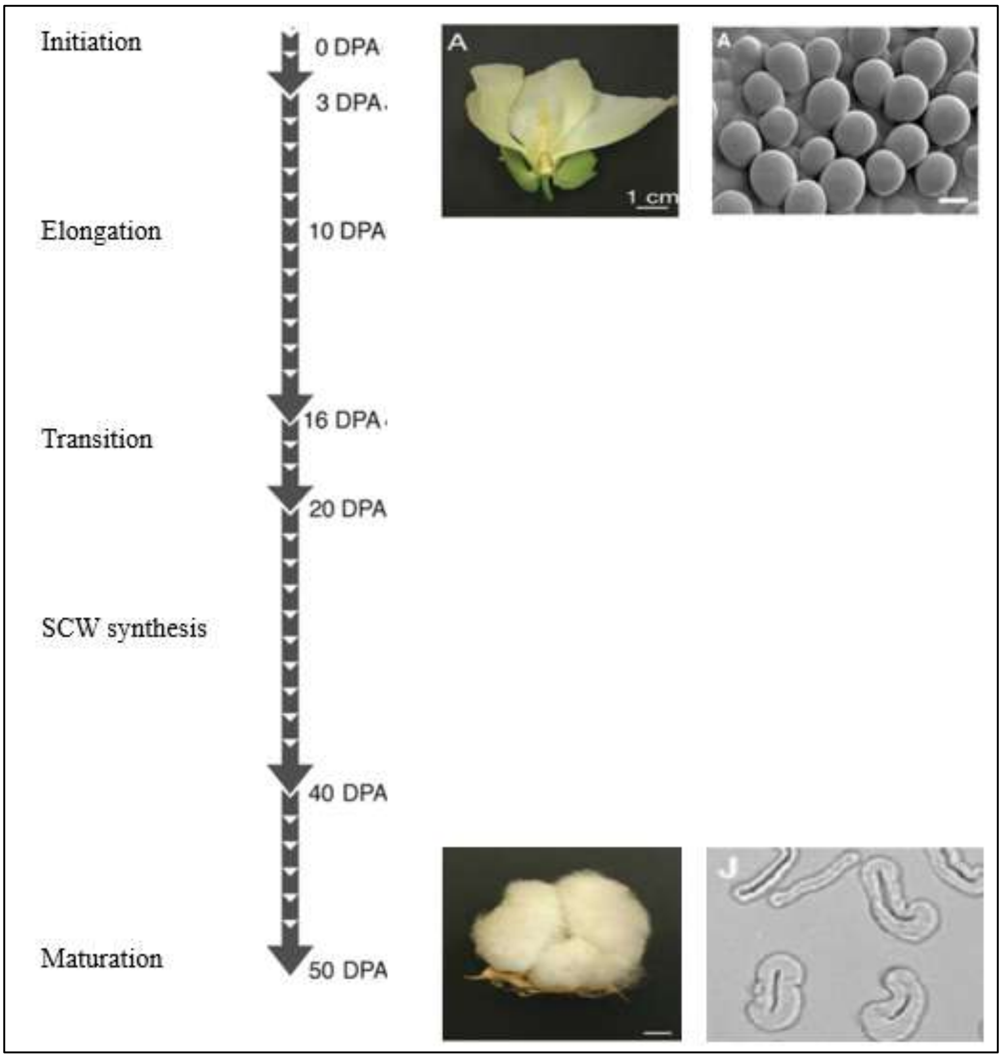

Figure 1. Cotton fiber development (modified from Haigler et al., 2012).

Similarities have been expressed between cotton fiber maturation and tracheary elements, the cells that form xylem vessels characterized by secondary cell wall formation, cytoskeletal reorganization, cellulose accumulation and programmed cell death. Cellular features of programmed cell death mechanisms include nuclear degradation, DNA and cytoplasmic degradation, and caspase-like activity (Love et al., 2008). The central vacuole, which contains most of the intercellular space in cotton fibers, disappears as the cytoplasm dries and is replaced by the lumen as the fiber cells dehydrate between 45 and 60 DPA (Kim and Triplett, 2001).

The Effect of Reactive Oxygen Species

It is hydroxyl radical (OH), a ROS, which plays a role in the remodelling of xyloglucan involved in microfibril attachment, leading to cell elongation (Cosgrove, 1999; Tokumoto et al., 2002; Demidchik et al., 2003). H^+-ATPase activation is involved in the induction of hydrogen peroxide production (Malerba et al., 2004) and acidification of the apoplast, leading to cell wall loosening and, thus, elongation (Rober-Kleber et al., 2003). Hydrogen peroxide (H2O2), notable for its ability to cause cell damage and cell death, has been detected in cotton fiber cells undergoing secondary cell wall synthesis (Potikha et al., 1999).

It was found that UmSrt1 expression in cotton increases the sugar content in the fibers with ROS, and accordingly, early secondary wall synthesis leads to short and thick fibers. It was emphasized that the high quality and long fibers of *G. barbadense* are due to its strong antioxidant capacity (Tuttle et al., 2015; Ding et al., 2021).

Sphingolipids and PCD Association

Sphingolipids, a class of lipid molecules commonly found in eukaryotes and composed of sphingosine, fatty acids and polar head groups, are involved in critical physiological processes, including programmed cell death processes in plants and fiber elongation in cotton (Liang et al., 2003; Wang et al., 2024). It was found that overexpression of GhLCBK1, decreased Sph levels, and increased S1P levels delayed PCD progression in fibers. This delay leads to an increase in fiber length and a decrease in micronaire value. In contrast, suppression of GhLCBK1 expression led to increased Sph content and decreased S1P content. Thus, advancing the PCD process in fibers shortened the elongation time and prolonged the secondary wall synthesis time, which resulted in a decrease in fiber length and an increase in micronaire value (Zhang et al., 2024).

Gland Formation

Pigment gland formation in cotton occurs through a purely lysogenic process (Benedict et al., 2004; Xu et al., 2004). PCD plays a critical role in the lysigenous development of pigment glands in cotton leaves by activating the ROS signalling pathway of H2O2 (Liu et al., 2010; Wang et al., 2016). One of cotton's most important breeding objectives is to obtain gossypol-free seeds. This highly desirable trait increases the value of commercial cotton varieties for both oil and protein utilization from cotton seeds. To achieve this, biotechnological manipulation of CGP1 increases the defense against biotic factors in shoot tissues. It is concluded that the cloning and characterization of CGP1 will be useful in studying the metabolites retained by the gland and their functions in cotton (Gao et al., 2020).

Heat Stress

Anther sterility is caused by altered carbohydrate metabolism or impaired tapetal PCD (Zhang et al., 2010). The Gossypium hirsutum casein kinase I (GhCKI) gene, which encodes a homolog of casein kinase I (CKI), is involved in the inactivation of glycogen synthase and regulation of apoptosis; GhCKI has been indicated as a target gene to improve anther fertility under HT conditions (Min et al., 2013). Two models have been proposed to explain how the stylar S-RNase gains specific access to incompatible pollen RNA. According to both models, the result is a non-autonomous inhibition of protein synthesis, leading to the observed arrest of cell growth and, ultimately, death. Although RNase activity is one of several hydrolytic markers for autolysis during tracheary element differentiation and leaf and petal senescence, stylar S-RNase appears to be the only lytic agent required for a process that could be initiated by the action of a single cell death promoter ± as yet unidentified pollen S-locus product.

Synergid Degeneration

Synergid death has been extensively characterized in cotton. PCD occurs in the embryo sac during fertilisation, and synergid degeneration occurs after pollen tube penetration (Beers, 1997). Significantly in cotton, GA and IAA promote synergid degeneration, with an increase in cytoplasmic density and vacuolar collapse representing early events in synergid death (Jensen et al., 1977).

CONCLUDING REMARKS AND FUTURE PERSPECTIVES

In conclusion, PCD plays a crucial role in various developmental processes and responses to environmental stress in plants, including anther maturation, pollen tube growth, seed germination, and fiber development in cotton. The mechanisms underlying PCD in plants often involve complex interactions between genetic and environmental factors, with pathways ranging from autophagy to caspase-like activity. ROS and sphingolipids are particularly significant in regulating these processes, as seen in the differentiation of tracheary elements and the maturation of cotton fibers. Future research should continue to explore the molecular and physiological aspects of PCD, focusing on how specific genes and signalling molecules contribute to cell death pathways. Additionally, understanding the impact of external factors like heat stress and the potential for biotechnological manipulation, such as gland formation in cotton, could lead to advances in crop improvement and stress resistance.

FIELD RESISTANCE OF BARLEY VARIETIES TO LEAF RUST

Vanya IVANOVA, Yordanka BACLAROVA

Agricultural Academy, Dobrudzha Agricultural Institute – General Toshevo, 9521, Bulgaria

**Corresponding author e-mail: vkiryakova@yahoo.com*

ABSTRACT

Leaf rust is an economically important disease on barley in Bulgaria. Since cultivated barley *Hordeum vulgare* is considered nonhost or an intermediate type of host of leaf rust on wheat *P. triticina* and is to some extent attacked by this heterologous fungus as well, our studies were carried out in an infection field of Dobrudzha Agricultural Institute – General Toshevo, Bulgaria, where wheat, triticale and barley materials were planted. The study was conducted in three consecutive harvest years, and the infection load included the natural population of *P. hordei* and the artificial and natural population of *P. triticina.* Thirty-four barley varieties of Bulgarian and foreign breeding were subjected to screening for resistance to leaf rust. The final disease attack, the average coefficient of infection and the resistance rate of these varieties were measured. The varieties were divided into four groups depending on the manifested resistance to the pathogens.
The four groups of varieties demonstrated different variations within the resistant type. Therefore, all investigated Bulgarian barley varieties, including also three varieties of foreign breeding, can be involved in breeding programs for developing of improved cultivars, which carry resistance to leaf rust.

Key words: Barley, cultivars, field resistance, *P. hordei*

INTRODUCTION

Barley is a main field crop in Bulgaria. Besides being a food-supply crop, it is also demanded on the market as a raw material for the brewing industry, as valuable animal food and as raw material for production of cellulose (Stefanov et al., 1986). The export of barley grain stimulates the interest of the producers and these advantages define it as a promising and strategic crop for the country under the conditions of modern agriculture. On a world scale, the crop ranks fourth by production, following wheat, maize and rice (Shulte et al., 2009). Traditionally, the EU is a leading exporter of malting barley to the world market. Bulgaria is able to meet the demands of its internal market almost entirely by own production. During the last 10-15 years, the areas sown with barley in Bulgaria varied within 2.5 – 4.0 million ha, according to data provided by the Ministry of Agriculture and Foods.
Barley production is often limited by various factors, some of which are the annual or sporadic occurrence of diseases. Although leaf rust caused by *P. hordei* is of sporadic occurrence, it may also be common and widespread disease on barley. The crop is often attacked by *P. triticina*, which is a biotrophic pathogen capable of rapid change, quickly becoming virulent to resistant hosts. Within the plant species, which are nonhosts to a given pathogen, sometimes there are genotypes moderately susceptible to a heterologous pathogen (Dracatos et al., 2016). Cultivated barley *Hordeum vulgare* is considered nonhost or an intermediate type of host for leaf rust on wheat *P. triticina*.

Studies have shown that it is sometimes attacked by *P. triticina* and some other heterologous fungi such as *P. hordei-murini*, *P. hordei-secalini*, etc. (Atienza et al., 2004; Jafari et al., 2006). The investigations of Neu et al. (2003) proved that there are plant species, which are resistant to most of the pathogens found in their environment. They believe that the resistance, which is not specific for the pathogen, is maintained through a combination of passive and active defense mechanisms; they called it resistance without a host.

In the past decades, an increase of leaf rust attacks has been observed in the regions with moderate growing of barley due to the more intensive agronomy practices. Although the disease does not lead to full loss of harvest, data has been reported indicating that yield decrease can be as high as 60% and more in the susceptible varieties under conditions of epidemics (Clifford, 1985; Cotterill et al., 1995; Griffey et al., 1994; Park et al., 2015). The development of varieties possessing a complex of valuable economic properties and characteristics, which are able to realize their production potential under the varied meteorological conditions of Bulgaria, is a main goal of cereals breeding, and of barley breeding, in particular.

Although in the recent years an increasing number of varieties of European breeding which set higher requirements of adaptability of the productivity and grain quality-related characters and properties are being introduced. As a result from the thorough and purposeful breeding work in Bulgaria, a number of varieties were developed, which are highly adaptable to the conditions of our country and largely meet the production standards, and which are carriers of such valuable properties as disease resistance (Baklarova Y., G., Mihova, 2020; Dimitrova-Doneva et al., 2012; Dyulgerova and Valchev, 2012; Gocheva, Valchev, 2014; Mihova et al., 2011; Valchev and Valcheva, 2010; Valchev and Gocheva, 2012; Valcheva and Valchev, 2009, 2010; Valchev and Dyulgerova, 2011; Valcheva et al., 2012).

The short lifespan of the resistance determined by race-specific genes is the reason why breeders keep on searching for other types of resistance, such as partial resistance, for instance, which is more durable and race non-specific (Parlevliet and van Ommeren, 1975).

The aim of this study was to test under field conditions some of the barley varieties developed in Bulgaria, as well as some foreign cultivars for resistance to leaf rust, so that the data obtained could be useful to the breeding for improved varieties with higher resistance to this pathogen.

MATERIAL AND METHOD

The investigation was carried out during 2019-2021 in an infection field at Dobrudzha Agricultural Institute – General Toshevo. There were natural populations of *P. hordei* and natural and artificial population of *P. triticina* present. Thirty-four barley varieties were subjected to testing for leaf rust; they are presented in Table 1.

Table 1. Barley varieties used in the study

Origin	Cultivar/ Variety
Institute of Agriculture - Karnobat	Izgrev, Veslets, Hemus, Obzor, Emon, Asparuh, Deviniya, Zagorets, Imeon, Kuber, Lardia, Odesey, Orphey, Perun, Sayra, Aheloy 2, Bori, Bozhin, Panagon
Dobrudzha Agricultural Institute-G. Toshevo	Kaskadyor 3, Radul, Pagane, Tangra, Ahat, Yaspis, Onyx, Fanagoria
Agrarian University - Plovdiv	Kristy, Kramy
Institute of Plant and Genetic Resources - Sadovo	Potok
Agrodimex Ltd	Flaviy
Foreign breeding	Vicky, Vanessa, Malvinta

The varieties were sown manually, in 1.5 m rows with 0.25 cm interspacing. Cultivar *Michigan amber* was used as a multiplier and propagator of the rust and was planted across every 10 cultivars or breeding lines, as well as along the plots. The artificial inoculation with the pathogen was performed according to a methodology adopted at the Plant Pathology laboratory of Dobrudzha Agricultural Institute for working with rusts (Ivanova, 2012).

The type of infection and the attacking rate were read according to Cobb's scale, modified by Peterson (1948), at milk maturity stage. Disease severity was assessed as a percentage of leaf area, covered by the rust uredinia. The average coefficient of infection (ACI) or the so called corrected relative attacking rate was calculated by introducing coefficients for the respective infection types (R-0.2; MR-0.4; M-0.6; MS-0.8; S-1).

Depending on the ACI values, the studied varieties were divided into several groups: Immune (ACI=0); very resistant VR (ACI = 0–5.99); resistant R (ACI = 6–25.99); moderately resistant MR (ACI=26–45.99); moderately susceptible MS (ACI = 46– 65.99); susceptible S (ACI = 66–100). The attacking rate of the standard susceptible cultivar *Michigan amber* was 60 – 100% over the years of investigation.

RESULTS AND DISCUSSION

The disease severity, ACI and the rating of the barley varieties tested under field conditions are given in Table 2.

Table 2. Field resistance of barley cultivars under infection field conditions

Cultivar	2019			2020			2021		
	DS	ACI	Rating	DS	ACI	Rating	DS	ACI	Rating

M. amber	100/4	100	VS	90/4	100	VS	60/4	100	VS

Depending on the final attacking rate and the average coefficient of infection, several groups of varieties were formed, which responded in certain ways.

The first group included varieties with varied reaction: from very resistant to resistant (VR – R) – Izgrev, Veslets, Hemus, Obzor, Zagorets, Panagon (breeding of Institute of Agriculture – Karnobat); Radul and Onyx (developed at Dobrudzha Agricultural Institute – General Toshevo), as well as the varieties of foreign breeding Vicky and Vanessa.

Within the second group fell varieties with stable reaction of resistance (R) in all three years of the study: Aheloy 2 and Bori (breeding of Institute of Agriculture – Karnobat); variety Tangra (developed at Dobrudzha Agricultural Institute – General Toshevo) and the foreign cultivar Malvinta.
The third group included varieties, which responded with high to moderate resistance (VR-MR). These were Asparuh, Lardea, Bozhin and Saira – breeding of Institute of Agriculture – Karnobat, as well as cultivar Yaspis – breeding of Dobrudzha Agricultural Institute – General Toshevo). With changeable reaction, though within the resistant type (VR-R-MR), a fourth group was formed during the years of studied, including varieties Imeon, Kuber, Odisey, Orfey, Emon, Perun, Deviniya – breeding of Institute of Agriculture – Karnobat, Kaskadyor 3, Ahat, Pagane and Fanagoria – breeding of Dobrudzha Agricultural Institute – General Toshevo; cultivar Flaviy developed at Agrodimex company and cultivar Krami developed at the University of Agriculture – Plovdiv. Cultivars Deviniya, Pagane and Krami responded with resistance type R-MR (Table 2).
Cultivar Deviniya is a two-rowed barley. Its authors pointed out that the variety was highly resistant to leaf rust under field conditions (Valcheva and Valchev, 2013). Our investigation confirmed that against artificial infection background this cultivar demonstrates resistant to moderately resistant reaction within the 3-year period of investigation. During the previous 3-year period, cultivars Pagane, Krami and Deviniya responded with very resistant to resistant reaction (VR-R) in the infection field (unpublished data). This new investigation revealed that the resistance during the current period of time was R-MR.
Two varieties, Potok, developed by the Institute of Plant and Genetic Resources – Sadovo and Kristy, developed at the Agrarian University – Plovdiv, responded with a susceptible reaction in one of the years, while in the other two years they demonstrated high resistance (Table 2). In the preceding 3-year period, these two cultivars responded as very resistant to resistant (unpublished data), but due to these differences registered in this study and the occurrence of susceptibility, they were not included in any of the groups formed.
It is noteworthy that the high susceptibility of these two cultivars was manifested in the same year, when a part of the varieties also reacted with a higher rate of attack than usual – up to moderate resistance (MR). It is possible that more aggressive pathotypes occurred in the respective year in the natural population of the pathogen; these pathotypes might have overcome the resistance of certain varieties, and the high susceptibility manifested as moderate.

CONCLUSIONS

Under the conditions of Bulgaria, all Bulgarian barley varieties tested for resistance to leaf rust, as well as the foreign cultivars Vicky, Vanessa and Malvinta, demonstrated good resistance to the natural population of *P. hordei* and the natural and artificial population of *P. triticina* in the field. They could all be involved in breeding programs for higher genetic diversity and developing of improved barley varieties, which carry resistance to leaf rust.

ABSTRACT

The study area is located at 25 km to El Eulma City, in the North - East of Algeria, where there exists a strong demand for water due to the socio-economic development of region. The development of agricultural has led to a notable use of water resources and lead farmers to use groundwater for irrigation of crops, which may affect the physico-chemical quality of groundwater and soil. In 2022, a sampling campaign conducted to assess the quality of groundwater for irrigation purposes. To achieve this objective, twenty groundwater samples were collected and analyzed for physical (pH, EC, TDS) and chemical (Na^+, K^+, Ca^{2+}, Mg^{2+}, HCO_3^-, Cl^-, SO_4^{2-}, NO_3) parameters. The analysis results are processed using hydro-chemical and multivariate statistical methods. These analyses show that the tendency of the cations in the most samples are in the order of $\mathbf{Ca^{++} > Na^+ > Mg^{++} > K^+}$**.** However, tendency of anions is in the order of $\mathbf{HCO_3^- > SO_4^{--} > Cl^-}$**.** Evaluation of the water types using stabler diagram, show that the majority of the samples represents the $\mathbf{HCO_3^-\ Ca^{++}}$ type of water. The suitability of groundwater for irrigation was determined according to a number of parameters such as salinity, sodium adsorption ratio, sodium percentage, residual sodium carbonate, permeability index, Kelly's ratio, potential salinity and magnesium hazard. The study concluded that the water from the study area is good and suitable for irrigation with few exceptions.

Keywords: Groundwater, irrigation water quality, agricultural activities, facies, El Eulma City.

INTRODUCTION

Groundwater accounts for 43% of the world's irrigation water and is better suited for irrigation purposes than surface water, it is clear that the quality of agricultural water has an impact on soil quality and thus on the harvests obtained. To avoid the negative impacts on soil quality and plants, it is important to monitor the water quality for irrigation. In this regard, the current research aimed two objectives: (i) to determine the hydro chemical characteristics of groundwater, (ii) to use a variety of methods for the overall assessment and monitoring of groundwater quality for irrigation.

- **Study area**

The studied area is located in the Eastern of Algeria (Fig.1). The climate of the study area is classified as semi-arid climate, with an annual precipitation ranging from 300 to 420 mm/year, and the average monthly temperature varies between -5 and 40 OC. The variability lithologic in the aquifer may have an impact on water composition because of its effect on rock/water interactions and directions of groundwater movement.

- **Sampling**

A total of twenty groundwater samples (Fig.1), were collected from private wells and analyzed for physical and chemical parameters. These parameters were determined using standard techniques recommended by Rodier (1996). The analysis results are processed using hydro-chemical and multivariate statistical methods.

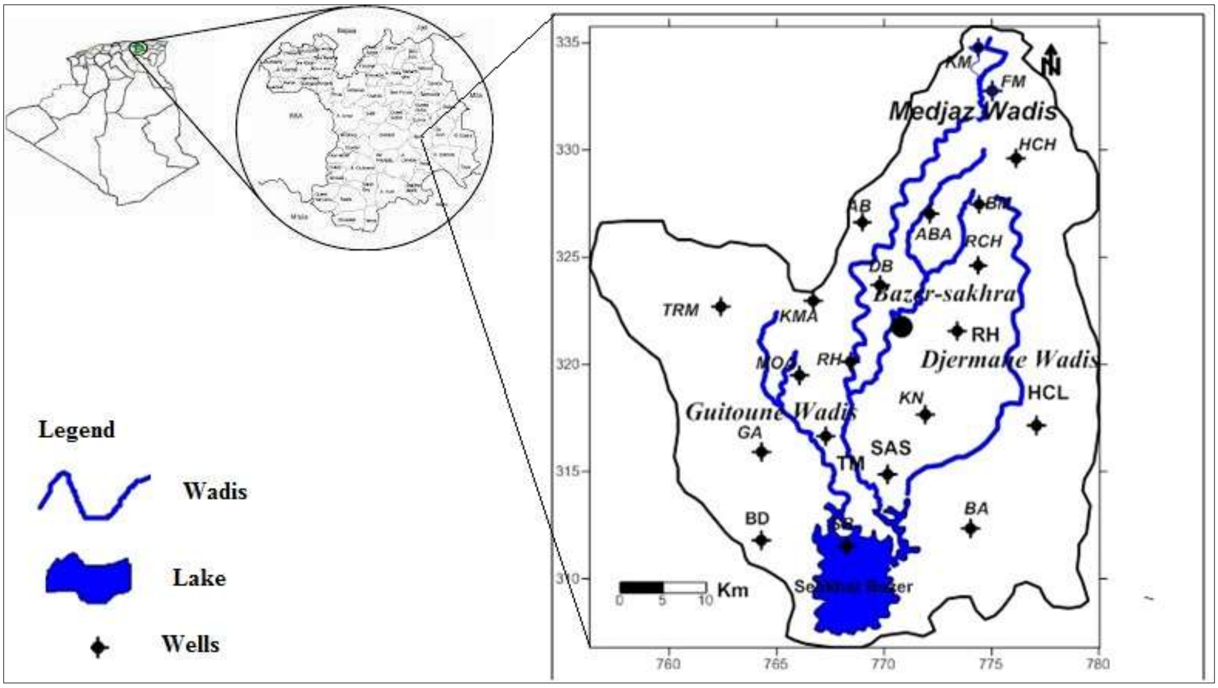

Fig. 1 Location of the studied site and the groundwater sampling location

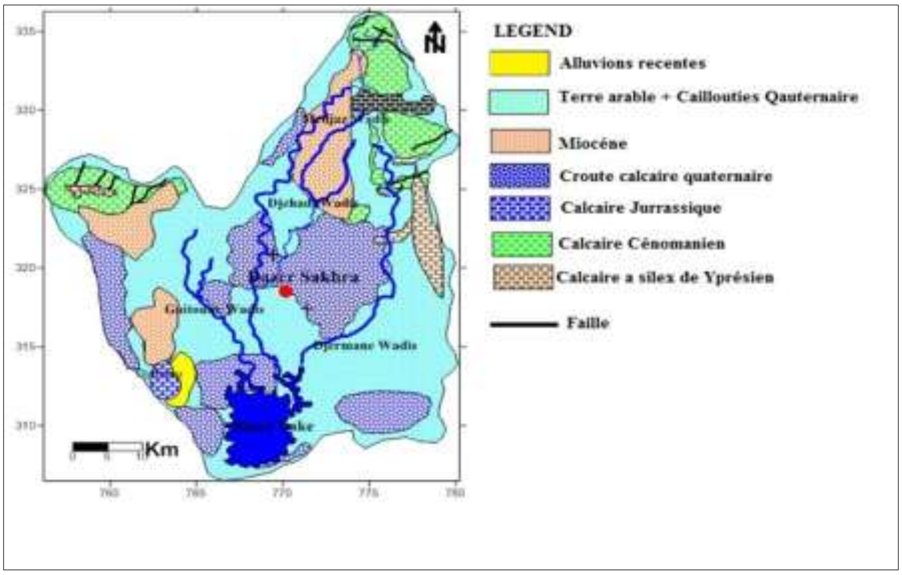

Fig. 2 Geological map of the studied area

- **Hydrochemistry of the groundwater samples**

These results indicate that, the cations tendency in the most of groundwater samples is in the order of
Ca2+>Na+>Mg2+>K+, which represent 70%, The tendency of anions is in the order of HCO3 ->SO4 2->Cl- represent 50% followed by HCO3 >Cl-> SO42--.Stabler (1944) diagram (Fig. 3) shows that, HCO3 - Ca2 type of water was predominant in the majority of samples (80%).

- **Irrigation groundwater quality**

The quality groundwater for irrigation purposes was evaluated and discussed by determining a several parameters such as, %Na+, SAR, RSC, PI, KR, PS, MH. Table1

Table 1**.** Statistics of the several groundwater parameters for irrigation

Variable	Min	Max	Mean
%Na	8.640	63.020	33.970
KR	0.050	1.655	0.539
SAR	0.240	11.980	2.372
MH	11.847	48.342	31.199
PI	26.946	75.387	52.314
PS	1.260	80.625	7.640
RSC	-44.300	-5.011	-9.200

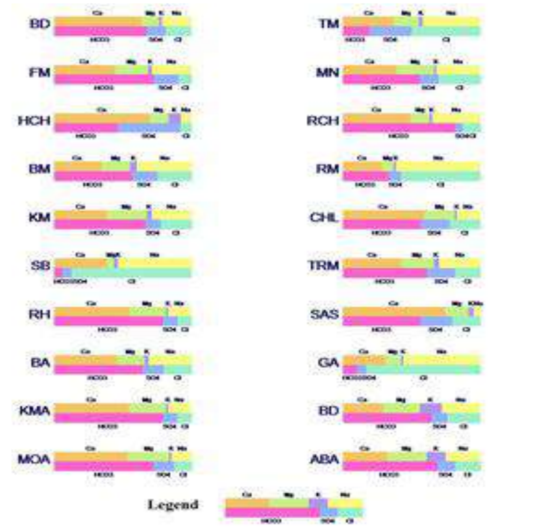

Fig. 3 Stabler diagram illustrating major ionic dominance in the samples

These irrigation parameters were calculated as follows: % Na was calculated using Eq.1 (Wilcox, 1955).

$$\%Na^{+} = (Na^{+} + K^{+}) \times \frac{100}{Ca^{2+} + Mg^{2+} + Na^{+} + K^{+}} \qquad (1)$$

SAR (Richards, 1954). It was calculated using the Eq. 2

$$SAR = Na^{+}/\sqrt{Ca^{2+} + Mg^{2+}}/2 \qquad (2)$$

RSC was computed using Eq. 3 (Ragunath, 1987).

$$RSC = (HCO_3^{-} + CO_3^{-}) - (Ca^{2+} + Mg^{2+}) \qquad (3)$$

MH was calculated using Eq. 4 (Szaboles & Darab, 1964).

$$MH = \frac{Mg^{2+}}{(Ca^{2+} + Mg^{2+})} \times 100 \qquad (4)$$

KR was computed using Eq. 5 (Kelly, 1940, 1963).

$$KR = \frac{Na^{+}}{(Ca^{2+} + Mg^{2+})} \qquad (5)$$

PI was computed using Eq. 6 (Doneen, 1964).

$$PI = Na^{+} + \sqrt{HCO_3^{-}}/(Ca^{2+} + Mg^{2+} + Na^{+}) \times 100 \qquad (6)$$

PS was calculated using Eq. 7 (Doneen, 1964).

$$PS = Cl^{-} + \sqrt{SO_4^{2-}} \qquad (7)$$

In these equations, all ionic concentrations were represented in mill equivalents per liter.

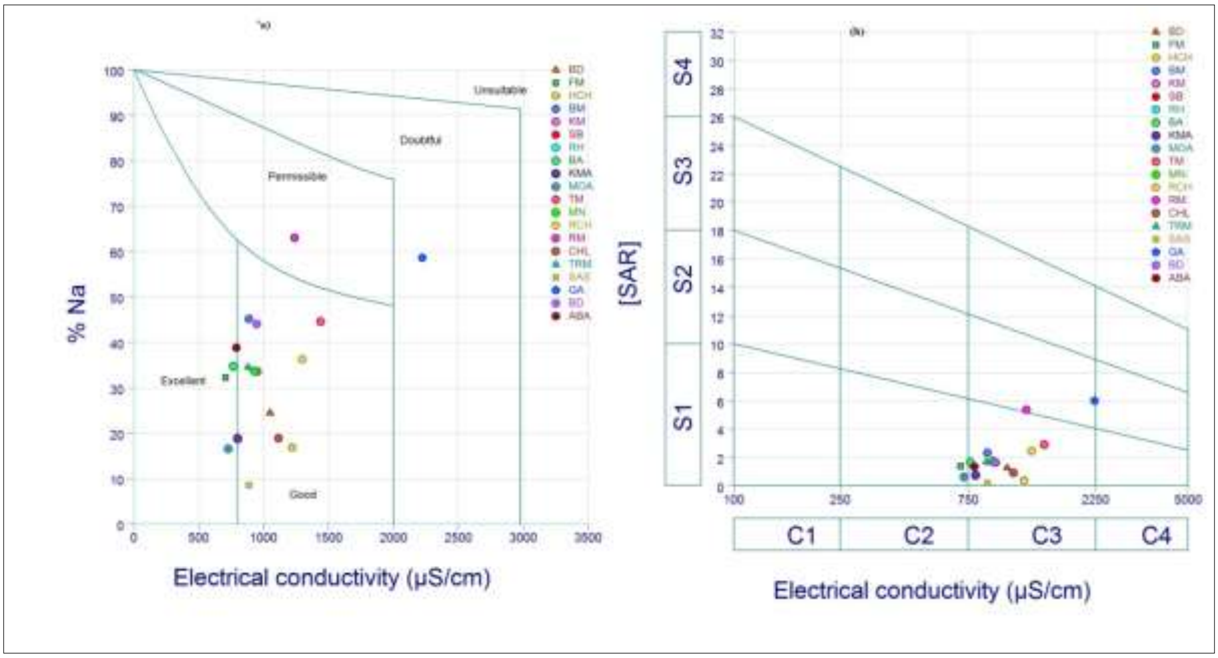

Fig. 4 Wilcox diagram (a) and Richards's diagram (b) of groundwater samples

Discussion

- ✓ The Na % values of samples ranged from 8.64 to 63.02 with mean of 33.97, 95 % of samples fall in "excellent" and "permissible" category (Table 1)
- ✓ *Sodium Adsorption Ratio (SAR)* values vary from 0.24 to 11.98 mg/l with a mean of 2.37 mg/l (Table 1). the majority of samples fall into excellent (95 %) to good (5%) classes similar to Na% classification.

- ✓ The electrical conductivity and SRA values plotted show that the most of the water samples belong into the C2S1class "medium salinity - low sodium" and C3S1 "high salinity - low sodium", According to the figure (Fig 4, b), all of the groundwater samples could be utilized for irrigation on practically every soil.

- ✓ Wilcox diagram, reveals that all groundwater samples fall in "excellent "to "permissible" category except one water sample (Fig.4),
- ✓ *The RSC* values of RSC range from (- 44.30 to - 5.01), these values are less than 1.25 meq/l (Table 1*)*, the entire water samples fall in good water category, "not hazard "so suitable for irrigation use
- ✓ *The MH* values range from 11.85 and 48.34 with a mean of 31.19 (Table 1). These values obtained are less than 50 and show that all groundwater samples are "good and suitable" for irrigation

- ✓ *Kelly's ratio (KR)* values are more than 1 in 85 % of the groundwater samples, the vast majority of samples from the studied area are suitable for irrigation use.
- ✓ *Permeability Index (PI)* values of the samples range from 26.94 to 75.4 with a mean of 52.31. It revealed that, 100 % of water samples fall into "good" water category which indicates that the water is suitable for irrigation purposes

- ✓ *Potential Salinity (PS)* values of groundwater samples range from 1.26 to 80.6 with a mean of 7.64

(Table 1).65% and 15% of the samples were classified as "excellent" to "good", and were "good" to "injurious" category of water quality respectively

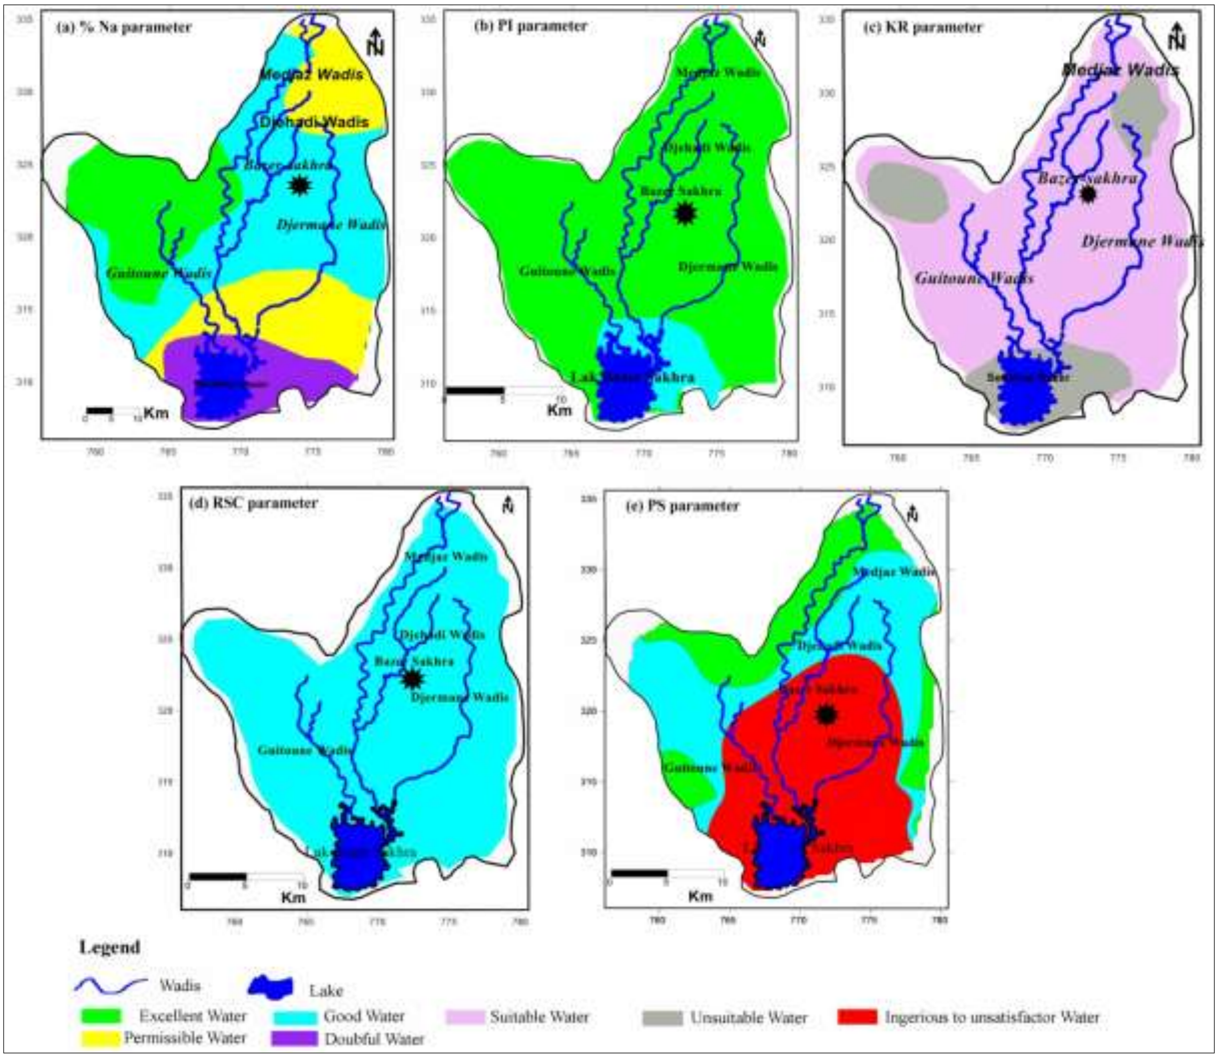

Fig. 5 Spatial distribution of parameters **a** %Na, **b** PI, **c** KR, **d** RSC, **e** PS

CONCLUSIONS

The Na % values of samples ranged from 8.64 to 63.02 with mean of 33.97, 95 % of samples fall in “excellent” and “permissible” category

- ✓ *Sodium Adsorption Ratio (SAR)* values vary from 0.24 to 11.98 mg/l with a mean of 2.37 mg/l. the majority of samples fall into excellent (95 %) to good (5%) classes similar to Na% classification.
- ✓ The electrical conductivity and SRA values plotted show that the most of the water samples belong into the C2S1class “medium salinity - low sodium” and C3S1 “high salinity - low sodium”, According to the figure, all of the groundwater samples could be utilized for irrigation on practically every soil.
- ✓ Wilcox diagram, reveals that all groundwater samples fall in “excellent ”to “permissible” category except one water sample,
- ✓ *The RSC* values of RSC range from (- 44.30 to - 5.01), these values are less than 1.25 meq/l, the entire water samples fall in good water category, “not hazard ” so suitable for irrigation use
- ✓ *The MH* values range from 11.85 and 48.34 with a mean of 31.19. These values obtained are less than 50 and show that all groundwater samples are “good and suitable” for irrigation
- ✓ *Kelly’s ratio (KR)* values are more than 1 in 85 % of the groundwater samples, the vast majority of samples from the studied area are suitable for irrigation use.
- ✓ *Permeability Index (PI)* values of the samples range from 26.94 to 75.4 with a mean of 52.31. It revealed that, 100 % of water samples fall into “good” water category which indicates that the water is suitable for irrigation purposes
- ✓ *Potential Salinity (PS)* values of groundwater samples range from 1.26 to 80.6 with a mean of 7.64 ; 65% and 15% of the samples were classified as “excellent” to “good”, and were “good” to “injurious” category of water quality respectively.

ABSTRACT

According to the Intergovernmental Panel on Climate Change (IPCC) Reports, an increase of 3 to 4 °C in surface average temperature values is expected by 2100 due to the increase in greenhouse gas emissions. Accordingly, a similar temperature increase is expected to be observed in Turkey. This situation, which appears as a global climate crisis, directly affects agricultural production. While sustainable and environmentally friendly production methods are supported with green transformation studies in industry, the implementation of similar approaches in agricultural activities is an important agenda item for the future of sustainable and environmentally friendly agriculture. For this purpose, it is necessary to identify important greenhouse gas sources that occur during agricultural activities and have an impact on global warming. In addition to the chemicals and fertilisers used during agricultural activities, water management is one of the most important focal points of sustainable agriculture. Therefore, adopting sustainable agricultural practices by moving away from traditional agriculture and making these practices a state policy will provide significant benefits in terms of sustainability in the long term. In this study, information is provided on strategies in agricultural systems foradaptation to climate change and technologies required to reduce greenhouse gas emissions. Inaddition, a comprehensive framework for agricultural sustainable development is presented by integrating literature studies in these areas.

Keywords: Sustainable agriculture; climate change; fertiliser management; water management

INTRODUCTION

Climate change is a concept used to refer to changes in long-term weather patterns and can result from both natural processes and human activities. Climate change has been increasing rapidly in recent years, especially due to anthropogenic activities and factors. Among the main causes of human-induced climate change are greenhouse gases released into the atmosphere as a result of intensive combustion of fossil fuels. Among these greenhouse gases, the most important ones are carbon dioxide (CO2), methane (CH4) and nitrous oxide (N2O). Greenhouse gases accumulate in the atmosphere, allowing short-wavelength radiation from the sun to reach the earth, while preventing the long-wavelength radiation reflected from the earth from escaping into space. This process is defined as the greenhouse effect and causes the average surface temperature of the earth to increase (Singh, Delgado-Baquerizo et al. 2023).

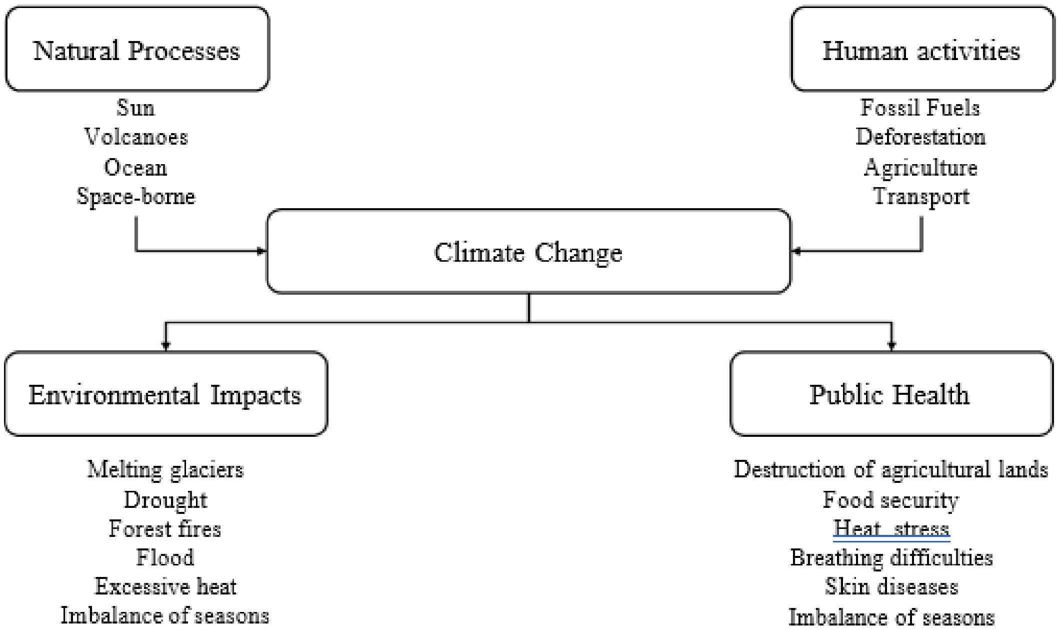

Figure 1. Climate change, causes, and effects.

Human-induced activities such as fossil fuel combustion, energy production, transport and industrial activities are among the main sources of greenhouse gas emissions. In addition, deforestation and destruction of green lands also have a significant impact on climate change. Forests play an important role in the carbon cycle; green plants and trees take CO_2 from the atmosphere through photosynthesis and store it in their biomass. However, the destruction of green areas and forests leads to both the loss of carbon sinks and the release of additional CO_2into the atmosphere as a result of the burning or decay of trees.

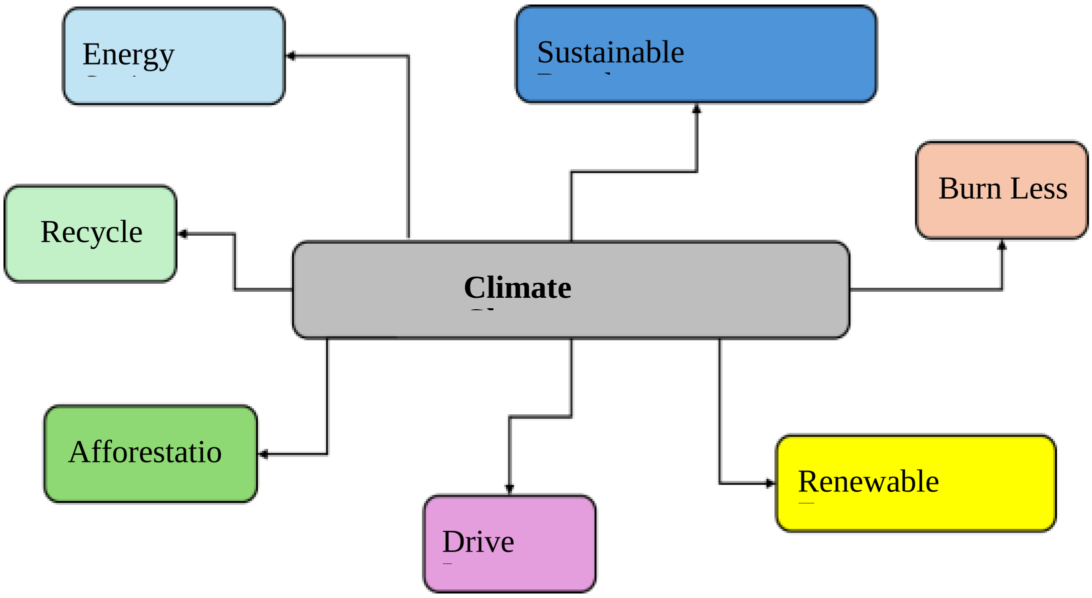

Figure 2. Climate change solutions.

The environmental impacts of climate change can be quite far-reaching. Climate changecan cause many environmental disasters such as global warming, melting of polar ice caps andmountain glaciers, rising sea levels and acidification of oceans. Sea level rise threatens coastalecosystems and human settlements, saltwater intrusion renders agricultural land unproductive and pollutes freshwater resources. Acidification of the oceans causes damage to calcium carbonate organisms (e.g. corals and some plankton species) in marine ecosystems and negatively affects marine biodiversity and fisheries (Louis, Carlson et al. 2023).

Climate change is also increasing the frequency and severity of extreme weather events (e.g. heat waves, severe storms, droughts and floods). These events threaten critical human activities such as agricultural yield-quality and food security. In addition, disasters such as floods can cause direct and indirect damage to human health by destroying infrastructure in settlements. For example, heat waves cause an increase in heat stress and heat-related diseases,while the decrease and deterioration of water resources can trigger the spread of water-borne diseases (Gössling, Neger et al. 2023).

As a result, climate change can have profound and widespread impacts on nature, the environment and ecosystems, as well as on human communities. Reducing greenhouse gas emissions, using renewable energy sources, protecting forests and green areas, sustainable practices and public-private, national-international collaborations are required to overcome thisglobal challenge and end or minimise these impacts. In addition, strategies for adaptation to climate change should be developed and these strategies should be implemented in a sensitive manner.

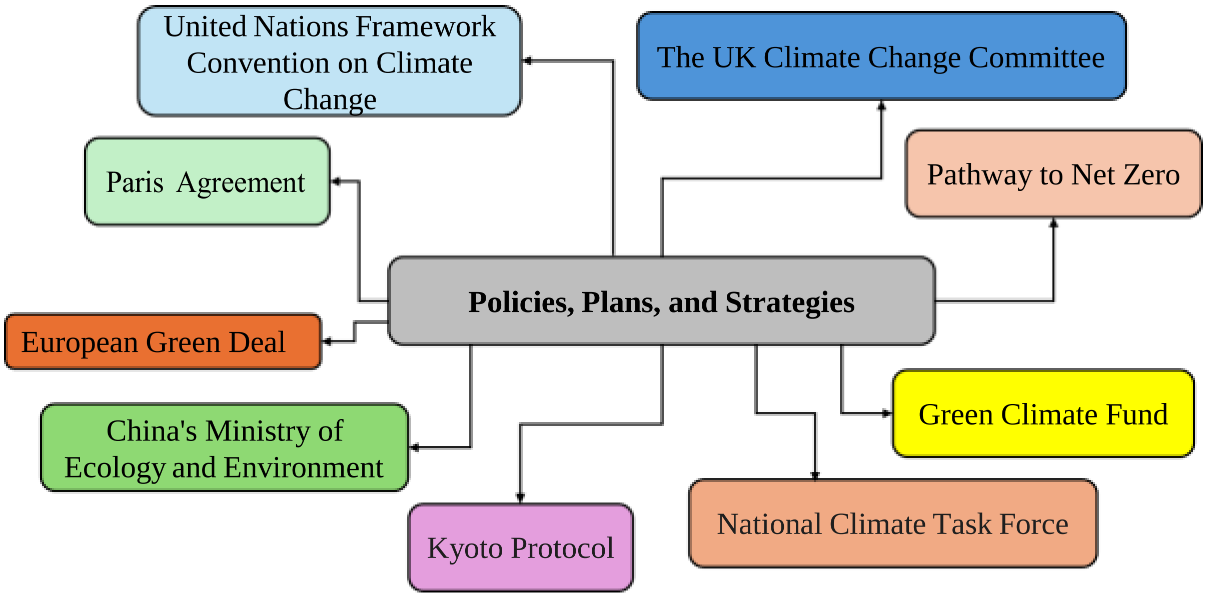

Figure 3. Climate change policies, plans, and strategies.

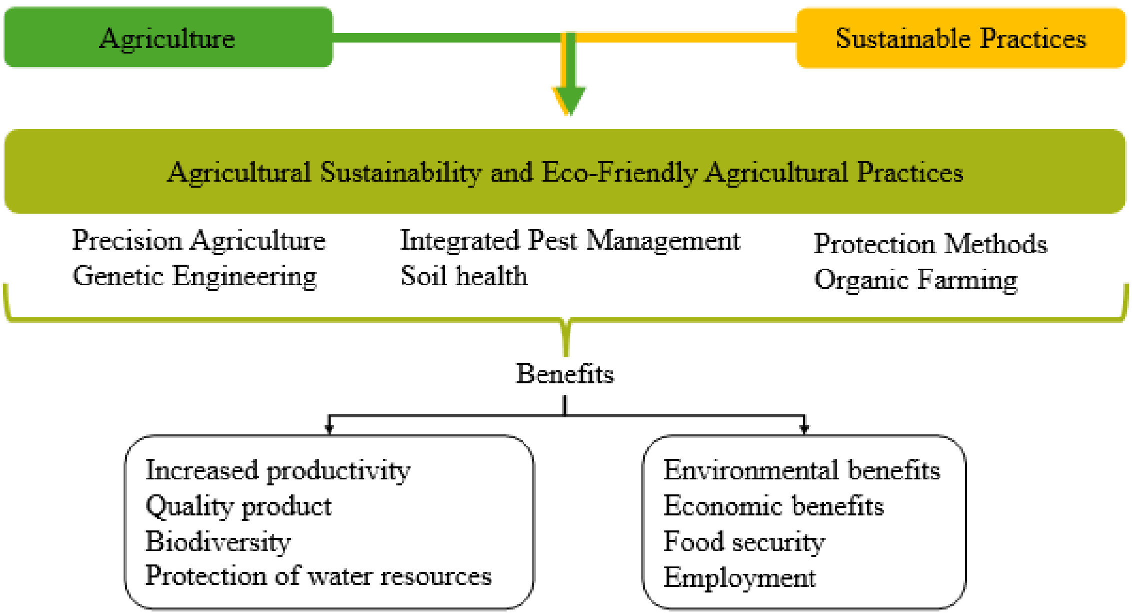

Figure 4. Agriculture and sustainability.

Agriculture also has a critical role in terms of food security and sustainable development. With the rapid increase in the global population, it is imperative to increase agricultural production. However, with the increase in agricultural activities, the environmental impacts of agriculture should also be taken into account. Intensive agricultural practices can lead to many problems such as soil erosion, depletion of water resources and reduction of biodiversity. Therefore, sustainable agricultural practices are important in protecting soil and water resources, maintaining ecosystem services and combating climate change. Alternative agricultural systems such as organic farming, agroecology and permaculture contribute to solving these problems by reducing the use of chemical inputs and increasing biodiversity. Therefore, innovative agricultural technologies and sustainable agricultural practices need to be adopted to increase agricultural productivity. These technologies and practices include precision agriculture, genetic engineering, integrated pest management and soil health protection methods. These practices increase production, yield and quality in agriculture, while at the same time minimising the impacts of agriculture on the environment and the health of living organisms and ensuring that agricultural activities are sustainable (Balasundram, Shamshiri et al. 2023).

RECENT PRACTICES

Rebouh et. al. (2023), investigated that embracing eco-friendly agricultural methods in the wheat farming system holds the potential to engender high and sustainable wheat yields, contingent upon a normative strategy that comprehensively addresses multiple factors. These include the intrinsic attributes of the grown wheat cultivars, plant nutritional parameters, soil agrochemical characteristics, and specific climatic conditions. Further in-depth investigations under field conditions are necessary to help in the discernment of appropriate environmentally agricultural techniques that can efficaciously optimize the yield potential of the different cultivated varieties.

Aroonsrimorakot et al. (2021), conducted a study on Application of Innovative Eco- Friendly Energy Technology for Sustainable Agricultural Farming and examined several technologies that provide sustainability in agriculture. These technologies can be lined as:

- Green Innovative Irrigation
- Sprinkler Irrigation
- Drip Irrigation with Fertilizer (Fertigation System) Technology
- Wind Turbine Energy
- Solar Panel Energy Technology
- Solar Panel Water Pump
- Solar Panel Energy in Agricultural Greenhouse

As a conclusion, they stated that there is an alarming fear of climate change and its impact on the global environment, global population, and the need of using innovative technology in human productive activities for sustainability, including agricultural farming, which is the mainsource of providing food to mankind. Adopting this green energy technology in agricultural farmers has some challenges, which made it to be adopted by only a few farmers and places, due to its high initial investment cost, lack of awareness or training. These difficulties can be overcome or solved through more research studies to optimize the combination of eco-friendlyenergy technology application and agricultural cultivation among the agricultural farmers due to environmental as well as well as economic feasibility (Aroonsrimorakot, Laiphrakpam et al.2021).

Nowak (2021) stated that precision agriculture is a management concept, which relies onintensive data collection and data processing for guiding targeted actions that improve the efficiency, productivity, and sustainability of agricultural operations. In his study, several studies have assessed the adoption rate of precision agriculture technologies at regional or national scale, but the literature lacks global evaluations of the development of precision agriculture. For this paper, a review of 17 papers was conducted to provide an evaluation of the adoption rate of precision agriculture technologies on field crops farms in developed countries.

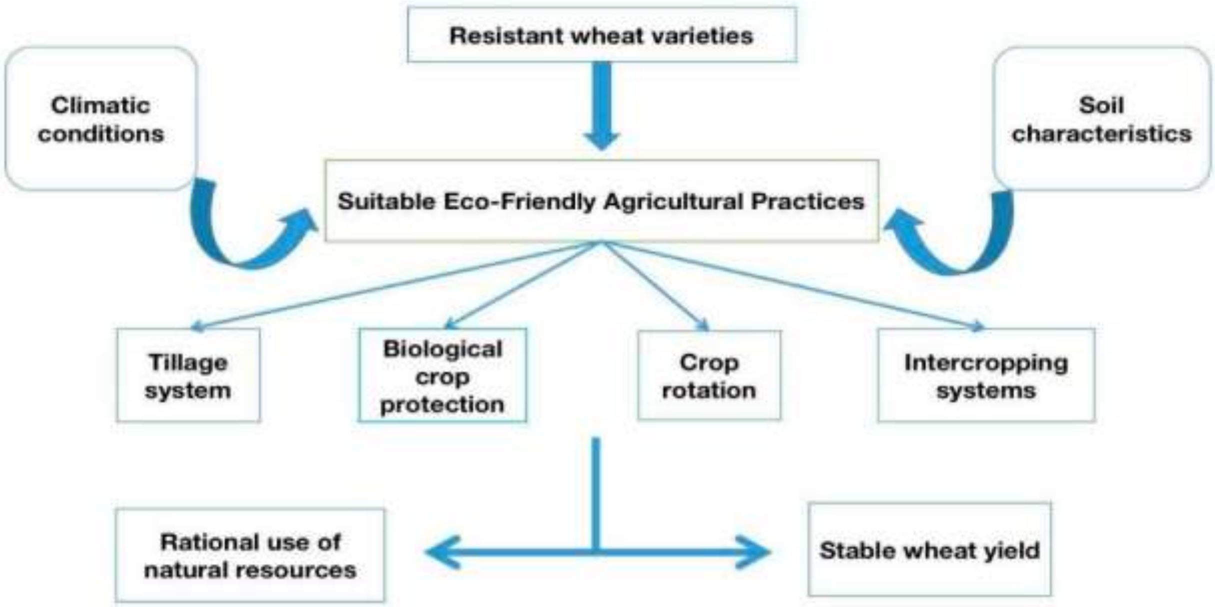

Figure 5. Diagram of integrated wheat farming system according to pedoclimatic conditions(Rebouh, Khugaev et al. 2023).

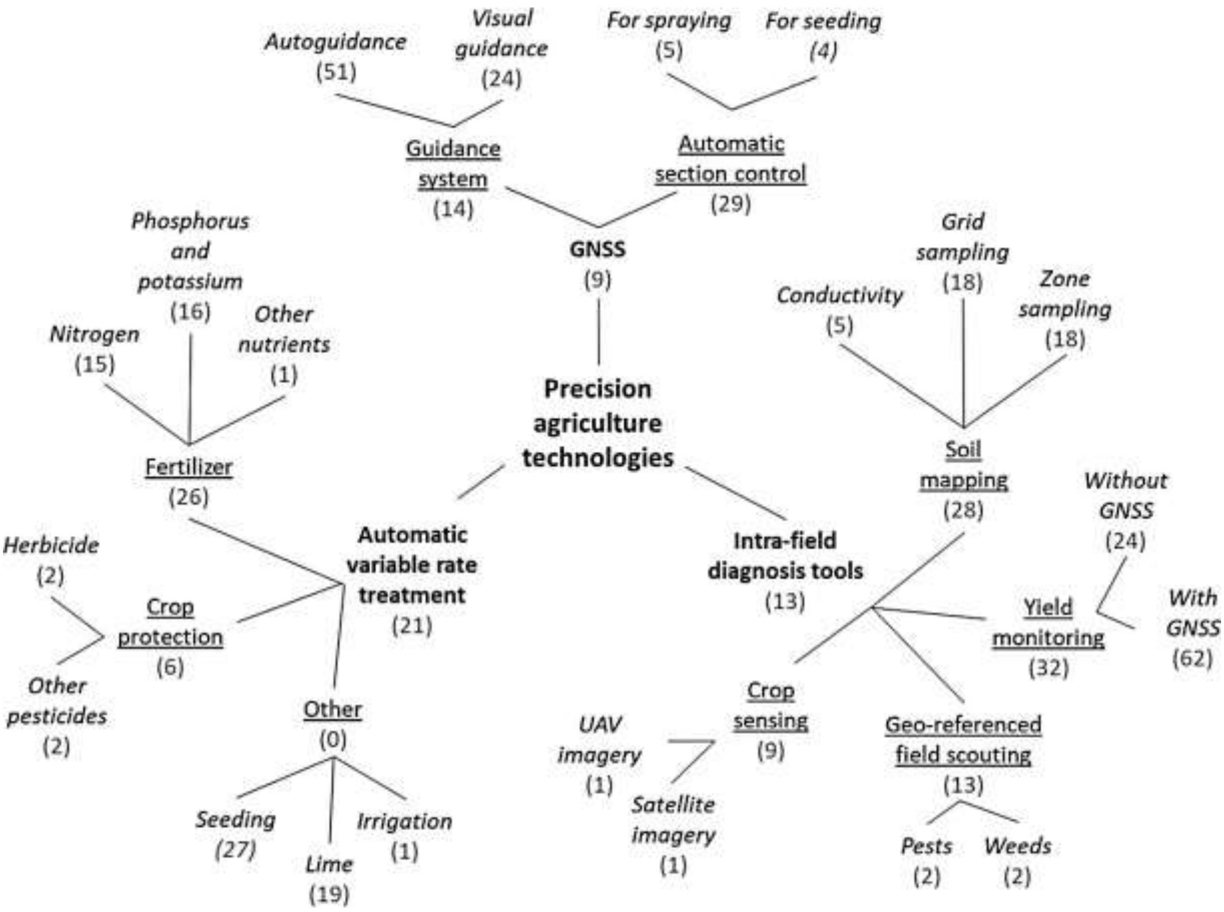

Figure 6. Typology of precision agriculture technologies surveyed in the literature (Nowak 2021).

Hassanisaadi et. al. (2022), investigated that role of agrochemical-based nanomaterials inplants: biotic and abiotic stress with germination improvement of seed. Nanotechnology has provided advancement opportunities in different fields of sciences related to plants such as agriculture. Plants are one of the most critical components of the ecosystem. Therefore, the perception of the behavior of plants in the presence of nanomaterials (NMs) plays an importantrole in achieving the goals of sustainable agriculture. NMs depending on physicochemical andstructural properties show positive or negative effects on plants exposed to them. Additionally,plant effects can be affected differently from species to species. The interaction of the plant with NMs leads to an effect on the morphology and physiology of plant organs. Some NMs play a significant role in improving stresses. The concept of engineered nano-carriers may be apromising route to address difficult challenges in agriculture that could perhaps lead to an increase in crop production while reducing the environmental impact associated with crop protection and food production.

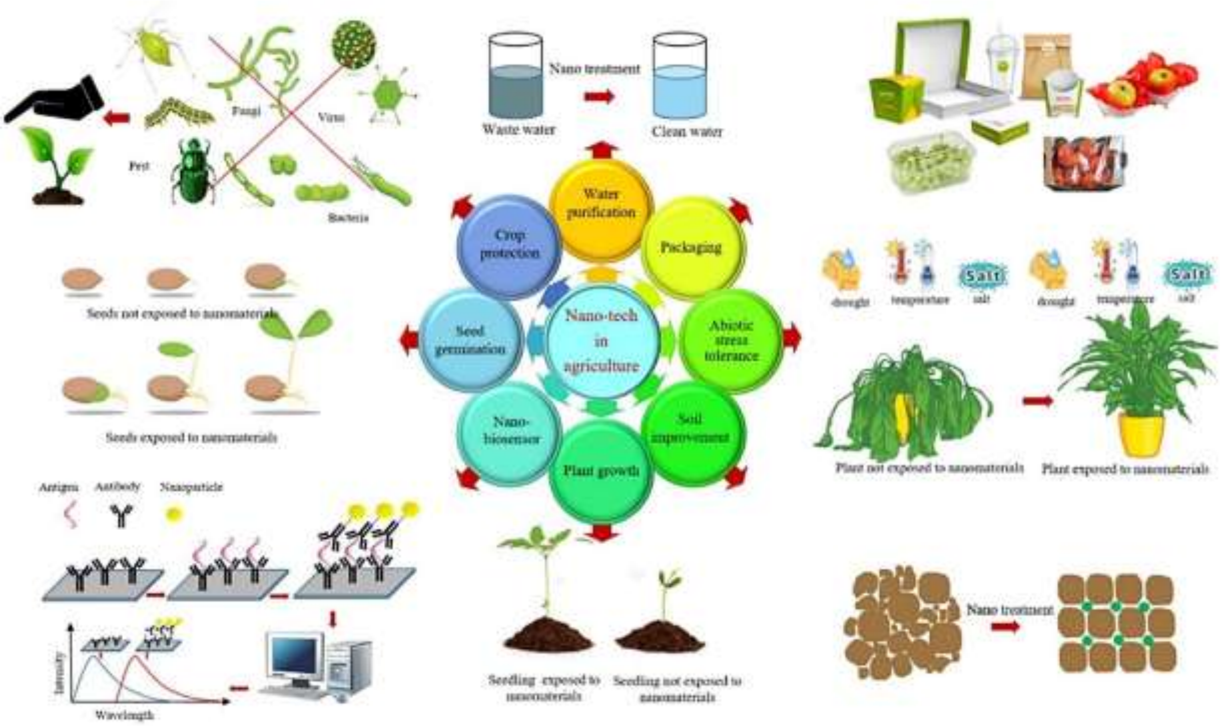

Figure 7. Application of nanomaterials in agriculture (Hassanisaadi, Barani et al. 2022).

CONCLUSION

Agricultural sustainability and eco-friendly practices are critical to ensure that future generations have access to sufficient, healthy and good quality food, water and other vital resources. Widespread adoption of eco-friendly practices such as organic farming, crop rotation,efficient irrigation technologies, eco-friendly fertilisers and the use of renewable energy sourcesin agricultural systems can significantly reduce the footprint of agricultural activities. These practices help maintain soil health, reduce greenhouse gas emissions and protect biodiversity. Modern agricultural practices, such as precision agriculture and sustainable irrigation systems, minimise resource wastage while increasing crop productivity. For a sustainable future in agricultural activities, it is important that farmers, politicians, governments, sectors, and consumers should work together to promote and implement these practices to ensure that farming systems remain resilient and productive without jeopardising the health of our planet.

ABSTRACT

In photovoltaic systems, the increase in panel temperature is one of the main factors that reduces efficiency. Each 1ºC increase in the temperature of the photovoltaic panel reduces electricity production by 0.45%. In this study, off-grid photovoltaic (PV) and photovoltaic/thermal (PV/T) systems are demonstrated in a low-capacity, low-slope roof application in Edirne, Turkey, and the effect of panel temperature on system performance is investigated by analysing the measurements taken simultaneously under the same environmental conditions. The PV/T system uses an air-heated solar collector with a perforated absorber panel. According to the results of 1 month measurements, in January 2021, the PV system produced 7.9 kWh of electricity and the PV/T system produced 11.3 kWh of electricity. The PV/T system produced 41.5% more electricity. The PV/T system also produced 138.24 kWh of thermal energy.

Keywords: Photovoltaic, Photovoltaic/Thermal, Solar energy, Off-grid

INTRODUCTION

Electricity is the most widely used form of energy in the world today. The fact that electricity generation is heavily dependent on the use of coal, natural gas and other petroleum products raises concerns about the sustainability of production and climate change. With the aim of contributing to the fight against global climate change and the development of renewable energy technologies, the use of renewable energy sources has increased worldwide. In the last 10 years, entirely new concepts in building design and technology have come to the fore and have rapidly spread, especially in the visionary goals of developed countries. Such buil ding designs have been associated with the efficient use of energy and renewable energy technologies that do not harm the environment. In our country, where electricity consumption in residential buildings accounts for more than 20% of total electricity co nsumption, one of the objectives of the Ministry of Energy and Natural Resources has been to use renewable energy sources for micro-generation. As a result of the shift in interest from conventional energy sources to renewable energy, by the end of Februar y 2024, the installed electricity capacity in Turkey was 107,594 MW, of which 54.9% can be supplied by renewable energy sources (Enerji.gov.tr).

Photovoltaic (PV) panels are one of the most common systems used to generate solar electricity from renewable energy sources. However, a systemic disadvantage is that the efficiency of PV panels decreases with increasing temperature. For every 1ºC increase in the temperature of the PV panel, electricity production decreases by 0.45%. Faced with this situation, PV/T systems have been developed to utilise the heat generated in the PV panel to cool it. In PV/T systems, on the one hand, the efficiency is increased by cooling the PV panel and, on the other hand, the thermal energy is recovered.

There are studies on PV and PV/T systems in the literature. Raghuraman established the one-dimensional model of flat plate solar collectors and PV/T collectors to analyse their performance. Finally, Raghuraman presented a number of methods to improve the performance of the collectors (Pattabiraman et al., 1981). Sujala (Sujala et al., 2013), Ruobing (Ruobing et al., 2015) and Jie (Jie et al., 2006) investigated the influence of different characteristics on PV/T collectors. The performance of four configurations of PV/T air collectors has been theoretically investigated by Hegazy (Hegazy, 2020) based on the energy balance concept. Researchers are interested in some of these systems with different end-use applications, including space heating (Sukamongkol et al., 2010) and drying processes (Rajoria et al., 2016). Under Algerian meteorological conditions, Slimani et al. compared three PV/T designs with a PV system (Slimani et al., 2017). Abdul-Ganiyu et al. compared a hybrid PV/T system with a conventional PV system over 25 years in Ghana (Abdul-Ganiyu et al., 2021). Electricity costs are $0.45/kWh for PV and $0.33/kWh for PV/T. Excluding batteries, the conventional PV system was found to be more economical (Abdul - Ganiyu, 2021). Sevela and Olesen studied a PV/T system integrated into buildings (Sevela and Olesen, 2013). By cooling the photovoltaic cells, the PV/T system increased the efficiency of electricity generation by up to 14.8% compared to PV. The PV/T system was found to be more advantageous for use in the Spanish a nd Danish climates (Sevela and Olesen, 2013). Buonomano et al. evaluated the technical and economic feasibility of PV/T collectors compared to conventional PV panels. In the study, an experimental setup consisting of 4 PV systems and 4 polycrystalline silicon PV/T systems with a total power of 2 kW and a surface area of 13 m^2 was constructed. Numerical modelling in TRNSYS simulates the PV/T and PV systems and shows that the PV/T efficiency is about 26%. Experimentally, the average thermal efficiency of PV/T collectors is about 13%, while the electrical efficiency of PV/T and PV systems is 15% (Buonomano et al., 2016). Yuan et al. compared the performance of aqueous PV/T systems, microchannel water tube PV/T systems and conventional PV systems at high ambient temperatures. The experiments showed that the average cell temperatures can reach up to 70°C for aqueous PV/T, 90°C for microchannel PV/T and 100°C for conventional PV module. The electrical efficiency decreased with increasing cell temperature, ranging f rom 11.2% to 10% for aqueous PV/T, 9.6% to 7.7% for micro-channel PV/T and 8.6% to 7.0% for conventional PV (Yuan et al., 2018). Barbu et al. investigated the performance of PV and PV/T systems to meet the growing demand for energy production. An experimen tal prototype system was installed on the campus of the University Politehnica Bucharest. The instantaneous power generation and overall system performance were calculated under four different weather scenarios. The results showed that the performance of the PV/T system is closely related to the effective distribution of the collected thermal energy to the storage tank (Barbu et al., 20 -23).

In this study, a performance analysis of off-grid PV and PV/T systems was conducted. A rooftop demonstration of the systems was set up at the Renewable Energy Systems Test Site of the Faculty of Engineering, Trakya University. The system consists of PV, PV/T, battery, weather station and necessary auxiliary equipment. In the study, a solar air collector with a perforated absorber panel was used as the thermal system. The measurements were used to evaluate both electrical and thermal energy production. The study will be a guide for the application of systems that will produce electricity and heat energy in Edirne and locations with similar climatic conditions.

MATERIAL AND METHOD

Theory

The output power P_{PV} (W) of the PV panel, whose operating voltage is V_{PV} (V) and current I_{PV} (A), is expressed with Equation 1. N_{PV} is the number of PV panels.

$$P_{PV} = V_{PV} \, . \, I_{PV} \, . \, N_{PV} \quad (1)$$

The thermal heat output Q (W) of the air collector is calculated with Equation 2.

$$Q = m \, . \, C_p \, . \, (T_ç - T_g) \qquad (2)$$

In Equation 2, m (kg/s) is the mass flow rate of the air, C_p (J/kg.K) is the specific heating heat of the air, $T_ç$ (ºC) is the air outlet temperature, T_g (ºC) is the air inlet temperature.

PV/T system thermal efficiency is expressed by Equation 3, and electrical efficiency is expressed by Equation 4. G_{rad} (W/m^2) is the solar radiation and $A_{PV/T}$ (m^2) is the collector area.

$$\eta_{th} = [\, m \, . \, C_p \, . \, (T_ç - T_g)]/(A_{PV/T} \, . \, G_{rad}) \qquad (3)$$

$$\eta_e = (V_{PV} \, . \, I_{PV})/(A_{PV/T} \, . \, G_{rad}) \qquad (4)$$

Site characteristics

Edirne is located between 41º-40º north parallel and 26º-34º east meridian (www.edirne.bel.tr). Edirne is about 41 m above sea level and has an area of 6,098 km^2. Due to its location, the city is a transitional zone under the influence of both the Mediterranean climate and the continental climate specific to Central Europe. With temperatures not falling below 30ºC during the summer period, the highest irradiation values per m2 are reached in June, while the longest period of sunshine is observed in July. Figure 1 shows the solar energy potential of Edirne.

Figure 1. Edirne province solar energy potential (solargis.com)

Since the renewable energy source varies according to the geographical structure, the region and field where the power plant is to be installed must be assessed for suitability. Solar radiation, outdoor temperature, wind speed and direction, and outdoor humidity in the installation area were measured by the meteorological station of Trakya University. The individual performances of the system components were determined for the climatic conditions of Edirne at the Renewable Energy Systems Test Site of the Faculty of Engineering, Trakya University, Edirne, Turkey.

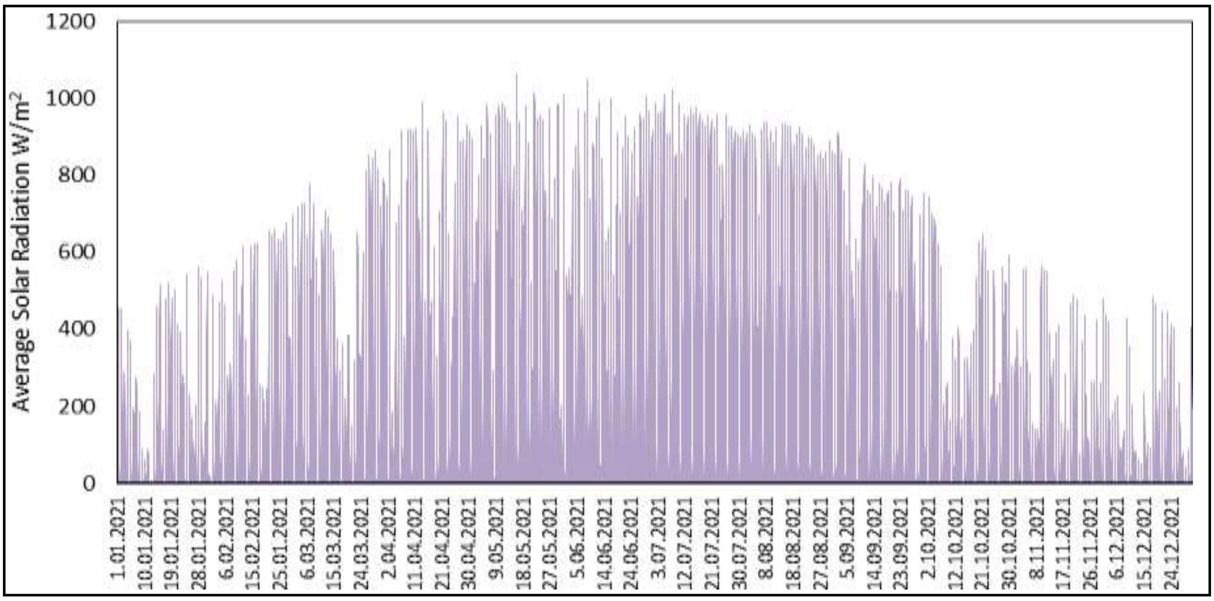

Figure 2. Average hourly solar radiation in Edirne 2021

As can be seen from the measurements in Figure 2, the solar radiation values are extremely good. Solar radiation reaches up to 1000 Watt/m^2 immediately and there is a good potential for PV systems. However, it has been observed that the air temperature reaches up to 40ºC in the summer months, and thus this situation, together with the high radiation, plays an important role in PV heating and reduces the efficiency of electricity generation. In this respect, PV/T systems together have an efficiency-enhancing function.

System characteristics
In order to compare the performance of rooftop PV and PV/T systems, two systems were installed to operate under the same conditions. In the first system installed, the PV panel was mounted on the sandwich panel roof covering. In the second system, the PV panel was tested integrated on a transpired solar air collector. PV panels with the same characteristics were used in both systems. An important component of the PV/T system is the solar air collector with perforated absorber panel. This is a façade cladding system made of metal material that is normally installed on the outside of buildings. The TSC is used for space heating in residential buildings, space heating and production of hot process air in industrial plants. The main element of the system is the perforated absorber panel, which absorbs solar energy. The absorber panel heats up because of solar radiation and, thanks to its many specially designed millimetre-sized holes, heats the outside air and sends it into the room. Due to this structure, the collector is used as one of the ideal systems for PV/T applications.

Both systems are positioned on the frame structure, facing south, simulating a 10 º roof pitch. The PV and PV/T system elements and characteristics are shown in Table 1, the PV and PV/T system schematics are shown in Figure 3, the PV and PV/T systems are shown in Figure 4, the PV/T system fan and data logger are shown in Figure 5. The inverter and batteries are shown in Figure 6, the data logger and charge controllers in Figure 7, and the LED projectors as power consumers in Figure 8. Table 2 shows the technical specifications of the PV panels. PV panels with the same characteristics were used in both systems. Table 3 shows the technical specifications of the solar air collector and Table 4 shows the specifications of the fan. Figure 9 shows the temperature sensors mounted on the PV system and Figure 10 shows the temperature sensors mounted on the PV/T system.

Figure 9. Temperature sensors installed on the PV system

Figure 10. Temperature sensors installed on the PV/T system

The current, voltage and temperature values of both systems were measured and recorded simultaneously. 7 temperature sensors were installed on the systems. The temperature sensors were connected to data recorders and the readings were recorded.

Solar radiation, outdoor temperature, wind speed and direction, and outdoor humidity in the installation area were measured continuously, 24 hours a day, 7 days a week, in all weather conditions by the meteorological station of Trakya University. Theweather station is shown in Figure

Figure 11. Trakya University meteorology station

RESULTS AND DISCUSSION

The energy production of the PV and PV/T systems was measured and recorded simultaneously. Using the data measured under the same climatic and operating conditions when the systems were operating simultaneously, the energy production, power profiles and system performances for PV and PV/T systems were determined and their performances were compared.

On 8 January 2021, Figure 12 shows the air temperature and solar radiation, Figure 13 shows the current and voltage values of the PV and PV/T systems, and Figure 14 shows the power production diagrams of the systems. As can be seen from the graph, the PV/T system produced 29% more power than the PV system.

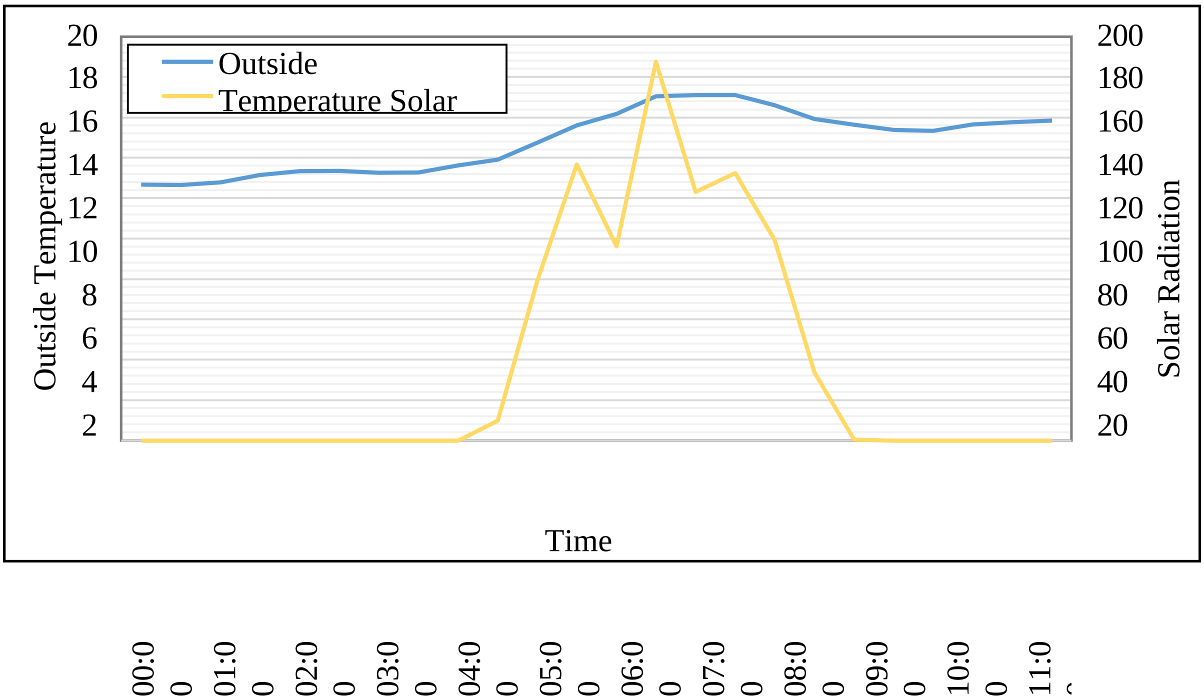

Figure 12. Air temperature and solar radiation on 8 January 2021

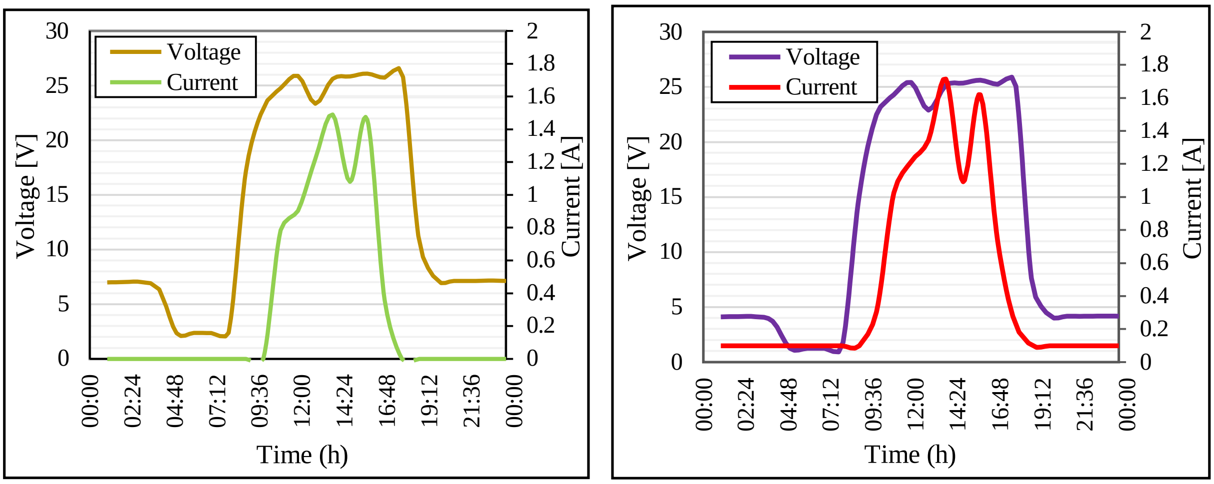

Figure 13. PV and PV/T systems current and voltage values on 8 January 2021

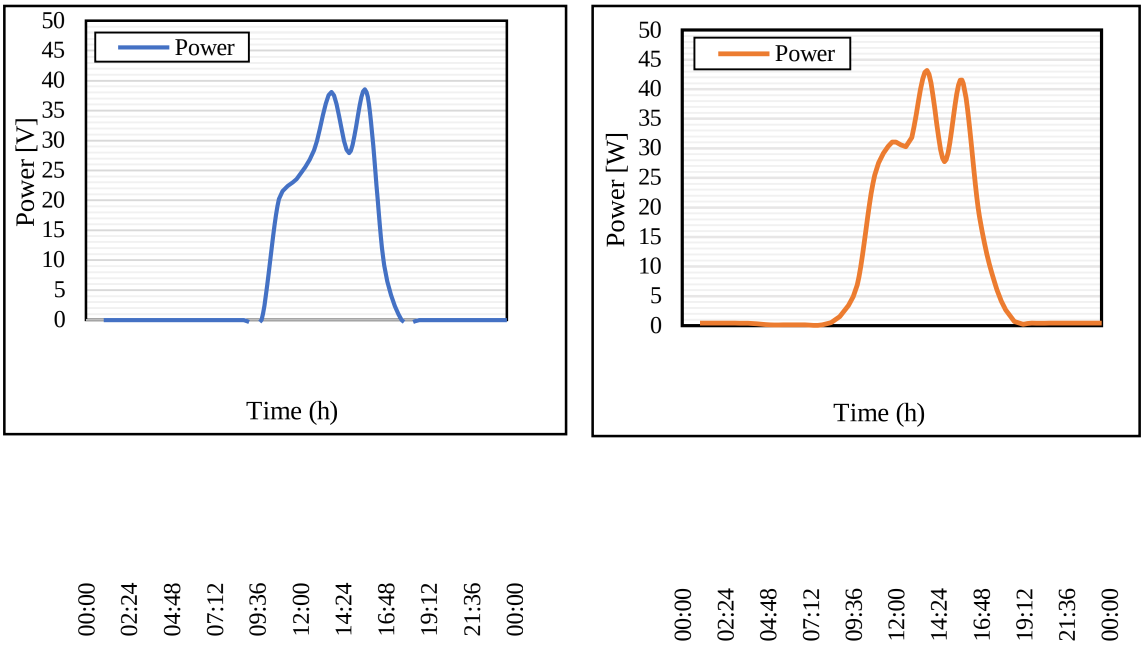

Figure 14. PV and PV/T systems power generation on 8 January 2021

Figure 15 shows the electricity production values of the PV and PV/T systems in January 2021. Figure 16 shows the thermal power distribution produced simultaneously by the PV/T system. The difference in panel temperatures reached 2.2 ºC in January 2020. A very important issue in cooling is the effect of the fan flow rate used. Normally, the cooling efficiency increases as the flow rate increases, but this effect was not investigated during the experiments. The system was operated at a constant flow rate because there are many parameters in the system and some basic functions were kept constant to study them effectively. In the future, the change in cooling efficiency for different flow rates will be investigated. Figure 17 shows the solar radiation data and efficiency comparison of the PV and PV/T systems.

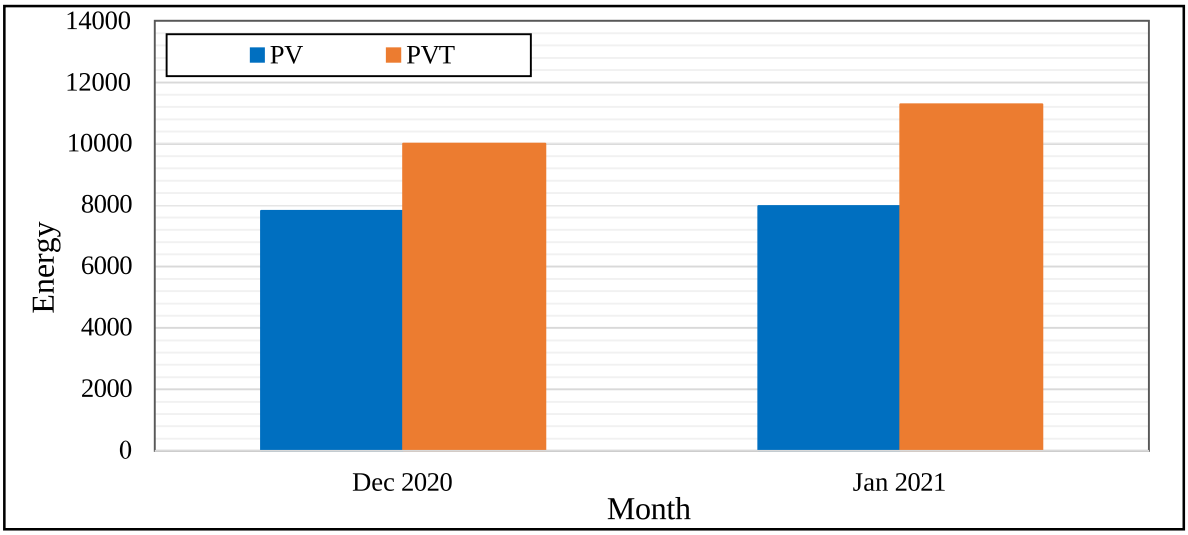

Figure 18. Total electricity production from PV and PV/T systems in December 2020 and January 2021

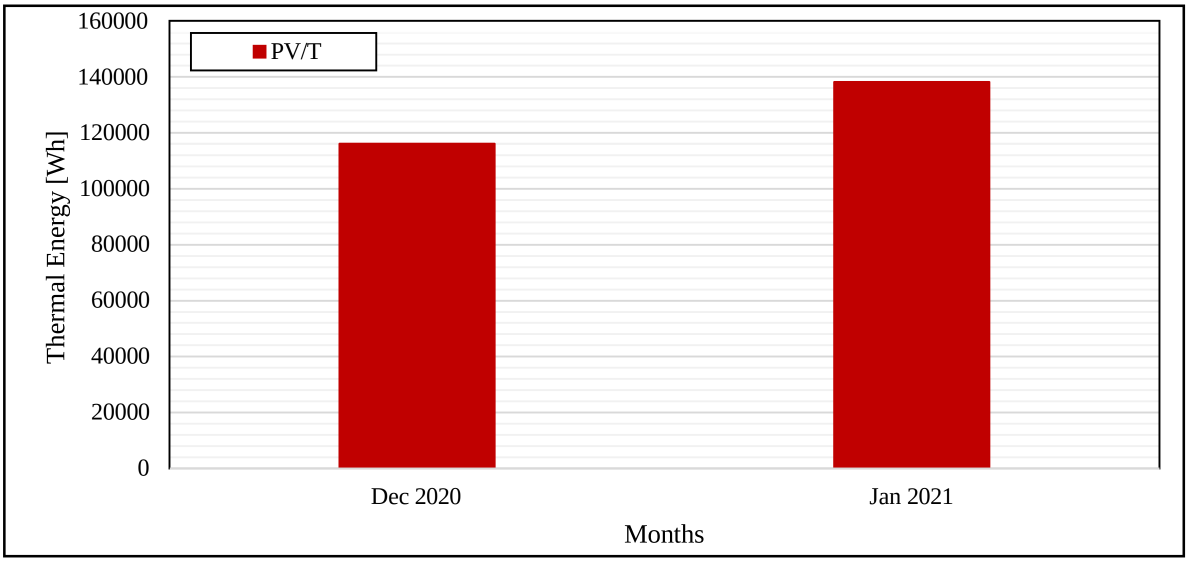

Figure 19. Total thermal energy production from PV/T systems in December 2020 and January 2021

Figure 18 and Figure 19 show the comparison of the total energy production of the PV and PV/T systems in December 2020 and January 2021. In December, the thermal energy produced by the thermal collector of the PV/T system is 116,095.7 Wh and the electrical energy is 7,812.8 Wh, and the electrical energy produced by the PV system is 10,000.2 Wh. In January, the thermal energy produced by the thermal collector of the PV/T system is 138,247.4 Wh and the electrical energy is 11,291.4 Wh, and the electrical energy produced by the PV system is 7,976.1 Wh. Comparing the energy production in January and December, the PV system produced 2% more electrical energy and the PV/T system produced 12% more electrical energy and 19% more thermal energy in January.

Looking at the energy production of the hybrid system, the PV/T system produces 41.5% more electricity than the PV system in January 2021, as expected. While the electrical energy produced by the cooled panel in the PV/T system increases significantly, the heat extracted from the PV panel is converted into useful energy.

CONCLUSIONS

The project evaluated the performance of Edirne province for off-grid applications of different solar energy technologies. In the analyses carried out within the framework of the project, the electricity production in small-scale production applications in Edirne province was determined to be 7,976.1 Wh for PV/T and 11,291.4 Wh for PV. At the same time, 138,247.4 Wh of thermal energy was produced with the PV/T system. Based on the analysis results, it appears that PV/T systems are more suitable to meet the electricity demand of buildings in Edirne and similar climatic conditions. In January 2021, the electricity production of the PV/T system was 41.5% higher than that of the PV system. Operating conditions, i.e. continuity at the point of consumption, also play a decisive role.

ABSTRACT

In Turkey, where residential electricity consumption accounts for more than 20% of the total electricity consumption, it is becoming increasingly important to use renewable energy sources for micro-scale electricity generation. In this study, two different micro-scale wind power generation systems that can be integrated into buildings have been installed. The performance of these systems is investigated theoretically and experimentally for real field conditions. As part of the study, a hybrid system consisting of a horizontal axis wind turbine and a vertical axis wind turbine with electricity storage and grid connection was installed at the Renewable Energy Systems Test Site of the Faculty of Engineering, Trakya University, and the electricity production of these systems was monitored for a period of two years. The data obtained was used to determine system performance and energy production. According to the measurement and analysis results, the HAWT system produced 153% more electricity in December 2020 and 168% more electricity in January 2021 than the VAWT system.

Keywords: Horizontal axis wind turbine, Vertical axis wind turbine, Wind energy, Off-grid

INTRODUCTION

As in the rest of the world, electricity consumption in Turkey is increasing day by day. Electricity consumption increases almost every year due to many factors such as population growth, widespread use of electrical appliances and technology products, and industrial growth. In 2023, Turkey's electricity consumption will decrease by 0.2% year-on-year to 330.3 TWh and electricity generation will decrease by 0.6% year-on-year to 326.3 TWh. In 2023, 36.3% of our electricity generation came from coal, 21.4% from natural gas, 19.6% from hydropower, 10.4% from wind, 5.7% from solar, 3.4% from geothermal and 3.2% from other sources. At the end of February 2024, Turkey's installed capacity reached 107,594 MW. At the end of February 2024, the breakdown of installed capacity by source is as follows: 29.7% hydro, 23.3% natural gas, 20.3% coal, 11.1% wind, 11.5% solar, 1.6% geothermal and 2.5% other sources. By the end of June 2022, the installed capacity based on wind energy was 10,976 MW, representing 10.81% of the total installed capacity. According to the results of Turkey's National Energy Plan, electricity consumption is expected to reach 380.2 TWh in 2025, 455.3 TWh in 2030 and 510.5 TWh in 2035 (enerji.gov.tr). In our country, the production of electricity using renewable energy sources is one of the goals of the Ministry of Energy and Natural Resources. At this stage, wind turbines used in wind power generation are becoming more and more important.

The most important studies on wind turbines in recent years: Zhao et al. studied the optimal geometric configurations for performance enhancement of vertical axis wind turbines (Zhao et al., 2006). In order to determine the turbine performance, parameters such as blade load and average rotor torque coefficient were obtained for different configuration cases. From the numerical studies, an increase of up to 23% could be calculated for the vertical axis wind turbine pair using a deflector. Kouloumpis et al. evaluated the potential of small-scale vertical axis wind turbines (VAWT) as a solution to climate change (Kouloumpis et al., 2020). A real example of a 5 kW H-Rotor Darrieus VAWT in Poland was studied for performance using real production data. Eltayesh et al. conducted experimental and numerical studies on a small horizontal wind turbine (Eltayesh et al., 2021). The effect of the number of blades on the turbine power and thrust coefficient was investigated. The results show that the power coefficient increases as the number of blades decreases. Zhao et al. review existing approaches to aerodynamic performance from the perspective of geometric parameters, flow control methods, blade shape modification, power boosting devices, hybrid systems and variable pitch control to further understand the performance improvement of vertical wind turbines (Zhao et al., 2022). In addition, several studies on the performance improvement of vertical wind turbines are summarised. Borg et al. investigated vertical wind turbines compared to horizontal wind turbines (Borg et al., 2014). It was concluded that vertical wind turbines had many advantages. These were siting, increased capacity and scale, challenging conditions and installation factor. Peng et al. review recent research on the turbulent aerodynamics of H-rotor vertical wind turbines (Peng et al., 2021). The results of these studies show that the turbulent motions generated in vertical wind turbines are characterised by features such as strong asymmetry and counter-rotating vortex motion. In addition, this study provides recommendations for the study of vortex and turbulent motions in vertical wind turbines. Pourrajabian et al. studied horizontal wind turbine blades using genetic algorithms (Pourrajabian et al., 2021). The study investigates the accuracy and precision of two different genetic algorithms for the wind turbine blade optimisation problem. The results show that the continuous genetic algorithm outperforms the binary one in terms of accuracy and computation time.

Comparative studies are important to determine which type of wind turbine has the higher potential. There are comparative studies in the literature on Horizontal Axis Wind Turbine (HAWT) and Vertical Axis Wind Turbine (VAWT) systems. In their study, Johari et al. compared the performance of two different designs to build a functional wind turbine and under the behaviour of wind at different speeds. They highlighted that the HAWT is able to generate higher voltage, but the voltage drops to zero when the wind angle changes. However, they observed that the VAWT generates lower voltage, but changes in wind angle do not affect the voltage output at all (Johari et al., 2018). Paraschivoiu et al. compared the aerodynamic performance and feasibility of multi-megawatt VAWTs with existing horizontal axis wind turbines of similar power rating. Two different types of three-blades VAWTs were designed: one with a Darrieus (H-type) and the other with a Troposkien (Φ-type) rotor configuration, in the rated power range of 2, 4 and 6 MW, based on an optimal parametric study. This comparative performance study showed that VAWTs have a simple design, which is not only characterised by superior performance, but also highly economical in terms of manufacturing, maintenance and cost (Paraschivoiu et al., 2018). Eftekhari et al. made a general comparison between HAWTs and VAWTs.

They also investigated the aerodynamic performance of newer VAWT designs. This comparative study showed that for large-scale VAWTs, three-bladed turbines positioned upwind are the most suitable option (Eftekhari et al., 2022). Fadil et al. investigated the effect of wind speed variations on the power output of wind turbines. They used an H-Darrieus type VAWT and a HAWT of the same size. Both turbines have three blades and NACA 4412 airfoils. The results showed that the CP of th e HAWT was 0.54 and the maximum power output was 1363.6 W, while the CP of the VAWT was 0.34 and the maximum power output was 505.69 W (Fadil and Ashari, 2017). Al-Rawajfeh and Gomaa made a comparison between VAWTs and HAWTs, emphasising the importance of both designs. HAWTs are considered more suitable in remote and offshore areas for large capacities with efficiencies up to 50%, while VAWTs are generally more suitable for smaller, urban and offshore installations with efficiencies around 40% (Al-Rawajfeh and Gomaa, 2017).

In this study, a comparative analysis of off-grid horizontal and vertical axis wind turbine systems is carried out. The application of both systems has been installed at the Renewable Energy Systems Test Site of the Faculty of Engineering of Trakya University. Both turbines are operated simultaneously, and their performance is compared under the same climatic and operating conditions. In this respect, it has been determined which type of turbine is more effective for small -scale energy production in Edirne's climatic conditions, for example for meeting domestic energy needs, under real field conditions. With the start of field measurements, both theoretical performance calculations and actual performances were measured, and the real efficiencies and capacity factors of each system were determined. The measurements were used to evaluate the electrical energy production. It was determined which system would have a higher performance in the climatic conditions of Edirne and proved with the analyses made with the data measured because of two years of experimental studies. The study will be a guide for the applications of wind energy systems that will produce electrical energy in Edirne and similar climatic conditions.

MATERIAL AND METHOD

Theory

This section presents the wind turbine power calculations of the hybrid power generation system. Considering that a wind turbine is a machine that rotates by momentum exchange of air mass particles flowing through the blade sweep area, the wind power in the sweep area A (m^2) is proportional to the cube of the size of this area, ρ (kg/m^3) the density of air and VH (m/s) the wind speed. Accordingly, the wind power PT (W) is expressed by Equation 1 (Simmons, 1975).

$$P = 1 \rho A V^{3} \qquad (1)$$

T ‾2 H

The wind turbine output power *PT* is expressed by Equation 2. Turbine operating voltage *VT* (V) and current *IT* (A) are expressed by the symbols.

$$P_T = V_T \, x \, I_T \quad (2)$$

Characteristics of the installation location

Since the renewable energy source varies according to the geographical structure, the location where the energy generation system is to be installed should be evaluated in terms of its suitability. Figure 1 shows the wind energy potential of Edirne provinc e. Thrace is a region with high wind potential. In the provinces of Tekirdağ, Kırklareli and Edirne, a total area of 2,234 km ^{2} is suitable for the installation of a wind energy system and a power generation plant with a capacity of 11,175 MW can be install ed. In addition, the provinces are suitable for the installation of solar energy systems with an average solar radiation of 1,400 -1,450 kWh/m^2.year (Thrace Development Agency, 2012). Solar radiation, outdoor temperature, wind speed and direction, and outdoor humidity were measured at the installation site with the meteorological station of Trakya University.

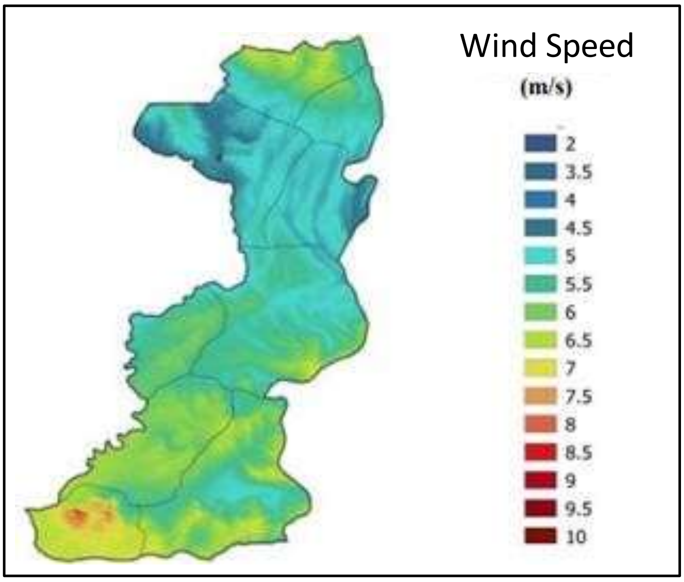

Figure 1. Edirne province wind energy potential (100 m) (repa.enerji.gov.tr)

System Specifications

In the study, an application consisting of a 500 W vertical axis wind turbine and a 500 W horizontal axis wind turbine was created. The application used two 12 V, 100 Ah batteries and a 24 V, 1200 W inverter. A timer relay socket was used for automation and the 50 W power consuming element was operated for 6 hours per day to ensure consumption. Table 1 shows the wind energy system elements and their technical specifications. Figure 2 shows a schematic drawing of the HAWT and VAWT systems and Figure 3 shows photographs of the system components.

Table 1. Wind energy system elements and their technical specifications

System Element	Specifications
Vertical axis wind turbine system	
Vertical axis wind turbine	500 W, 12 V, 30 A
Charge Controller	24 V
Horizontal axis wind turbine system	
Horizontal axis wind turbine	500 W, 24 V, 18 A
Charge Controller	24 V
Other equipment	
Battery	100 ah, 12 V
Inverter	1200 W, 24 V
AC led floodlights (Resistance, load)	150 W
Data Loggers

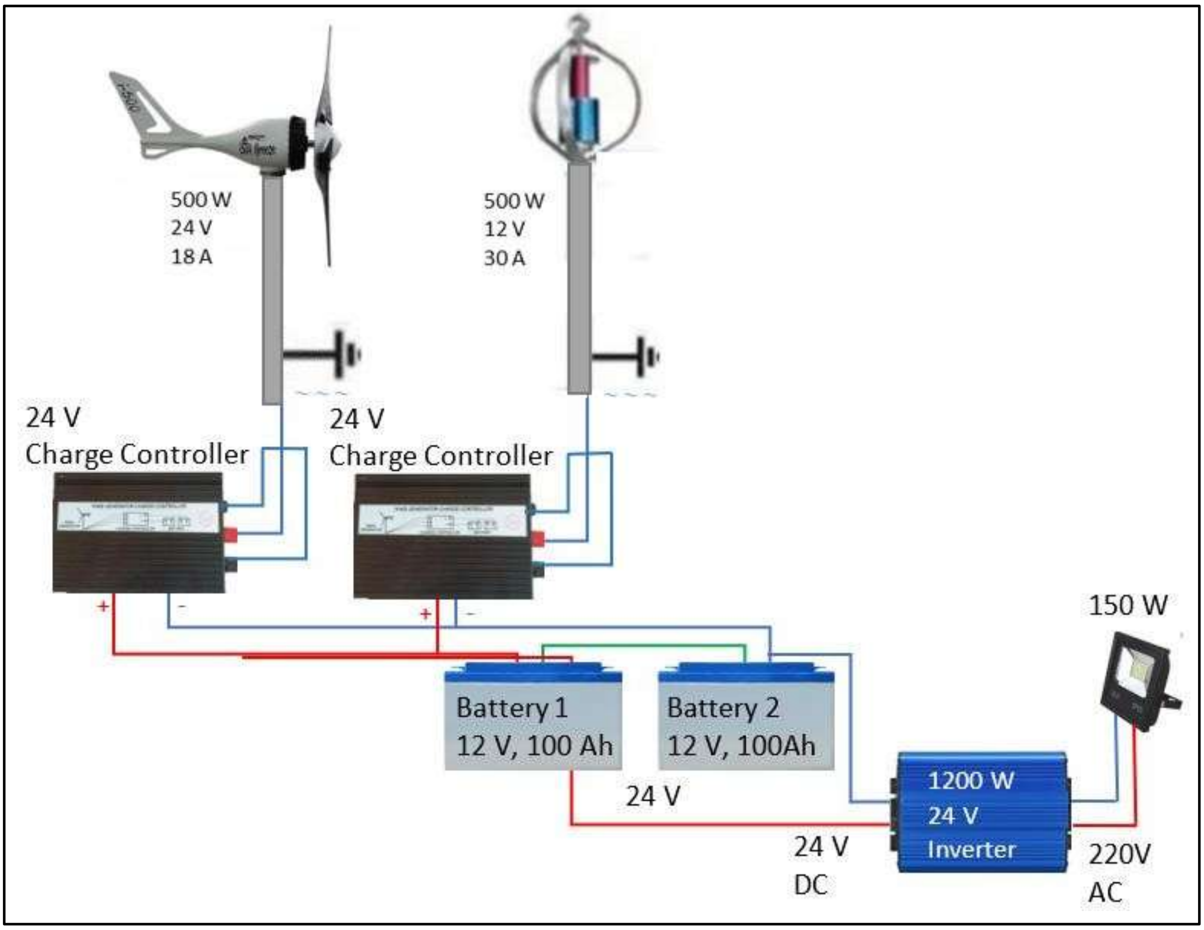

Figure 2. Schematic drawing of the wind energy system

a) b)

Figure 3. a) Horizontal axis wind turbine, b) Vertical axis wind turbine

The vertical turbine system consists of two different structures with airfoil and trailing blades. At low wind speeds, the drag blade structure produces energy, while the airfoil blade continues production at high wind speeds. The horizontal axis wind turbine has 3 blades and a rotor diameter of 105 cm and starts producing energy from 3 m/s. Both turbines are installed at the same height and do not interrupt each other's air flow. The technical specifications of the HAWT and VAWT are given in Table 2 and the power curves are shown in Figure 4.

Table 2. Horizontal axis and vertical axis wind turbine technical specifications

Specification	**Horizontal Axis Wind Turbine (HAWT)**	**Vertical Axis Wind Turbine (VAWT)**
Turbine type	 Horizontal axis wind turbine (Three blades)	 Savonius-Darrieus
Rated Power	500 W	500 W
Body material	Composite	Aluminium
Alternator type	Mono-phase	Mono-phase
Alternator material	Aluminium	Aluminium
Starting wind speed	2,0 m/s	1,5 m/s
Working wind speed	2.0 – 15 m/s	1,5 – 15 m/s
Blade number	3	3
Rotation (rotor) diameter	1,25 m	1,1 m
Weight	27 kg	35kg
Blade material	Composite (Carbon)	Aluminium
Output voltage	DC 24 V	DC 24 V
Noise rating	40 dB	35 d
Tower height	3 m	3 m

b)

Figure 5. a) Off-grid inverter and charge controller, b) Data logger

Meteorological station data, solar radiation, outdoor temperature, wind speed and direction, outdoor humidity measurements, energy production of vertical axis turbines and horizontal axis turbines were simultaneously measured and recorded.

RESULTS AND DISCUSSION

The energy production of HAWT and VAWT systems was measured and recorded simultaneously. The energy production, power profiles and system performances of HAWT and VAWT systems were determined, and their performances were compared by using the data measured under the same climatic and operating conditions with the systems operating simultaneously.

On 10 December 2020, the maximum and average wind speed are shown in Figure 6, the current and voltage values of the HAWT and VAWT systems are shown in Figure 7, and the power generation is shown in Figure 8.

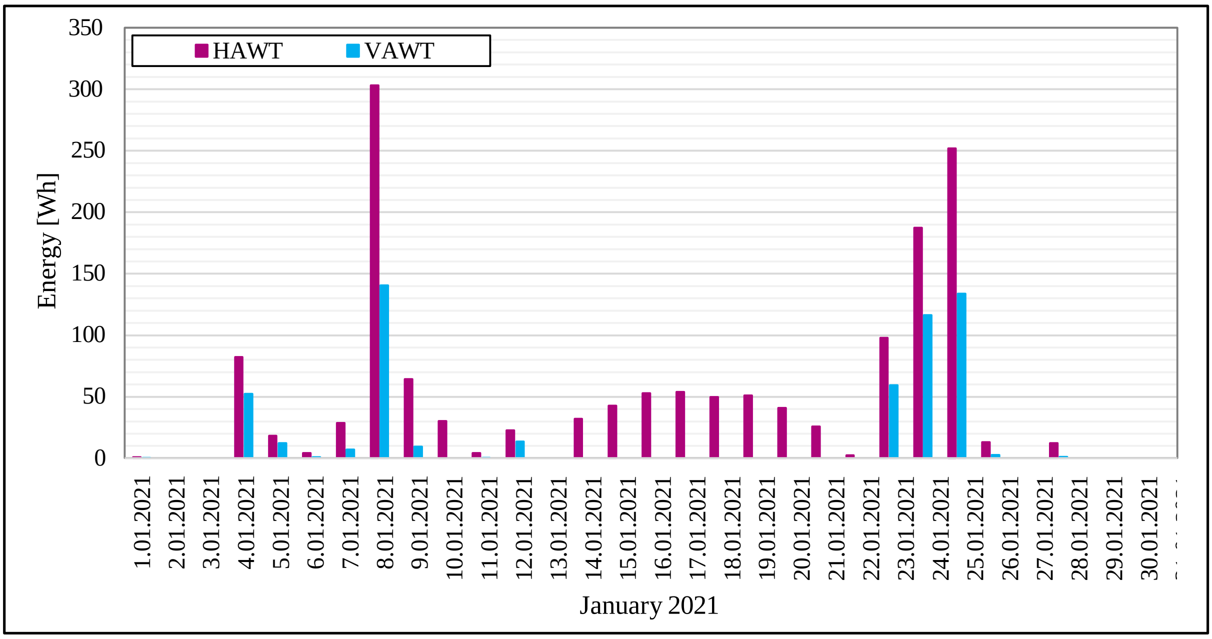

Figure 17. Daily energy production from HAWT and VAWT systems in February 2021

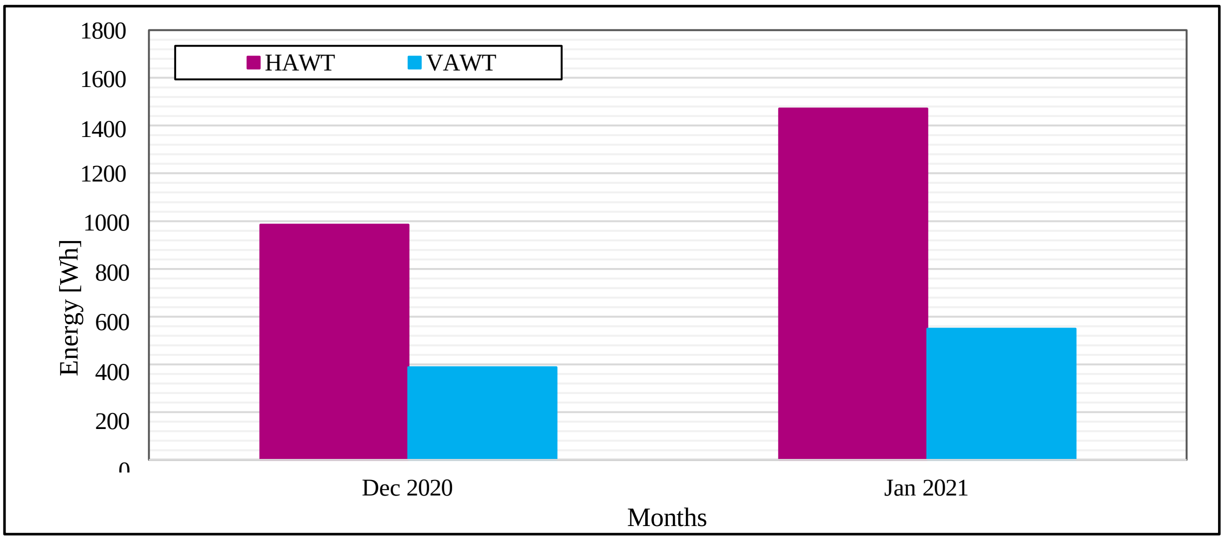

Figure 18. Total energy generated by HAWT and VAWT systems in December 2020 and January 2021

Figure 18 shows the total energy produced by the HAWT and VAWT systems in December 2020 and January 2021. When analysing the electricity generation performance of both systems, the total energy produced by the HAWT system is

984.9 Wh and 1,471.1 Wh, and the total energy produced by the VAWT system is

387.8 Wh and 548.8 Wh in December 2020 and January 2021, respectively. Both systems generated more energy in January. Comparing the energy production in January and December, the HAWT system produced 49.4% more electrical energy and the VAWT system produced 41.5% more electrical energy in January. In addition, the HAWT system produced 153% more electricity in December 2020 and 168% more electricity in January 2021 than the VAWT system.

CONCLUSIONS

In the analyses carried out within the project, the total two-month average electrical energy production of small-scale production applications in Edirne province was determined to be 1,228.0 Wh for horizontal axis wind turbines and 468.4 Wh for vertical axis wind turbines. Based on the results of the analysis, PV/T systems are more suitable for meeting the electricity needs of buildings in Edirne and similar climatic conditions. According to the results of the analysis, the HAWT system provided on average 2.6 times more energy production than the VAWT system.

ABSTRACT

Background. Blue swimming crab (*Portunus pelagicus*) is an important fishery in the Indo-Pacificregion, including Indonesia. However, many *P. pelagicus* populations are experiencing over- exploitation. Maintaining healthy reproductive output and potential recruitment is a crucial step inconserving and managing crab stocks. **Aims**. We assessed spawning potential of *P. pelagicus* by examining sex ratio, spawning season, size of ovigerous females, fecundity, and environmental factors. **Methods**. We sampled crabs captured in a small-scale local fishery in Pare-Pare Bay, South Sulawesi, Indonesia. A total of 5278 crabs were collected from monthly samples collected July 2023 through June 2024. We used Chi-square (χ^2) tests to compare sex ratios. A principal component analysis (PCA) was used to determine the influence of environmental factors on the abundance of ovigerous females. **Results**. Ovigerous crabs were most abundant in the 8-11 cm size range. The average sex ratio was about 0,6:0,4 (M:F). The proportion of female catch that wasovigerous ranged from 11% in May to 32% in March. The fecundity ranged from 107,640 eggs to1,308,400. The environment condition at that time is Salinity (32,2 □ 1,7 ppt), Dissolve Oxygen (7,2 □ 0,8 ppm),pH (8,3 □ 0,0), temperature (33,5 □ 0,3 ^{o}C), and current (0,063 □ 0,009 m/s). **Conclusion**. Sex ratio and the abundance of ovigerous female crabs fluctuates throughout the yearwithin the small-scale fishery. 34 % of the ovigerous females are under the legal size limit (< 10 cm). While crabs in Pare-Pare Bay spawn throughout the year, we observed peaks in activity, withthe highest in March. Water temperature and pH had the strongest association with the abundanceovigerous crabs. It shows that there is a strong influence between spawning season and environment, especially the temperature. The results of this research indicate that the potential forspawning blue swimming crabs in Pare-Pare Bay is still good, but great attention is needed to limitthe capture of female crabs, especially those that ovigerous female for sustainability and protect the habitat damage.

Keywords: Crab, Environment, Pare-Pare Bay, *Portunus pelagicus*, Reproduction

INTRODUCTION

Blue swimming crab (*Portunus pelagicus*) is an important fishery commodity worldwide, including Indonesia. However, the threat of over-exploitation is urgent and widespread, with decreased catches and increasingly small sizes becoming prevalent issues. Hamid et al. (2016) reported that blue swimming crab stocks in Lasongko Bay, Central Buton, Indonesia, have been overfished and are considered critical. Thus, effective management is necessary. La Sara et al. (2019) also reported that in Southeast Sulawesi waters, fishing activities of blue swimming crabs had reached an over-exploitation level. Ernaningsih et al. (2024) reported that the exploitation rate of blue swimming crabs from the Bawasalo Waters Pangkep Regency, South Sulawesi, is about E

= 0.55. It means that the stock of *P. pelagicus* was slightly higher than that of an optimally exploited stock. Nurdin et al. (2022), from the research in Spermonde Archipelago, Indonesia, stated the blue swimming crab stock status in Spermonde is over-fishing with an SPR value of 7%. However, Tirtadanu and Chodrijah (2019) reported that the exploitation status of blue swimming crabs in Kwandang Waters, North Sulawesi, Indonesia, showed no overfishing, based on the current fishing mortality (Fcur=0,86), which was less than the reference point F0.1=2,8 and based on the estimated SPR of 24% so the fishing effort could continue. The government could implement the minimum legal size of 117 mm CW for the future management strategy.

One crucial step to save stock is to maintain healthy reproductive activity. Reproductive status was used as an indicator to identify spawning habitat, and data from long-term fishery- independent surveys were used to evaluate spatiotemporal trends in the abundance of spawning females (Ogburn and Habegger, 2015) and to assess the sustainability of crab fishery. According to Hilborn 2004 and Purcell, 2004 in Aguilar et al. (2018), successful rebuilding of depleted stocks through stock enhancement, a process of increasing the abundance of a fish stock through human intervention, can occur only when the factors responsible for the stock decline are addressed concurrently through sound fishery management.

Spawning season and fecundity are essential information for understanding the complete status of crab populations. Basic information regarding the reproductive biology of P. pelagicus can help policymakers and managers establish regulatory measures to conserve populations. More than that, studying reproductive biology, especially spawning season, concerning environmental conditions such as Salinity, Temperature, and pH is essential information for developing crab hatchery technology to support cultivation.

In this paper, the sex ratio of males and females, spawning season, size of females at sexual maturity, size at 50% of ovigerous females, fecundity, and environmental factors that affect the spawning season are presented for P. pelagicus in Pare-Pare Bay. Understanding the reproductivebiology of P. pelagicus is essential for sound scientific advice for future fisheries management. It opens up possibilities for stock enhancement and hatcheries, providing a hopeful outlook for the future of crab populations.

MATERIAL AND METHODS

The research area, Pare-Pare Bay, South Sulawesi, Indonesia, is of significant importance due to its unique characteristics and its role as a habitat for P. pelagicus. The bay, with latitudes $119^o34,440$'E to $119^o38,220$'E and $4^o1,660$'S to $3^o58,140$'S, is a bay on the western coast of South Sulawesi Province that faces the Makassar Strait. Crabs were sampled at the crab landing site in Watang Suppa Village, Suppa District, Pinrang Regency (Figure 1). The crab samples were caught by fishermen using gill nets with a length of 21 m, a height of 0.46 m, and a mesh size of 3 inches. Were 5278 samples collected from July 2023 to June 2024 at the landing site. The crab data was measured in situ, and fecundity was measured at the Hatchery Laboratory, Faculty of Marine and Fisheries Sciences, Hasanuddin University. Environmental parameters were taken from four stations, which were determined based on differences in bottom substrate and vegetation.

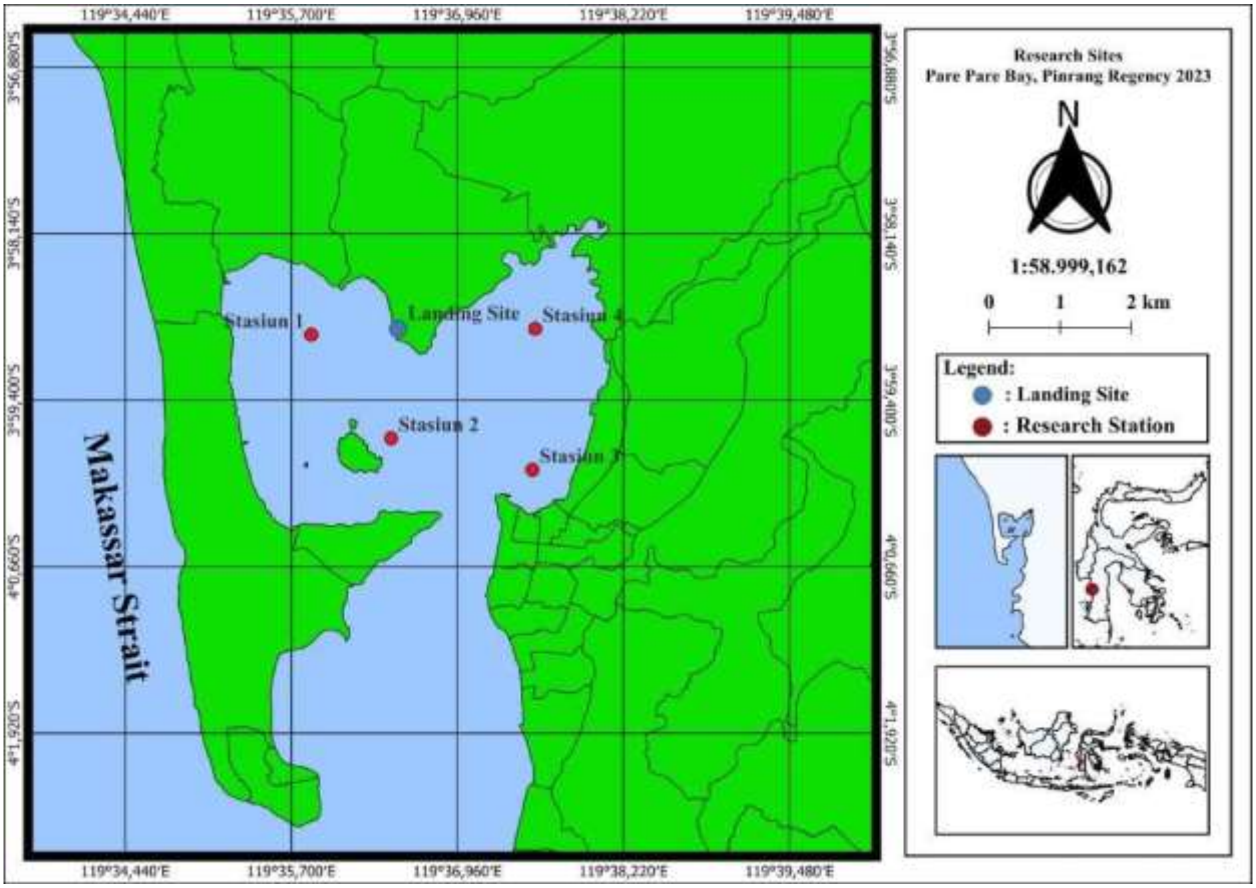

Figure 1. Locations of sampling sites for *Portunus pelagicus* in the Pare-pare Bay South Sulawesi,Indonesia.

Crab Size

The crab sizes measured were outer carapace width, body weight, and egg mass weight. Outer carapace width is the distance between the most extended spine on the right and left side ofthe crab's body. Carapace width was measured using a caliper with an accuracy of 0.01 mm, and weight was measured using a digital scale with an accuracy of 0.01 g. The first step is male, female, and ovigerous, differentiated crabs. Then, the size and condition of the crabs were recorded. Onlyintact crabs were used to analyze length-weight relationships and size comparisons between sexes.The egg mass (sponge) is taken out from under the abdomen and weighed together with the pleopod where it is attached.

Sex-Ratio

In this research, sex ratio analysis was carried out by monthly data sets of the total number of male and female crabs (Figure 2). Gender can be identified based on the shape of the abdomen. Male crabs have a more tapered abdomen, while females have a broader shape. Apart from being based on the shape of the abdomen, gender can also be determined from the color of the crab itself. The bright blue color with white spots on the shell indicates the male, while the darker color indicates the female crab, as in Figure 2.

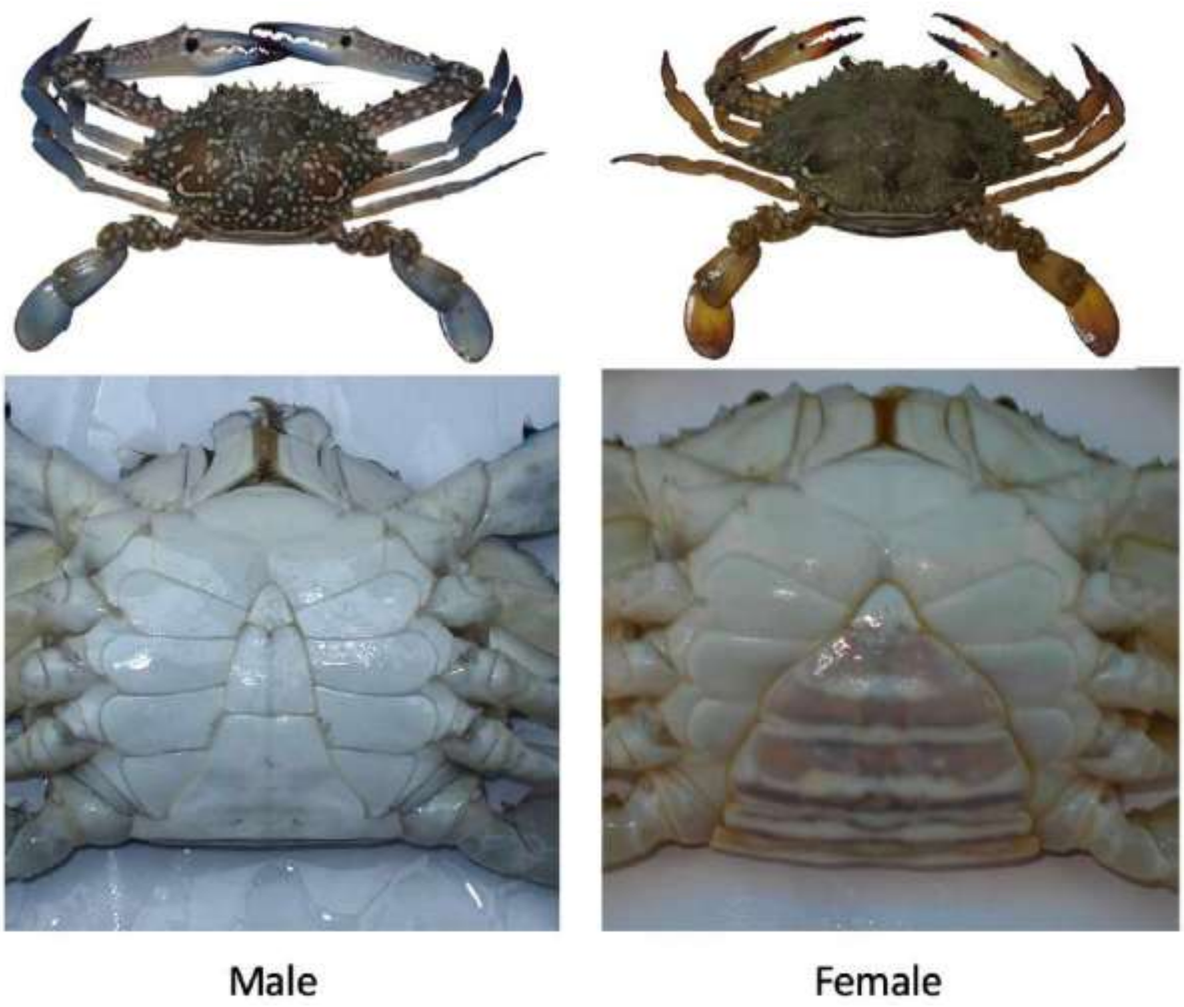

Figure 2. Male and female Blue Swimming Crab (Portunus pelagicus)

Spawning Season

The spawning season of this species was determined by the percentage of ovigerous females each month. An ovigerous female is a crab carrying eggs under the abdomen or apron (Figure 3). The ovigerous female used in this study is just a crab carrying eggs in orange color.

Figure 3. The ovigerous female

Fecundity

Fecundity is calculated as the number of eggs carried externally by the female (Kumar et al., 2000). This study sampled 129 ovigerous females from crab landing sites with a wide range ofsizes. Caliper measured the carapace width of each ovigerous female to the nearest 0,01 mm. Egg-bearing pleopods were removed carefully; the wet weight of the whole egg mass was measured tothe nearest 0.01 g using an electronic balance. The corresponding carapace width to the egg sac mass was also recorded. Approximately 0.1 g sub-samples were taken from three different placesof the egg sac. Egg samples were preserved with Gilson Solution until eggs were dispersed and were ready to count. Gilson's solution: 100 mL 60% ethanol or methanol, 880 mL water, 15 mL 80% nitric acid, 18 mL glacial acetic acid, and 20 g mercuric chloride (Snyder, 1983 in Lowerre-Barbieri and Barbieri, 1993). The total fecundity was estimated using the following equation:

Where w = the number of eggs in the sub-sample, W = the total weight of the sub-sample, and OW

$$TF = \frac{w}{W} * OW$$

= the total weight of the preserved ovaries of the particular specimen. Relative fecundity was calculated as the number of eggs per gram of body weight. Using an Excel program, regression analyses were performed to establish the relationships between fecundity (F) and carapace width (CW).

Environmental parameters measured

The environmental parameters measured in this study were Dissolved oxygen (DO), Salinity, pH, Temperature, water depth, and current speed. Measure DO in water using a DO meter, Salinity using a hand refractometer, pH using a pH meter, Temperature using a thermometer, water depth using a Secchi disk, and water current using a current kite. The current kite is put into the water at the same time as activating the stopwatch and then letting the current carry it along a ropeof a predetermined length. When the rope is straight, turn it off, and then note how long it takes toreach the specified distance. All environmental data is taken every month in the morning around 7

- 8 am.

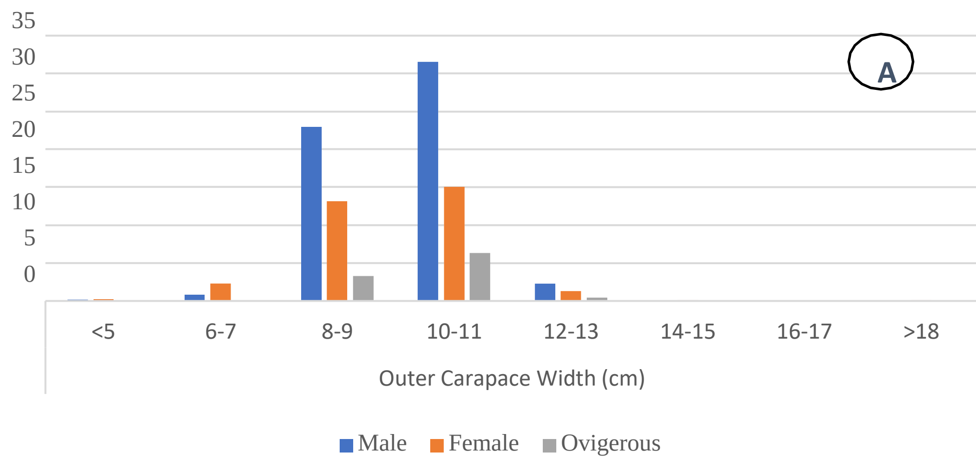
Data Analysis

Chi-square (X^2) statistical was performed to test the difference between ratios in both sexes. To determine the influence of physico-chemical parameters of water on the abundance of ovigerous females in each month, the Principal component analysis (PCA) by Xlstat software wasused (Yao et al., 2012).

RESULT

Crab Sizes

In this research, 3021 male crabs and 2218 females were collected. Among females, there were 1876 non-ovigerous and 342 ovigerous. The size of the crabs at the Watang Suppa village crab landing varies. Both males, females, and those who are ovigerous are dominated by crabs with a Carapace Width of 8-11 cm and weight 31-90 g (Figure 4).



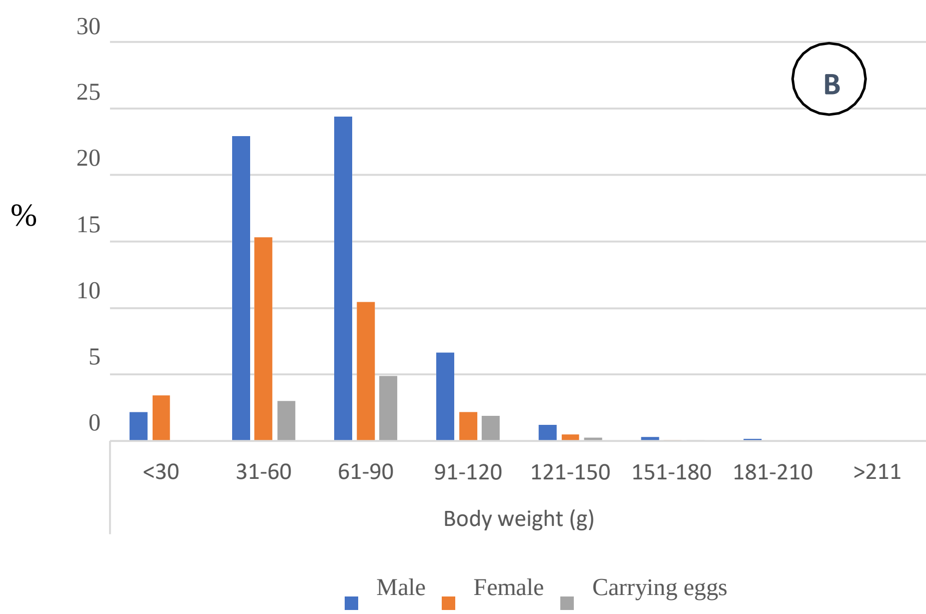


Figure 4. Size distribution of crabs landed from July 2023 to June 2024. A, based on Carapacewidth, and B, based on weight.

Sex Ratio

It was found that the average sex ratio varied every month, and there was a tendency for males to have more numbers than females. The condition of sexual imbalance occurred during observations from January to June 2024 (Figure 5).

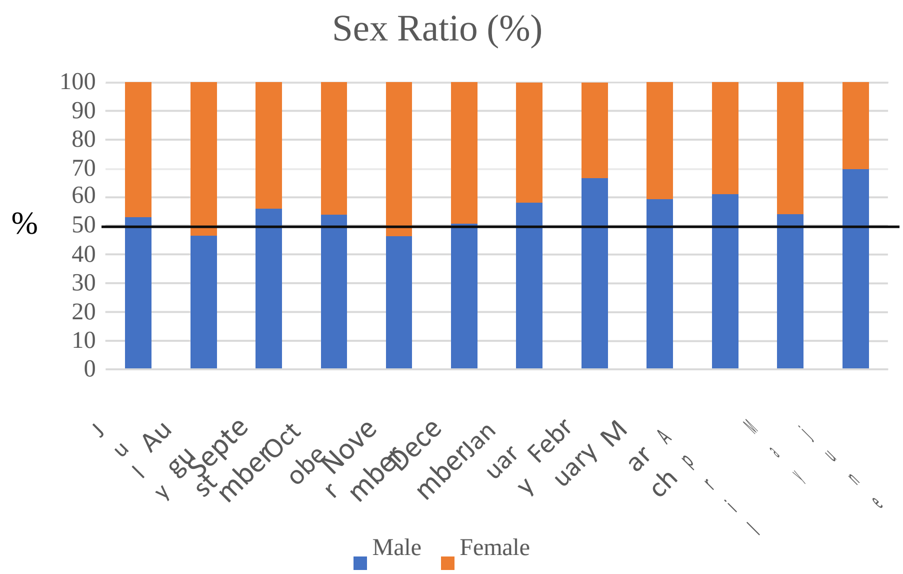

Figure 5. Sex ratio (%) of crabs landed by month (N=5278)

The overall male-female ratio from July 2023 to June 2024 is 1.3: 1, but based on the Chi-square test, the different ratio is non-significant ($p > 0.05$) or statistically, the ratio is comparable to 1:1. However, the Chi-square test results by month is significant ($p<0.05$), this means that thereare disproportionate ratios (not 1:1), namely in February, April, and June 2024, while the other sampling months have comparable ratios.

Spawning Season

Based on observations of ovigerous crabs that were caught and landed, it can be seen that crabs in Pare-Pare Bay spawn throughout the year. However, there are peaks in spawning in certain months, and the highest is in March (Figure 6).

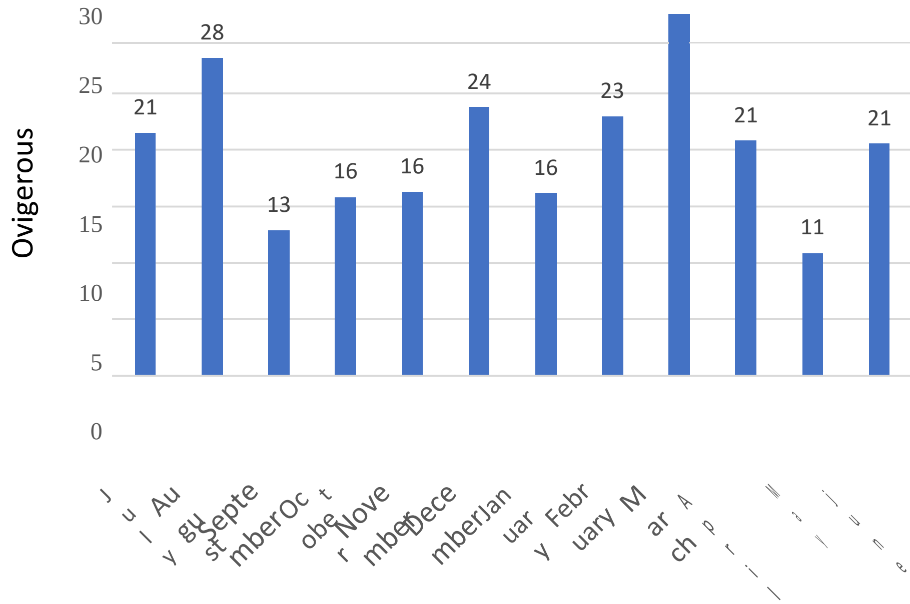

Figure 6. The monthly proportion (%) of ovigerous crabs landed in during July 2023 – June 2024

Fecundity

The fecundity of ovigerous females varied depending on the size and biomass of eggs. In this study, the fecundity of crab eggs found in Pare-Pare Bay ranges between 107,640 eggs for crabs with a carapace width of 8 cm to 1,308,400 for crabs larger than 12 cm. The relationship between carapace width and fecundity follows the equation, $y = 14218e^{0,3289x}$, with the coefficient of correlation R = 0,8230 (Figure 7).

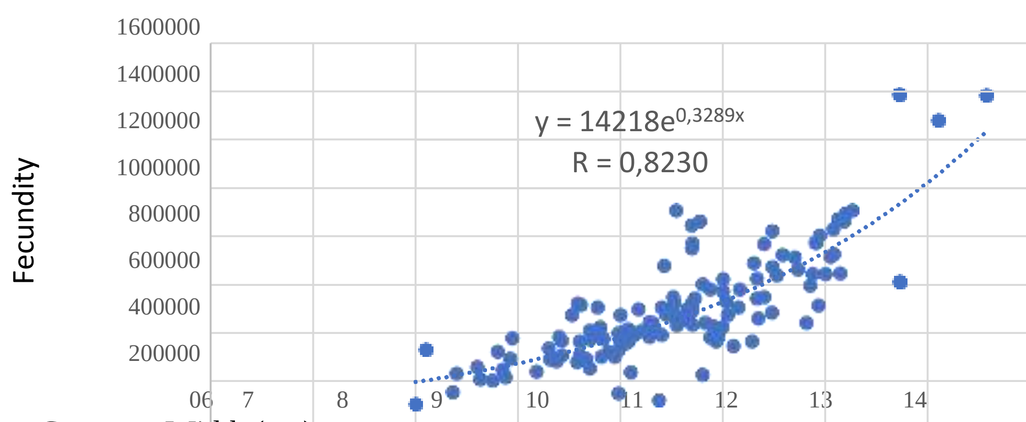

Figure 7. The relationship between carapace width and fecundity

Environmental Parameters

The environmental conditions in Pare-Pare Bay are very dynamic. Water salinity ranges between 30-38 ppt, Dissolved Oxygen 5,4 – 9,2 ppm, pH 7,8 – 8,29, Temperature between 28 – 35, Depth 1,5 – 11,67 m, and current about 0,059 – 0,330 m/s (Table 1).

Table 1. The average value of environmental parameters at each station in Pare-Pare Bay from July2023 to June 2024.

Years	Months	Salinity (ppt)	Dissolve Oxigen (ppm)	pH	Temperature (ºC)	Depth (m)	Current (m/sec)
2023	July	34,3 +/- 1,7	6,6+/- 0,5	7,9 +/- 0,1	28,9 +/- 2,7	5,4 +/- 4,1	0,244 +/- 0,086
	August	34,3 +/-1,6	6,4 +/- 0,4	7,9 +/- 0,1	28,5 +/- 2,6	5,8 +/- 4,2	0,201 +/- 0,070
	September	34,3 +/- 1,6	6,4 +/- 0,4	7,9 +/- 0,1	28,5 +/- 2,6	5,8 +/- 4,2	0,108 +/- 0,091
	October	32, 9 +/- 0,9	7,1 +/- 0,6	8,1 +/- 0,0	30,3 +/- 0,5	5,1 +/- 3,8	0,180 +/- 0,079
	November	33,0 +/- 0,4	6,4 +/- 0,7	8,2 +/- 0,0	31,8 +/- 0,6	4,8 +/- 1,7	
	December	30,8 +/- 1,0	6,2 +/- 0,9	8,1 +/- 0,7	31,3 +/- 1,0	6,0 +/- 4,2	
2024	January	30,5 +/- 0,4	6,3 +/- 0,8	8,2 +/- 0,0	32,8 +/- 1,4	4,8 +/- 3,1	0,079 +/- 0,010
	February	30,4 +/- 3,8	6,0 +/- 1,2	8,2 +/- 0,0	34,8 +/- 0,6	3,5 +/- 1,7	0,087 +/- 0,027
	March	32,2 +/- 1,7	7,2 +/- 0,8	8,3 +/- 0,0	33,5 +/- 0,3	4,8 +/- 3,1	0,063 +/- 0,009
	April	32,3 +/- 1,3	7,7 +/1,0	8,2 +/- 0,0	33,5 +/- 1,0	3,0 +/ 0,8	0,157 +/- 0,095
	May	32,6 +/- 2,1	7,4 +/- 0,1	8,4 +/- 0,1	32,6 +/- 0,5	4,8 +/- 2,1	0,127 +/- 0,024
	June	37,0 +/- 0,8	6,8 +/- 0,5	8,3 +/- 0,0	30,5 +/- 0,6	6,5 +/- 3,3	0,124 +/- 0,030

The results of PCA analysis showed that there was a relationship between spawning seasonand various environmental parameters. Three main factors had Eigenvalues greater than one (>1)with variability respectively 52.4, 21.62, and 16.99 % (Table 2). This shows that factor 1, factor 2, and factor 3 have the most significant influence on crab spawning in Pare-Pare Bay. Factors 1,2, and 3 can be seen from the essential values obtained in factors loading in the supplementary variable: pH and Temperature as factor 1, Salinity and Dissolve Oxygen as factor 2, and current asfactor 3 (Table 3).

Table 2. Eigenvalues of environmental factors in Pare-Pare Bay

	Factor1	Factor2	Factor3	Factor4	Factor5	Factor6
Eigenvalue	3.14	1.30	1.02	0.28	0.24	0.02
Variability (%)	52.40	21.62	16.99	4.64	3.99	0.35
Cumulative %	52.40	74.02	91.01	95.66	99.65	100.00

Table 3. Factor loading of supplementary variables

	Factor1	Factor2	Factor3	Factor4	Factor5	Factor6
Salinity	-0.677	0.520	-0.364	-0.364	0.082	0.017
Dissolve Oxygen	0.285	0.904	0.168	0.138	-0.231	0.023
pH	0.779	0.362	-0.425	0.122	0.249	-0.068
Temperature	0.979	-0.044	0.006	-0.068	0.151	0.111
Depth	-0.754	-0.055	-0.577	0.304	0.012	0.058
Current	-0.687	0.271	0.587	0.123	0.308	0.011
FCE	0.006	-0.100	0.032	-0.079	0.034	0.837

Note: FCE, Female Carrying eggs

Based on a biplot between Factor 1 (F1) and Factor 2 (F2), there is a cumulative variability of 52,40% and 74.02%. The Biplot image shows that four variables have high vector values, namely Temperature, DO, pH, and Salinity, but Temperature has the most significant influence onfemales carrying eggs (FCE) (Figure 8).

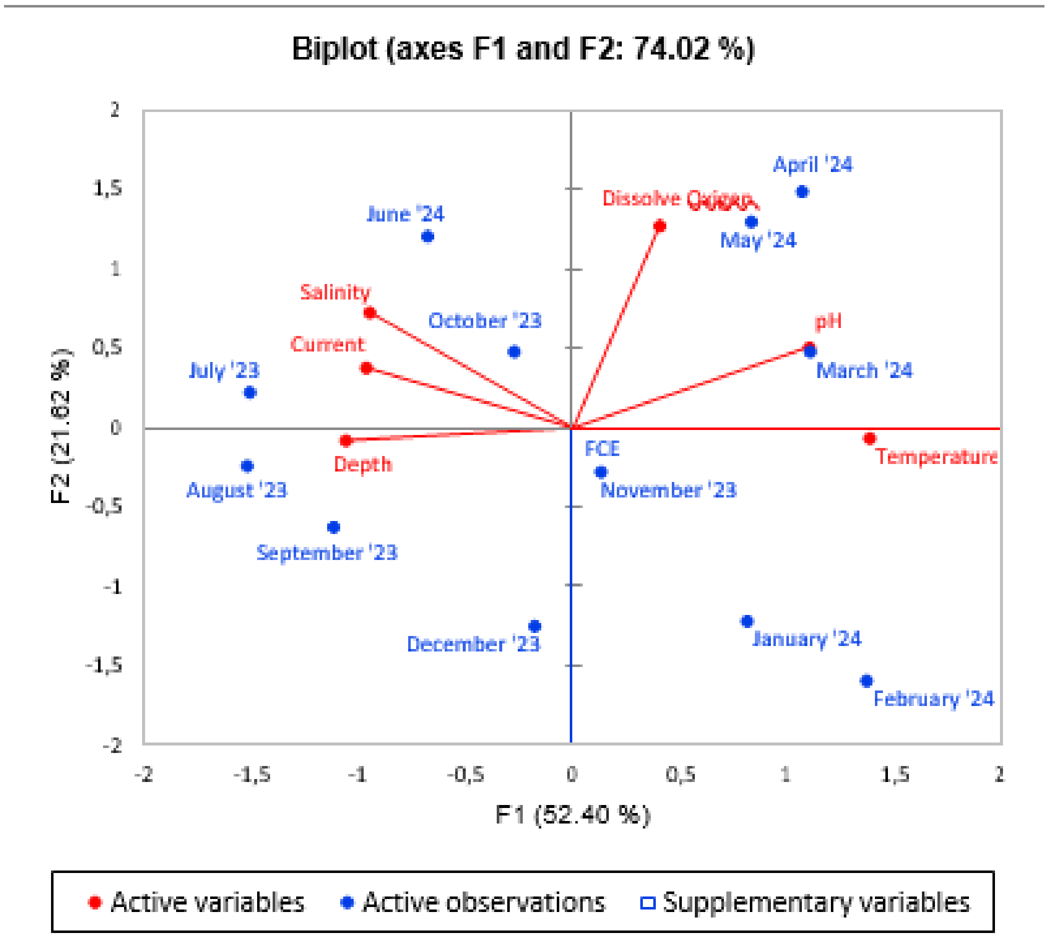

Figure 8. The relationship between physicochemical environmental parameters and the abundance of spawning crab crabs in the waters of Pare-Pare Bay using Principal Component Analysis (PCA)

DISCUSSION

Based on this study, 43% of crab landings are under-sized based on the Indonesian government regularly, and 10% of those crabs are ovigerous (Figure 4). The catching of small crabs is caused by using gill nets with a small mesh size. In this location, the fisherman uses a mesh size of 3 inches. Yu et al. (2024) said that Increased mesh size decreased the capture probability of undersized crabs. The optimal gill net size for crab fisheries has yet to be scientifically established, and the current use of gill nets with different mesh sizes often results inproblems with the bycatch and discarding of small-sized crabs. Small crabs caught cannot be returned to the sea because they are usually damaged when removed from the gill net. These injuries can cause death or delayed death after release into the ocean or affect somatic growth, negatively impacting fishery yields.

Catching undersized crabs, especially ovigerous females, is very harmful to sustainability.Even though the Indonesian government, through the Ministry of Maritime Affairs and Fisheries, has issued regulations limiting the catching of small-size crabs (<10 cm) and prohibiting catchingegg-laying crabs, it seems that these regulations cannot yet be enforced in the crab fishing area inPare-Pare Bay. Digamadulla and de Croos (2023) said in developing countries, the limited humanand financial resources for fisheries management often result in the lack of continuity of fisheriesstatistics, lack of standardized data collection methods, and under-representation of landing sites,which leads Small Scale Fisheries (SSF) to data-poor or data-limited (DLM) fisheries. Management of SSF in tropical developing nations is generally embarrassed by inadequate government funding, lack of political will, open access regimes, numerous scattered landing sites, and shortage of resource users' participation in decision-making.

Apart from the high level of exploitation and the use of non-selective fishing gear such asgill nets, the unique shape of the location is curved inward, making it difficult for crabs to migrateto other areas or not go far from the fishing location. As a result, catching tends to be more accessible, and the number of crabs caught is smaller. This is a big challenge for the crab fishery in Pare-Pare Bay. Fishing for ovigerous crabs is also the biggest threat to the sustainability of crabfisheries in Pare-Pare Bay.

This study found that the fecundity of female blue swimming crabs varied from 107.640 eggs to 1.308.400 eggs (Figure 7). Low fecundity is generally found in petite females about 8 mmin Outer Carapace Width. Kumar et al. (2000) found that a female blue swimming crab can produce 650.000 – 1.760.000 eggs. Haputhantri et al., 2022, also reported low fecundity of blue swimmingcrabs caught in Northern Coastal Waters in Sri Lanka. The lowest fecundity was reported to be around 123,482 eggs from the small size of crabs, and the highest fecundity was around 3,179,928eggs. The carapace width of the *P. pelagicus,* which was used for fecundity estimate, varied from113 mm to 177 mm. Here, whether the carapace width is outer or inner is not explained. Near Pare-Pare Bay, Nurdin, et al., 2022 reported that the fecundity of Blue Swimmer Crab from SpermondeIsland Waters was higher. It varied from 918.091 eggs to 2.095.253 eggs from 91 mm to 140 mmberried females. Kumar et al. (2003) stated that the fecundity of female crabs is size-dependent and increases up to a carapace width of 134 mm and decreases after that. Fecundity increased by 83,9% with an increase of carapace width from 105 mm to 125 mm, implying that a single large female could produce as many eggs as petite females.

Pare-Pare Bay is a semi-enclosed bay with a submarine canyon, a contour that juts inward. The water area of Pare-Pare Bay is 2,778 hectares, with a coastline of Pare-Pare Bay of 34 km, starting from the coastal region of Pare-Pare City, which borders Barru Regency to the coastal areaof Ujung Lero, Suppa District. The depth of seawater is in the range of 0.75 meters in the northernpart, and the middle of the bay has a depth of about 20 meters depending on the tide and water supply from rivers. Pare-Pare Bay receives water from several rivers: the Majannang River, Tae River, Maraulang River, Barangkasanda River, Cakeala River, Sabbamparu River, and Agalacangnge River.

The results of this research reveal that there is a close relationship between the physico-chemical dynamics of water and the spawning season. March is the peak of crab spawning in Pare-Pare Bay, where the water temperature increases and the Current is relatively slow (Table 1). Currie and Hooper (2006) stated that in tropical waters, female blue swimmer crabs are found to carry eggs throughout the year; however, there is seasonal variation in the number of egg-bearing females.

CONCLUSION

Based on the results of this research and the analysis that has been carried out, it can be concluded that the reproductive status of crabs in Pare-Pare Bay is unhealthy. The increasingly petite size of egg-laying females and fishing activities that ignore the capture of egg-laying female crabs seriously threaten the sustainability of the crab population and the crab business in Pare-Pare Bay. Strategic steps are needed to restore the health of crab stocks in Pare-Pare Bay. Monitoring the implementation of the Ministry of Maritime Affairs and Fisheries Regulation, limiting fishingat the peak of the spawning season, stock enhancement through restocking, and hatchery efforts for restocking and cultivation are necessary for the sustainability of this species as an essential business commodity. Apart from that, maintaining a healthy aquatic environment is no less criticalfor stock breeding.

ABSTRACT

Studies and research about Lepidoptera (butterfly) are numerous. This is due to the continuous nature of the research, which can never be fully completed. Butterflies are one of the most important groups in various habitats and environments, as well as one of the largest fauna groups. These organisms play a significant ecological role in these environments. The collection of biological material for this paper was conducted during the period of 2021-2022 at various stations in the Korça region, specifically: Drenova, Voskopoja, Dardha, Morava, Polena, and Voskop, among others. We collected biological material from May to September, which coincides with the flight period of these species. During the study, 290 individuals belonging to 25 species were collected. The family with the highest biodiversity of species is Nymphalidae, with 12 species, while the family with the fewest species is Papilionidae, with 2 species. The station with the highest diversity observed was Morava, with 15 species, and the station with the lowest diversity was Voskop, with 3 species.

Keywords: Lepidoptera, ecosystem, insect's, biodiversity, Korça.

INTRODUCTION

The history of Lepidoptera studies in Albania has seen significant developments in understanding and mapping the distribution of these species. The first publications on Lepidoptera in Albania were made in the early 20th century by foreign authors who explored the Albanian territories of that time. This was followed by contributions from both foreign and local authors (Beshkov, 1995; Beshkov and Misja, 1995; Beshkov et al., 1996). The first distribution maps of butterflies in Albania were published by Misja (Misja, 2005). In recent years, there has been a growing interest in studying Albanian Lepidoptera, resulting in new distribution maps for various species (Cuvelier et al., 2018; Verovnik et al., 2013). These studies represent comprehensive efforts across Albania, contributing to the discovery and documentation of numerous butterfly species. Currently, 205 butterfly species have been confirmed for Albania, but it is believed that there are potentially another 10-15 species yet to be identified (Cuvelier et al., 2022, Qirinxhi et al., 2024). A key role in conserving butterfly populations lies in protecting specific habitats that are particularly susceptible to serious human threats (Cuvelier et al., 2022).

In the region of Korçë, the biodiversity of insects of the order is important for the local ecosystem. The Korçë area covers an area of approximately 3711 km² and is geographically located in the southeast of the country. It presents a variety of habitats preferred by Lepidoptera species. The Korçë district has geographic coordinates between 40° 37′ and 40° 57′ northlatitude, and between 21° 4′ and 20° 19′ east longitude (Qiriazi, 1998). The Korçë area is rich in terms of flora and fauna. In this region, we find the presence of almost all plant categories. Despite its limited extension, at very low altitudes above sea level, the Mediterranean scrubland layer extends. More broadly, the layer of scrubland extends along the edge of the brown lands. Above the barren forest lands rise the layers of heaths and halos with dense forests. In the mountain meadowlands, we find shrubs and alpine meadows with a wide variety of grasses and flowers (Dida, 2003).

MATERIAL AND METHODS

Detailed descriptions of the habitat types where Lepidoptera specimens are collected are crucial. This could include data on vegetation composition, dominant plant species, and other relevant environmental factors (Kremen et al., 1993).

Biological material was collected during the years 2021-2022 in the Korçë region during the period from May to September, coinciding with the flight season of Lepidoptera and their life cycle.

a. Study Area

We collected biological material in the Korçë region, specifically at six main stations: Drenovë, Voskopojë, Dardhë, Moravë, Polenë, and Voskop (Figure 1). Drenovë (40.587624 N, 20.788493 E, according to Google Earth Version 7.1) is predominantly characterized by terrain consisting of a combination of fields, gardens, and small forests, creating a suitable habitat for a variety of organisms.

Figure 1. Collection of species photo by

The relief of Voskopojë (40.627708 N, 20.588973 E according to Google Earth Version 7.1) is characterized by hills and low mountains. It is rich in extensive forests and shrubs (Qiriazi, 1998).

The relief of Dardhë (40.517698 N, 20.824692 E according to Google Earth Version 7.1) combines open fields, hills, and dense forests. This area has an average elevation above sea level of about 800-900 meters (Qiriazi, 1998).

The relief of Moravë (40.6270 N, 20.8542 E according to Google Earth Version 7.1) is located east ofKorçë, 30 km long and 10 km wide. The dominant elevations are between 1000-1500 m. Its vegetation cover consists of beech, pine, maple, as well as grasslandplants (Qiriazi, 1998).

The relief of Polenë (41.8445 N, 23.1047 E according to Google Earth Version 7.1)includes a variety of landscapes, from wide and flat fields to low hills and high mountains (Qiriazi, 1998).

The relief of Voskop (40.6050 N, 20.6982 E according to Google Earth Version 7.1) is located at an average altitude of about 1,160 meters above sea level, making it a place with a cool mountain climate during summer and cold winters (Qiriazi, 1998).

b. Collection and Conservation of Material

The collection of material was conducted between 09:00 and 18:00 hours, varying depending on climate and seasons. To minimize damage to captured Lepidoptera specimens, we employed soft nets and careful handling during transfer and storage (Janzen, 2004). Field collection of Lepidoptera individuals was performed using aerial entomological nets made of muslin or nylon, with a diameter of 30 cm and a length of 70-80 cm, attached to a wooden or metal handle of 100 cm (Paparisto & Misja, 2005). The collected material was kept dry during the study period. Before starting the identification process, specimens were relaxed by placing them on an absorbent paper in a standard glass desiccator with a 40 cm diameter reservoir filled with water at 100°C, maintained under vacuum for 24 hours. After relaxation, specimens underwent mounting procedures. The mounted material was dried at room temperature (18- 23°C) for about 3-4 weeks (Paparisto & Misja, 2005). Proper drying techniques are crucial to prevent mold growth and ensure long-term preservation. This involved controlled drying environment with specific temperature and humidity setting (Robinson et al., 1970). During collection, it was crucial to keep detailed records including GPS coordinates, dates, habitat descriptions, photographs of habitats of collected or observed species in the field (Paparisto & Misja, 2005). Responsible collecting practices dictate taking only the minimum number ofspecimens necessary for identification and avoiding over collecting from a population (Gullan & Cranston, 2010). To create collections of Lepidoptera species, individuals were placed in entomological boxes measuring 70 by 60 cm and 10 cm deep, lined with a 1 cm thick layer of cork and covered with 24 sheets of 80 gsm white paper. Adequate spacing between individuals, ranging from 1-2 cm depending on size, was maintained. Specimens were arranged in boxes according to order/family and genus. Data were crucial for understanding new classifications, information about Lepidoptera, and data updates (Walker et al., 1999). Each specimen was accompanied by a label containing the scientific name, place of collection, collection date, and identifier's name. A second label provided supplementary information such as collecting plant or habitat, and a third label was used for identification, containing the specimen's name, identifier's name, and identification date (Walker et al., 1999). To ensure data accuracy, implementing a quality control process is essential. We double-checked specimen identification by a second taxonomist (Turner et al., 2001). Digital photographs were captured of each Lepidoptera specimen. This approach provides a permanent record for future reference and identification purposes (Eliot & Kawahara, 2005). We used Microsoft Excel to organize and explore basic patterns in species diversity, abundance, and potential habitat associations within the Korça region (Magurran, 2013). For long-term preservation, entomological boxes were stored in a cool, dry, and dark location to minimize degradation (Emmel, 1973). Collaboration with museums or research institutions can be beneficial for long-term specimen storage and accessibility (Gullan & Cranston, 2010). Collections were deposited in a museum to prevent issues related to habitat

destruction or minimization (Gullan & Cranston, 2005). Each entomological box containing biological material was labeled with a sequential number and the identifier's name (Paparisto & Misja, 2005).

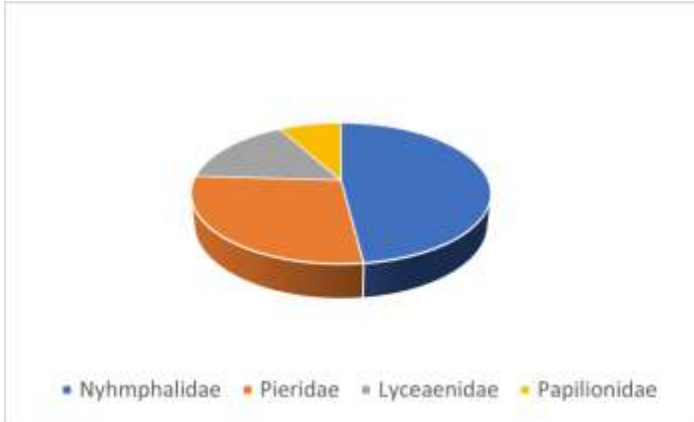
RESULTS AND DISCUSSIONS

This study determines the list of all Lepidoptera species in the Korçë region across their 6 collection stations (Annex 1). From the taxonomic determination of 290 collected individuals in reference to the Korçë area, 25 species were identified distributed across 4 families.

From the analysis of families based on the number of species (Table 1, Graph 1), it results that the family Nymphalidae exhibits the highest species diversity, with 12 species or 48%, followed by the family Pieridae with 7 species or 28%, Lycaenidae with 4 species or 16%, and Papilionidae with 2 species or 8%. Based on monitoring conducted over the past two years, we believe that natural habitats in the Korçë area are most suitable for species of the Nymphalidae family.

Table no. 1. Number of species per families

No.	Family	Specie No x family	Specie % x family
1.	Nyhmphalidae	12	48%
2.	Pieridae	7	28%
3.	Lyceaenidae	4	16%
4.	Papilionidae	2	8 %

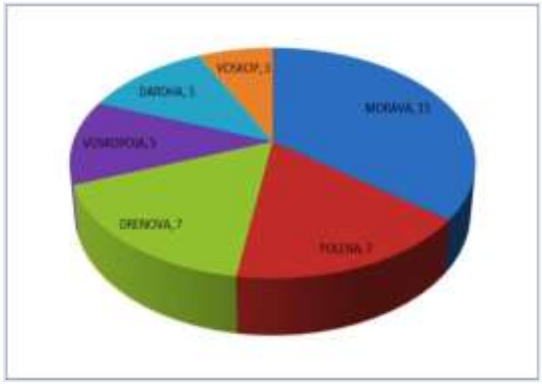


Graph no. 1: Percentage of species per family

From the analysis of stations based on the number of species (Table 2, Graph 2), it is evident that Moravë station has the highest diversity with 15 species, followed by Polenë and Drenovë stations with 7 species each. Next, Voskopojë and Dardhë have 5 species each, while Voskop station shows the lowest diversity with 3 species. Our observations indicate that this station has fewer species due to environmental pollution from industrial and anthropogenic activities such as land excavation, cultivation, and burning, which negatively impact the life cycle of butterflies (Choudhary & Chishty, 2020).

Tabela 2. Number of species by stations

Stations	**Number of species**
Morava	15
Polena	7
Drenova	7
Voskopoja	5
Dardha	5
Voskop	3



Graph no. 2: Number of species per station

The main factor influencing the population of Lepidoptera during our observation, and material collection, was human activity through unregulated construction and environmental pollution (Van Swaay et al., 2012). During our material collection over these two years, it was found that the highest number of butterflies occur in the months of July, August, and September due to humidity, precipitation, and flowering, which influence their numbers (Sharma & Sharma, 2013; Priya & Krishnaraj, 2017).

CONCLUSION

Our study identifies 25 species of Lepidoptera across 6 collection stations. The family Nymphalidae exhibits the highest biodiversity with 12 species, while the family with the lowest biodiversity is Papilionidae with only 3 species. Moravë area shows the highest species diversity with 15 Lepidoptera species, whereas Voskop area exhibits the lowest number of Lepidoptera species with only 3. During the study, it was found that the decline in species numbers is due to unfavorable ecological conditions, habitat disturbance, degradation, isolation, habitat loss, and climate change.

ACKNOWLEDGMENT

This study was conducted with the support of Fan S. Noli University of Korçë, as part of scientific research projects.

ABSTRACT

A study was conducted to document the butterfly diversity in the Korçë area from May to September 2022-2023 across four stations: Moravë, Drenovë, Ersekë, and Pirg in the Korçë region, located in the southeastern part of Albania. A total of 241 individuals from the families Nymphalidae, Pieridae, Papilionidae, Lycaenidae, and Hesperiidae were collected, identified into 36 species. Our analysis revealed that the family with the highest species biodiversity is Nymphalidae, while the family with the lowest biodiversity is Lycaenidae. The area with the highest diversity is Drenovë, and the area with the lowest diversity is Pirg.

Keywords: Lepidoptera, Nymphalidae, Pieridae, Papilionidae, Lycaenidae, Hesperiidae biodiversity, ecology, Albania.

INTRODUCTION

The Korçë region covers an area of approximately 3711 km² and is geographically located in the southeast of the country, featuring a variety of habitats favored by Lepidoptera species.The Korçë area has an elevation of 869 meters above sea level, with geographic coordinates of 40° 37′ to 40° 57′ northern latitude and 21° 4′ to 20° 19′ eastern longitude (Qiriazi, 1998). In the mountainous meadowlands, there are alpine pastures and meadows with a wide variety of grasses and flowers (Dida, 2003). Korçë is rich in forests of pine, fir, beech, hawthorn, willow, poplar, and oak. The forested areas host a wealth of endemic vegetation, including medicinal plants suchas wild mallow, savory, chamomile, black juniper, jujube, agrimony, eyebright, and many other species (Belba, 2013).

Nymphalidae represents a family with a significant number of well-known Europeanbutterflies. Among the most distinctive characteristics of this family are the conspicuous colors (Higgins & Riley, 1980). Pieridae is a family with a very large number of species. The species inthis family are generally easy to distinguish, with white or yellow wings and upper surfaces marked with black (Higgins & Riley, 1980). Papilionidae is another family with a considerable number of species that vary greatly in appearance and structural construction. A distinctive characteristic is the single anal vein on the hind wing and the slightly concave inner margin (Higgins & Riley, 1980). Lycaenidae are small or very small butterflies, with males typically having blue, copper, or brown coloring, while females are usually less vibrant. One of the distinguishing features of this family is the hind wings, which have small spots and streaks that are usually identical in both sexes (Higgins & Riley, 1980). Hesperiidae are small butterflies characterized by a broad head, widely separated antennae, and a strong thorax (Higgins and Riley, 1980). Butterflies are considered good indicators of the health of any terrestrial ecosystem and are therefore treated as an important group of organisms for studying environmental and evolutionary processes (Chen et al., 2016).

MATERIAL AND METHODS

The research was conducted during the years 2022-2023 in the Korçë region from May to September. Biological material was collected specifically at four main stations: Moravë, Drenovë, Ersekë, and Pirg (Figure 1). These areas present a great variety in terms of their terrain,climate, altitude above sea level, vegetation cover, and wildlife. Moravë Mountain Station(40.6167° N, 20.6833° E):** Located east of Korçë, it is 30 km long and 10 km wide. This mountain lies between the Devoll plain to the east, the Korçë plain to the west, the Cangonj gorge to the north, and the Kazani Pass to the south (Qiriazi, 1998). Its vegetation cover consists of fir, pine, beech, and herbaceous plants (Qiriazi, 1998). Drenovë Station (40.5667° N, 20.7333° E):** This is a rural area located 4.7 km from Korçë. Its vegetation cover consists of fir, beech, black pine, and herbaceous plants (Qiriazi, 1998). Ersekë Station (40.337° N, 20.678° E):** Located at an altitude of approximately 1,050 meters above sea level. The area is rich in water resources and has fertile soil that favors agriculture, making it well-known for its agricultural andlivestock products (Qiriazi, 1998). Pirg Station (40.600° N, 20.780° E):** Located near the city of Korçë, in the southeast of Albania. The altitude of the Pirg area is around 1,100 meters above sea level (Qiriazi, 1998).

To ensure data comparability across different studies, employing consistent butterfly collection methods is crucial (Van Swaay et al., 2006). This includes using nets of similar size and mesh, along with standardized capture times and weather conditions. Butterflies were captured using entomological nets made of canvas or nylon, with a diameter of 30 cm, a lengthof 70-80 cm, and a handle made of wood or metal, 100 cm long (Paparisto & Misja, 2005). Studies suggest that butterfly activity levels peak during warmer hours with moderate sunlight. Targeting these periods can optimize capture success (Dennis & Sparks, 1991). The capture process began in the morning around 09:00 and continued until 18:00 (Figure 1). Once captured, butterflies should be stored in paper envelopes to minimize damage before pinning (Gullan & Cranston, 2010). This helps to maintain the integrity of their delicate wings and bodies. The collected material was kept dry during the study period.

Before starting the identification process, the specimens are softened by placing them on absorbent paper in a standard glass desiccator with a diameter of 40 cm. The reservoir is filled with water at a temperature of 100°C, and the specimens are kept in a vacuum state for 24 hours. After softening, the specimens undergo the pinning procedure (Paparisto & Misja, 2005). To form the necessary collections for study, butterflies were carefully pinned to avoid damaging their wings, antennae, or legs. For this procedure, entomological pins, 36-38 cm long, were used (Paparisto & Misja, 2005). The pins were inserted vertically into the butterfly's back, between the forelegs and midlegs. For spreading, blocks made of cork material were used (Paparisto &Misja, 2005).

Figure 1. Collection of species photo by @Xh.Qirinxhi

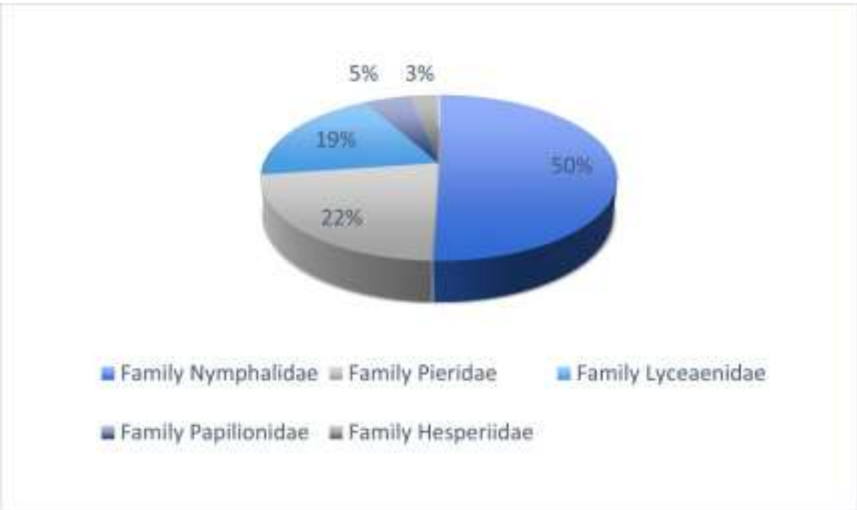
Following pinning, butterflies require a controlled drying period at room temperature to prevent mold growth and ensure long-term specimen preservation (Emmel, 1973). The pinned material is dried at room temperature (18-23°C) for about 3-4 weeks. The dried butterflies are labeled with two tags. One tag indicates the collection location and capture date, while the other displays the scientific name of the species. The butterflies, equipped with the appropriate labels, are placed in collection boxes, typically measuring 40 x 50 cm, which must be sealed hermetically (Paparisto & Misja, 2005). Creating digital images of pinned specimens can be a valuable archiving technique, allowing for wider accessibility of data and facilitating future research (Gullan & Cranston, 2005).

RESULT AND DISCUSSION

This study identifies a list of 241 individuals in the Korçë region, consisting of 36 species distributed across 5 families. From the analysis of families based on the number of species (Table 1, Graph 1), it is evident that the family Nymphalidae exhibits the highest species diversity, with 18 species or 50%, followed by the family Pieridae with 8 species or 22%, Lycaenidae with 7 species or 19%, Papilionidae with 2 species or 5%, and Hesperiidae with only1 species or 3%.

Table no 1. Number of species per family

No.	Family	Specie No x family	Species % x family
1.	Nymphalidae	18	50%
2.	Pieridae	8	22%
3.	Lyceaenidae	7	19%
4.	Papilionidae	2	5%
5.	Hesperiidae	1	3%



Graph no 1: Percentage of species per family

From the analysis of stations based on the number of species (Table 2, Graph 2), it appears that the station in Drenovës exhibits the highest diversity with 24 species. This is due to the variety of natural habitats and favorable climate conditions that create ideal environments for the survival and proliferation of different species. Following Drenovës, Moravës station has 19 species, and Erseka station has 9 species. The lowest diversity is observed at Pirg station with 5 species, likely due to habitat destruction from human interventions such as construction, intensive agriculture, and deforestation (Sharma & Sharma, 2013; Priya & Krishnaraj, 2017).

Table no. 2: Number of species per station

Stations	No. of species
Drenovo	24

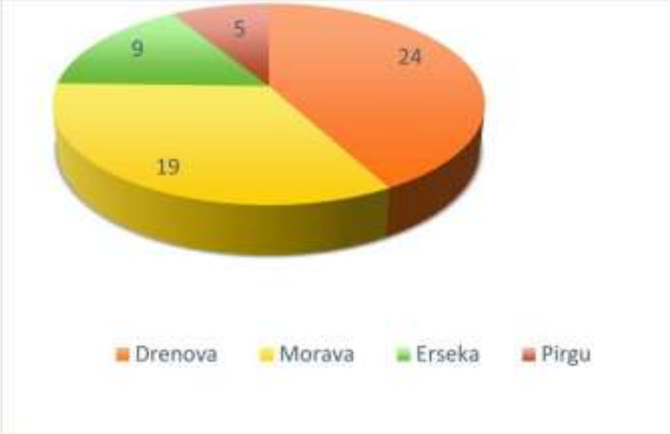
Graph no.2: Number of species per station



CONCLUSION

Our study identifies 36 species of Lepidoptera collected from 4 sampling stations. The family Nymphalidae exhibits the highest biodiversity with 18 species, constituting 50% of thetotal species studied, while the family Hesperiidae shows the lowest biodiversity with only 1 species or 3%.

The Drenovë area shows the highest species diversity with 24 Lepidoptera species, whereas the Pirg area exhibits the lowest with only 5 species. During the study, it was observedthat the decline in species numbers is due to unfavorable ecological conditions, habitat disturbance, degradation, isolation, habitat loss, and climate change.

ACKNOWLEDGMENT

This study was conducted with the support of Fan S. Noli University of Korçë, as part of acall for scientific research projects.

ABSTRACT

The aim of the study is to establish the species composition of the harmful and beneficial entomofauna, the dominant harmful species and these entomophages, as well as the species diversity indices. The observations were carried out in the period 2021-2023 in an experimentalfield in the land of Tsar Samuil village. To establish the species composition of the entomofauna, the population density of the dominant harmful species and their entomophages,the classic method - mowing with an entomological bag - was used.

Surveys were carried out during the following periods: outside the sunflower growing season; from the budding phase to the flowering phase of the sunflower and from the floweringphase to the ripening phase of the sunflower.

The study of the entomofauna in the sunflower crop will support the development of goodplant protection practice.

Protecting the sunflower from enemies is a good prerequisite for its cultivation.

Monitoring of the entomofauna showed differences in the quantitative and qualitative composition of harmful and beneficial insects during the three years of the study.

Keywords: sunflower, entomofauna, plant protection practice

INTRODUCTION

The sunflower (*Helianthus annus L.*) is the main and most widespread oilseed crop for Bulgaria and one of the most suitable predecessors for cereal crops.

An important role in realizing the potential of a given variety or hybrid is played by boththe genetic characteristics and the region with the specific soil and climatic conditions in whichsunflower is grown. (Tălmaciu (2018), Lanjar (2014). With the coming changes in the climateand especially with the looming warming, the sunflower is becoming an increasingly preferredcrop, especially from an economic point of view. The inclusion of new varieties and hybrids ofsunflower in the crop rotation allows the diversification of the culture, as well as the reductionof some economic risks.

Sunflower is a crop where short-term drought has no significant economic impact. Of greater importance are the precipitation amounts during separate periods of the vegetation (Altieri M.A. (1999), Jadhav (2011). Regardless of the fact that sunflower is a crop with good ecological plasticity, the choice of a hybrid should be made specifically for agro-ecological regions in order to realize its productive potential to the maximum in the relevant soil and climate conditions.

In Bulgaria, there are more than 70 species of sunflower enemies of economic importance-soil, trunk beetles, plant bugs, crickets and others. In some areas, sunflower cutting reduces yield by about 50-60%. Young plants are attacked by the larvae of the meadow butterfly andby swarming grasshopper species in individual years.

In recent years, as a result of the created extreme conditions, the regulating role of beneficial entomofauna has gained particular importance.

MATERIAL AND METHOD

We carried out the study in an experimental field in the land of the village of Tsar Samuil, commune. Tutrakan during the period 2021 - 2023. We established the species composition of the enemies through standard entomological methods - visual observations, soil excavations, route inspections, mowing with an entomological bag and laboratory determinations. We carried out the surveys during the periods: outside the sunflower growing season; from the budding phase to the flowering phase of the sunflower and from the flowering phase to the ripening phase of the sunflower.

The analysis of these factors during the three years of study (2021 - 2023) shows that theydiffer in terms of precipitation, while the average monthly temperatures are close to those of the multi-year period and fully satisfy the heat requirements of sunflower from sowing to maturation (Figs. 1 and 2).

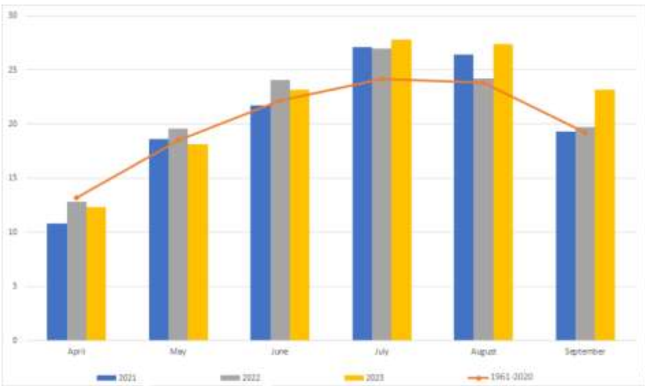

Figure 1. Average monthly air temperature, °C (2021-2023), A multi-year period (1961-2020)

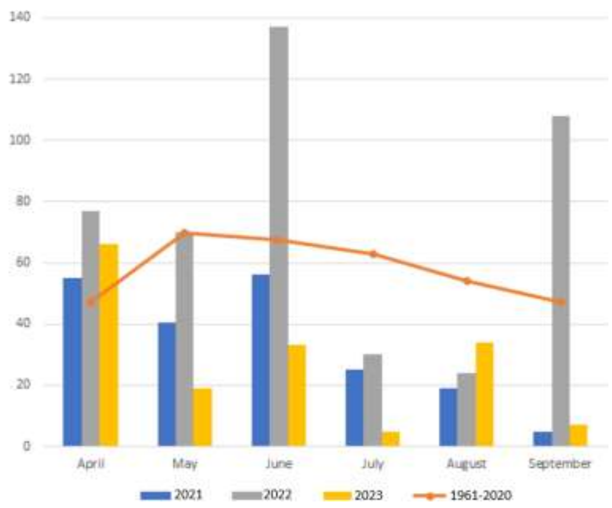

Figure 2. Rainfall, mm (2021-2023), A multi-year period (1961-2020), mm

RESULTS AND DISCUSSION

In the areas intended for sunflower sowing, during soil excavations, the enemies indicatedin table 1 were found.

Table 1: Lists of harmful insects of the sunflower, established in the experimental section

	Scientific name	Order: Family

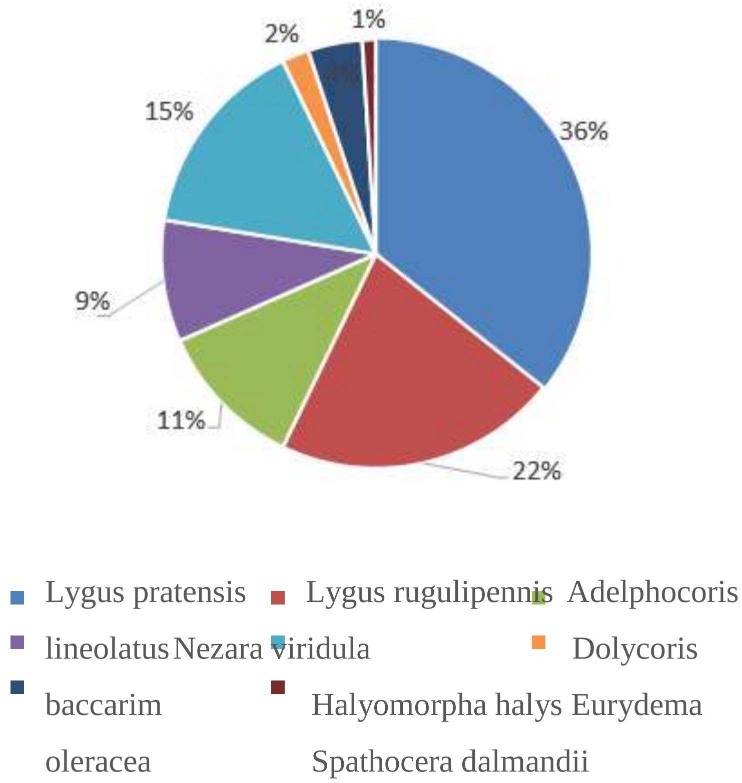

Figure 1. Percentage ratio of bed bug species in a sunflower crop

The collections were made at ten days, starting from sowing to plants harvesting. The collected samples were analyzed in the laboratory at the binocular magnifying glass, determined and separated by species. For each species it was calculated the average density/sqm on the plant entire vegetation period. The results obtained from the collection and determination of thebiological material were calculated and interpreted using some ecological parameters such as: abundance (A%), dominance (D%), constancy (C%) and the index of ecological significance (W%), which highlights the characteristics of the recorded biocenosis. The abundance of species (A%) represents the number of individuals of a species from the catch in a certain place at a certain time. The dominance (D%) shows the participation percentage of each species in the total catches. It is calculated using the formula:

$$D = \frac{AX100}{N}$$

A - species abundance; N - the total number of individuals of all species.

Depending on the obtained values, the species fall within the following classes ofdominance:

D_1-subrecedent species

P<1.0%;D_2-recedent species

P=1.1-2.0%;

D_3-subdominant species P=2.1-

5.0%;D_4 -dominant species P=5.1-

10.0%; D_5 -eudominant species P

>10.1%.

The constancy (C%) represents the species participation proportion in the realization ofthe biocenosis structure. It is calculated using the formula:

$$C = \frac{npA}{Np} X\ 100$$

C - species constancy;

npA - number of samples in which the A species

occurs;Np - total number of collected samples.

Depending on the constancy value, the species are classified as

follows:C_1 - accidental species (1-25%);

C_2 - accessories species (25.1-

50%);C_3 - constant species

(50.1-75%); C_4 - euconstant

species (75.1-100%)

Regardless of the presence of another sunflower crop at a distance of about 1 km from the experimental plot, at no point in the phenological development of the crop did the established enemy species exceed the threshold of economic harm.

The species composition of beneficial insects - predators and parasitoids - is indicated intable 2. The low density of aphids is the probable reason for the establishment of only two species of ladybirds - aphidophages: 7-spot ladybird and variable ladybird. The 22-spotted ladybird, which feeds on mealybug mycelium, was found in the crop only in isolated reports and most likely feeds on mealybug mycelium on some weed species. The predatory bedbug

Nabis sp. was also found on sunflower plants, but its victims (thrips, aphids and other small insects) are mainly on weedy plants. The most abundant predators in May-June were the molluscs Cantharis fusca and Rhagonycha fulva, which have a mixed diet. Adults of the syrphidfly Eopeodes corollae are attracted to flowering plants on whose nectar they feed. No syrphid fly larvae were found in the sparse aphid colonies.

Table 2: Lists of useful insects of the sunflower, established in the experimental section

	Scientific name	Order: Family
1	*Psyllobora vigintiduopunctata* (L.)	Coleoptera: Coccinellidae
2	*Coccinella septempunctata* L.	Coleoptera: Coccinellidae
3	*Hippodamia variegate* Goeze	Coleoptera: Coccinellidae
4	*Cantharis fusca* L.	Coleoptera: Cantharidae
5	*Rhagonycha fulva* (Scopoli)	Coleoptera: Cantharidae
6	*Nabis* sp.	Hemiptera: Nabidae
7	*Eopeodes corollae* Fabricius	Diptera; Syrphidae

As already mentioned, the harmful insect species found on the sunflower were in very low density (Fig. 3).

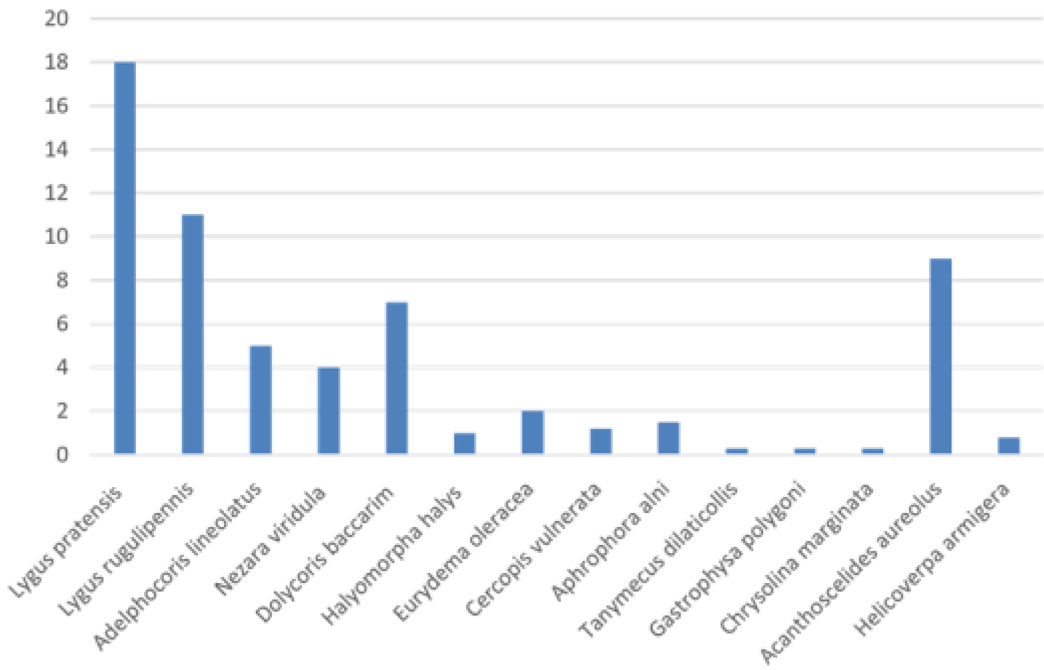

Fig. 3. Average population density of sunflower enemies

In none of the readings from the beginning of the growing season to harvest of the sunflower, there was no enemy that exceeded the defined thresholds of economic harm and necessitated the implementation of a treatment or another plant protection measure.

CONCLUSIONS

Successful pest management depends on the correct identification of the pest, the study of its biology, establishing the population density and comparing it with the economic thresholdof harm, as well as choosing appropriate control methods. The use of integrated management ensures that control decisions will be cost-effective and achieved with minimal negative impacton the environment, as little impact on non-target organisms as possible and with a reduced likelihood of secondary pests. Integrated pest management combines resistant varieties, biological control, and the application of insecticides only when pest populations have reachedeconomically harmful levels. Low-cost components of pest management include crop rotation,modified planting dates, host plant resistance, and conservation of natural enemies (predators, parasitoids, and pathogens).

It is necessary to note that regardless of the many species of entomophages inhabiting sunflower crops and feeding on harmful insects, the regulation of their density by means of natural populations of entomophages is not possible for all enemies, especially for those that are polyphagous. Many occasional insect pests of sunflower can cause high levels of damage, but they are not consistent enough to justify the long-term resources needed to develop integrated management plans. In these cases, efforts are made to use the resistance of the host plants as the main tool to limit their damage. However, in a given area two or three species are considered dangerous pests and the cumulative costs and risks of dealing with them is anincentive to develop more detailed control plans.

ABSTRACT

The experiment was conducted through the period 2021-2023 in the Northeast region of Bulgaria. The test was conducted in the block method in four repetitions with the size of the experimental plot - 20 m^2. The tested corn hybrids are mid-early (FAO 300-399).

The aim of the study was to establish the elements of productivity and the yield of mid-early maize hybrids, cultivated for grain under non-irrigation in NorthEast Bulgaria. All the stages of the established technology for maize growing were followed. The grain yield is determined with standard grain moisture of 13%. The indices; length of the cob (cm), number of the row per cob, number of the grains per row, mass of the cob, mass of the grains per cob (g) thousandkernel weight (g), test weight (kg), and grain yield (kg/da) were determined. The analysis of the results showed that the production possibility of hybrids maize is determined to a great degree by the meteorological conditions of the year mostly by the precipitation quantity.

Keywords: maize, hybrids, elements of productivity, yield of grain

INTRODUCTION

Maize (*Zea mays L.*) is one of the most important cereal crops grown in the world and plays a key role in the agriculture and economy of Bulgaria. In the north-eastern part of the country, where the climatic conditions are characteristic with their specifics, growing maize isa challenge, especially in non-irrigated conditions. Changes in climatic conditions and the increasing frequency of drought periods require farmers to select suitable hybrids that guaranteestable yields and high grain quality with minimal irrigation resources.

In this context, the testing of early maize hybrids for grain is essential. Early hybrids offeran optimal balance between growing season and yield and free up areas for tillage in time for the following economic year. This makes them suitable for the conditions in North-Eastern Bulgaria, where significant variations in temperatures and rainfall are observed.

The creation and implementation in practice of new corn hybrids, as well as their cultivation under different agro-ecological conditions, are the subject of many scientific studies.(Valchinkov et al., 2003, 2005; Genova, 2005; Genova, 2005; Yordanov, 2006; Angelov, 1995).

The elements of high yield and quality in agricultural crops are a complex of interrelated factors such as: correct crop rotations, quality soil treatment, selection of suitable varieties or hybrids for the specific agro-ecological region, as well as the use of high-quality seeds (Valkova, 2007; Kirchev, 2001; Angelova, 2022, Mohamed et al. 2008).

The selection of the most suitable hybrids for each region in accordance with the conditions and cultivation technology leads to obtaining high results and ensuring stable yields.

The purpose of the study is to determine the elements of productivity and grain yield of early hybrids of corn grown under non-irrigated conditions in North-Eastern Bulgaria.

MATERIAL AND METHOD

The trial covers the period 2021-2023, and it includes key parameters such as cob length,number of rows in the cob, number of grains in a row, number of grains in a cob, mass of grainsin a cob and grain yield. Through a comparative analysis of these indicators, the most suitable hybrids for cultivation in the area are established, which will contribute to a more efficient useof available resources and an increase in yields.

This research will not only provide important data for agronomists and farmers, but will also help to optimize breeding work and improve agricultural practices in the area. The ultimategoal is to increase the resistance of corn under non-irrigated conditions and to increase the competitiveness of Bulgarian agriculture on the international market.

The experimental work was carried out during the period 2021-2023, on a soil type of slightly leached chernozem in the area of the land of the village of Tsar Samuil, Silistra district

- North-Eastern region.

The experiment was set up according to the block method in four repetitions with the sizeof the experimental plot 20 m^2 after predecessor wheat. Maize is grown according to traditionaltechnology.

For the purposes of the study, 5 early hybrids of corn from the AQUAmax® line, of the company "Corteva agriscience" - P9363 (FAO 340), P9300 (FAO 360), P9241 (FAO 370), P9610 (FAO 370), P9415 (FAO 380) were included), grown according to generally accepted technology under non-irrigated conditions for the area. P9300 was used as the standard, being the most widely grown in the area.

Sowing was carried out with previously disinfected seeds (Lumipoza 625 FS), in the period 10 - 12 April at a seeding density of 7200 plants/da. Pre-sowing mineral fertilization with NPK 16/8/10 of the Yara Milla TRIPLE company was applied at a rate of 20 kg/day.

To fight against annual and perennial wheat and broadleaf weeds, in phase BBCH 12-19(dissolution of the second leaf - ninth leaf), the herbicide Principal Gold - 48 g/da (combinationof a.v. Nicosulfuron, Rimsulfuron, Dicamba) was used and adjuvant 0.1% Vivolt 90.

The indicators were reported: cob length (cm), number of rows in a cob, number of grainsin a row, number of grains in a cob, mass of grains in a cob (g) and grain yield (kg/da).

The data on the obtained yields were processed mathematically by the method of varianceanalysis, and the differences between the variants were established by Duncan's multiple rank test SPSS for Windows, v 9.00; Duncan's Multiple Range Test.

RESULTS AND DISCUSSION

The main climatic factors determining the growth, development and productivity of corn are temperatures and precipitation, their combination and distribution during the growing season.

The analysis of these factors during the three years of study (2021 - 2023) shows that theydiffer in terms of precipitation, while the average monthly temperatures are close to those of the multi-year period and fully satisfy the heat requirements of maize from sowing to maturation(Figs. 1 and 2). Of the three years of the studied period, 2022 was the most favorable in terms of moisture, during which the highest yields were recorded.

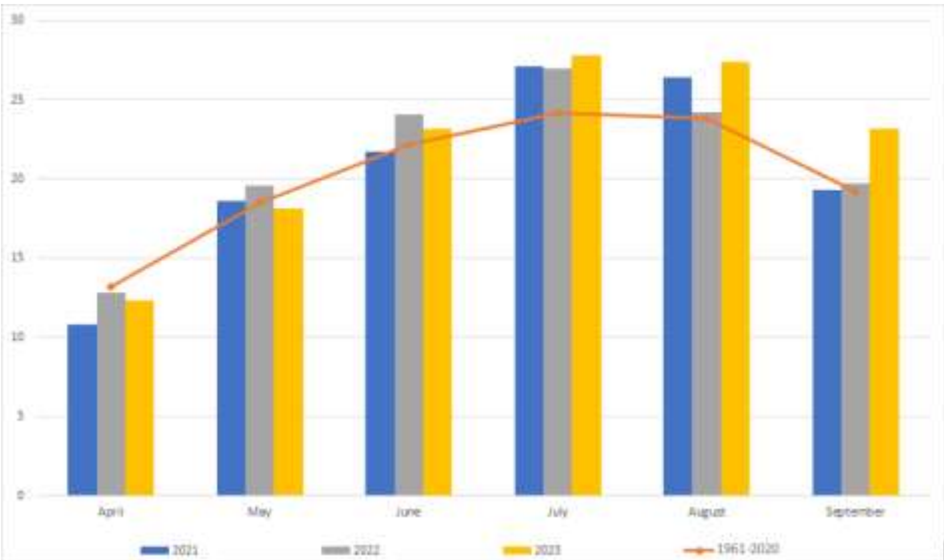

Figure 1. Average monthly air temperature, °C (2021-2023), A multi-year period (1961-2020)

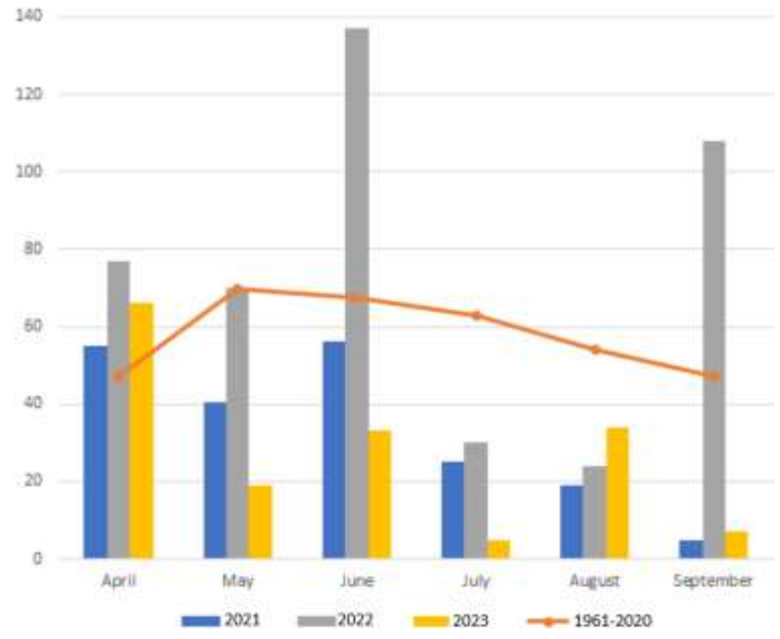

Figure 2. Rainfall, mm (2021-2023), A multi-year period (1961-2020), mm

The established data on the structural elements of yield are indicated in Table 1. They show that these indicators change under the influence of weather conditions during the years ofstudy. The highest values of the main structural elements of production were reported in the economic year 2022, followed by those obtained in 2021, and the lowest in 2023.

Table 1. Structural elements of the yield

In 2022, the length of the cob varies from 20,7 cm in hybrid P 9241 to 22,9 cm in P 9610,while in 2023 the values of this indicator are significantly lower and are in the range of 19,4 cmin hybrid P 9241 up to 21,2 cm for the standard, and in 2021 from 20,5 to 22,9 cm. On averagefor the research period, regarding the feature cob length, the results show that the highest valueswere recorded for the standard P 9300 – 22,3 cm and hybrid P 9610 – 22,0 cm, and the lowestin hybrid P 9241 – 20,3 cm.

The number of rows in the cob is a genetically determined trait (Genov, 2005, Angelova2022). The reported values from 15,4 to 17,9 pcs. in 2021, from 15,2 pcs. up to 18 pcs. in 2022and from 14,6 pcs. up to 18 pcs. in 2023 show that this parameter, compared to cob length, is less affected by conditions during the years of study. On average, for the study period, higher values of the indicator number of rows in a cob were reported for hybrids P 9610 and P 9300. The hybrid P 9610 has 18 rows in a cob and exceeds the standard by 2,9 %. All other hybrids have lower values.

Regarding the indicator number of grains in a row, the highest values were reported in 2021, from 38,5 for hybrid P 9415 to 40,5 for the standard. The remaining two years are characterized by lower values of 37,0 pcs. to 38.5 in 2022 and from 38.0 to 39,0 pcs. in 2023. On average for the research period, the highest values were reported for hybrid P 9300 – 39,5 pcs., and the lowest 38,2 pcs. at P 9241 and P 9415.

The indicator of the number of grains in a cob in the tested hybrids changed over the yearsand varied from 479,0 in P 9241 to 589,2 pcs. at P 9610, from 468,7 to 574,3 pcs. in 2022, andfrom 467,2 to 577,5 pcs. in 2023. During the three years of the study, the standard hybrid P9300and hybrid P9610 have reported higher values compared to the other hybrids. On average for the period, hybrid P9610 exceeded the standard by 1,6%.

Table 2 Grain yield, kg/da

	Grain yield, kg/ da – year						Average	
Hybrids	2021		2022		2023		kg/da	%
	kg/da	%	kg/da	%	kg/da	%		
P9300 st.	**691**	**100**	**793**	**100**	**631**	**100**	**705.0**	**100**
P9363	707***	102.00	778	98.10	634	100.4	706.33	100.2
P9241	599	86.66	765	96.46	658***	104.2	674.0	95.60
P9610	613	88.87	822***	103.60	597	94.61	677.33	96.07
P9415	603	87.26	889***	112.10	678***	107.4	723.33	102.6
GD 5 %	6,1		5,5		5,7		91,8	
GD 1 %	8,6		7,7		8,0		133,5	
GD 0.1 %	12,1		10,9		11,3		200,6	

The mass of grains in the cob is one of the most important structural elements of yield and determines to some extent the productivity of maize hybrids (Kirchev, 2016). The values of this indicator for all studied hybrids were the highest in 2022 and ranged from 156,5 g for hybrid P 9241 to 216,0 g for P 9610, while in 2021 they ranged from 156,3 g to

217,3 g and from 141,3 years to 194,5 years in 2023. On average for the period, the highest values were reported for hybrid P 9610 – 209,3 years and exceed the standard by 16,9%.

The obtained results for grain yield from the tested corn hybrids show that both the elements of productivity and the values of this indicator change depending on the weather conditions during the years of the experiment (table 2).

In 2022, the vegetation rains that fell, their good distribution and in combination with average monthly temperatures favor obtaining higher grain yields compared to 2021 and 2023.In 2022, hybrid P 9415 realized the highest yield of 889 kg/da and exceeds the standard by 12,1%, followed by hybrid P 9610 – 3,4%, and the lowest was recorded at P 9241 – 765,0 kg/daor by 3,5% lower than the standard.

In 2021, yields for individual hybrids ranged from 599.0 kg/da for P 9241 to 707.0 kg/dafor P 9363, which exceeded the standard by 2.0%. The difference is proven at P 0,1%. Lower yields were recorded for the remaining hybrids.

The uneven distribution of precipitation during the 2023 growing season, and especially its shortage during the grading and dehulling of corn, are the reason for reported lower grain yields. In the tested hybrids, they vary from 597,0 to 678,0 kg/da. During the year, the highestyields were reported by the hybrids P 9241 658,0 kg/da and P 9415 (678,0 kg/da), with the differences compared to the standard being proven at P 0,1%.

On average for the research period 2021 - 2023, of the tested hybrids, the highest yieldinghybrid was P 9415 – 723,33 kg/da. It exceeds the standard by 2,6%, and the lowest yielding hybrid is P 9241 (674,00 kg/da).

The dispersion analysis of grain yield shows a strong statistically proven influence of bothyears (72%) and hybrids (46%) on the variation of the values of these indicators (table 3). Theweakest influence (18%) was shown by the interaction between the two factors (hybrid x year).

Table 3 Analysis of variance for grain yield for the period 2021-2023

Source of Variation	Sum of Square	DF	Mean Square	Sig of F	Degree of influence, %, η^2

CONCLUSIONS

The productivity of the tested early hybrids of corn in the Northeast region is determinedto a large extent by the weather conditions of the year and especially by the amount and distribution of precipitation during the growing season.

The hybrid P 9300 - standard and the hybrid P 9610 stand out with the highest values of the structural elements, and the hybrid P 9241 with the lowest.

On average for the research period (2021-2023), a higher grain yield was realized by thehybrid P 9415 – 723,33 kg/da, followed by the hybrid P 9363 – 706,33 kg/da, standard P 9300

– 705,00 kg /da, and the lowest P 9241 – 674,00 kg/da.

From the studied early hybrids of corn for the North-Eastern region, the cultivation of hybrid P9415 is recommended, as it has a higher yield in years with different climatic conditions.

ABSTRACT

The study was conducted at two locations in South Sulawesi, Barru and Bone Regencies. Balipolled cattle from local horned Bali cattle, which are starting to develop in South Sulawesi. The study aims to evaluate the diversity and distance genetics levels in the two development areas. Sample Cow blood has been taken, which is Bali polled / hornless from the results of mating between horned Bali cattle female and Bali polled bull; Bali cattle have horns from results mating between horned Bali cattle female with horned Bali cattle bull, and horned Balicattle with Bali Polled /hornless bull. The technique is to take blood through the jugular vein using a tube venojet. Cattle blood samples from two areas have their DNA extracted, then amplification with the PCR-RAPD method uses six primers. Then, PCR results are visualizedwith electrophoresis. Diversity genetic in and between populations and phylogenetic trees is also analyzed. Diversity and differences genetically were analyzed statistically based on the *Band Sharing Frequency* (BSF) mark. Correlation of genetics between Bali *polled* cattle withBali cattle horns using The Program Software Phylogenetics Trees (MEGA 5.0). The Mark ofBSF for Bali polled cattle between individuals in the population of the district of Bone and Barru ranged from 0.8008 to 0.9025 and 0.840 to 0.9043, respectively. Meanwhile, for hornedBali cattle, BSF values ranged between 0.5745 - 0.7917 and 0.7929 - 0.9721. The genetic distance between Bali cattle populations was 5% - 20% in both livestock development areas. The results showed that the genetic diversity of Bali polled cattle was low compared to Bali cattle with horns. The genetic relationship between Bali cattle and both development areas is still near.

Keywords: Bali polled cattle, genetic diversity, genetic distance, PCR-RAPD, smallholderfarm

INTRODUCTION

Bali cattle have a strategic role in advancing the economy, opening fieldwork, and fulfilling animal protein requirements for Indonesian society. The development of Bali cattle is centered in traditional communities with low levels of livestock ownership; around 98% of the Bali cattle population is distributed among traditional breeders with extensive rearing systems. One of the variants of Bali cattle that is starting to be developed in South Sulawesi is the Bali Polled cattle. This cattle does not have horns so that it is easier to maintain and does not cause risk to other cattle. in 2016, Bali polled cattle began to be developed at the Maiwa Breeding Center, Hasanuddin University in the Enrekang Regency. The Developing Program of the polled Bali Cattle was a collaboration with the Government of the Directorate General Innovation Strengthening, Ministry of Research, Technology and Higher Education. The research and development is a priority program development in Animal husbandry. In 2020, Bali polled cattle were made superior local beef cattle that must be produced and developed inthe livestock farming community. Since then, the production of frozen semen from Bali polledcattle has been massively increased by collaborating between Hasanuddin University, the National Research Agency and the South Sulawesi Provincial Government and several regionalgovernments in South Sulawesi, including Barru and Bone Regencies.

In its development, polled Bali cattle were developed together with horned Bali cattle that exist in the livestock farming community with limited patterns of livestock ownership (SmallholderFarm). Parent cattle used in breeding in the field use Horned Cattle Bali, owned by the breeder,with application technology insemination artificial (IB). Morphologically, it seems that the Balipolled offspring have good performance, but the genetic potential for breeding on people's farms with the Smallholder Farm system like pure Bali cattle (horned) have not yet been recorded. Therefore, research is needed to conduct a study genetic diversity analysis both within and between polled Bali cattle and pure Bali cattle (horned) populations at the two cattledevelopment locations. The specific target that want to achieve is to obtain information about the relationship between environmental factors, phenotypes and genotypes so that superior cattle seedstock can be selected, which have high productivity and fertility levels [1] and can then be utilized by smallholder farmers in South Sulawesi, especially plasma farmers for breeding to support the improvement of the genetic quality of local Bali polled cattle as the forerunner of new superior national beef cattle. One method to reach the above-mentioned objective is DNA analysis using polymerase chain reaction-random amplified p*olymorphic DNA (*RAPD-PCR). This method can analyze the diverse of genomes of species as quickly and efficiently as possible applied to poultry or animals. Specifically, research was designed toparticipate in priority programs on the field farm that enhance the productivity of local cattle, significantly increasing the quality of the seed stock of Bali polled cattle through genetic and molecular studies to improve the genetic quality of local cattle nationwide [2];[3](Figure 1).

Figure 1. Polled Bali Cattle Bull has a Body Weight Reaches 500 kg at the Age of 4.5 Years,and Cows Female *Polled*

This Bali cattle variant, Bali polled cattle, has begun to be developed and even becomea national priority in the development of superior local cattle in Indonesia. Diversity is a normalphenomenon in living things. In principle, diversity genetics studies aim to study individuals' genetic composition within or between Bali cattle populations, polled Bali cattle, and horned Bali cattle.

RESEARCH METHODS

Blood Sample

Blood samples were taken from the jugular vein of Bali cattle in two rearing areas, namely Bone Regency and Barru Regency. 27 and 24 heads of Bali cattle were taken, respectively, ineach region. DNA samples collected from selected cattle from each different rearing location were taken based on the offspring group, that is, Bali polled / hornless as a result of mating between horned Bali cattle cows and Bali polled cattle bull, Bali cattle have horns from resultsof mating between Bali cattle cow with horned and horned Bali cattle bull, and horned Bali cattle from the results of mating between horned Bali cow with Polled /hornless bull. A schemeof the research flow can be seen in Figure 2. DNA was extracted from blood using standard methods, and PCR amplification was carried out using the techniques of [4] and [5]

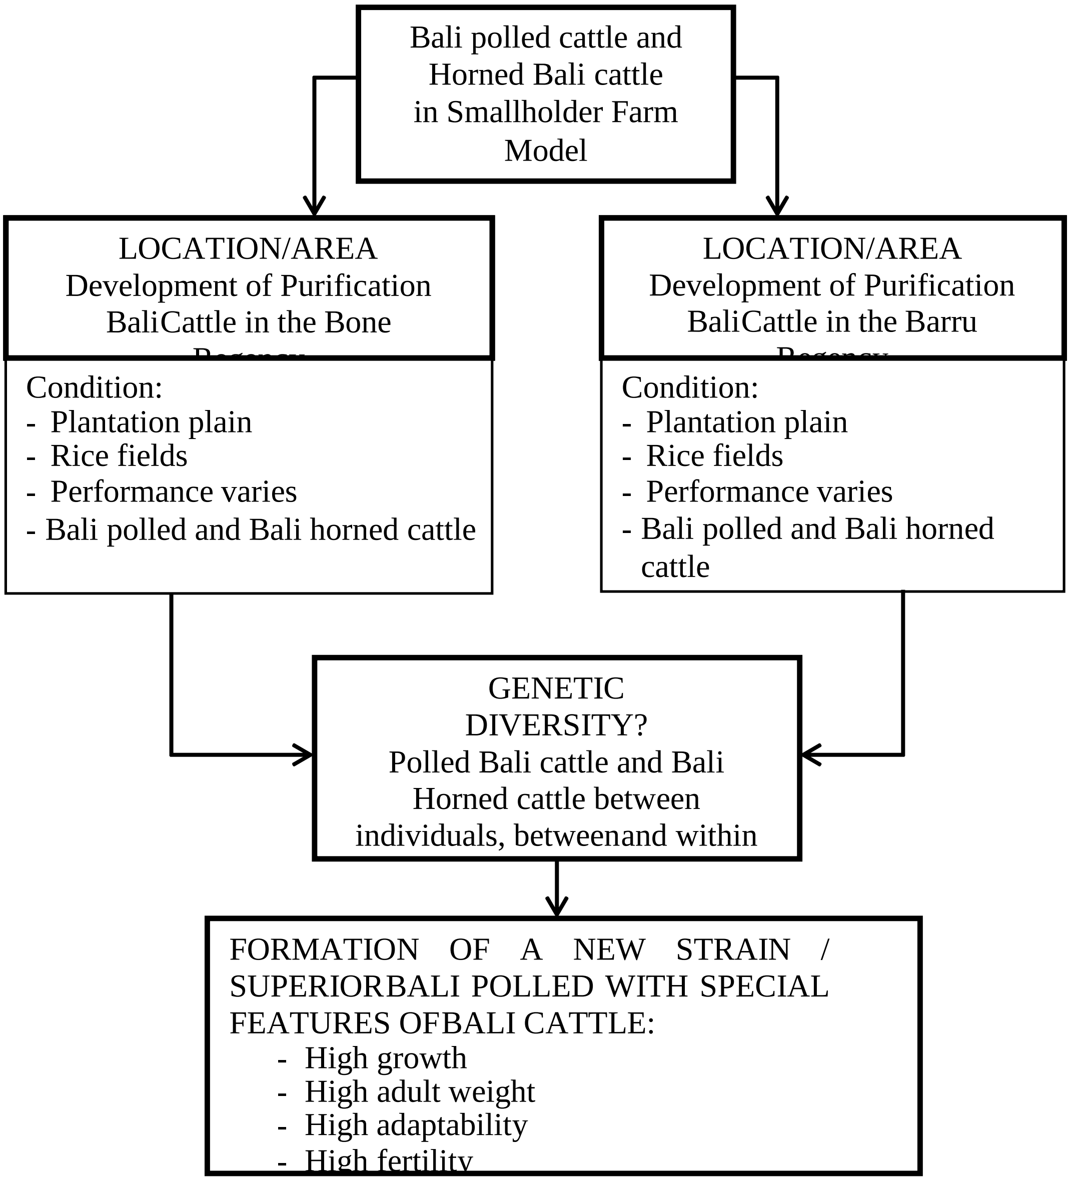

Figure 2. Scheme of Genetic Diversity Research Flow

Blood DNA extraction

DNA extraction was carried out to obtain genomic DNA. A total of 1 ml of blood was mixed with EDTA, transferred to a tube conical 10 ml, 4 ml lysis buffer, and 5 □l proteinase K 20 mg/ml, then shaken for 1 hour and then added phenol with ratio 1: 1, shaken for 30 minutes, and centrifuged at 2800 rpm for 15 minutes. The supernatant entered the conical, and then 1/10volume of 3 M Na acetate supernatant and 1:1 absolute ethanol were added, cooled at -80^{O}C for 1 hour, and centrifuged. Pellets obtained were washed with 70% ethanol and laminar dried

After drying, add 75 □l TE and store at 4^{O}C overnight. The DNA sample is ready to be used for further processing.

DNA amplification with PCR-RAPD

The primer used is six random primaries that will look for which one gives the best results amplification, composed of 10 bases. The PCR program starts with denaturation at an initial temperature of 95 ^{O} C for 4 minutes, a denaturation cycle at a temperature of 94 ^{O} C for 1 minute, *annealing at* a temperature of 35^{O}C for 1 minute, polymerization at72^{O}C for 2 minutes,polymerization finally at 72^{O}C for 10 minutes, next maintained at 4^{o}C for 5 minutes. Total cycles performed 45 times. Tube Stored in the freezer -20^{O}C until electrophoresis and documentation are completed.

Electrophoresis PCR product

The results of DNA amplification are separated based on heavy the molecule using 2 grams ofagarose gel in 100 ml of TAE buffer 1 x. Staining was carried out by adding 4 µl of ethidium bromide to the agarose gel, then pouring it into a mold that already had a comb. The comb is taken when the gel has hardened, then poured with 250 ml TAE 1 x. The DNA sample was provided with a solution of blue juice with a ratio of 5:2, and then the sample was entered intosuitable electrophoresis. Besides, It also has a marker installed as molecule standard. Electrophoresis runs at 50 volts for 60 minutes. DNA bands were observed under UV light andthen photographed with Polaroid film.

Data analysis

The bands from the electrophoresis results were analyzed statistically using the BSF method. The BSF calculation results are used to calculate differences or genetic diversity between the population of Bali cattle from the Bone district and district Barru. To calculate the BSF value in the population (between individuals within the population) it is calculated using the formula:

$$B_{ab} = 2b_{ab} / (ba + b_b)$$

Where ba and bb are the bands found in individuals a and b, bab is the number of bands in common between individuals a and b. BSF in the population (B) is the average B ab of possible pairs between individuals within the population [6]

The BSF value between individuals between populations (B') is calculated using the formula: $B' = 1 + B_{xy} – 0.5(B_x + B_y)$

B_x and B_y are the B values in populations x and y, and B_{xy} is the average band sharing betweenindividuals in populations x and y being compared [7]. Genetic differences and diversity werealso tested with SAS [8]. Genetic distance measurements $(\delta\mu)^2$ were used to measure genetic changes and were calculated by Microsat [9]. Based on the results of DNA fragment sequencing, a phylogenetic tree was created using the Computer software program MEGA 5 (Molecular Evolutionary Genetic Analysis) with the UPGMA (unweighted pair-group methodwith arithmetic).

RESULTS AND DISCUSSION

Phenotypic Characteristics of Polled Bali Cattle and Horned Bali Cattle

Results of observations of the characteristics of Bali cattle samples originating from twodifferent locations, namely Bone district and Barru district, show that Bali cattle have relatively uniform characteristics. The color of female Bali cattle is usually light brown, with athin black line running along the middle of the back. The color of the bull is brown when young,but then the color changes slightly darker at the age of 12-18 months, approaching black at maturity, except for castrated bulls that will retain their color chocolate. The characteristics of Bali cattle are generally uniform, namely brown in both females and males when young and close black when mature, white on the back of the thighs, the edge of the upper lip, the feathersat the tip of the tail are black, there is a clear black line on the part over the back [10]. This research used polled Bali and Bali cattle with horns, still calves under one-year-old. All livestock samples are the results of artificial insemination (AI) using polled Bali bull straw (Celebes and Kazep) and straw cow Bali horned (BIB Pucak belonging to the South Sulawesi Provincial Government).

Genetic Diversity of Bali Cattle Based on Molecular

This research analyzed PCR using several 10-base RAPD primers suitable for Bali cattle. In analyzing genetic diversity using RAPD, the level of consistency in the appearance ofa character under certain PCR conditions is very important, as the optimum reaction conditions for each type of organism may be different and must be determined first. Therefore, various PCR temperatures were also tested, apart from several primers.

The success of this technique is based more on the suitability of the primers, efficiency,and optimization of the PCR process [11]. Non-specific primers can cause other regions to be amplified in the genome that are not targeted or, vice versa, no genome regions are amplified. PCR optimization is also needed to produce the desired characters. This optimization concernsthe temperature of denaturation (separation of chains) and annealing (attachment of primer) ofDNA in a PCR machine. A low denaturation temperature can cause the double-stranded DNAnot to open, so new DNA polymerization is impossible. Attaching the primer to an open DNAstrand requires an optimum temperature because a temperature that is too high can cause amplification not to occur or vice versa; too low a temperature causes the primer to stick to theother side of the genome that is not the sidehomolog. As a result, many non-specific regions can be amplified in the genome.

Table 1 shows the results of amplification by using six RAPD primers on 51 samplesof Bali cattle originating from two different areas produced PCR products that could be readusing qualitative and quantitative analysis. From these results, there are bands with certain basepair sizes with specific patterns that do not always appear in all individuals or distinctivebands (Polymorphic bands), and bands that have a basepair size with *specific* patterns that always appear in each individual (Monomorphise bands).

Qualitative Analysis

The number and intensity of bands produced after DNA amplification by PCR-RAPD highly depend on the primer used. Primary selection in RAPD analysis influences the polymorphism of the resulting band because each primer has its binding sites. As a result, the polymorphic bands produced by each primer become different in size, number of base pairs, andamount of DNA bands.

The results of DNA amplification using six primers sometimes produced bands with different intensities. The purity and concentration of DNA greatly influence the intensity of theamplified bands on each primer. Specific bands are only found in individuals from certain populations with particular sizes. Table 1 shows the sequences of the six primers and the number of RAPD markers produced.

Table 1 shows the number of bands and polymorphic bands formed on the six primers. The banding pattern of DNA amplification results was obtained using different random primers.The results of PCR-RAPD amplification showed a banding pattern that needed to be more diverse, which can be seen from the total 61 bands, 68.9% of which were polymorphic bands in Bone Regency and 51.7% in Barru Regency. These results show that the genetic diversity of Bali cattle in the Bone Regency is still relatively high compared to the Barru Regency. The RAPD marker indicated this used had a high polymorphism level (68.9% vs 51.7% polymorphic bands). This may be because the Barru Regency is the center of Bali cattle breeding in South Sulawesi, so there is a possibility of higher inbreeding than in the Bone Regency. According to Hadiati and Mansyah [12], the difference in the number of polymorphicDNA fragments in the analysis of genetic diversity determines a population's diversity level. The difference in the number and polymorphism of DNA bands produced by each primer illustrates the complexity of the observed genome. Polymerase in cow Bali is also diverse, which can be seen by blood variations that reflect genetic differences.

It is said that the genetic diversity of Bali cattle in Bone Regency still has relatively high diversity due to the influence of genetic and environmental factors [13]. Opinion that observable diversity is caused by genetic diversity that arises from interactions between genetic and environmental factors. Genetic diversity is essential because of the factors that influence the response of a population to selection, both natural and artificial selections carried out by humanto exploit these biological resources according to their needs [14]. Populations with high levelsof genetic diversity have a better chance of survival. This is because each gene or combinationof genes has a different response to environmental conditions. The more diverse the genetic resources, the more resistant the population will be to survive in the long term and the higher the population's adaptability to increasingly more significant environmental changes. Genetic diversity is also essential in maintaining sustainability and increasing the productivity of a species.

Table 2 shows the differences in the number and intensity of bands in each primer. Thehighest percentage of polymorphic bands was in primer P04, with a percentage of 87.5%, and the lowest was in primer P10, with a rate of 11.1% in livestock samples in the Barru regency development area. This indicates that the DNA amplification results using the six primers aboveonly sometimes obtained bands with the same intensity. This difference was caused by the presence or absence of primer sequence pairs used in the DNA template. In primers P01 and P09, the number of bands produced is more significant than those made by other primers. Thebands obtained are the result of primer and DNA template amplification. The more sequences can be recognized by the primer on a DNA template, the more bands will be produced. The intensity of the amplified DNA band on each primer is greatly influenced by the purity and concentration of the DNA template containing compounds such as polysaccharides and phenolic compounds. Too small a concentration of DNA template often produces faint or unclear amplified DNA bands. Purwanta *et al,* [15] states that the DNA fragment patterns are determined by the presence or absence of primer attachment sites and by the purity and integrityof the DNA print. Impure template DNA prints/template will interfere with the attachment of the primer to its site and will inhibit the activity of the DNA polymerase enzyme. This enzymefunctions to polymerize DNA. Meanwhile, template DNA that experiences much fragmentation can eliminate the primer attachment site. This was clarified by the opinion of Prana and Hartati(2003), who stated that the success of genomic DNA amplification using the RAPD techniquewas determined not only by the sequence of primer bases used and their amount (primer contentin each reaction) but also by the suitability of PCR conditions including primer annealing temperature and extension.

Table 1 shows that the DNA bands from the six primers are 250 - 3000 base pairs, producing 61 polymorphic bands. The number of DNA bands was obtained from observationson 2% Agarose gel after electrophysics for 1 hour. This result was due to the range of DNA sizes that can be analyzed using the 2% agarose gene, which was around 100 - 2000 bp / 0.1 -

2.0 kb. The general range of DNA sizes that can be analyzed by 2% agarose gel is 0.1 - 2.0 kb[16].

Quantitative Analysis

A quantitative analysis was carried out by calculating the Band Sharing Frequency (BSF) values between individuals within the population and between populations in Bali cattlesamples in two Bali cattle development areas in South Sulawesi. Table 2 shows that the BSF value between individuals in the Bali polled cattle population both in the Bone Regency and Barru Regency ranges from 0.8008-0.9025 and 0.840-0.9043, respectively, while the horned Bali cattle BSF value ranges from 0.5745-0.7917 and 0.7929-0.9721, respectively. This showsthat the genetic diversity in both populations is still relatively high, although there are indications of inbreeding in Bali cattle in Barru Regency. However, with a good and continuousselection and breeding program, re-introducing the original variant of the Bali cattle bull everytwo years in the breeding program can control severe inbreeding.

The genetic diversity between individuals in the Bali cattle samples from a populationof Bone Regency or, in other words, the genetic similarity is relatively the same compared tothe Bali cattle samples population from Barru Regency, namely with BSF values of 1.0031 and 0.9846, respectively. This is because individuals in the Bali cattle population in both development areas have relatively the same genetic relationships. This is the opinion of Suwardi et al. [14], who stated that the factors that influence the formation of the population's genetic structure include factors that cause genes or increase genetic diversity, including mutation and immigration factors. At the same time, factors that reduce genetic diversity include natural selection and genetic drift.

Table 3 shows that the BSF value between individuals within and between populations is relatively large. This indicates that the genetic similarity between the two populations is quite significant, with an average BSF value with several primers approaching1,000. The high BSF value is due to excellent and continuous breeding or reintroducing of the original Bali cattle variant with superior offspring or inbreeding (Artificial Insemination)in Bali cattle in both Bali cattle development areas of South Sulawesi.

Genetic Relationship and Distance

The genetic relationship of the polled Bali cattle population, horned Bali cattle descendantsof polled Bali bulls, and horned Bali cattle population descendants of horned Bali cattle in two Balicattle development areas in Bone and Barru districts can be seen in Table 4. The table shows the genetic relationship of polled and horned Bali cattle in both development locations with communityfarming (smallholders Farming) patterns ranging from 84 - 99%. This shows that Bali cattle developed by livestock communities in both areas still have a very close genetic relationship.

PTBn : Horned Bali cattle offspring of Bali polled bull in Bone Regency;
TTBn : Horned Bali cattle offspring of horned Bali cattle bull in Bone Regency;

Table 4 also shows the genetic distance between the 5 % - 20 % of the Bali cattle populationin the two development areas and has a very close genetic identity (85 - 98%). This indicates crossbreeding or interbreeding between relatives in the Bali cattle population in the two Bali cattledevelopment areas. Furthermore, genetic diversity (genetic distance) was seen in the dendrogram image (Figure 3), showing that five identified clusters were present in the samples of the two Bali cattle development areas, polled and horned.

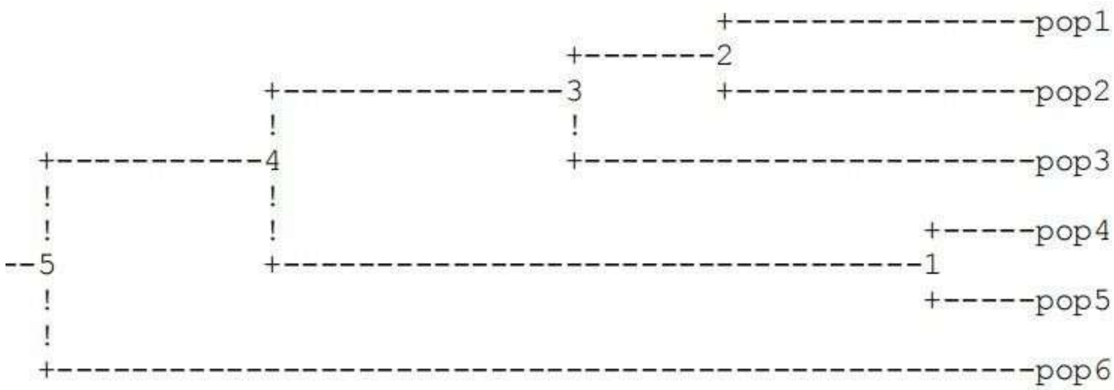

Figure 3. Genetic Relationship Dendogram with Several Different Primers

Description: Clusters 1 - 5, and pop1 - pop6

Between	And	Length
5	4	1.7902
4	3	2.3198
3	2	1.1837
2	Pop1	2.5570
2	Pop2	2.5570

Between	**And**	**Length**
3	Pop3	3.7408
4	1	5.1170
1	Pop4	0.9436
1	Pop5	0.9436
5	Pop6	7.8508

Pop1 : Bali polled cattle offspring of Bali polled bull in Barru Regency; Pop2 : Horned Bali cattle offspring of Bali polled bull in Barru Regency;

Pop3: Horned Bali cattle offspring of horned Bali cattle bull in Barru Regency;Pop4 : Bali polled cattle offspring of Bali polled bull in Bone Regency;
Pop5 : Horned Bali cattle offspring of Bali polled bull in Bone Regency;
Pop6 : Horned Bali cattle offspring of horned Bali cattle bull in Bone Regency;

The statistical analysis results of the NTSys program with the UPGMA method, it showsthat the fifty-one samples with six different primers were divided into 5 cluster groups and based ongenetic characters, the results depicted in the dendogram as showed in Figure 3, its show that thecoefficient of diversity of the relationship between populations is between 0.9436 - 7.85. This shows that the diversity of genetic kinship relationships at this level is still relatively high. The closest genetic distance is cluster 1 which highly closed pop5 and pop4. This is because the cattle in pop5and Pop4 are descendants of the first generation of Bali polled Bull in Bone district. While the furthest genetic distance is the cattle in Pop6 in cluster 5 with other cattle. This shows that the development of Bali polled cattle in Barru Regency has been carried out earlier than in Bone Regency, as indicated by the closer genetic distribution in the Barru area.

CONCLUSION

The BSF values between individuals in the population and the polled Bali cattle populationin the Bone and Barru districts fluctuated from 0.8008 to 0.9025 and 0.840 to 0.9043, respectively.In contrast, the horned Bali cattle BSF value ranged from 0.5745 to 0.7917 and 0.7929 to 0.9721. The genetic distance between the Bali cattle population was 5% to 20% in both livestock development areas. The results showed that the genetic diversity of polled Bali cattle was low compared to horned Bali cattle. The genetic relationship between polled and horned Bali cattle between the two development areas remained relatively close.

ACKNOWLEDGMENT

The authors express their most profound appreciation and gratitude for the assistance in carrying out this research, especially to Hasanuddin University through the Research and Community Service Institute, which has provided financial support in carrying out this research. Integrated Laboratory of the Faculty of Animal Husbandry, Hasanuddin University. We express ourgratitude to friends and colleagues who have helped with the success of this research and for all their assistance and support. Thanks very much.

ABSTRACT

Artemia is a necessary live food for a successful larval culture of many fish and crustaceans which has good adaptability with a broad food spectrum. Information on the response of *Artemia* to different feeds on a laboratory scale provides basic information, especially in enrichment cases. The present research was conducted at the CNRDPA Laboratory under standard conditions. *Artemia parthenogenetica* were fed on three different diets, Micro-algae with *Dunaliella sp*, the second treatment were fed on yeast, and the last on the *Ulva lactuca* powder. A statistical analysis was used to compare *Artemia* growth between various feed treatments. a significant difference in total length was observed between the three treatments for the juvenile stage and the adult stage where the yeast-fed nauplii became adults after only 15 days of culture with an average total length of

7.2 mm compared to the individuals from the 2nd batch (fed by the algal powder) with an average total length of

4.5 mm and individuals from the 3rd batch (fed by the micro-algae) with an average total length of 5.3 mm. The growth rate of *Artemia* individuals fed with yeast was more important for the juvenile and adult stages with values of 1.9 mm/Day and 0.3 mm/Day, respectively unlike the individuals fed with *Ulva* powder (0.3 mm/Day and 0.09 mm/Day for juveniles and adults, respectively) and individuals fed with micro-algae (0.7 mm/Day and

0.28 mm/Day for juveniles and adults, respectively). Regarding the survival rate, individuals fed with micro- algae have an important final survival rate (75%) compared to individuals fed with yeast (45%) and individuals fed with *Ulva* powder (20%). *Artemia* adopts a strategy of responding to different food conditions; it takes more time to reach an adult size for a high survival rate.

Keywords: *Dunaliella sp*, growth, Micro-algae, Survival rate, *Ulva lactuca,* yeast

INTRODUCTION

Artemia (Leach, 1819) (Branchiopoda, Anostraca) is the most abundant and common genus in hypersaline waters habitats worldwide, except in Antarctica (Van Stappen, 2002). *Artemia* belongs to Anostraca, the most ancient and primitive group among crustaceans, and has an advanced osmoregulation system among all animals, allowing them to exist in an extreme salinity habitat (Gajardo and Beardmore, 2012; Lantushenko et al., 2022).

Because Brine shrimp *Artemia* is the most used and important live feed in the crustacean, marine fish, and freshwater fish larvae-culture (Dhont and Sorgeloos 2002), the nutritional value, bio-ecological characterization, culture, and *Artemia* population dynamics have been relatively well studied in recent years (e.g., Amarouayache et al., 2009, 2012; Amarouayache and Kara, 2015; Chabet dis et al., 2021; Chabet dis et al.,2023), except under different feeding conditions.

In the face of the climate change scenario hitting the earth and affecting wetlands directly and indirectly through rising temperatures, changes in the intensity and frequency of rainfall, climatic events such as drought (Salimi et al., 2021), the culture of organisms that are essential on the market and for the development of aquaculture such as *Artemia*, proves to be essential. The main objective of this study is to evaluate the response of *Artemia* individuals to different feeds under standard conditions by studying growth and survival characteristics.

MATERIAL AND METHODS

The diameter of 100 hydrated cysts of *Artemia parthenogenetica* population from El Bahira Lake (Setif, Algeria)(in freshwater for 2 hours) and 100 decapsulated cysts after hydratation (immersion in sodium hypochlorite according to Lavens and Sorgeloos (1996)) was measured under a binocular microscope (Optika, Italy), equipped with a camera. The chorion thickness was calculated according to Vanhaecke and Sorgeloos (1980) according to the following formula:

chorion thickness =(diameter of hydrated cysts - diameter of decapsulated cysts)/2

Artemia parthenogenetica cysts from El Bahira Lake (Algeria) were hatched in seawater 35 PSU, at a temperature of 24 ºC and pH 8, and under continuous aeration and fluorescent lighting. After 24 hours of hatching, the nauplii were collected and cultured in standard laboratory conditions as described by Hontoria and Amat (1992).

For the hatching success, the hatching percentage and efficiency was calculated as:

Hatching percentage (%) = (Total number of cysts hatched/Total number of cysts)*100Hatching efficiency (nauplii/g) = Total number of nauplii/Mass of cysts (g)

The length of 30 nauplii was estimated under a binocular microscope (Optika, Italy), equipped with a

camera.

The study was conducted at 24 ± 1 °C under constant light in separate 2 L glass containers, with three feeding treatments (100% Micro-algae (*Dunaliella sp*), 100% brewer's yeast, and 100% *Ulva lactuca* powder) and three replications. *Ulva lactuca* powder was obtained after collection, cleaning, drying in the dark, and grinding. *Dunaliella sp* was cultured in standard conditions. The brewer's yeast was obtained from local market.

Survival was monitored by a direct count of each feeding treatments and of three replicates during the culture. Dead individuals were removed and the survival rate was calculated for each treatment.

For the growth experiments, the total lengths of 30 *Artemia* individuals were recorded using a binocularmicroscope (Optika, Italy) equipped with a camera, after anesthesia according to the method of Dana and Lenz (1986).

Absolute growth rate (AGR) was estimated as calculated by Wooton (1991): AGR = (final length-initial length)/culture days.

RESULTS

The average diameter of normal, hydrated and decapsulated cysts were 177.4 ± 14.1 µm, 235.26 ± 9.4 µm, 217.1

± 14.6 µm, respectively.

The hatching percentage of cysts of *Artemia parthenogenetica* from El Bahira Lake was 55.78% with a hatching efficiency of 28986.67 nauplii/g.

The average length of nauplii of *Artemia parthenogenetica* from El Bahira Lake was 377 ± 2.05 µm.

Survival rate decreased with increasing time culture. After 15 days, the highest survival was observed for *Artemia* individuals fed with micro-algae (75%), compared to *Artemia* individuals fed with brewer's yeast (45%) and *Artemia* individuals fed with Ulva powder (20%) (Fig.1).

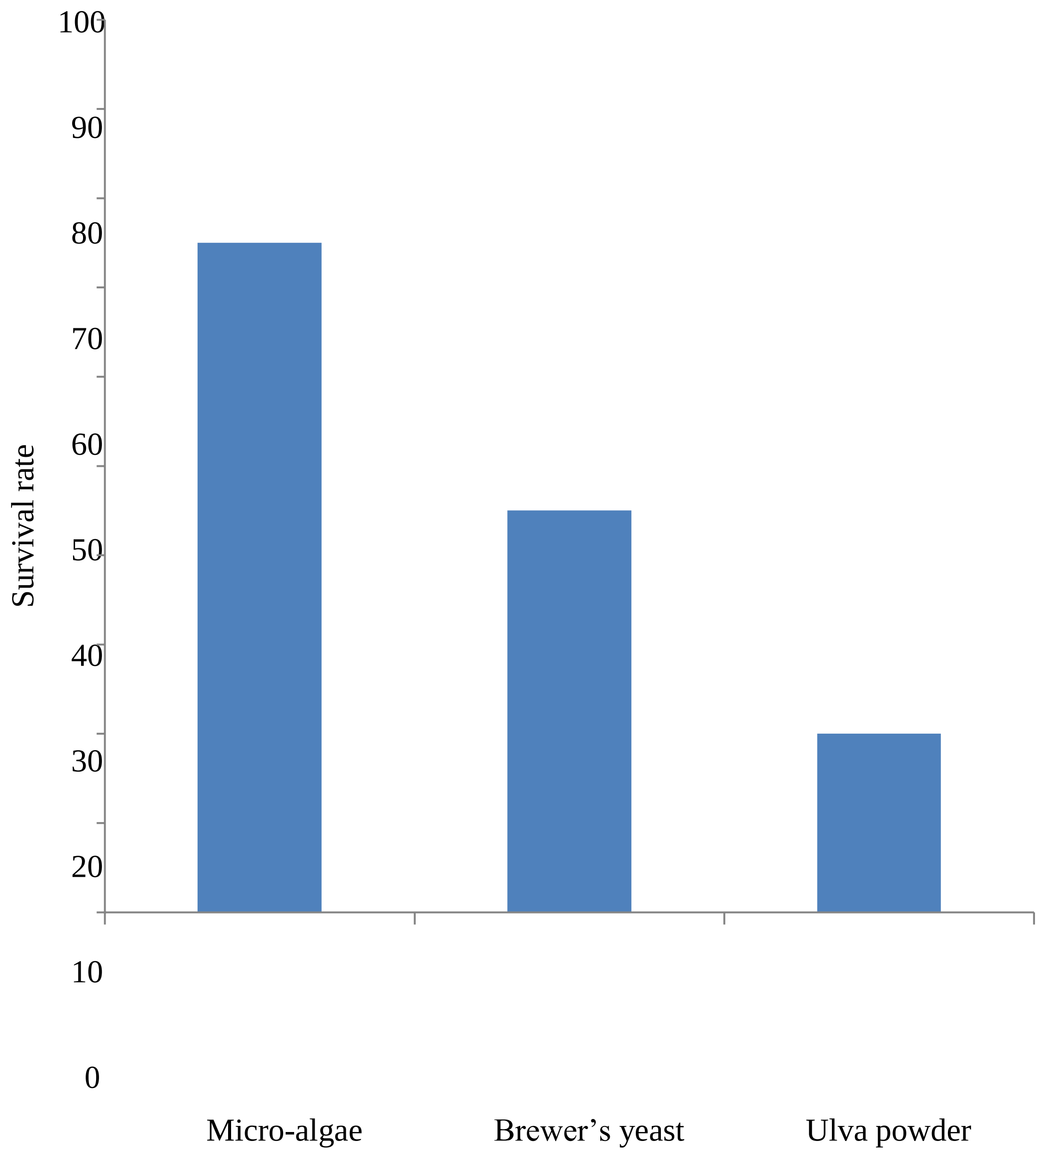

Figure 1. Percent survival of *Artemia parthenogenetica* from El Bahira fed on different feeds.

The growth experiments (total body length TL) for the three treatments are presented in Fig. 2,3,4.

At juvenile and adult, the average lengths were found to be significantly between the three treatments ($P<0.05$)

The nauplii fed on brewer’s yeast become adults after only 15 days of culture with an average total length of 7.2mm compared to the individuals from the 2nd treatment (fed by the algal powder) with an average total length of

4.5 mm and individuals from the 3rd treatment (fed by the micro-algae) with an average total length of 5.3 mm.

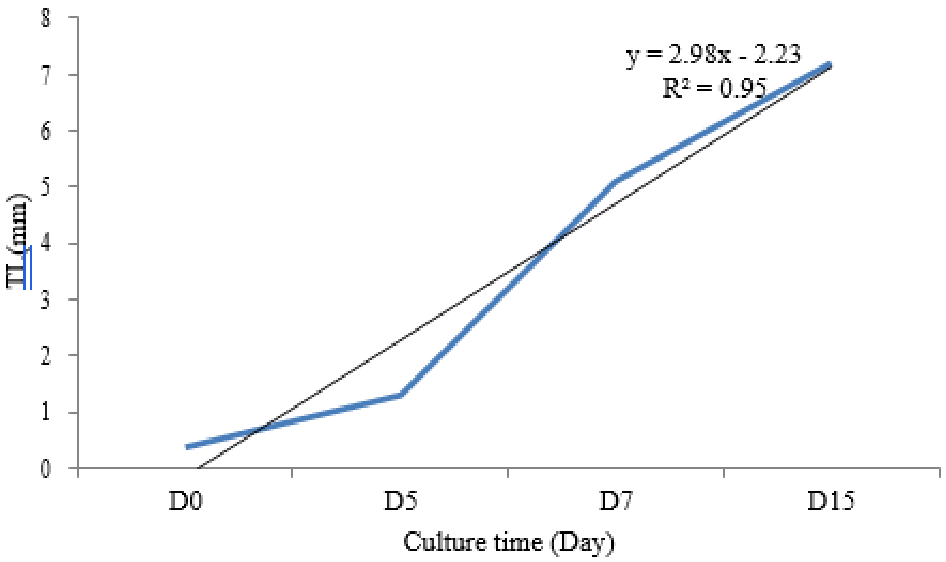

Figure 2. Growth of *Artemia parthenogenetica* from El Bahira fed on brewer's yeast.

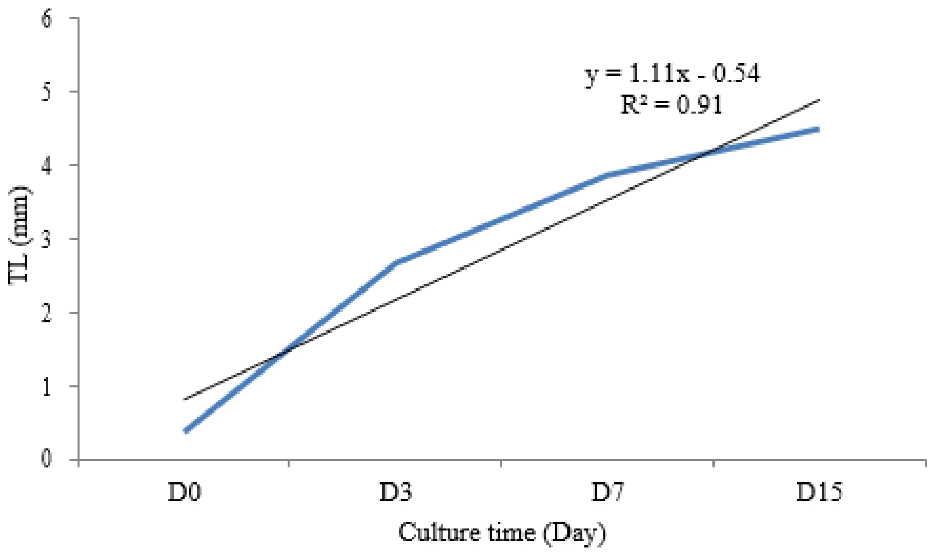

Figure 3. Growth of *Artemia parthenogenetica* from El Bahira fed on *Ulva lactuca* powder.

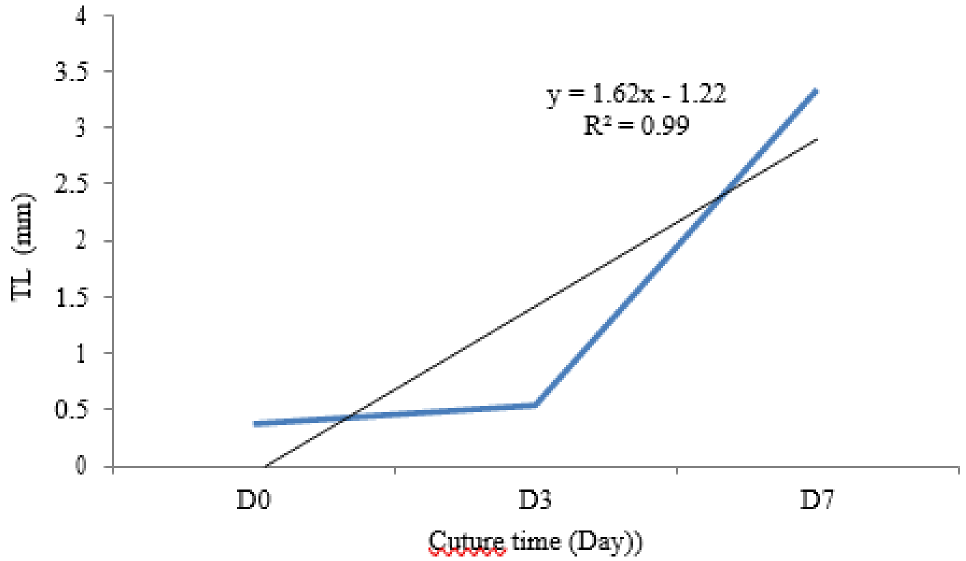

Figure 4. Growth of *Artemia parthenogenetica* from El Bahira fed on micro-algae.

The growth rate of *Artemia* individuals fed with yeast was more important for the juvenile and adult with values of 1.9 mm/Day and 0.3 mm/Day, respectively unlike the individuals fed with *Ulva* powder (0.3 mm/Day and

0.09 mm/Day for juveniles and adults, respectively) and individuals fed with micro-algae (0.7 mm/Day and 0.28mm/Day for juveniles and adults, respectively).

DISCUSSION

Artemia parthenogenetica from El Bahira Lake produced smaller cysts compared to the *Artemiaparthenogenetica* from Bethioua Sebkha (Chabet dis et al., 2021) located in western Algeria and *Artemia salina*

from Timimoune Sebkha (Chabet dis et al., 2021) located in southern Algeria. Vanhaecke and Sorgeloos (1980) reported that food and salinity variations in the biotope can affect cyst diameter and suggested that the diameter of the cysts was related to genetic characteristics.

The cyst hatching percentage of El Bahira is close to the hatching percentage of the El Melah (53.2%) and Bethioua (64.2%) populations in southern and western of Algeria, respectively. (Chabet dis et al., 2021). The result of the hatching efficiency for El Bahira cysts is lower than the values reported by Chabet dis et al. (2021) for the populations of El Melah (southern Algeria), Timimoune (southern Algeria) and Bethioua (western Algeria). Compared with other cysts, the hatching percentage obtained in the present study can be considered average and acceptable compared to the values reported by several authors between 20% and 90% hatching (Sorgeloos et al., 1986). However, Chabet dis et al. (2021) reported that hatching quality can be improved by decapsulation of cysts. Therefore, harvesting at the time of cyst production is important to ensure better hatching quality.

Also, *Artemia* from El Bahira Lake produced smaller nauplii than other Algerian strains (Bethioua (478.73 ± 0.2 µm), Timimoune (453.26 ± 0.3 µm) reported by chabet dis et al. (2021)). Chabet dis et al. (2021) reported that Naupliar size is important in view of the potential use as live food in aquaculture.

Percent survival and growth of *Artemia* from El Bahira Lake varied depending on each food used. *Artemia* is known to be filter feeder zooplankton nonselective (Dhont and Sorgeloos, 2002), based on diet size ranging between 1µm and 50µ and optimal about 16 µm (Fernández, 2001). Among the foods reported in *Artemia*, we find yeast (Dhont and Sorgeloos, 1996; Lavens and Sorgeloos, 1991). Amarouayache et al. (2007) fed *Artemia* from Sebkha Ez-Zemoul with yeast and reported a growth rate of 0.33 ± 0.3 mm/Day with a longer juvenile stage, about 10 Days where metanauplii grow from a total length of 1.73 mm to 5.11 mm to become pre-adults. However, micro-algae are the natural food of *Artemia* (Mohebbi, 2016). Micro-algae are used as standard feed to standardize culture and reproduction conditions (Chabet dis et al., 2023) even though it is expensive (Sulistiyarto and Bakrie, 2024). Other sources have been reported to be food for *Artemia* such as bacteria, waste products from the food industry and dried algae (Dhont and Sorgeloos, 1996; Lavens and Sorgeloos, 1991). Coming out obtained results, *Artemia* displayed an adaptive strategy to food category based on time and energy costs.

ABSTRACT

Household Drinking Water Purification Systems (WPS) enable us to produce healthy and high-quality water in our homes. However, in this application, it is very important to maintain our device and change its filters periodically. Original equipment market (OEM) filters are those that are manufactured and sold by the same manufacturer as the original equipment piece. On the other hand, unoriginal aftermarket (UAM) filters are those that have not been made by the same manufacturer but have been fashioned to fit as well as the original parts. In this study, the performances of OEM filter and UAM filter for one of the most popular WPS in Türkiye were evaluated. Unpurified and purified tap water samples were taken from İstanbul Province in winter season of 2021. Four significant potentially toxic elements including nickel (Ni), arsenic (As), cadmium (Cd) and lead (Pb) were measured in drinking water samples and how much the WPS with OEM and UAM filters improves these parameters were determined. As a result of this research, it has been clearly demonstrated that the OEM filtered WPS significantly improved the drinking water quality by decreasing the total elemental content approximately 50%, while the UAM filtered WPS did not improve the water quality, and even increased the levels of many pollutant parameters in the water (total elemental content increased by approximately 30%).

Keywords: Water purification systems, OEM – UAM filters, Potentially Toxic Elements

INTRODUCTION

The history of water purification is indeed highlighting the evolution of the technology over time. Water is known as purified by using natural materials like stones, sand, and by boiling at the ancient times. Modern water treatment milestones may be summarised as: in 1903, the first water softening device was developed; in 1980, the first membrane for water purification devices was developed; in 1995, UV technology was integrated to the purification devices; in 2001, the first closed water purification system was developed; in 2007, carbon filters that provide the mineral support in water purification devices were developed; in 2015, more portable water purification systems were developed. These advancements reflect the continuous efforts to improve water quality and accessibility. Each milestone represents a significant leap in technology, making water purification more efficient and accessible (Maden et al., 2019; Tokatlı and Ustaoğlu, 2021).

Toxic elements have numbers of hazardous effects both on the ecological balance of environment and on the human health. They may cause various non-carcinogenic and carcinogenic health problems and diseases (Tokatlı, 2015; 2017; 2019; 2021; Wagh et al., 2018; Xiao et al., 2019; Tokatlı and Ustaoğlu, 2020; Köse et al., 2020; Tokatlı et al., 2021; Varol and Tokatlı, 2021; Tokatlı and Varol, 2021).

The healthy operation of household WPSs, which are found in many people's homes today, depends on their periodic maintenance being meticulously carried out and their filters being changed regularly. In addition to the original equipment market (OEM) filters provided by the manufacturers, many unoriginal aftermarket (UAM) filters that have not been made by the same manufacturer are also quite common in the market. In the current investigation, the performances of OEM and UAM filters for one of the most popular WPS in Türkiye were evaluated by measuring four significant potentially toxic elements (Ni, As, Cd and Pb) in filtered and unfiltered drinking water samples.

MATERIALS AND METHODS

Collection of Water Samples

Drinking water samples were taken from the tap water of İstanbul Province (Küçükçekmece District), where is known as the most populated city in Türkiye, and from the purified tap water treated by OEM and UEM filters by a widely used household water purification system with reverse osmosis in the winter season of 2021. Water samples were taken to the 1 L pre-cleaned and acid washed polyethylene bottles. pH of water samples to be used in the elemental analyses were reduced with nitric acid in order to make them below 2 (APHA, 2005).

Water Purification Stages of Investigated Household WPS

5 different filtering systems are used in the investigated WPS. Sediment Pre-Filter (SPF) (1) collects coarse dirt. Granular Activated Carbon Filter (GACF) (2) retains chlorine and other gases and gives clarity to water. Block Carbon Filter (BCF) (3) is a second carbon filter in addition to the GACF filter. It makes the incoming water to enter the membrane. It holds even the finest particles. Membrane (M) (4) is the heart of the reverse osmosis system. It separates all negative elements in water except water molecules. The Final Carbon Filter (FCF) (5) gives flavour to the water and removes the odour that may occur in the tank (http://www.cebilon.com.tr/).

Potentially Toxic Element Analysis

Water samples were filtered and their volumes have been set to 50 ml with ultra – pure water. Then the macro – micro element contents were measured by an Agilent branded (7700 XX) ICP-MS in the central laboratory of Thrace University (accreditation certificated laboratory). All the macro – micro element analyses were listed as the average of triple reads (TS EN / ISO IEC 17025) (EPA, 2001).

RESULTS AND DISCUSSION

The detected potentially toxic element levels in tap and purified water samples by OEM and UEM filters and the percent exchanges between the tap and purified water by OEM and UEM filters are given in Table 1 and Figure 1.

Arsenic, nickel, cadmium and lead are known as carcinogenic, hazardous and quite toxic elements. Exposure of these toxicants may cause many significant health problems (Çiçek et al., 2013; Köse et al., 2015; Bhowmick et al., 2018; Ustaoğlu et al., 2022; Din et al., 2023; Haque et al., 2023; Mia et al., 2023; Mutlu et al., 2023; Yüksel et al., 2024). In this study, the highest improvement rates were determined in the OEM filters for arsenic and nickel parameters, which were recorded as 64% and 58%, respectively. It was also determined that the UEM filters reduced the arsenic parameter by only 10%, while it was determined that the nickel levels increased in purified drinking water by the UEM filters by approximately 96% instead of decreasing. In addition, the OEM filters reduced the lead and cadmium levels by 36% and 15%, respectively, while the UEM filters increased these element levels by 27% for lead and 18% for cadmium.

Table 1. Detected data (ppm) and percentage exchanges

	İstanbul Tap Water	**Purified by UEM Filter**	**Percentage Exchange***
Ni	3.880	7.595	+95.75
As	0.273	0.246	-9.83
Cd	0.067	0.079	+18.48
Pb	0.656	0.833	+26.96
	İstanbul Tap Water	**Purified by OEM Filter**	**Percentage Exchange***
Ni	5.133	2.145	**-58.21**
As	0.223	0.080	**-63.89**
Cd	0.053	0.045	-15.23
Pb	0.940	0.599	**-36.33**

*Reduces after purification more than 30% are marked in bold

CONCLUSIONS

In this study, the performances of the OEM and UEM filters in a widely used water purification system (WPS) in Türkiye were evaluated. According to the results of this research, it has been clearly documented that the OEM filtered WPS significantly improved the drinking water quality by decreasing the total elemental content approximately 50%, while the UAM filtered WPS did not improve the water quality, and even increased the levels of many pollutant parameters in the water (total elemental content increased by approximately 30%). Therefore, in line with our research data, it is recommended to use original products provided by the manufacturer in the household water purification systems.

ABSTRACT

The European eel, *Anguilla anguilla*, is currently facing a critical endangerment primarily due to fishing activities and the numerous obstacles it encounters on its journey to its breeding area. Initiated in 2022, this research is a component of a thorough three-year study and serves as the primary exploration of the European eel population in the South-Eastern area of the Adriatic Sea. The present research was conducted in the Karavasta lagoon, in the Albanian territory, where a total of 140 eel specimens were collected by the end of December 2023 using a fyke-net barrier placed both upstream and downstream of the fish barrier, a common method used to capture this species in Albanian lagoons. This phase of the study focuses on biological aspects such as the distribution of length and weight frequencies, as well as the sex ratio of the eels. Furthermore, parameters like eye diameter, pectoral fin length, and Hartmann's index were analyzed to determine the maturity stage of the eels. At the same time, the health status of migratory silver eels was assessed, with special attention paid to parasitic infestations with the nematode *Anguillicola crassus*. The results from this part of the research indicate a negative allometric growth trend in the samples. It is worth noting that the eels did not display any signs of parasitic infestions, as none of the 140 individuals were found to be infested with the nematode *Anguillicola crassus*. As the study progresses to include additional parameters for future examination, it is expected that valuable insights will be obtained regarding this specific area of the Adriatic Sea, which has not been thoroughly investigated in relation to the European eel.

Keywords: *European eel**;** length frequency; stock; growth.*

INTRODUCTION

The European eel (Anguilla anguilla, Linnaeus 1758) is classified as a catadromous species, origination in the North Atlantic. Through an extensive migratory journey and a series of metamorphic changes from leptocephalus to glass eels, they eventually inhabit regions across Europe, North Africa, and the Mediterranean Sea [1]. During this phase, they occupy freshwater, brackish, and coastal environments, undergoing a transformation into yellow eels. Upon reaching sexual maturity as silver eels, they undertake a singular migration back to the Sargasso Sea to spawn, after which they die [1, 2].

The European eel is a species of particular concern due to the dramatic decline in its population over the past decades [3]. Since the 1970s the population of European eels has experienced a staggering decline of 99%. This significant reduction can be attributed to unsustainable fishing practices and various anthropogenic factors. Longitudinal studies of eel species (Anguilla spp.) over the past forty years reveal a substantial global decrease in their populations. *Anguilla anguilla* has already been placed on the IUCN Red List of critically endangered species [4]. Following the 1970s, the European eel, which is the most commercially significant species, has faced a 99% reduction in its population [1]. Contributing factors to this decline include overfishing, climate change, decreased recruitment of glass eels, obstacles to migration in river systems, habitat degradation, increased parasitism, pollution, the re-oligotrophization of freshwater ecosystems, a decline in available prey, and predation by cormorants *(Phalacrocorax spp.)*[5,6]. The alarming status of eel populations in Europe has prompted the implementation of recovery measures in accordance with European Council Regulation 1100/2007 [7], alongside management strategies for eel fisheries (http://ec. europa. eu/fisheries/marine_species/wild_species/eel/ management_plans/) [8].
Albania has a long history of utilizing eel for culinary purposes, yet comprehensive research on this species within its territory remains lacking. The current study seeks to investigate the morphometric relationships between length and weight (LWR), marking the inaugural research on this species in one of Albania's eight lagoons, specifically the Karavasta lagoon. The LWR serves as a valuable metric for evaluating the health of silver eel individuals as they prepare for their migratory journey to the Sargasso Sea for spawning. Additionally, this LWR can facilitate the identification of potential variations among different stock units of the same species or highlight differences between sexes [9].

MATERIALS AND METHODS

Data Collection
Site and Sampling: The study was conducted in the Karavasta lagoon, Albania. A total of 140 individuals were collected using a fyke net by the end of December 2023.
*Biological Parameters***:** Each specimen was assessed for Total Length, which varied from a minimum of 34.9 cm to a maximum of 61.7 cm, yielding a mean of 45.93 cm, and for Weight, which ranged from 76 g to 452 g, with an average of 171 g. The sample comprised 140 silver eels with a sex distribution of 56 males and 84 females.
*Data Analysis***:** Length-frequency histograms were constructed by categorizing individuals into 1 cm length intervals, revealing a bimodal distribution within the dataset. The sex ratio was determined, highlighting a significant sexual dimorphism, with a threshold indicating that all individuals exceeding 44 cm in length were females. The relationship between length and weight was analyzed, indicating negative allometric growth, which was particularly evident when the Length-Weight relationship was examined separately for each sex.

RESULTS AND DISCUSSION

The results of this research uncovered several noteworthy findings:

- A bimodal distribution of lengths within the sample.
- A distinct sexual dimorphism, characterized by a clear breakpoint at 44 cm total length, above which all individuals were identified as female.
- Evidence of negative allometric growth, particularly evident when analyzing the Length-Weight relationship by sex.

- The health evaluation of the migrating silver eels demonstrated optimal health, as none of the 140 individuals were found to be infected with the *Anguillicola crassus* nematode.

The observed bimodal length distribution and the marked sexual dimorphism observed, with females predominating the larger size category, are typical traits of *Anguilla anguilla*. This sexual dimorphism may be associated with the eel's intricate life cycle, wherein females undertake migration to the Sargasso Sea for reproductive purposes, necessitating a larger body size.

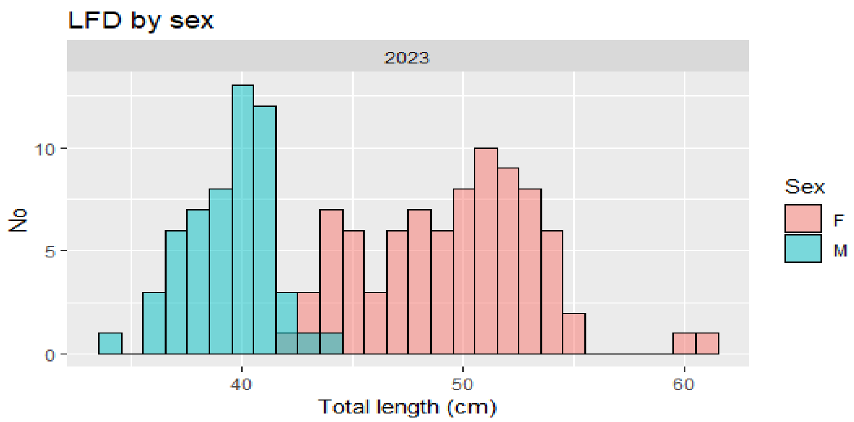

Table 1: Length frequency distribution (LFD) by sex

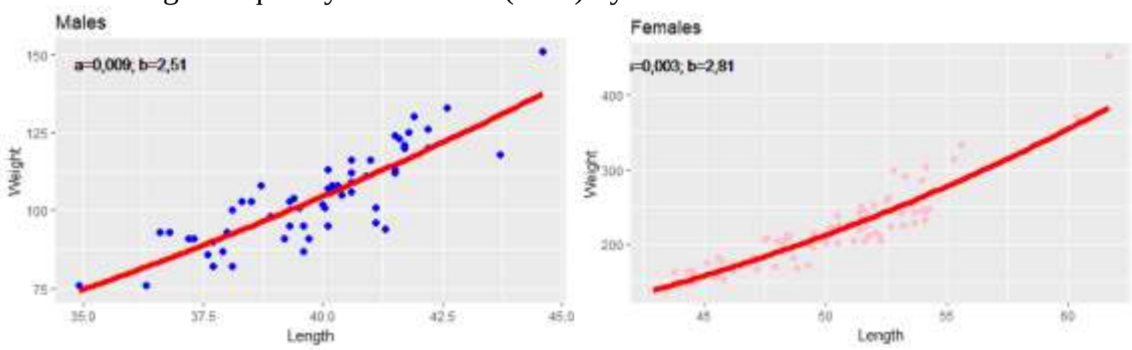

Table 2&3: Length-Weight relationship divided by sex

The lack of *A. crassus* nematode infection in the migrating silver eels indicates a positive health status for this population. This observation is encouraging for the conservation efforts of European eels in the Karavasta lagoon.

CONCLUSION

This research marks an important advancement in the comprehension of the local stock of European eels within the Karavasta lagoon in Albania. The results indicating a bimodal length distribution and distinct sexual dimorphism offer critical insights into the population dynamics of this species, which is classified as critically endangered. Moreover, the favorable health status noted among migrating silver eels serves as an encouraging indicator for their conservation efforts. It is essential that additional studies be undertaken to achieve a more thorough understanding of the local stock in the Karavasta lagoon, thereby aiding in the responsible management of European eel populations.

ABSTRACT

The primary purpose of our study is to determine the effects of different doses of phosphorus fertilization on the development and essential oil yield of lavender and to determine the phosphorus doses required to obtain the best yield in the *Lavandula Angustifolia* mill. variety. The study was established and conducted in Niğde Ömer Halisdemir University, Faculty of Agricultural Sciences and Technologies, medicinal plants application area according to the randomized blocks experimental design with three replications. The experimental area established with lavender *Angustifolia Sevtapolis* species was divided into plots as P0: 0 kg P_2O_5/Da, P6: 6 kg P_2O_5/Da, P12: 12 kg P_2O_5/Da, P18: 18 kg P_2O_5/Da, P24: 24 kg P_2O_5/Da, and phosphorus fertilization in the form of triple superphosphate (42-44%) was applied twice before lavender planting and in March 2023 in accordance with the experimental design. The average plant height of lavender was 59,997cm, and the longest plant height was 61,522cm in the P6 group. The shortest plant height was 56,289cm in the P0 group. In our study, the average fresh and dry flower yields of lavender plants were 131.48kg/ha and 111.22kg/ha, respectively. The highest fresh and dry flower yields were 144,49kg/da and 121,60kg/da in P6 group, while the lowest yields were 122,33kg/da and 102,87kg/da in P0 group. In lavender plants with an average essential oil yield of 3,757kg/da, the highest essential oil yield was found in P6 group (4,550kg/da) and the lowest essential oil yield was found in P0 group (3,182kg/da) and the difference between the groups was significant ($p<0,001$).

Key words: Lavender, Angustifolia Sevtapolis, phosphorus fertilization, essential oil, yield.

INTRODUCTION

Lavandula (*Lavandula angustifolia* mill.), also known as English lavender or true lavender, one of more than 50 varieties of the lavandula genus belonging to the *Lamiaceae* family, consisting of aromatic plants such as mint, rosemary and basil, originates from the Mediterranean region (Erland & Mahmoud, 2016). Lavender, a valuable essential oil plant, is a perennial and semi-shrub-like plant (Guenther, 1952). This shrub is frequently preferred in lavender cultivation for use in medical applications due to the sedative, antidepressant and anti-inflammatory effects of the essential oils it contains (Denner, 2009; Jianu et al., 2013). In various studies, the essential oil yield of lavender was determined between 0.2-4.5% and in studies on the effects of phosphorus fertilization on *Lavandula angustifolia* plant, results were found that phosphorus fertilization increased the essential oil yield of lavender (Peçanha et al., 2021). The primary purpose of our study is to determine the effects of different doses of phosphorus fertilization on the development and essential oil yield of lavender and to determine the phosphorus doses required to obtain the best yield in the *Lavandula Angustifolia* mill. variety. *Lavandula angustifolia*, which can grow in any soil that is not overly acidic and well-drained, reaches the highest essential oil yield in light sandy soil and its scent is more pronounced in calcareous soil (Lim, 2012). Lime application to the soil improves the soil by providing neutralization and positively affects the development of lavender (Valcheva, 2020). In line with this information, we preferred a field with alkaline (pH:7,8) and high calcareous soil (42,1%) for our study. In the studies on phosphorus fertilization of lavender in the existing literature, the characteristics of the soil used in the experiments were not frequently mentioned. This may be related to the significant essential oil yield results obtained from measurements on the same variety of lavender (*Lavandula angustifolia* mill.) plants (Peçanha et al., 2021). Therefore, the secondary aim of our study was to characterize the soil used in the experiment and to discuss our results with respect to the characteristics of the experimental soil.

MATERIALS AND METHODS

1.1. Plant materials

Lavandula Angustifolia Sevtapolis variety was used as plant material. The seedlings used in the study were cut from clonal rootstocks and produced in the Fruit Research Institute Directorate (Isparta/Turkey). These seedlings were supplied as 1+1-year-old bare root seedlings.

1.2. Experimental design

The study was established and conducted with three replications according to the Randomized Complete Blocks Design at Niğde Ömer Halisdemir University, Faculty of Agricultural Sciences and Technologies, Medicinal Plants Application Area (37.94” North and 34.62” West, Turkey). The region has typical continental climate characteristics. The average climate data of Nigde province, where the study was conducted, is given in table 1.

This meteorological data were obtained from Nigde provincial meteorology directorate.

Before the establishment of the experiment, the field soil was analyzed at Soil and Water Analysis Laboratory of Nigde Special Provincial Administrationand and it was found that the saturation was 41.8%, pH 7.8, salt content 0.01%, lime ($CaCO_3$) content 42.1%, organic matter content 0.2%, available phosphorus (P_2O_5) content 2.4 Kg/Decar. The experimental area was divided into plots as P0: 0 kg P_2O_5/ha, P6: 6 kg P_2O_5/ha, P12: 12 kg P_2O_5/ha, P18: 18 kg P_2O_5/ha, P24: 24 kg P_2O_5/ha, and phosphorus fertilization in the form of triple superphosphate (42-44%) was applied twice before planting lavandula and in March 2023 in accordance with the experimental design. The seedlings were planted in the experimental field in March 2022 with a distance of 120 cm between rows and 50 cm above rows (McGimpsey & Porter, 1999). Irrigation was done at two-day intervals and 4 hours a day using drip irrigation system. Pure nitrogen fertilization was applied to the field twice a year at a dose of 10 kg/da.

1.3. Measurements

The first harvest of lavender was made in August 2022, and the first harvest data were not taken into consideration in the evaluation of the yield potential of lavender, which is a perennial plant, since the second harvest data are more appropriate (Giannoulis et al., 2020). Before the second harvest, morphological measurements (plant height, habitus diameter, number of flower spikes) were made. Immediately after the morphological measurements, lavender plants were cut 10 cm above the soil in August 2023 and harvested for the second year (Hassiotis et al., 2014). Wet weight and flower yield (kg/ha) were measured without waiting after harvest. Plants were left to dry in a dark place at temperature. After drying, dry weight and dry flower yield (kg/ha) were measured.

For each plot, 25 g of dried flower samples were taken for oil analysis by Batı Akdeniz Tarımsal Araştırma Enstitüsü Müdürlüğü (BATEM) and essential oils of the samples were obtained by water vapor distillation method in Clevenger device and essential oil ratios were calculated as percentage (Skoula et al., 2000). Basic scent components of the essential oils were analyzed by GC/GC-MS (Gas chromatography (Agilent 7890A)-mass detector (Agilent 5975C)) using a capillary column (HP Innowax Capillary; 60.0 m x 0.25 mm x 0.25 µm). The amounts of phenolic substances were determined as gallic acid equivalent (mgGAE/100g) using the Folin-Ciocalteu colorimetric method (Singleton & Rossi, 1965).

1.4. Statistical analyses

In the analysis of the data, the results of morphological measurements and chemical analyses obtained from the plots divided in coincidence blocks in accordance with the field experiment design were given as mean, standard deviation, minimum and maximum. The differences between the groups treated with different doses of phosphorus were tested by one-way analysis of variance (ANOVA). The interactions of the parameters showing statistically significant differences as a result of one-way analysis of variance with phosphorus dose were examined by quadratic regression analyses and effective phosphorus fertilization doses were calculated. Correlation analyses were performed to determine whether there is a relationship between the data obtained in the study. All data were analyzed with 95% confidence interval and IBM SPSS Statistics for Windows (Ver22.0, IBM Corp., Armonk, NY: USA, 2013) was used for data analysis.

2. RESULTS

In the 1st and 2nd year, soil analysis was repeated after all fertilization treatments were applied. Saturation was 36.45%, pH 7.67, salt content 0.01%, lime ($CaCO3$) content 37.91%, organic matter content 1.97%, available phosphorus ($P2O5$) content 31.26 kg/decar.

Descriptive data of the study parameters and the results of the analysis of variance of the study parameters between the groups administered different doses of phosphorus are presented in Table 2.

Table 2. Mean, standart deviation, minimum and maximum datas of the lavander plants and the results of one way variance analysis between the different phosphorus dose groups.

	Descriptives				Differences between the groups	
	Min.	**Max.**	**Mean**	**S.D.**	**F**	**p-value**
Plant Height (cm)	52.90	68.40	60.00	4.11	2.88	0.035

2.1. Correlation analyses

Correlation analysis was performed between the study parameters and the results of correlation analysis are given in table 3. There was a strong positive correlation between plant height, habitus diameter and number of flower spikes and wet and dry yields. There is a strong positive correlation between essential oil yield (kg/ha) and habitus diameter and a positive correlation between essential oil yield (kg/ha) and number of flower spikes.

Table 3. Correlation between the study parameters.

	P. Dose	Plant Height	Habitus Diameter	Number of FS	Fresh Flower Yield	Dried Flower Yield	EOY (kg/da)	Amount of PS

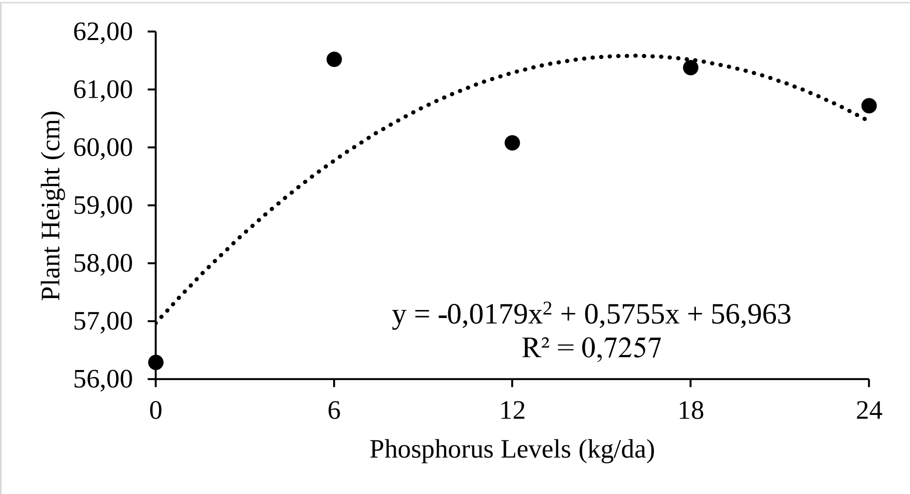
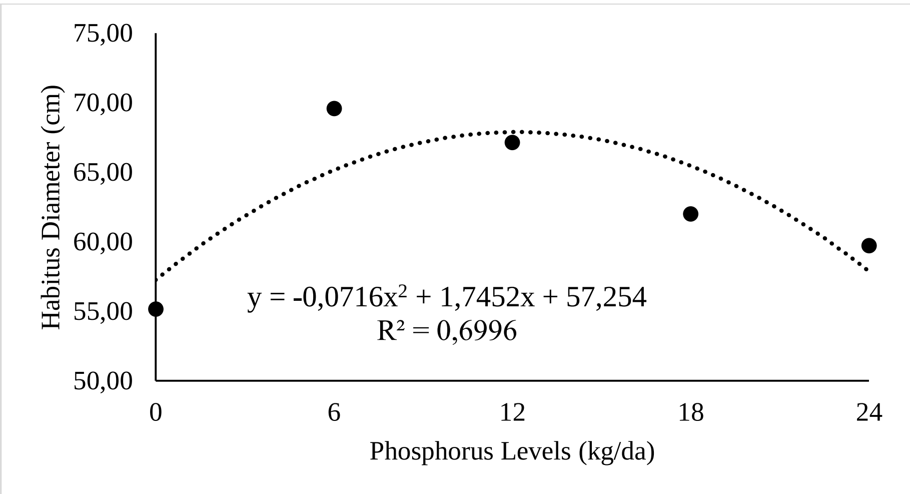
2.2. Regression analyses

The average plant height of lavender was 59,997±4,114 cm, the longest plant height was 61,522±1,143 cm in P6 group. The shortest plant height was 56,289±2,761 cm in P0 group. The effect of phosphorus applied at different doses on plant height was significant (p=0.035) and quadratic regression analysis was performed between them (y = -0.0179x2 + 0.5755x + 56.963, R2=0.7257, Figure 1). According to this regression, the effective phosphorus dose required to obtain the longest plant height was calculated as 16,075 kg/ha. The average habitus diameter was 62,724±7,922cm, the widest was 69,589±4,788cm in P6 group and the narrowest was 55,156±8,344cm in P0 group. The difference in habitus diameter between the groups was significant at p<0.001 level and the effective phosphorus dose for the widest habitus diameter was determined as 12.185kg/ha (y = -0.0716x2 + 1.7452x + 57.254, R² = 0.6996, Figure 1). The average number of flower spike of lavender plants was 100,45±20,25. The highest number of flower spike was 105,51±3,47 in P12 group and the lowest number of flower spike was 86,18±6,57 in P0 group and the difference between the groups was significant (p=0,011). The effective phosphorus dose required to reach the maximum number of flower spike was calculated as 15,315kg/ha (y = -0,0821x2 + 2,5148x + 88,009, R² = 0,8844, Figure 1).





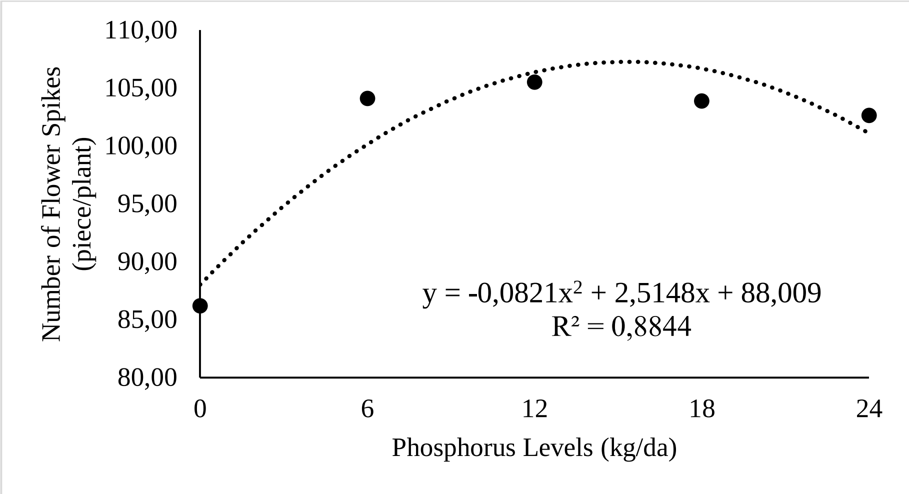


Figure 1. Regression analysis between phosphorus doses and plant height, habitus diameter, number of flower spikes.

In our study, the average fresh and dry flower yields of lavender plants were 131,48±12,16kg/da and 111,22±10,12kg/da, respectively. The highest fresh and dry flower yields were 144,49±12,19kg/da and 121,60±9,87kg/da in P6 group, while the lowest yields were 122,33±3,79kg/da and 102,87±3,35kg/da in P0 group. The differences between fresh and dry flower yields were statistically significant at p=0.001 level. The effective phosphorus dose to obtain the best fresh flower yield was calculated as 13,197kg/da ($y = -0{,}0394x2 + 1{,}0399x + 127{,}51$, $R^2 = 0{,}1158$) and the effective phosphorus dose to obtain the best dry flower yield was calculated as 13,442kg/da ($y = -0{,}0397x2 + 1{,}0673x + 106{,}98$, $R^2 = 0{,}1809$) (Figure 2). In lavender plants with an average essential oil yield of 3,757±0,593kg/ha, the highest essential oil yield was found in P6 group (4,550±0,354kg/ha) and the lowest essential oil yield was found in P0 group (3,182±0,602kg/ha) and the difference between the groups was significant ($p<0{,}001$). The effective phosphorus fertilization dose to be applied to lavandula to obtain the highest essential oil yield was calculated as 11,680kg/ha ($y = -0{,}0047x2 + 0{,}1098x + 3{,}4478$, $R^2 = 0{,}3909$, Figure 2). The mean phenolic content of lavender was 0,925±0,149GAE/100g. The highest phenolic content was measured in P12 group lavender with 0,999±0,189GAE/100g and the lowest phenolic content was measured in P6 group lavender with 0,833±0,173GAE/100g. There was no statistically significant difference in phenolic content between the groups (p=0,087). The average antioxidant activity (EC50) of lavandulas was 1,937±0,396µL, the highest antioxidant activity was found in P24 group (2,239±0,414µL) and the lowest antioxidant activity was found in P6 group (720±0,212µL). There was a significant difference between the groups (p=0,028). Although 9.52kg/da phosphorus dose application was predicted to cause the lowest antioxidant activity ($y = 0.0025x2 - 0.0476x + 1.9625$, $R^2 = 0.948$), no significant correlation was found between the phosphorus doses applied, wet yield, dry yield and essential oil yield.

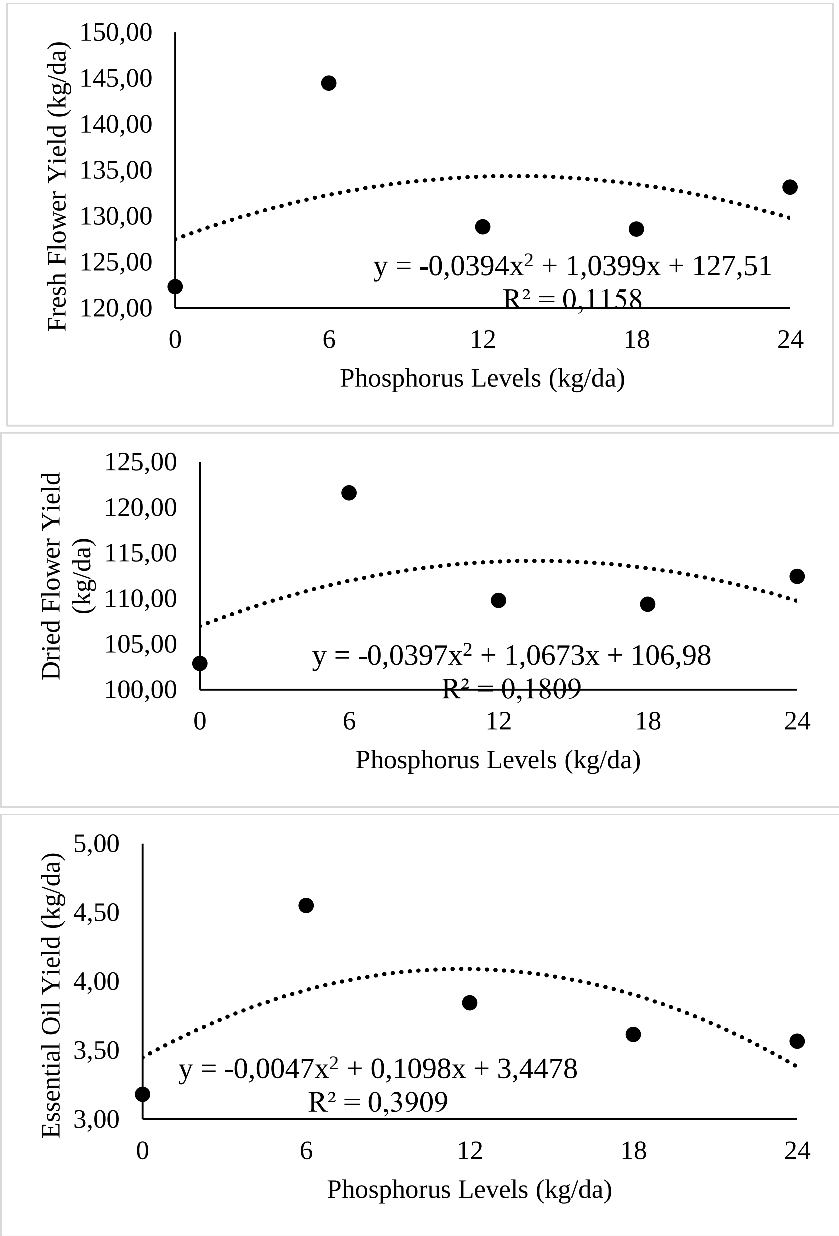

Figure 2. Regression analysis between phosphorus doses and fresh flower yield, dry flower yield, essential oil yield.

DISCUSSION

Although it has been classically shown that the productivity of lavender increases at pH 6.4 (neutral) and pH 8.2 (slightly alkaline) acidity values (Crișan et al., 2023), recent studies have shown that soil pH should be between 6.5 and 7.5 for good development of lavender (Crummitt & Drost, 2012). The lime content of the soil in the experimental field where our study was conducted was as high as 42.1% and accordingly, the pH value was measured as 7.8 before the application. Even though this lime content was 37.9% and pH was 7.67 after fertilisation, pH did not fall below 7.5 as a result of the high lime content of the experimental soil. Nevertheless, the data obtained in our study were generally similar to the literature and this situation suggests that the high pH and lime content of the soil does not have a negative effect on lavender growth. Although lavender plant height is related to the genetic potential of the variety, it is also known to be affected by different growth environment or environmental factors (Arabaci & Bayram, (2005). Although lavender can grow up to 1 metre in length under optimum growth conditions, similar to our study, in other studies, researchers reported that plant height varied between 60.4-69.5 cm (Arabaci & Bayram, (2005), 43.2-79.5 cm (Chrysargyris, 2018) and 40.8 cm in another study (Özyilmaz et al., 2022). In our study, the longest plant height was obtained in P6 group and the shortest plant height was obtained in P0 group. Erbaş et al., 2017 investigated the effects of 0, 5, 10 and 15 kg/da phosphorus applications on lavandin and the longest plant height was measured in the group fertilized at 10 kg/da (104.7 cm) and the shortest plant height was measured in the control group (93.0 cm). In the same study, plant height was measured as 94.3 cm in the group with 15 kg/da phosphorus fertilization (Erbaş et al., 2017). In our study, the phosphorus dose required to reach the maximum plant height was found to be 16.075 kg/da. In our study, the habitus diameter of lavender plants was found to be the widest in P6 group and the narrowest in P0 group parallel to plant height. In another study investigating the effects of different types of fertilizations on lavender growth, habitus diameters were measured and it was observed that habitus diameters were parallel to plant height (Pryvedeniuk et al., 2023). In our study, a strong positive correlation was shown between plant height and habitus diameter measurements for Lavandula angustifolia. We also found that habitus diameter showed a strong positive correlation with essential oil content and according to our results, habitus diameter was the most effective morphological measurement to show the essential oil content of Lavandula angustifolia. The number of flower spike, which is determined by counting the spikes formed on the flower stalks of the plant, is one of the important parameters affecting flower yield and may vary according to species and varieties (Karık et al., 2017). Researchers found that the number of flower spikes varied between 55.9 and 471.9 pieces/plant (Aslan & Sarihan, 2021). In our study, the average number of flower spike was 100.45±20.25, the highest number of flower spike was determined in P12 group and the lowest number of flower spike was determined in P0 group and it showed positive correlation with other morphological parameters. In the other two studies in which different treatments were applied, fresh stem flower yield in lavender varied between 462.6-613.8 kg/da (Kara & Baydar, 2013) and 541.7-569.9 kg/da (Karık et al., 2017), dry stem flower yield varied between 219.7-312.0 kg/da (Kara & Baydar, 2013), 85.6-450.7 kg/da (Karık et al., 2017) and 185.0-366.0 kg/da (Pistelli et al., 2017). Erbaş et al., who investigated the effects of phosphorus application at different doses, found that both dry and fresh flower yields of plants treated with 10kg/da phosphorus were significantly higher than the other groups, while the control group was significantly lower than the other groups (Arabaci & Bayram, (2005). These results were similar to our results. In our study, the average fresh and dry flower yields of lavender plants were 131.48±12.16kg/da and 111.22±10.12kg/da, respectively, and the highest fresh and dry flower yields were measured in P6 group and the lowest fresh and dry flower yields were measured in P0 group. In our study, it was calculated that phosphorus application at doses of 13,197kg/da for the highest fresh flower yield and 13,442kg/da for the highest dry flower yield. In previous studies, it was reported that the essential oil yield in lavender varied between 3.17-4.13 kg/da (Ceylan et al., 1988), and in Lavandula angustifolia, the essential oil yield varied between 1.49-2.53 kg/da (Atalay, 2008) and 0.83-13.47 kg/da (Arabaci & Bayram, (2005) in two different studies. In our study, in lavender plants with an average essential oil yield of 3,757±0,593kg/da, the highest essential oil yield was found in P6 group (4,550±0,354kg/da) and the lowest essential oil yield was found in P0 group (3,182±0,602kg/da) and the difference between the groups was significant ($p<0,001$). In the study of Erbaş et al., 2.09% and 2.10% essential oil content was determined in 15kg/da and 10kg/da phosphorus dose groups, respectively, and it was significantly different from the control group (Erbaş et al., 2017). In our study, the phosphorus dose required to obtain the best essential oil yield was calculated as 11,680kg/da. In another study conducted as a pot experiment under tropical conditions, regression curves and effective doses were calculated and the ideal phosphorus dose for the best essential oil yield was found to be 77 mg/dm3 (Peçanha et al., 2021). However, this study is different from our study both because it was a pot study and because the climatic conditions were kept under controlled conditions.

In conclusion, lavender has adapted to the slightly alkaline soil with high lime content of our trial area. Phosphorus fertilization is known to be beneficial for Lavandula angustifolia. In this study, in which we aimed to find out this beneficial effect in more detail, we calculated by means of regression graphs that phosphorus should be applied at a dose of 13,197kg/da for maximum fresh flower yield, 13,442kg/da for maximum dry flower yield and 11,680kg/da for maximum essential oil yield. Our study stands out as one of the pioneering field studies in which Lavandula angustifolia effective phosphorus dose calculation was made by regression analyses.

THE AGRICULTURAL USE OF BIOMASS: TRANSFORMING WASTE INTO RESOURC

Serdar ÜÇOK*[1]

[1]*Kahramanmaras Sutcu Imam University, Faculty of Agriculture, Department of Biosystems Engineering, Kahramanmaras, TURKEY*

ABSTRACT

The agricultural use of biomass represents a vital strategy for enhancing sustainability, improving waste management, and reducing greenhouse gas emissions in farming practices. Biomass, derived from organic materials such as crop residues, animal manure, and dedicated energy crops, can be converted into renewable energy, soil amendments, and other valuable products. This approach not only mitigates environmental impacts but also supports the transition to a circular economy by repurposing agricultural waste. Technologies such as anaerobic digestion, pyrolysis, and fermentation play a crucial role in efficiently converting biomass into bioenergy and bio-based products, contributing to the resilience and productivity of agricultural systems. Furthermore, the adoption of biomass technologies promotes rural economic development, creating jobs and stimulating local economies. However, to fully realize the potential of biomass in agriculture, ongoing research, technological advancements, and supportive policies are essential. This abstract provides an overview of the benefits, challenges, and future prospects of biomass utilization in agriculture, highlighting its role as a cornerstone in the transition towards more sustainable and climate-resilient farming practices.

INTRODUCTION

Agriculture is a cornerstone of human civilization, providing food, fiber, and fuel for centuries (Popp et al, 2014). However, modern agriculture faces significant challenges, including the need for sustainable practices, waste management, and the reduction of greenhouse gas emissions. One promising solution to these challenges is the use of biomass. By transforming agricultural waste into valuable resources, biomass can enhance the sustainability and efficiency of agricultural systems. This article explores the agricultural use of biomass, its benefits, technologies, and future prospects (Sims et al, 2006).

In the face of mounting environmental challenges and the imperative for sustainable agricultural practices, biomass emerges as a potent solution (Popp et al, 2014). Biomass, derived from organic materials such as plants, agricultural residues, and animal waste, has been used by humans for millennia. However, modern advancements in technology have vastly expanded its potential applications, transforming it into a cornerstone of sustainable agriculture (Tshikovhi and Motaung 2023).

Agriculture is both a contributor to and a victim of climate change, generating substantial greenhouse gas emissions while also being highly vulnerable to the impacts of a warming planet. One of the key strategies to mitigate these effects and enhance the sustainability of agricultural practices is the effective use of biomass **(Smith et al, 2007).** By converting agricultural waste into valuable resources, biomass can address issues of waste management, renewable energy production, soil health, and carbon sequestration (Lal, 2004), (McKendry, 2002).

The use of biomass in agriculture not only helps in reducing the environmental footprint of farming activities but also supports the transition to a circular economy (Ghisellini et all, 2016). This approach ensures that waste materials are not merely discarded but are repurposed to create energy, improve soil fertility, and sequester carbon. As global populations grow and demand for food increases, the agricultural sector must innovate to meet these needs sustainably (Van et al, 2011). Biomass offers a versatile and effective means to do so, integrating seamlessly with existing agricultural practices and enhancing their overall sustainability (Tshikovhi and Motaung 2023).

This article delves into the myriad ways biomass can be utilized within agriculture, exploring its sources, conversion technologies, environmental benefits, economic impacts, and future prospects (Sims et al, 2006). By understanding the full scope of biomass's potential, we can better appreciate its role in fostering a more sustainable and resilient agricultural system.

What is Biomass in Agriculture?

In the context of agriculture, biomass refers to organic materials derived from plants and animals that can be used for energy production, soil enhancement, and other applications. Common sources of agricultural biomass include crop residues (such as straw, husks, and stalks), animal manure, and dedicated energy crops (like switchgrass and miscanthus). Additionally, waste from food processing and other agricultural by-products can be considered biomass (McKendry, 2002), (Lewandowski et al, 2003), (Cherubini and Ulgiati, 2010), (Monti and Alexopoulou, 2013).

Benefits of Biomass in Agriculture

1. Waste Management

Agricultural activities generate substantial amounts of organic waste, which, if not managed properly, can contribute to environmental pollution and greenhouse gas emissions. Utilizing this waste as biomass for energy production or soil amendments can significantly reduce the environmental footprint of agriculture. This approach transforms waste into a resource, promoting a circular economy in agricultural practices (Ghisellini et al, 2016).

2. Renewable Energy Production

Biomass can be converted into various forms of renewable energy, such as biogas, bioethanol, and biodiesel. These biofuels can be used to power farm machinery, generate electricity, and provide heat, reducing reliance on fossil fuels and lowering greenhouse gas emissions. For instance, anaerobic digestion of animal manure produces biogas, which can be used for electricity generation or heating, while the digestate can be applied as a fertilizer (McKendry, 2002), (Scarlat et al, 2018), (Weiland, 2010).

3. Soil Health and Fertility

Biomass can enhance soil health and fertility through the application of biochar and compost. Biochar, prodced through the pyrolysis of organic materials, improves soil structure, increases water retention, and enhances nutrient availability. Composting agricultural residues enriches the soil with organic matter, promoting microbial activity and plant growth. These practices contribute to sustainable soil management and increased agricultural productivity (Basu, 2013).

4. Carbon Sequestration

The use of biomass in agriculture can contribute to carbon sequestration, the process of capturing and storing atmospheric carbon dioxide (Tilman et al, 2006). Biochar application, in particular, sequesters carbon in the soil for long periods, reducing the overall carbon footprint of agricultural activities (Lal, 2004). This practice helps mitigate climate change by removing CO_2 from the atmosphere and storing it in stable forms.

Technologies for Biomass Utilization in Agriculture

1. Anaerobic Digestion

Anaerobic digestion is a biological process that breaks down organic matter in the absence of oxygen, producing biogas and digestate (Scarlat et al, 2018). This technology is widely used for the treatment of animal manure and other agricultural residues (Tilvikiene and Malakauskiene, 2019). The biogas produced can be used for energy production, while the nutrient-rich digestate serves as an excellent fertilizer, returning valuable nutrients to the soil (McKendry, 2002), (Weiland, 2010).

2. Pyrolysis

Pyrolysis involves the thermal decomposition of organic materials at high temperatures in the absence of oxygen, resulting in the production of biochar, bio-oil, and syngas. Biochar is particularly valuable for its soil-enhancing properties, while bio-oil and syngas can be used as energy sources. Pyrolysis offers a way to convert agricultural residues into high-value products, contributing to both energy production and soil health (Basu, 2013), (Zhang et al, 2019).

3. Composting

Composting is the aerobic decomposition of organic matter by microorganisms, resulting in the formation of humus-like material. This process can be used to convert crop residues, animal manure, and other organic waste into nutrient-rich compost. Compost improves soil structure, enhances nutrient availability, and promotes healthy plant growth. It is a simple yet effective way to recycle agricultural biomass and improve soil fertility (Bernal et al, .2009), (Insam and de Bertoldi, 2007).

4. Fermentation

Fermentation is a biochemical process that converts sugars in organic materials into alcohols, such as ethanol, through the action of microorganisms. This technology is commonly used to produce bioethanol from crops like corn and sugarcane. Bioethanol can be used as a renewable fuel for vehicles, reducing reliance on fossil fuels and lowering greenhouse gas emissions. Advanced fermentation technologies are also being developed to convert lignocellulosic biomass, such as crop residues, into bioethanol (Balat et al, 2008), (Limayem and Ricke, 2012), (Hahn et al, 2006), (Sanchez and Cardona, 2008), (Zhang, 2013).

Future Prospects of Biomass in Agriculture

The future of biomass in agriculture is promising, with ongoing research and technological advancements expanding its potential applications. Some key areas of development include (Sims et al, 2006):

1. Integration with Other Renewable Energy Sources

Combining biomass with other renewable energy sources, such as solar and wind, can create more resilient and efficient energy systems for farms. For example, integrating biogas production with solar panels can provide a stable and continuous energy supply, even when solar energy is not available (Sokhansanj and Fenton, 2006).

2. Precision Agriculture

The use of precision agriculture technologies can optimize the application of biomass-derived products, such as fertilizers and biochar. Precision agriculture involves the use of sensors, data analytics, and GPS technology to tailor agricultural practices to specific field conditions. This approach can enhance the efficiency and effectiveness of biomass utilization, promoting sustainable and productive farming (Mulla, 2013), (Jha et al, 2019), (Zhang et al, 2002), (de Oliveira et al, 2018), (Bhatt 2016).

3. Advances in Biomass Conversion Technologies

Ongoing research is focused on improving the efficiency and sustainability of biomass conversion technologies. Innovations in anaerobic digestion, pyrolysis, and fermentation can increase the yield and quality of biomass-derived products, making them more economically viable and environmentally friendly. Developing new methods to convert a wider range of biomass feedstocks into valuable products can further expand the potential of biomass in agriculture (Smeets et al, 2007).

4. Policy Support and Incentives

Government policies and incentives play a crucial role in promoting the use of biomass in agriculture. Supportive policies can encourage investment in biomass infrastructure, research, and development. Financial incentives, such as subsidies and tax credits, can make biomass technologies more accessible and affordable for farmers. Additionally, regulations that promote sustainable biomass sourcing and utilization can ensure that the environmental benefits of biomass are fully realized (Scarlat et al, 2015), (.Sims et al, 2015), (IRENA, 2016), (Gunningham and Sinclair, 2002), (Panoutsou and Castillo, 2020).

CONCLUSION

The agricultural use of biomass offers a sustainable and versatile solution to some of the most pressing challenges in modern agriculture. By transforming waste into valuable resources, biomass can enhance waste management, produce renewable energy, improve soil health, and contribute to carbon sequestration (Lal, 2004). The development and adoption of advanced biomass conversion technologies, supported by precision agriculture and favorable policies, can unlock the full potential of biomass in agriculture (Smeets et al, 2007). As we continue to seek sustainable practices and innovative solutions, biomass stands out as a key component in the transition towards a more resilient and sustainable agricultural future (Tshikovhi and Motaung 2023).

The agricultural use of biomass represents a crucial intersection of sustainability, innovation, and economic viability. As we face the dual challenges of feeding a growing global population and mitigating the adverse impacts of climate change, biomass offers a multifaceted solution that addresses both issues simultaneously. The ability to convert agricultural waste into renewable energy and valuable soil amendments not only reduces the environmental footprint of farming practices but also enhances the overall productivity and sustainability of agricultural systems.

The benefits of biomass in agriculture are manifold. From improving waste management and reducing greenhouse gas emissions to enhancing soil health and fertility, the integration of biomass into agricultural practices can lead to significant environmental and economic gains. The application of advanced technologies such as anaerobic digestion, pyrolysis, and fermentation further expands the potential of biomass, allowing for the efficient conversion of a wide range of organic materials into useful products (Zhang et al, 2019).

Moreover, the adoption of biomass technologies can drive rural economic development by creating new job opportunities and stimulating local economies. This is particularly important in agricultural regions, where biomass resources are often abundant. By supporting the development of a bio-based economy, we can promote a more sustainable and equitable distribution of economic benefits (Ghisellini et all, 2016).

However, realizing the full potential of biomass in agriculture requires concerted efforts across multiple fronts (Smeets et al, 2007). Technological advancements must continue to improve the efficiency and sustainability of biomass conversion processes. Policies and incentives are needed to support the adoption of biomass technologies and ensure sustainable sourcing and

utilization of biomass resources. Additionally, education and outreach efforts are essential to raise awareness about the benefits of biomass and encourage its widespread use.
Looking to the future, the integration of biomass with other renewable energy sources and precision agriculture technologies holds great promise. Hybrid energy systems that combine biomass with solar, wind, and other renewables can provide a stable and resilient energy supply for farms. Precision agriculture, with its data-driven approach, can optimize the use of biomass-derived products, enhancing their effectiveness and sustainability.
In conclusion, the agricultural use of biomass is a powerful tool for achieving a more sustainable and resilient agricultural sector. By transforming waste into valuable resources, biomass can help address some of the most pressing environmental and economic challenges facing agriculture today. As we continue to innovate and develop new technologies, the potential of biomass will only grow, offering new opportunities for sustainable development and climate change mitigation. Embracing biomass in agriculture is not just a step towards sustainability; it is a stride towards a future where farming practices are in harmony with the environment, ensuring food security and prosperity for generations to come (Popp et al, 2014).

A DNA-BASED CHARACTERISATION FOR DUS TESTS: MOLECULAR MARKERS

Didem Karalar[1], Mehmet Emin Caliskan[1]*

[1] *Department of Agricultural Genetic Engineering Nigde Ömer Halisdemir University, Faculty of Agricultural Sciences and Technologies*

didemkaralar@ohu.edu.tr

ABSTRACT

Plant variety protection was implemented initially by registration of seeds by the Distinctness, Uniformity, and Stability (DUS) testing criteria. Since the late 90s, discussion of DUS criteria inefficiency and searching for a novel DNA-based method has shown up. The inefficiency of DUS criteria with the time and cost needed for every step of field testing regarding the thousands of plant registrations yearly makes the process debated. Also defining, characterizing, and distinguishing plants solely based on phenotypic and biochemical standards are not reliable. Recent advancements in the biotechnology area have led to the registration system in another way. The International Union for the Protection of New Varieties of Plants (UPOV) has proposed the use of molecular markers to address these constraints. Contrary to traditional DUS tests, the application of molecular markers pointed to significant advancement. Some molecular markers such as Single Nucleotide Polymorphisms (SNP) and Simple Sequence Repeats (SSRs) provide greater precision and annihilate one of the main hesitations; what if the chosen marker is not related to phenotype? There are case studies so far in crops like corn, wheat, rice, and others that have shown better performance than standard DUS traits to distinguish and fit pedigree information. Despite these advancements, the adoption of molecular markers in DUS testing faces several challenges, including the need for standardized protocols and the development of robust marker-trait associations. Additionally, the cost and infrastructure requirements for these technologies pose significant barriers, particularly in developing countries. Continuous research and globalisation are needed to standardise the molecular markers, develop the databases, and increase the reliable use of molecular markers in DUS testing across different crops and regions. This review highlights an overview of current practices, perspective on molecular marker utilisations the need for further innovations in DUS testing.

Keywords: DUS test, molecular marker, UPOV, plant variety protection

INTRODUCTION

Variety registration is the registration of novel plant varieties which are the Distinct - characters (either morphologic or biochemical) that are not greatly influenced by the environment so the cultivar must be unique and not have been registered before, Uniform - level, and type of variation of individuals within the cultivar which variation should be commercially acceptable, and Stability - refers to a cultivar must remain true to its description when it is reproduced or propagated. DUS tests have long been critical, serving as the principal framework for plant variety protection and registration by the International Union for the Protection of New Plant Varieties (UPOV) internationally. DUS tests adapted for each plant variety by time. DUS testing has traditionally placed a heavy emphasis on morphological variables such as plant seed color and size, plant length, leaf color and shape, flower color, etc.(Yu & Chung, 2021), biochemical markers on some plants, and recently molecular markers have begun to integrate (UPOV, 2019a). For many years, phenotypic methods have offered a strong basis for distinguishing between plant varieties, especially in established crops like rice, wheat, and maize, where these characteristics are generally constant and well-understood.

As biotechnology has advanced new tools and approaches emerged that aid in fastening and easing plant breeding, and a new era started. In this way, breeding techniques have become increasingly sophisticated, and the limitations of relying solely on morphological traits have become more apparent. Trials are time-consuming, by increasing numbers and in some countries exceeding numbers of candidate varieties make the process drastically expensive and labor-intensive along with the problem of decreased variability and need for reference collections (Bernet et al., 2003; Gunjaca et al., 2008). The stated problems lead to inconsistencies, particularly when environmental factors influence the expression of the traits (Jamali et al., 2019). The distinctions between varieties become less evident as breeding programs push the genetic variety boundaries, it is becoming more difficult to differentiate based solely on visual features. In some crops such as soybeans and barley, it is especially obvious where phenotypic changes between varieties can be subtle and difficult to detect using typical DUS testing methods (Achard et al., 2020; Cockram et al., 2012).

Despite the undeniable advantages of the utilization of molecular markers in DUS tests, the fact remains that they have some limitations and disadvantages. First of all, the utilization of these markers requires special equipment and expertise and in developing countries where biotechnological developments are uneven and access to resources is limited, that is a concerning circumstance (Ribaut et al., 2010). On the other hand where there's another side of concerns already rising, dependence on proprietary technology and genetic data creates questions about the availability of these resources to all stakeholders involved in the agriculture industry and intellectual property rights (Blakeney, 2011). Accessibility in terms of biotechnological applications and genetic data, the width and depth of databases, and the density of studied plants also vary, and the scarcity and quality of studies that will help distinction of varieties that will cover the entire genome for each plant reduces access to markers that can be utilized in this way. These difficulties demonstrate the need for continued investment in infrastructure and studies to ensure the benefits of molecular marker-based DUS testing are realized on a global scale. A plethora of investigations that began with PCR advent such as RAPD markers (Kresovich et al., 1992), microsatellite markers (Rongwen et al., 1995), and AFLP markers (Lombard et al., 2000) in the case of plant variety distinction. By the time UPOV stated the need for a DNA-based method due to reliability, grand potential, and high resolution on distinctiveness, toward this demand two different strategies had been created and a subgroup of Technical and Legal Experts of Biochemical and Molecular Techniques (BMT Review Group) stepped in.

The evolution from a purely phenotypic to a molecular marker-based approach to DUS testing constitutes a significant advancement in plant variety protection. This shift is a proactive response to the evolving demands of contemporary agriculture as well as a reaction to the shortcomings of conventional approaches (De Riek, 2001). Molecular markers offer promise for plant variety protection and global food security as they continue to be refined and their applications expanded. Nonetheless, molecular markers have the potential to revolutionize plant variety protection, but there are several issues that need to be handled before this can be fully realized.

CURRENT PRACTICES IN TRADITIONAL DUS TESTING

Plant variety protection continues to be based on Distinction, Uniformity, and Stability (DUS) testing, which verifies that new plant varieties meet strict requirements prior to receiving legal protection and being made available for commercial release. DUS testing is based on the Protection of Breeders' Rights governed by the Convention of the International Union for the Protection of New Varieties of Plants (UPOV). Breeders' rights protection systems provide exclusive rights to owners of plant varieties on production, distribution, and marketing, and compensate for the cost of developing new varieties (Yu & Chung, 2021). UPOV offers a uniform framework for the protection and registration of new plant varieties that should meet some requirements; the variety should be original, distinguishable from other varieties, and stable in between generations (UPOV, 1991). A key component of this protection is the need for new varieties to be subject to DUS testing and accepted successfully before they can receive legal protection.

A new variety must be Distinct from others based on a specific phenotypic trait (including morphological, physiological, or biochemical traits). Uniformity is achieved by consistent expression of these traits, with variations allowed only within predefined limits. By observing the variety over multiple generations (at least two generations for DUS test trials) to ensure that its essential characteristics remain stable through repeated propagation, stability is confirmed (UPOV, 1991). Phenotypic traits such as plant length are vital in cereal crops like wheat for U (uniformity) and D (distinctness). To achieve the DUS standards varieties need to exhibit uniformity across various habitats. For example in the testing of ornamental plants, like roses, leaf shape and size play a crucial role in determining distinctiveness; in the case of vegetables, like tomatoes, fruit size and shape determine uniformity for instance, a new tomato variety must reliably yield fruit with a specific form, such round. In crops like wheat, the primary morphological characteristics that contribute to distinctness are spike length, awning, and grain color (Yu & Chung, 2021). For example a study done on durum wheat, to test the uniformity and stability of the new variety, variety distinction closely monitored key components of grain yield, such as grain protein content and grain yield per spike (Blanco et al., 2011). In the utilization and development of molecular markers to account for environmental heterogeneity and assure comprehensive evaluation, field trials are carried out in a variety of locations and growing seasons and these are labor and resource-intensive, high cost, and documenting and expertise are necessary (Akbari et al., 2024; Bonow et al., 2009; Gupta et al., 2022; Kresovich et al., 1992; Li et al., 2008; Thapa Magar et al., 2021).

DUS testing is conducted on various plant species, including rice, wheat, and maize, are assessed annually to ensure that food safety standards are met worldwide (Jamali et al., 2019) demonstrating the continuous progress in plant breeding and the introduction of new varieties for various agricultural and horticultural purposes. There are 338 testing guidelines, as of August 2024, to conduct DUS tests. The identification of phenotypic traits is limited by phenotype-based DUS testing due to environmental influences that complicate the determination process. The reliability of DUS testing can be compromised by varieties that appear uniform across different environmental conditions (Yang et al., 2021). Additionally, it can be difficult to identify closely related varieties due to potential inconsistencies and possible errors in variety registration, which is due to the subjective nature of morphological markers (Korir et al., 2013). Applicability of DUS tests has been restricted due to the cost of extensive field trials, vast numbers of new plant varieties to register annually, and complex processes, especially for developing countries and small breeding programs with limited labor and funding. Countries like China, India, and Brazil, which have vast agricultural industries, encounter considerable difficulties when it comes to DUS testing. Every year, China alone assesses thousands of new plant varieties; this puts tremendous strain on the DUS testing system to guarantee that every variety satisfies the required standards for stability, distinctness, and uniformity. It is revealed that in China, almost 6200 thousand novel varieties were registered in 2013, and that demonstrates the extent of the problem (Jamali et al., 2019; Tian et al., 2015).

Significant regulatory changes have recently been approved to simplify and improve the DUS testing process. Recent UPOV changes strongly emphasize the use of molecular markers in addition to traditional phenotype-based DUS tests to increase efficiency and sensitivity (Yang et al., 2021). Efforts by the UPOV community, particularly the Biochemical and Molecular Methods (BMT) subgroup, and IMMODUS (Integration of Molecular Data into DUS Testing) project have shown that incorporating molecular methods in addition to standard phenotypic assessments into DUS testing is a useful way to overcome these issues (UPOV, 2019b; UPOV, 2021).

Although the powerful application of molecular markers in various plants with objective and repeatable evaluations, integration into DUS tests has been slow. Existing regulations have not kept up with these developments and have not provided the training, infrastructure, and protocol adjustments needed. Anyhow DUS tests are evolving into a new era that includes genomic technologies, new sequencing technologies (such as NGS), improving of MAS (marker-assisted selection to ensure plant variety Distinctnes, uniformity and stability evaluations with the fastening of rapid screening of large populations (Torkamaneh et al., 2018; Xu & Crouch, 2008).

To reduce the cost and time of traditional testing methods, recent efforts aim to integrate genomic data into the DUS framework. DUS tests measurements, criteria, and tools need to be standardized, and global cooperation is very important to facilitate trade and protect plant breeder's rights. The UPOV Convention sets global standards for DUS testing and plant variety protection by requiring member countries to adopt national laws that conform to UPOV recommendations (V. et al., 2023). By incorporating genomic markers, recent changes aim to improve DUS testing procedures by reducing arbitrary assessments and increasing accuracy. DUS testing remains important to ensure the distinctness, uniformity, and stability of new varieties despite challenges such as high costs, subjective morphological indicators, environmental factors, and slow adoption of genomic techniques.

MOLECULAR MARKERS IN DUS TESTING

Molecular markers have begun to be considered as very important tools in Distinctness, Uniformity, and Stability (DUS) tests which might improve or replace phenotype-based DUS tests. The most commonly used molecular markers in this field are Simple Sequence Repeats (SSR), Amplified Fragment Length Polymorphisms (AFLP), and Single Nucleotide Polymorphisms (SNP). SSRs, in particular, are highly sought-after markers due to their codominant nature and high level of polymorphism and can distinguish even very close plant varieties (Gunjaca et al., 2008). In the case of SSR markers do not provide sufficient resolution to assess genetic diversity, AFLPs can help with the abundance of markers within the plant genome (Noli et al., 2008). SNPs are the most abundant type of variation in the genome due to accuracy and within-reach situations due to high throughput genotyping technologies they become more important in a variety of distinction and genetic studies like mapping (Sun et al., 2020). Over morphological markers and biochemical markers, molecular markers offer numerous advantages. Molecular markers demonstrate higher sensitivity on distinction even phenotype is affected by the environment (Yu & Chung, 2021). As mentioned, stability and reproducibility of molecular markers provide consistent results (Sammour, 2014). By facilitating the simultaneous analysis of numerous traits, they also increase efficiency by lowering the time and resources required for DUS testing (Smýkal et al., 2008).

Applications of molecular markers in important crops have proven successful. SSR markers have been used in maize to supplement morphological data. This has increased distinction resolution and consistency with pedigree information, allowing for more precise identification of various varieties (Gunjaca et al., 2008). Microsatellite markers have been successful in rice, increasing the reliability of variety identification by differentiating varieties that would otherwise be challenging to identify just by traditional DUS tests based on phenotypic assessment (Pourabed et al., 2015). Similar to this, in durum wheat, AFLP, and SSR markers have exceeded morphological markers in distinguishing closely related genotypes, making them extremely beneficial for DUS testing (Noli et al., 2008).

However, the use of molecular markers in DUS testing faces challenges, including insufficient correlation between markers and phenotypic features. Phenotypic variability due to outer factors might still exhibit in some varieties that appear uniform at the molecular level which is crucial for DUS assessments (Gilliland & Gensollen, 2010). The reliability of molecular markers is also greatly influenced by the availability of deeply studied plants and databases. A lack of data can lead to incorrect conclusions about similarities or differences among varieties and complicate the validation process. Nevertheless, standardized markers are essential. Such diversity in applications, marker selection, and data validation can produce incorrect and inconsistent results due to environmental interactions that influence phenotypic expression (Arens et al., 2010). One major concern is the phenotype-marker association caused by the nature of the traits. Generally, they are used the identify genetic variations at specific loci but somehow a number of phenotypic traits could have complex expressions that is either not well understood or difficult to determine by only one marker such as yield, plant vigor, height, etc. controlled by many genes and effect by environmental factors. Thus it is difficult to determine these traits with a single marker or multiple markers (Cockram et al., 2012).

Resources and cost management are the factors that molecular markers couldn't fully integrate into plant variety distinctions and widespread utilization. In developing countries need for biotechnological instruments, maintaining and expanding marker databases, and researcher numbers make it difficult to implement (Ribaut et al., 2010). Achieving homogeneity and stability in DUS testing requires a comprehensive method that takes into account genetic and phenotypic data, and as technologies evolve, these limitations must be taken into account to fully utilize molecular marker technologies.

FUTURE DIRECTIONS AND CLOSING REMARKS

DUS testings will be improved with the utilization of molecular markers in the testing of distinctness, uniformity, and stability and it become more relevant, accurate, and efficient. This has come about despite the fact that progress has been made because of the challenges posed by using and developing molecular markers and even more so attempting to integrate genetic data and phenotypic assessments. Novel developments such as next-generation sequencing (NGS) technology that aids in the development of dense genome-wide markers that enable high-throughput analysis that positively influences DUS testing are expected in the future. The need for sequencing using NGS has also changed the field of biology including any form of structural molecular biology, by the rapid, low-cost, high-throughput genetic analysis. This lays the foundation for the – enabling strategies that may be appropriate for marker development and application in plant breeding and DUS evaluation in the future (Torkamaneh et al., 2018).

It is expected that the use of these emerging technologies such as NGS in DUS testing of crops will spur further new molecular markers development that will help in data mining large datasets and detecting even minor differences among plant species. These technologies, according to Davey et al. (2011), offer views about possibilities to modernize genetic and breeding approaches like GWAS and genomic selection. There is also a need for infusion of current practices, technological advancements, and appropriate legislation to harmonize the application of molecular markers with DUS testing. Alongside the application of NGS, the creation of multi-omics approaches that merge metabolomics, transcriptomics, proteomics, and genomics will allow for other high-level data processing technologies to be applied to DUS testing in the future.

In order to make the most of the opportunities offered by modern molecular methods, international legislation should be adapted to incorporate these aspects within DUS testing frameworks. This will extend support to the cross-border trade while safeguarding plant breeding rights and plant varieties, and will also enhance the scientific and legal continuity of the domain. Future work should aim at the creation of bioinformatics applications that are more advanced in terms of processing NGS data, developing markers, and testing the associations between molecular markers and phenotypes. This will help overcome the disadvantages of DUS testing, including a stronger correlation between genotype and phenotype and the influence of the environment on phenotypic traits. Combining modern molecular markers and technologies with traditional phenotypic-based assessments may provide greater accuracy, efficiency, and global application in DUS testing in the future.

ABSTRACT

The present experiment was conducted to investigate the effect of supplementing poultry feed with graded levels of *Algerian sodium bentonite* (Na-B) on growth performance and the development of villus height in jejunum and some biochemical parameters during 50 days in broiler chickens. A number of 420 one-day old broiler chicks (Arbor Acres) were obtained from a commercial hatchery. The birds were randomly allocated into six groups (A, B, C, D, E and F). The treatments were 0 (control), 1%, 2%, 3%, 4% and 5% of Algerian Na-B levels. The results obtained indicate clearly that weight gain in the chickens fed treatments containing 4% Na-B had greater weight gain than the chickens fed different treat- ments (0, 1%, 2%, 3% and 5% Na-B). Feed conversion rate (FCR) was lower birds supplemented with Na-B 4% (2.45) than control group (3.06). Maximum feed consumption was observed in the birds' control (5,655.3 g), while the lowest was noted in the chickens with diet added 4% Na-B (5,009.5 g) ($p< 0.05$). The weight of duodenum, jejunum and ileum was decreased for the Algerian Na-B supplemented group, compared with the control group. The villus height was affected by dietary treatments (1%, 2%, 3% and 5%) on days 18 and 50 ($p< 0.05$). Feeding the supplemented graded levels Na-B resulted in an increase in plasma cholesterol, triglyceride and HDL concentrations at 50 days of age, compared with the control group. These results showed clearly that the Na-B from Algeria can improve the growth performance in broiler chickens. Thus, dietary inclusion of Na-B had positive effect on plasma triglyceride, cholesterol and HDL values in broiler chickens at the end experiment.

Keywords: Algeria, clay, growth performance, feed supplementary, poultry.

INTRODUCTION

Clay is a natural economic substance and a highly abundant product in the nature. Bentonite, one main constituent of clays, is white, light weight rock deposit, composed mostly of salts of hydrated aluminosilicates of sodium (Na), potassium (K), calcium (Ca) and occasionally iron, magnesium, zinc, nickel, etc. The special properties of bentonite, such as hydration, swelling, water adsorption and viscosity, made it a valuable material for wide range of applications in industrial and farming systems (Miazzo *et al.,* 2000). Bentonite as a feed additive has been used successfully in poultry without any harmful effects (Prvulović *et al.,* 2008; Safaeikatouli *et al.,* 2010). The use of clay supplements in animal and poultry feed manufacturing is not new.

Several studies showed that poultry feed supplemented with so- dium bentonite (Na-B) can improve growth performance (Damiri *et al.,* 2010; Prvulović *et al.,* 2008; Safaeikatouli *et al.,* 2010; Salari *et al.,* 2006). Dietary clay supplements (bentonite and kaolinite) have been used as binding and lubricating agents in the production of pelleted feeds for chickens (Owen *et al.,* 2012).

Bentonite, as a toxin binder, de- creased the adverse effect of aflatoxin (Shi *et al.,* 2009) improved the performance (Pasha *et al.,* 2007) and reduced mycotoxin concentration in the livers of affected birds (Bailey *et al.,* 2006). In natural breeding farms, the consumption of soil is a natural phenomenon observed in all animal species. It is know that hens consume the soil fauna voluntarily or by eating earthworms and insects.

There are two types of naturally occurring bentonites: calcium and Na-B (Wright, 1968); there are clays originating from the smectites and their physical properties are those of this mineral group. Variations in interstitial water and exchangeable cations in interlayer of the different space affect the properties of bentonite and, thus, the commercial uses of the different types of bentonite (Adamis *et al.,* 2005). Indeed, Khanedar *et al.* (2012) showed that the use of either kinds of bentonite in diets at 1% could improve the broiler performances; however, addition of 1.5% bentonite had not any significant effect in this study. Today there is a variety of commercial clay, especially bentonite, available in the market in the form of animal feed additives with different chemical characteristics (Magnoli *et al.,* 2008).

In Algeria, the Na-B is abundant in the North West area (Mostaganem, Maghnia) and it is the most important deposit witha production of 20,000 tons per year (Ministry of Energy and Mines, 2015). To our knowledge, there are very few works published showing the effects of different levels of clay from Algeria on broiler performance. The present experiment was conducted to investigate the effect of supplementing poultry feed with graded levels of Algerian Na-B on growth performance and the development of villus height in jejunum and some biochemical parameters during 50 days in broiler chickens.

MATERIALS AND METHODS

Animals and dietary treatments

This study was conducted in Misserghin farm in Oran (western Algeria). The experimental protocol was approved by the Scientific Faculty Council of the University M. Istambouli (Mascara, Algeria).

A number of 420 one-day old broiler chicks (Arbor Acres) were obtained from a commercial hatchery.

The birds were randomly allocated into six groups (A, B, C, D, E and F; 70 birds/group) and housed in pens of identical size (2.35 × 6 m) in a deep litter system with a straw floor. The birds were fed a balanced commercial broiler ration *ad libitum* for a period of 7 weeks. Chicks were managed according to the guidelines suggested by Cobb Broiler Commercial Management Guide. Birds were vaccina- ted against Gumboro (IBDL, Ceva), Newcastle (HB1, Ceva) according to laboratory recommendations. In order to prevent coccidiosis, the chicks were treated by anticoccidial during 36 days (Salinomycine 200). The chicks were reared for 7 weeks maintaining all the hygienic measures in a well-ventilated poultry house.

The treatments were 0 (control), 1%, 2%, 3%, 4% and 5% of Algerian Na-B levels for starter (0 to 14 days), grower (15 to 28 days) and finisher (29 to 50 days) periods. Clay used in this experiment was grayish abundant in the area of study (Maghnia, Algeria). The chemical composition of Algerian Na-B is presented in *Table 1* (Debieche and Kaoua, 2014).

Growth performances

All birds were weighted individually after their arrival from the hatchery to the experimental farm (initial weight) and on day 50. Feed intake, body weight gain and feed conversion ratio (FCR) were calculated every 5 days. The daily weight gain (DWG) was calculated as follows: DWG (g/d) = (Final weight – Initial weight) / 50. The FCR used the following formula: FCR = Total feed consumption / Total final weight. Mortality was recorded daily for each pen.

Histomorphological and blood samples

During the experiment, after weighting, five chicks per treatment were randomly selected and killed by cervical dislocation for histomorphological analysis of the intestinal mucosa. The gastrointestinal tract was weighted after removal of the content. The tissue samples for histology were taken from the jejunum at days 18 and 50. The samples were fixed in 4% buffered formalin for 48 hrs. The processing consisted of serial dehydration, clearing, and impregnation with paraffin. Tissues sections, 5 µm thick were cut by a microtome and were fixed on slides. A staining procedure was carried out using hematoxylin and eosin. The slides were examined on an optical microscope.

Table 1 - Chemical composition (%) of sodium bentonite (Na-B) from Algeria (Maghnia, North West area)

Compositional profile	%
SiO_2	64.98
Al_2O_3	16.08
Fe_2O_3	2.93
CaO	0.61
MgO	3.51
K_2O	2.02
Na_2O	3.88
TiO_2	0.2
Loss on ignition	6.07

The images were analyzed using Neubauer ruling. Villus heights were measured according to the method described by Ritz *et al.* (1995).

Blood samples were collected randomly from brachial vein in tubes containing heparin at days 18, 29 and 50. The plasma obtained was centrifuged (1500 × g for 15 min) and stored at -20°C until measurement for cholesterol, triglycerides and high density lipoprotein (HDL) concentrations using a spectro-photometer reader, according to the manufacturer recommendation (Spinreact, S.A./S.A.U. Sant Esteve de Bas, Spain).

Data analysis

Statistical analyses were carried out in Statview (Version 4.55). Statistical analysis was performed using *t*-test to compare between different groups. The data were expressed as mean ± SE, and $P< 0.05$ was considered significant.

RESULTS AND DISCUSSION

Initial and final body weight (BW), weight gain, feed intake, FCR and mortality rate of the chickens fed different levels treatments are presented in *Table 2*. The initial body weight of chicks did not differ between the dietary treatments. At the end of the experiment (day 50), birds supplemented with graded levels of Algerian Na-B had a greater body weight, compared with control group (1,847.9 g). The birds supplemented with Na-B 4% had a higher body weight (2,044.1 g) than other groups. The average daily weight gain (from day 1 to 50) was higher for chicks supplemented with graded levels of Algerian Na-B (38.2 to 40.1 g) than for control group (36.4 g). The results obtained indicate clearly that weight gain in the chickens fed treatments containing 4% Na-B had greater weight gain than the chickens fed different treatments (1%, 2%, 3% and 5% Na-B).

Feed conversion rate (FCR) was lower in birds supplemented with Na-B 4% (2.45) than in control groups (3.06). In addition, Na-B supplemented birds (Group C) had a higher FCR than groups B, D, E and F (*Table 2*). Feed intake and increased weight gain in the chickens fed ration containing 4% Na-B recorded an improved FCR, in comparison with the control and all other diets treatment. Maximum feed intake was observed in the birds' control (5,655.3 g), while the lowest was noted in the chickens with diet added 4% Na-B (5,009.5 g). There is a significantly difference between the control and the chicken fed different treatments ($p< 0.05$). The mortality rate was lower for the birds fed supplemented with Na-B 4% (1.4%) than other groups. The groups that received the Na-B 1%, 2% and 3% showed higher mortality rate (8.6%, 7.1% and 12.9%, respectively) than the control group (4.3 %).

The means of the weight of intestinal part for dietary treatments are shown in *Table 3*. The weight of duodenum, jejunum and ileum was decreased for the Algerian Na-B supplemented group, compared with the control group. *Fig. 1* shows the means of jejunum villus height from broilers fed different diets. The villus height was affected by dietary treatments (1%, 2%, 3% and 5%) on days 18 and 50. However, birds fed supplemented Na-B 4% decreased the villus height, compared with the control group on day 18 ($p< 0.05$).

The effects of different dietary treatments on plasma lipids on broiler chickens are presented in *Table 4*. When compared with control group, feeding the supplemented graded levels Na-B resulted in increase in plasma cholesterol, triglyceride and HDL concentrations at 50 days of age.

Table 2 - Effect of graded levels of Algerian Na-B on the performance of broiler chickens

Item	Diets treatments (Sodium bentonite %, n=70)					
	0	1	2	3	4	5
Initial body weight (g)	41.08	41.14	40.31	40.31	40.25	40.87
Final body weight (g)	1847.88	1948.94	2035.75	2025.08	2044.06	1995.78
Daily weight gain (g)	36.14	38.16	39.91	39.70	40.08	39.10
Feed intake (g/bird)	2223.63[a]	1907.73[b]	2003.93[b]	1917.47[b]	1856.33[b]	1916.60[b]
Feed conversion rate (%)	2.12	1.66	1.75	1.72	1.79	1.94
Mortality rate (%)	4.28	8.57	7.14	12.85	1.42	5.71

[a,b] A significant difference in mean feed intake (g/bird) between the control group (0 Na-B level) and the treated groups (1%, 2%, 3%, 4% and 5% Na-B level) is indicated by letters (p < 0.05).

The present study shows that inclusion of Algerian Na-B in diets of broilers chickens improves weight gain and decreases the values of FCR (*Table 2*). In addition, the final body weight (day 50) of broilers containing different levels Algerian Na-B was higher than that of control group. The reason for this improvement may be the action of silicate minerals enhancing the digestibility of certain nutrients (Safaei Katouli *et al.*, 2012). Similar results have been described by Eser *et al.* (2011), who used the sepiolite in broiler diet.

Also, a higher growth response caused by bentonite supplemented diets has been reported in several animal species (Ibrahim *et al.*, 2000; Ivan *et al.*, 1992; Jacques *et al.*, 1986). However, the bentonite level above 4% could decrease the body weight gain in broiler chicken. A positive effect of bentonite on body gain seems to be inclusion dose on broiler dietary (Grosicki *et al.*, 2000). The feed efficiency of Algerian Na-B at different levels revealed non- significant difference statistically, but decreases the rate of FCR in broilers chicken, compared with control group. Bentonite at 4% level rather depressed the performance of chicks (Tauqir *et al.*, 2001). In the present experiment, we noticed that Algerian Na-B 5% in diet decrease the daily weight gain of broiler chicken, compared with all treated groups. Besides, additional Na-B level in feed higher 5% reduces the growth performance of birds (Mabbett, 2005). Damiri *et al.* (2012) reported that best results by addition low Na-B levels may be due to increased retention time of digesta in intestinal tract and more nutrients using. Therefore, the retention time increased had no negative effects on feed intake and increased performance.

Low weight gain and feed intake obtained in broiler with a Na-B level were in agreement with those reported by Tauqir and Nawaz (2001). It may be due to viscose nature of Algerian Na-B, which absorbs much water and decreased passage rate of digesta in lumen (Damiri *et al.*, 2012).

Table 3 - Effect of graded levels of Algerian Sodium bentonite (Na-B) on weight intestinal part of broiler chickens

Sodium bentonite (%)	Weight intestinal part (mean ± SE), g		
	Duodenum (n=5)	Jejunum (n=5)	Ileum (n=5)
0	17.97 ± 3.97^a	25.00 ± 6.78^a	23.20 ± 5.33^a
1	13.29 ± 1.49	21.06 ± 3.12	20.83 ± 6.61
2	12.20 ± 1.68	15.75 ± 2.86^b	13.94 ± 2.64^b

Data presented in *Table 2* demonstrates that addition of the Algerian Na-B in feed had significant effect on the feed intake, compared with the control group ($p< 0.05$). Our results are different from of those obtained by Tauqir *et al.* (2001), who reported the use of level diet Na-B 2.5% improved feed consumption, compared with high Na-B level (>2.5%) that might have deleterious effect on the performance of birds.

However, Pasha *et al.* (2007) indicated that the indigenous Na-B 0.5% and 1% levels gave better results at the level of levels on birds' performance (Kubena *et al.,* 1993; Dale and Wyatt 1995).

Due to highly adhesive nature of the Na-B, it was suggested that Na-B absorbs moisture resist the flow of digesta through the gastrointestinal tract affecting negatively the feed intake (Van Olphen, 1963). This could be partially explained by the effect of clay on bile salts preservation (Prvulović *et al.,* 2007).The role of clinoptilolite, one of the clay, is involved in the adsorption and immobilization of the pathogenic flora and protection against their bile salt conjugation (Habold *et al.,* 2009).

In this study, the results of FCR were lower in birds receiving graded Na-B diets than those of the control group. The different levels of Na-B had clearly an effect on FCR, but the FCR was improved by adding in diet Na-B 4%. This is in accordance with the results of some studies showing that the use of Na-B in broiler chickens diet would improve their weight gain (Prvulović *et al.,* 2008; Tauqir *et al.,* 2001). Moreover, some researchers found that animal diets containing kaolin and zeolite have been shown an improvement body weight gain and FCR in chicken (Cabuk *et al.,* 2004; Hesham *et al.,* 2004; Incharoen *et al.,* 2009;Safaeikatouli *et al.,* 2010).

Table 4 - Effect of different levels of Algerian Sodium bentonite (Na-B) on broiler plasma lipids

	Plasma lipids (n=5, mean ± SE)		
Diets treatment	**Cholesterol (mg/dL)**	**Triglyceride (mg/dL)**	**HDL (mg/dL)**
0%

^{a,b} Values with different superscripts in the same groups at different days that differ statically (p< 0.05).
^{A,B,C,D,E} Values with differences in the same day between different groups differ significantly (p< 0.05).

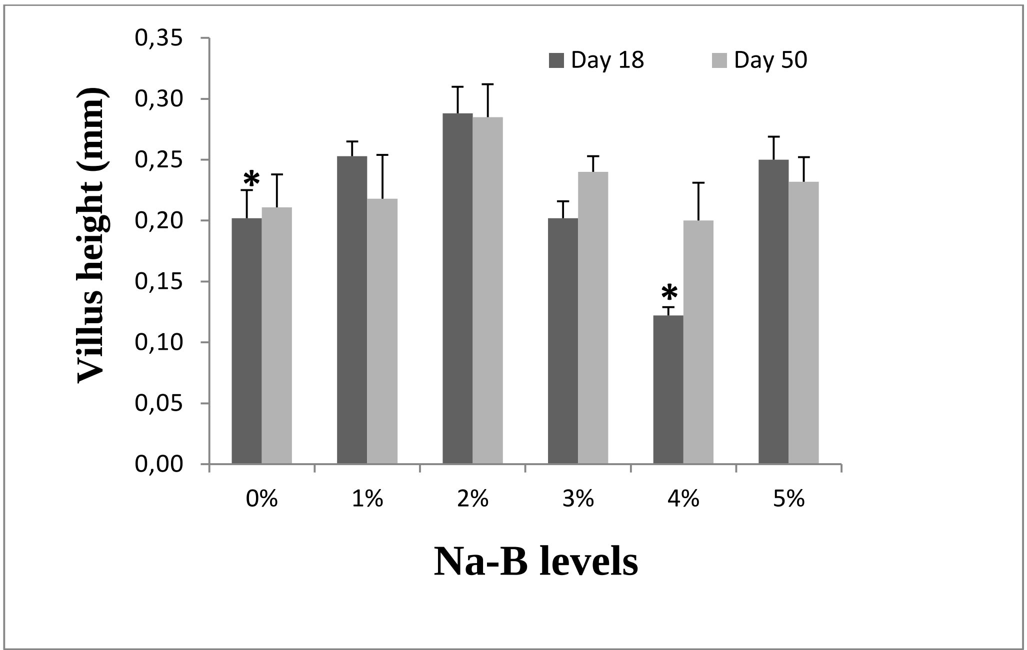

Figure 1 - Effect of different levels of Algeria Sodium bentonite (Na-B) on villus heights (mm) of broiler chickens (n=5). A significant difference in mean villus height between the Na-B level treated groups (0%, 1%, 2%, 3%, 4%and 5%) at Day 18 and Day 50 is indicated by asterisk (*)(*P* < 0.05).

Our results agree with the data obtained by Safaeikatouli *et al.* (2010), where the FCR was increased in broiler diet Na-B 3%, compared with kaolin 3% and Na-B 1.5% treatments. Also, Damiri *et al.* (2012) observed that addition of Na-B 3.75% in diet of broilers fed decreased feed intake and weight gain. Salari *et al.* (2006) indicated that chickens fed diets containing 1% and 2% of Na-B consumed more food. These latter had more weight gain and less FCR. Several studies have reported that weight gain in chicks given low energy diets is not affected by bentonite (Sellers *et al.,* 1980). Likewise, Tauqir *et al.* (2001) indicated that the interaction between diet Na-B and energy was found in broiler chickens.

According to Xu *et al.* (2003), a shortening of the villus and deeper crypts may lead to poor nutrient absorption, increased secretion in the gastrointestinal tract and lower performance. It has been suggested that greater villi height is an indicator that the function of intestinal villi is activated (Langhout *et al.*, 1999; Shamoto and Yamauchi 2000). In the present experiment, the histological aspect of the jejunum of broiler chickens gives orientation concerning the potential for using Na-B in broiler feed. The result of the present study indicates that supplementation of broiler with Algerian Na-B increased the villi height of jejunum at the end of experiment (*Fig.1*). The feed supplemented with graded Algerian Na-B had no effect statistically, but decreases slightly on the weight intestine parts, compared with the control group.

The results of this study correspond with those reported by Xia *et al.* (2004), who noted that the diet supplemented with montmorillonite increased the villus height and decreased crypt depth. Similarly, other study has reported that higher villus height were observed when the diet was treated with prebiotics and probiotics (Pelicano *et al.,* 2005). This could be explained by an increased epithelial cell turnover due to feeding of fed microbial (Awad *et al.,* 2008). According to Cera *et al.* (1988), maximum absorption and digestion capacity is given by a large luminal area with high villi and mature enterocytes, and is essential to animal development. As regards the weight of intestine parts, the present data showed a decrease for birds fed with Algerian Na-B, compared with the control group what demonstrate that the feed supplemented with different Algerian Na-B levels had no effect on the weight intestine of broilers (*Table 3*).

When compared with the control group, diets supplemented with different levels Na-B resulted in a remarkable increase in the plasma triglyceride, cholesterol and HDL concentrations. Kececi *et al.* (1998) have shown that some serum bioche- mical changes could be ameliorated by bentonite administration to the diet in broiler chickens. Habold *et al.* (2009) reported that the presence of clay in the intestinal lumen promotes the hydrolysis of triglycerides and increases the concentration of free fatty acids.

Decreased plasma cholesterol in chicks given Na-B in diet is consistent with the general reduction of lipo- genesis (Donaldson *et al.,* 1972) and impaired lipid transport (Tung *et al.,* 1972) in chicks and specific inhibition of hepatic cholesterol biosynthesis (Kato *et al.,* 1969).

CONCLUSIONS

The results obtained under the conditions of this experiment showed that the Algerian Na-B can improve the growth performance in broiler chickens. The inclusion of 4% Algerian Na-B in diets is more effective on the weight gain and feed intake. Also, supplementation of grade Algerian Na-B at 4% level was found beneficial in ameliorating the feed conversion rate in broiler chickens. Thus, dietary inclusion of Na-B had positive effect on plasma triglyceride, cholesterol and HDL values in broiler chickens at the end experiment.
