ABSTRACT

This study aims at investigating the effect of *Saccharomyces cerevisiae* (SC) supplementation on reproductive performance, haematological parameters and fertility of rabbits under Algerian conditions. The animals were divided into three groups and received the same feed ration during the experimental period. The control group received a basal diet without feed additives (Group#0) and the two yeast SC groups received 0.3 and 0.6 g/day per head (Group#1 and Group#2, respectively). Semen and blood samples were collected for determination of semen parameters and haematology. The weights of rabbits treated with SC 0.3 g/day were statistically significantly different ($P< 0.05$) from the control groups and group treated with SC 0.6 g/day. There were significant differences between the treatment groups for (RBCs), haemoglobin (HGB), haematocrit (HCT) and mean corpuscular haemoglobin (MCH) values, with higher values in rabbits supplemented with SC 0.3 g/day and 0.6 g/day, compared to those in the control group. The scrotal diameter did not differ between the dietary treatments. When compared with the control group, feeding rabbits graded levels of SC resulted in an increase in the average semen volume, mass motility and individual motility at day 51 of the experiment. On the other hand, the sperm concentration was significantly lower ($P< 0.05$) in rabbits supplemented with SC 0.3 g/day and 0.6 g/day during the two months compared to that in the control group. The spermatozoa mortality rate was lower for the rabbits supplemented with SC 0.3 g/day and 0.6 g/day (15.7% and 11.4%, respectively), compared to that in the control group (24%). In conclusion, this study has shown that inclusion of SC 0.3 g/day and 0.6 g/day in the diets of rabbit has positive effects on body weight and sperm analysis. Moreover, it increases the level (RBCs), haemoglobin (HGB), haematocrit (HCT) and mean corpuscular haemoglobin (MCH).

Keywords: *Saccharomyces cerevisiae*, feed, haematological parameters, sperm, rabbits.

INTRODUCTION

It is known that high levels ofantibiotics have been used in food- producing animals as growth promoters and for disease prophylaxis.However, there is a major problem among human consumers due to theoccurrence of antibiotic residues in meat because of the wide use ofantibiotics and antibiotic-resistantbacteria in animals. Therefore, theEuropean Union

Commission banned the use of antibiotics as a growth enhancer in the diets of animals (Castanon, 2007). It is therefore imperative to replace the overuse ofantibiotics and to search for a new safealternative for health improvement andinfection control in animals.

The probiotics (bacterial and yeastcultures) are non-pathogenic microbialadjuncts, which have been used as feedsupplements and also as growthpromoters, improving the immune system of animals by promoting thecomposition and microbial balance in its gut. Several studies have garnered attention over the years on the use of probiotics as alternative feed additives in order to replace antibiotics and synthetic chemical feed supplements (Higginbotham and Bath, 1993; Brydt*et al.,* 1995; Sumeghy, 1995; Strzetelski, 1996). Yeasts are being widely used in food, medicine and the cosmetic industry due to their bioactive and nutritional components, such as peptides, amino acids, beta-glucan, glutathione, cerebroside and zinc (Cha *et al.,* 2004, 2008; Kinosita *et al.,* 2007;Lee *et al.,* 2005).

Moreover, it increases the levelof some haematological parameters, such as RBCs, HGB, HCT, and GCTs.There has been scientific interest over the last two decades in the supplement *Saccharomyces cerevisiae* (SC), whichincreases the cellulolytic rumenbacteria (Ogunade *et al.*, 2019). Pinheiro *et al.* (2020) and Arif *et al.* (2020) reported that the strains of SC have potential as probiotics and are adsorbent of aflatoxin B1. The Algerianrabbit represents a significant portion of the agricultural economy. The statistical data revealed that more and more breeders are interested in rabbit farms where the production of rabbit meat is the first activity (Saidj *et al.,* 2013). Rabbit meat is an important source of protein, rich in precious nutrients (essentially amino acids and lipids and low in fat content and cholesterol (< 59 mg/100 g) (Combes and Dalle Zotte, 2005). In the last years, the Algerian Department ofAgriculture has adopted a policy of diversifying animal production by encouraging rabbit farmers to invest more. Therefore, this research study was conducted to explore the impact ofSC supplementation on some reproductive parameters and haematological balance in male rabbitsunder Algerian conditions. It is known that high levels of antibiotics have been used in food-producing animalsas growth promoters and for diseaseprophylaxis.

MATERIALS AND METHODS

With regard to the ethical aspects,this experimental procedure was approved by the Scientific Committee at the University of Chlef (Report of Faculty Scientific Council #04 dated 30 September 2015).

Animal groups and feeding

The experiment was conducted in an experimental farm of the Department of Agronomic and Biotechnological Sciences(36°10' N, 1°19' E; University of Chlef, Algeria). This study was conducted from1 March 2016 to 30 April 2016. A total of nine rabbits aged 10 months were used for this study. The rabbits were in a good condition during the experimental period. The animals were divided into three groups and received the same feed ration during the experimental period. Before the beginning of the feeding experiment, the pre-trial period consisted of an adaptation period of two weeks for animals who werefed SC supplementation. Then, the rabbits were followed over six weeks, during which the collection and analysis of sperm were performed.

The animals were divided into three groups and received the same feed ration during the experimental period. The control group received a basal diet without feed additives (Group#0), and the two yeast SC groups received 0.3 g/day and 0.6 g/day per head (Group#1 and Group#2, respectively). The supplemented SC (CNCM I-1077, Lallemand Animal Nutrition) is marketed by the Vetam Company (Mostaganem, Algeria) and contains 20 × 10^9 CFU/g of live yeast. The water was distributed *ad libitum* for the study period. The rabbits were weighted at the start of the experiment and then on the following days 1, 15, 29, 44 and 51. Weight gain (WG) was calculated as follows: DWG (g/day) = (Final weight – Initial weight).

Blood and semen sampling

Whole blood samples were withdrawn from the marginal vein into EDTA tubes for haematological analysis. Haematological indices, such as red blood cells (RBCs), platelets (PLTs), haemoglobin (HGB), white blood cells (WBCs), lymphocytes (LCTs), monocytes (MCTs), granulocytes (GCTs), haematocrit (HCT), mean corpuscular volume (MCV), mean corpuscular haemoglobin (MCH), mean corpuscular haemoglobin concentration (MCHC) and red blood cell distribution index (RBDI), were measured. All these measurements were performed using an automated haematology analyser (SWELAB alfa, Boule Medical AB, Spanga, Sweden).

The semen was collected on days 21, 35, and 42 to analyse the various parameters of spermatozoa. The collected semen was transported quickly to the laboratory and kept at body temperature. The study protocols of the semen preparation and analysis were done according to Wyrobek and Bruce (1975). The volume of semen was simply measured using the graduations on the collection tube. The pH was measured with a digital pH meter. Sperm motility was estimated after semen collection by examining a small drop of semen placed on a warm slide and examined by light microscope. Sperm concentration was determined using a Thoma cell counting chamber. The determination of live and dead sperm cells was analysed using the eosin-nigrosin staining procedure according to Esteso *et al.* (2006).

Scrotal diameter was measured at the widest point of the scrotum with a graduated tape on days 14 and 45. Sexual activity (libido) was estimated by the time between introduction of the female into the male's cage and ejaculation. At the end of the experiment, the sexual behaviour of rabbit bucks was determined. A sexually receptive female was then dropped from one side of the chamber and allowed 30 min of stimulation (Sanna et al., 2015; Cicero et al., 2001). Mounting latency (ML) was estimated as time from female introduction into the cage to the occurrence of first mount. The intromission latency was defined as the duration interval between the introduction of the female and intromission by the male (Dabhakar and Zade, 2013; Pare et al., 2014; Mutwedu et al., 2019).

Statistical analyses

Statistical analyses of the results were carried out in Statview (Version 4.55). Statistical analysis was performed using t-tests to compare between different groups. The data were expressed as mean ± SE and $P < 0.05$ was considered significant.

RESULTS AND DISCUSSION

The final body weight of the rabbits fed different levels of treatment are presented in Table 1. The weights of rabbits treated with SC 0.3 g/day were significantly decreased (P< 0.05), compared to the group control and group treated with SC 0.6 g/day.

At the end of the experiment (day 51), the rabbits supplemented with graduated levels of SC had a slightly lower body weight than the control group (3.282 kg). Also, the rabbits supplemented with SC 0.3 g/day showed a continuous increase in body weight, as compared to the other groups.

The mean ± SE values of the blood parameters of treated and non- treated rabbits is shown in *Table 2*. There were significant differences between the treated groups for RBCs, HGB, HCT and MCH values, with higher values in rabbits supplemented with SC 0.3 g/day and 0.6 g/day, compared to the control group. PLT, WBCs and GCTs for the control group were higher than the treated groups. On the other hand, MCTs and LCTs were low in the control group compared to those in the treated groups, which was statistically insignificant (*P*> 0.05). Rabbits supplemented with SC showed slightly higher values in h haematological parameters, such as MCV and RBDI, compared to those reported for the control group.

The effect of SC supplementation on the scrotal diameter, sexual behaviour and sperm analysis of the rabbits is illustrated in *Table 3*. The scrotal diameter did not differ between the dietary treatments. The rabbits fed rations containing 0.3 g/day and

0.6 g/day SC recorded high intromission latency values in comparison to the control group. However, there was a significant difference in sexual behaviour between the controls and rabbits fed different levels of SC supplementation (*P*> 0.05).

Red blood cells (RBCs), haemoglobin (HGB), platelets (PLT), haematocrit (HCT), white blood cells (WBCs), lymphocytes (LCTs), monocytes (MCTs), granulocyte (GCTs), mean corpuscular volume (MCV), mean corpuscular haemoglobin (MCH), mean corpuscular haemoglobin concentration (MCHC), red blood cell distribution index (RBDI).
[a,b] Values by the same letters between the treated groups on different days are statistically different in the same row ($P < 0.05$).

The pH of semen seems to be stable in rabbits supplemented with SCand in the control group, ranging from 7.33 to 8.00. When compared with control the group, rabbits fed diets with graded levels of SC (Group#1 and Group#2) had increases in mean semen volume, mass motility and individual motility at day 51 of the experiment. On the other hand, the sperm concentration was significantly lower ($P < 0.05$) in rabbits fed SC supplementation at 0.3 g/day and 0.6 g/day over the two months of the experiment compared to the control group. The spermatozoa mortality rate was lower for the rabbits fed SCsupplementation at 0.3 g/day and 0.6 g/day (15.7% and 11.4%, respectively), compared to that in the control group(24%).

Table 3 - Effect of graded levels of SC on scrotal diameter, sexual behaviour and sperm analysis in rabbits

Values by asterisks between the treated groups on different days are statistically different in the same row (P< 0.05).

The present study was to investigate the effects of inclusion of the yeast SC in the diet on the haematological and sperm parameters of rabbits. According to the results of this study, the body weight gain of rabbits was not significantly affected by dietary SC supplementation. Thisconfirmed the previous findings of several studies, which noted no significant differences in the growth performance of rabbits fed a ration containing SC supplementation (Kimsé*et al.*, 2008; Brümmer *et al.*, 2010; Darwish *et al.*, 2011; Seyidoglu *et al.*, 2013; Seyidoglu and Galip, 2014; Belhassen *et al.*, 2016). Kimsé *et al.* (2012) noted that yeast did not affect final body weight, daily weight gain orfeed intake in New Zealand rabbits.Another study reported that the administration of SC to mice showed an insignificant improvement in growth performance (Abdel-Aziz *et al.*,2010). On the one hand, these differentresults may be due to the dose or kind of yeast used, strain of broilers, basal diet, and environmental conditions or refer to the mechanisms of growth promotion of yeast culture in rabbits, whereas generally, the positive relationship between SC and animal performance characteristics have been reported by several authors (Omat *et al.,* 2010; Saied *et al.,* 2011; Abou El- Naga *et al.,* 2012; Ezma *et al.,* 2012; Onwurah and Okejim, 2014, Mohamed*et al.,* 2015). On the other hand, Onifade and Babatunde (1996)reported that a diet supplemented with SC at 6.0 g/kg improved the feed quality in broiler chicks. Likewise, Waché *et al.* (2006) observed that the addition of SC can enhance diet and protein digestibility, which revealed better growth and food efficiency with yeast supplements. Moreover, Mohammadi *et al.* (2016) confirmed that using a 2% concentration of yeast in the diet improved growth and food utilization in three spots cichlid(*Cichlasoma trimaculatum*). Thedivergence of yeast results on weight gain could be due to the age of the rabbit, livestock conditions, type of feed, and type and dose of yeastincorporated into the food (Akpa *et al.*,2012).

Data are presented in *Table 2* anddemonstrate that the RBCs, HGB,HCT, GCT and MCV were significantlydifferent in rabbits receiving graded SC diets as compared to the controlgroup. This is in divergence with the previous results revealing that the use of SC in the diets of rabbits had no effect on some haematological parameters (Seyidoglu and Galip, 2014; Belhassen *et al.,* 2016). Seyidoglu *et al.* (2013) revealed no significant variations in hematological parameters in treatment groups, although they noted a slight rise in hematocrit and hemoglobin concentrations in rabbits supplemented with yeast. Other findings are supported by researchers where the values of HGB, HCT, RBCs, MCV, MCH and MCHC were unchanged in broiler chicks fed diets containing probiotics (Gheisari *et al.,* 2008; Shareef *et al.,* 2009; Saied *et al.,*2011). Moreover, Onifade *et al.* (1999)noted that HCT, HGB, MCV and MCH rose significantly (P< 0.05) in rabbits receiving SC supplementation. In another investigation, Paryad *et al.* (2008) observed that the addition ofboth 1.5% and 2% SC yeast significantly elevated WBCs and decreased the LCT ratios of chicks. Moreover, Mulatu *et al.* (2019) revealed that WBCs, packed cell volume (PCV) and HGB were higherin chickens fed a diet containing SC.In addition, Saied *et al.* (2011) showedthat dietary yeast has no effects on the PCV values of broiler chickens. However, Elghandour *et al.* (2019) observed that yeast-fed rabbits had more WBCs and LCTs, compared to the rabbited fed the control diet. It is noted that the LCT content may be a signal of improvement of humoral immune responses in rabbits fed diets supplemented with SC. Also, a relationship between dietary levels of SC and hematological parameters has been reported, and it could be a promoter of supplemental yeast in rabbits (Onifade *et al.,* 1999). Likewise, our results show that SC does not affect animal health. This was demonstrated by Krzysztof *et al.* (2012), who observed that probiotics have immunostimulatory effects.

The results of our present study were in agreement with those of Sharawy *et al.* (2015), who reported a non-significant increase in testicular volume in the probiotics group, compared to that in the non-treated groups, while other researchers noted that scrotal circumference in rams was significantly greater in the probiotics fed group than in the control group (Fernandez *et al*., 2004; Kerban, 2008). Moreover, Kheradmand *et al.* (2006) indicated that both the testicular size and scrotal circumference of rams were influenced by alimentation, and the scrotal circumference was greater in the treated groups than in the control group. This result can be explained by testicular growth being associated with the nutritional value of food. The present study revealed significant differences in the sperm analysis, namely, mass motility, individual sperm motility and sperm concentration (P< 0.05) and were similar to those seen in rams (Sharawy *et al.,* 2015). This result is in accordance with Emmanuel *et al.* (2019) and Helal *et al.* (2018), who observed remarkable enhancement in the sperm concentration and motility of rabbit bucks, which were supplemented with SC. These results are in agreement with results obtained previously, which recorded that the ingestion of probiotics might be recommended to improve sperm motility in human males (Valcarce *et al.*, 2017). The antioxidant activity of SC may be the key to improvement in the sperm parameters (Uskova and Kravchenko, 2009; Spyropoulos *et al.*, 2011; Ewuola, 2013; Mymrin *et al.*, 2017; Shehu *et al.*, 2016). It has been reported that yeasts and their extracts are sources of natural antioxidant cmpounds (Nishino and Ishikawa, 1998; Gazi *et al.*, 2001).

Our results are similar to those obtained by Helal *et al.* (2018), who reported insignificant differences in dead spermatozoa in the experimental groups (P> 0.05), while the lowest proportions of dead spermatozoa were recorded in the SC groups. Nevertheless, studies claim that compounds with antioxidant properties, such as SC, have the potential to inhibit oxidative damage in the cell membranes of sperm cells and fragmentation of sperm DNA caused by free radicals (Castellini, 2008; Mourvaki *et al.*, 2010). Our study showed an insignificant difference (P> 0.05) in semen pH values in rabbits fed dietary inclusions of SC. However, Emmanuel *et al.* (2019) showed a significant reduction in the pH of rabbits on a SC diet. Then, the pH in spermatozoa plays a principal role in regulating sperm motility and fertility competence (Holm *et al.*, 1998).

Generally, both mount and intromission latencies were used as indicators of sexual motivation (Dabhakar and Zade, 2013; Nchegang *et al.*, 2016). The effect of the addition of SC on male sexual capability measured by sexual behaviours, such as mounting and intromission latencies, were insignificant (P> 0.05), compared to controls. Helal *et al.* (2018) showed identical observations, with SC having a non-significant effect on the libido of rabbits. In another investigation, the mount and intromission latencies of the *Monsonia angustifolia* extract-treated groups showed insignificant differences compared to the control group (Gerda Fouche *et al.*, 2015).

CONCLUSIONS

The results of the present study showed that inclusion of SC in the diets of rabbits containing 0.3 g/day and 0.6 g/day have positive effects on the body weight and semen analysis of rabbits. Moreover, it increases the levels of some haematological parameters, such as RBCs, HGB, HCT and GCTs. More investigations are desired to document the benefits of dietary inclusion of SC required in rabbits under diverse environmental conditions using an appropriate number of animal experimental units.

EVALUATION OF MARE'S CONFORMATION PARAMETERS AND ITS RELATIONSHIP WITH PREGNANCY RATE

Amel NAJJAR [1] and Emna ARARI [1]

[1] *Department of Animal Sciences, National Institute of Agronomy of Tunisia, University of Carthage, Tunisia.*

Corresponding author e-mail: amel.najarbenmaatou@inat.ucar.tn

ABSTRACT

The objective of the study was to determine mare's conformation parameters and their pregnancy rate. Thirty (30) Arabian and twenty (20) Thoroughbred mares were used in this study, and their conformation parameters were determined. The mare's weight was calculated from the chest circumference which was noted using a horse specific tape measure. The mare's vulva conformation was studied by the determination of the Caslick index. ANOVA showed that chest circumference and the weigh varied according to the breed, age and status of mares ($p<0.05$). However, the Caslick index varied only according to the breed ($p<0.01$), and it was lower in Thoroughbred mares compared to the Arabian mares (129±20 *vs* 147±32). The results showed that the pregnancy rate was higher in Thoroughbred mares compared to the Arabian ones ($p<0.01$). According to these findings, the conformation parameters were improved in Thoroughbred mares and which explains their higher pregnancy rate compared to the Arabian mares. These differences could be due to the breed's genetic traits.

Keywords: mares, conformation, chest circumference, Caslick index, pregnancy rate.

INTRODUCTION

Conformation parameters play a crucial role in determining the overall health and reproductive success of a mare. The evaluation of mare's conformation can provide valuable insight into her ability to carry a pregnancy and successfully a deliver healthy foal. Mares with poor conformation may have a lower pregnancy rate and be at a higher risk for reproductive issues. The objective of the study was to determine mare's conformation parameters and their pregnancy rate.

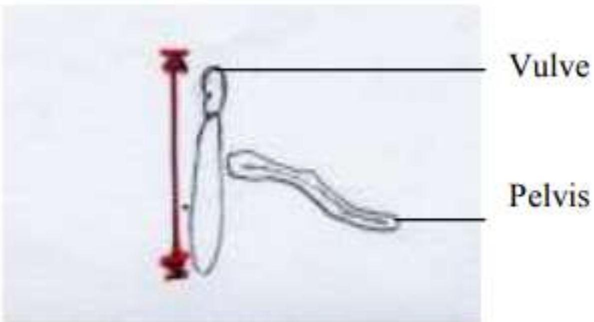
MATERIEL AND METHODS

The study took place at a private stud farm during the breeding season, from 01 February to 31 May. The stud farm is located in the delegation of Borj El-Amri, in the north of Tunisia, 25 km from Tunis. The area has an average annual rainfall of 456 mm and an average annual temperature of 17.8 °C.

Thirty (30) Arabian and twenty (20) Thoroughbred mares were used in this study, and their conformation parameters were determined. The mare's weight was calculated from the chest circumference which was noted using a horse specific tape measure (Merck & Co tape) according to the Reavell method (Reavell, 1999). The reading is taken directly from the tape measure when it was in place and properly adjusted.
The conformation of the mare's vulva was recorded using the Caslick index (Figure 1). This involves determining the length of the vulva between the pelvic floor and the dorsal commissure. The angle of inclination to the vulva was determined using a protractor (Papa et al., 2014).

Caslick index = Length of vulva (L) X angle of vulva (a) (Caslick, 1937)

If the index value obtained is less than or equal to 100, the vulval conformation is normal and the mare's fertility is considered good. If the index value is greater than 100, the vulval conformation is poor and the mare's fertility is considered low (AFDA, 2018).



Normal vulva conformation

Abnormal vulva conformation

Figure 1. Comparaison between normal and abnorla vulva conformation.

ANOVA was carried out using SAS software. Proc GLM was used to study the effect of breed, age and status of mares on conformation parameters. The DUNCAN test was performed to compare the means between groups.

RESULTS AND DISCUSSION

The results showed that chest circumference varied according to the breed, age and status of mares ($p<0.05$, Figures 2, 3 and 4). The weight was higher in Thoroughbred mares compared to the Arabian ones (574 kg vs 504 kg, $p<0.001$). The Thoroughbred mares are characterized by a greater growth potential than Arabian mares. This difference leads to inter-breed precocity. The Caslick index varied only according to the breed ($p<0.01$), and it was lower in Thoroughbred mares compared to the Arabian mares (129±20 *vs* 147±32). Thus, It can be concluded that Thoroughbred mares have better vulva conformation compared the Arabian mares. However, The findings of Talluri et al (2015) showed that the Caslick index was affected by the age and parity of the mare.

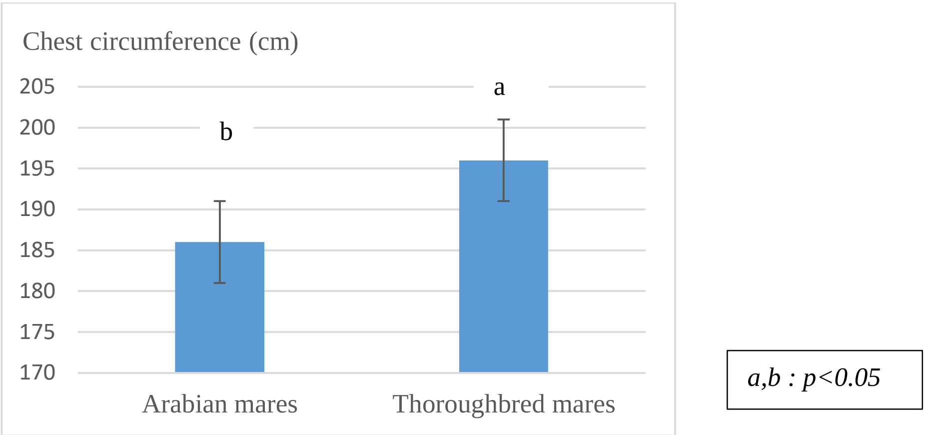


Figure 2. Variation of the mare’s chest circumference according to the breed (Means±SD).

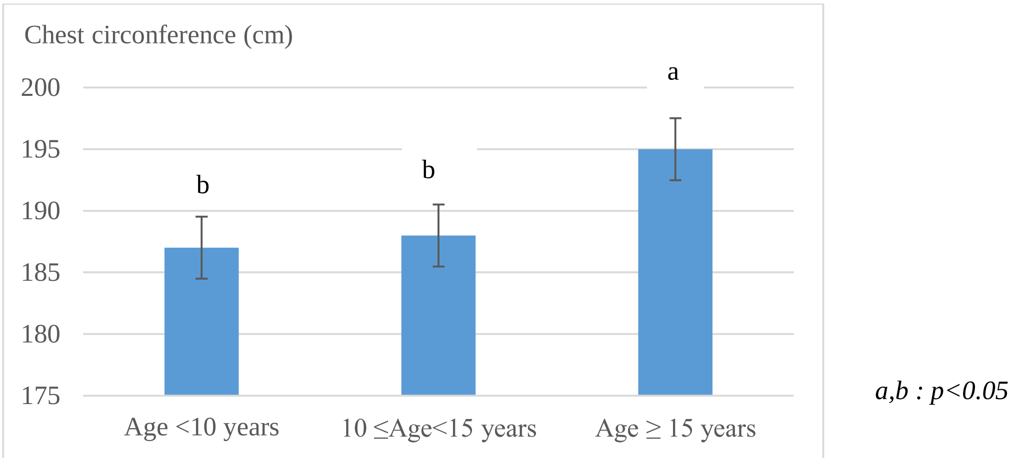

Figure 3. Variation of the mare’s chest circumference according to the age (Means±SD).

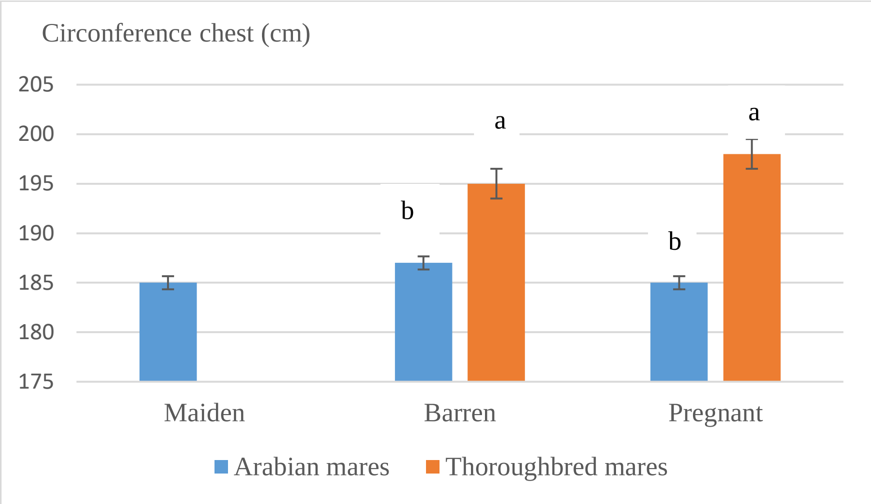

a,b : p<0.05

Figure 4. Variation of the mare's chest circumference according to the status (Means±SD).

The results showed that the pregnancy rate was higher in Thoroughbred mares compared to the Arabian ones (p<0.01).

CONCLUSIONS

According to these findings, the conformation parameters were improved in Thoroughbred mares and which explains their higher pregnancy rate compared to the Arabian mares. These differences could be due to the breed's genetic traits.

ABSTRACT

This study investigated the effects of exogenous enzymes on the nutrient composition of fermented rosehip pulp in the solid-state fermentation method. The research was conducted in a 3 x 2 factorial experiment. Three different fermentation periods were employed: 3, 5 and 7 days. Two different enzyme additions (yes, no) were made in each period. Five replicates were conducted for each treatment group, with the total number of samples reaching 35, including the control group. Before fermentation, the rosehip pulp was ground to a particle size of 1 mm and added to the fermenter. To facilitate microbial growth, 85.5 g of nutritional salt (glucose:urea:$(NH_4)_2SO_4$:peptone:KH_2PO_4:$MgSO_4.7H_2O$ = 4:2:6:1:4:1) was added to 1 lt of distilled water. The samples were sterilized at 121 °C for 15 minutes. The enzyme used in this study was obtained from a private company and comprises a combination of phytase, xylanase, and beta-glucanase. The enzyme was then added to a quantity of 1 g to each fermentation media and sterilized via UV light. *L. acidophilus* was incubated in a shaking incubator at 30 °C and 120 rpm for 48 hours using MRS broth. Then, 1 ml of the *L. acidophilus* culture (10^8 cfu/ml) was added to the sterilized fermenters. The highest crude protein, ash, and the lowest crude fiber were observed in the group fermented for seven days and enzyme was used ($P < 0.001$). The highest ether extract level was detected in the unfermented sample ($P < 0.001$). This research also corroborates these findings, as crude protein levels increased and crude fiber levels decreased. The optimal fermentation time for rosehip pulp with *L. acidophilus* was seven days, with the addition of enzymes.

Keywords: Solid-state fermentation, rosehip pulp, *L. acidophilus*, enzyme

INTRODUCTION

Rosehip is a shrub-shaped plant belonging to the *Rosaceae* family, which can grow in many regions of Turkey. The pulp is a waste product after juice extraction from the rosehip fruit. Rosehip contains high levels of vitamin C and vitamins A, B1, B2, B6, D, E, and K (Koczka et al., 2018). In addition, rose hips are a rich source of color substances, including lycopene, β-carotene, β-cryptoxanthin, gazaniaxanthin, and zeaxanthin (Grigorova et al., 2021).

Rosehip also contains potassium, phosphorus, calcium, magnesium, manganese, and zinc minerals (*Ercisli, 2007*). Rosehip seeds are notable for their high content of polyunsaturated fatty acids, including linoleic acid (45-55%), α-linoleic acid (18-32%), and oleic acid (13-20%) (Koczka et al., 2018). Additionally, rosehip is a rich source of phenolic compounds, including tannins, flavonoids (quercetin, catechin, chemical, rutin), phenolic acids (ellagic acid, protocatechuic acid, chlorogenic acid), and anthocyanins (Koczka et al., 2018). Rosehip pulp contains 10.8% crude protein, 4.6% ether extract, 2.4% ash, 55.8% crude fiber, and a total energy level of 4800 kcal (Vlaicu et al., 2018). Although rosehips are rich in beneficial compounds, their high fiber content limits their use, particularly in monogastric animals. The solid-state fermentation method has been demonstrated to be an effective means of eliminating anti-nutritional factors (Altop et al., 2019).

Fermentation applications utilizing microorganisms, including bacteria, fungi, and yeasts, can generally be divided into submerged and solid-state fermentation (Pandey, 2003). Solid-state fermentation is defined as the growth of microorganisms on moistened solid substrates without free water. This process is preferred to submerged fermentation due to its economic, abundant, and cheap substrates and its relatively lower risk of contamination (Sargın, 2003; *Pérez-Guerra et al., 2003). Solid-state fermentation is a process by which the nutritional composition of various feedstuffs can be enhanced, antinutritional factors reduced, phenolic substance content increased, enzyme activity augmented, and the in vitro digestibility of the feedstuffs improved (Güngör & Erener, 2023; Altop et al., 2018; Altop et al., 2021; Güngör et al., 2020).* This study investigated the effects of exogenous enzymes on the nutrient composition of fermented rosehip pulp in the solid-state fermentation method.

MATERIAL AND METHOD

The research was conducted in a 3 x 2 factorial experiment. Three different fermentation periods were employed: 3, 5 and 7 days. Two different enzyme additions (yes, no) were made in each period. Five replicates were conducted for each treatment group, with the total number of samples reaching 35, including the control group. The experimental plan of the research is presented in Table 1.

Table 1. Plan of the research

<table>
<tr><td colspan="2" rowspan="2"></td><td colspan="4">Days</td></tr>
<tr><td>0 days</td><td>3 Days</td><td>5 days</td><td>7 days</td></tr>
<tr><td rowspan="2">Enzyme</td><td>With enzyme</td><td></td><td>Fermented with enzyme for 3 days</td><td>Fermented with enzyme for 5 days</td><td>Fermented with enzyme for 7 days</td></tr>
<tr><td>Without enzyme</td><td>Control</td><td>Fermented without enzyme for 3 days</td><td>Fermented without enzyme for 5 days</td><td>Fermented without enzyme for 7 days</td></tr>
</table>

The rosehip pulp used in the study was obtained from a local business, and the samples were dried at 75 °C. The samples were stored at 4 °C until use in the study. The microbial inoculant, *L. acidophilus* (ATCC 4356), was obtained from the American Type Culture Collection (ATCC).

Before fermentation, the rosehip pulp was ground to a particle size of 1 mm and added to the fermenter. Subsequently, 100 g of the ground rosehip pulp and 500 ml of distilled water were added to each fermenter. To facilitate microbial growth, 85.5 g of nutritional salt (glucose:urea:(NH4)2SO4:peptone:KH2PO4:MgSO4.7H2O = 4:2:6:1:4:1) was added to 1 lt of distilled water (Cao et al., 2012). Subsequently, the samples were sterilized at 121 °C for 15 minutes. The enzyme used in this study was obtained from a private company and comprises a combination of phytase, xylanase, and beta-glucanase. The enzyme was then added to a quantity of 1 g to each fermentation media and sterilized via UV light.

L. acidophilus was incubated in a shaking incubator at 30 °C and 120 rpm for 48 hours using MRS broth (Güngör & Erener, 2020). Then, 1 ml of the *L. acidophilus* culture (10^8 cfu/ml) was added to the sterilized fermenters. The inoculated samples were fermented at 30°C for the specified duration (3–5–7 days). Once the fermentation process had been completed, dry matter, ash, crude protein, crude fiber, and ether extract analyses were conducted by Akyıldız (1984).

The data obtained from the research was subjected to analysis of variance using the GLM ANOVA/MANOVA procedure in the statistical software Statistica (1984) in a 3 x 2 factorial arrangement. This involved three fermentation periods (3, 5 and 7 days), two enzyme additions (yes or no), and a randomized-block design. Once the statistical significance of the differences between the groups had been established ($P < 0.05$), Tukey's HSD test was used to identify the specific group to which the difference applied ($P = 0.05$).

RESULTS AND DISCUSSION

The nutrient composition of rosehip pulp fermented using *L. acidophilus* in a solid-state fermentation method was found to be positively affected at the conclusion of the study. The highest crude protein, ash, and the lowest crude fiber were observed in the group fermented for seven days and enzyme was used ($P < 0.001$). The primary objective of fermentation studies in animal feeds is to reduce crude fiber levels and increase crude protein levels (Wu et al., 2015). The observed increase in crude protein content may be attributed to microbial protein production by microorganisms (Özlü and Altop, 2023). These findings align with those of Hajimohammadi et al. (2020), where sesame meal was fermented with *S. cerevisiae* and *L. acidophilus*, resulting in a notable increase in crude protein levels. Crude fiber components are structural carbohydrates found in the cell wall of plants and are present at high levels in agricultural wastes (Graminha et al., 2008). Crude fiber includes cellulose, hemicellulose, lignin, pectin, and xylan compounds (Özlü and Altop, 2023). The reduction of these compounds increases the digestibility of feeds. The reduction of crude fiber content in the solid-state fermentation method is possible thanks to the use of enzymes such as cellulase, hemicellulase, and β-glucosidase (Wu et al., 2015). This reduction is achieved both by the use of enzymes and by enzymes produced by microorganisms (Chuang et al., 2019; Maiorano et al., 2022).

The increase in ash level is comparable to that observed by Özlü and Altop (2023). This increase may be attributed to the relative increase in mineral content resulting from the consumption of organic material in the rosehip pulp by microorganisms and the nutritional salt added to the fermentation medium (Rajesh & Raj, 2010). The highest ether extract level was detected in the unfermented sample ($P < 0.001$). Similarly, Chi and Cho (2016) reported that the ether extract content of soybean meal fermented with L. acidophilus decreased.

CONCLUSION

It has been demonstrated that fermentation has a positive effect on the nutrient composition of various agricultural wastes, including rosehip pulp. This process allows for the increased use of feedstuffs in diets while also conferring additional benefits due to the probiotic effects of microorganisms. This research also corroborates these findings, as crude protein levels increased and crude fiber levels decreased. The optimal fermentation time for rosehip pulp with L. acidophilus was seven days, with the addition of enzymes.

ABSTRACT

This study investigated the effects of exogenous enzymes on the nutrient composition of fermented soybean meal in the solid-state fermentation method. The research was conducted in a 3 x 2 factorial experiment, with three different fermentation periods (3, 5 and 7 days), two different enzyme additions (yes, no) in each period, and five replicates in each group for a total of 35 samples, including the control group. Before fermentation, the soybean meal was ground to a particle size of 1 mm and added to the fermenter. Subsequently, 100 g of the ground soybean meal and 500 ml of distilled water were added to each fermenter. The enzyme used in this study comprises a combination of phytase, xylanase, and beta-glucanase. The enzyme was then added to a quantity of 1 g to each fermentation media and sterilized via UV light. 1 ml of the *L. acidophilus* culture (10^8 cfu/ml) was added to the sterilized fermenters. The inoculated samples were fermented at 30 °C for the specified duration (3–5–7 days). The study concluded that the nutrient composition of soybean meal was positively affected. Overall, crude protein and ether extract levels increased significantly ($P<0.001$). Additionally, a fermentation time x enzyme interaction was observed regarding nutrient composition ($P<0.001$). The highest crude protein level was in the sample fermented for three days without an enzyme ($P<0.001$). The lowest crude fiber level was in the fermented for three or five days without an enzyme ($P<0.001$). The highest ether extract level was in the seven days with enzyme, however same sample had lowest crude protein level ($P<0.001$). The optimal fermentation period for soybean meal with *L. acidophilus* and without enzymes was found to be three days.

INTRODUCTION

Meat and meat products are crucial protein sources for ensuring optimal and balanced nutrition for the global population. With the anticipated 58% surge in demand for meat products due to population growth (Makkar et al., 2014), the production of broiler chickens in Turkey plays a vital role in meeting this escalating need. To keep pace with the rising demand, there is a necessity to elevate the production rate of broiler chickens, which in turn will escalate the requirement for feedstuffs. As some feed ingredients used in animal nutrition also have applications in human nutrition, it is imperative to explore alternative sources.

In poultry farming, feed expenses constitute around 60-70% of the total costs. By incorporating alternative materials and feed supplements in lieu of conventional feed ingredients, it's plausible to curtail feed expenditure. The practice of using antibiotics as growth promoters in broiler feeds can pose risks and leave residues in the end product. Consequently, novel alternative additives have been developed post-2006 to amplify broiler performance, safeguard intestinal health, and provide supplementary benefits. Notably, the utilization of diverse raw materials categorized as agricultural waste has garnered attention in recent years.

Soybean (*Glycine max*) is a plant that is cultivated in numerous regions across the globe and is utilized in the oil industry (Smith & Huyser, 1987). Once the oil has been extracted, the remaining portion is referred to as soybean meal and is utilized in animal nutrition. SM is one of the most highly regarded vegetable protein sources utilized in animal nutrition (Banaszkiewicz, 2011). Consequently, it is a crucial ingredient in livestock diets. Soybean meal is utilized in animal nutrition at a rate of 20-25% in laying hens, 25-35% in broiler chickens, 10-20% in pigs, and 15-20% in cattle (Brzóska, 2009; Brzóska et al., 2009). Soybean meal is obtained through a variety of processes (Berk, 1992). The differences in the extraction methods result in variations in the nutrient composition of the meal (Banaszkiewicz, 2011). In general, it has a crude protein content of 44-56%, an ether extract content of 0-3%, and a crude fiber content of 4-8% (Ensminger et al., 1990; NRC, 1998; Poultry Feeding Standards, 2005). The high protein content and high amino acid digestibility by monogastrics indicate that SM is a high-quality protein source (Ravindran et al., 2005). Nevertheless, the presence of anti-nutritional factors in its structure represents a limitation to its use in livestock nutrition (Liener, 1994; Liener, 2000; Hoeck et al., 2000; Fasina et al., 2003). While numerous feed processing methods exist to eliminate these factors, the fermentation method has proven to be particularly effective.

Solid-state fermentation (SSF) is defined as the growth and metabolic activity of microorganisms on solid substrates that have been moistened without free water (Mitchell et al., 2000). The SSF process facilitates the conversion of nutrients through the enzymatic interactions of microorganisms on waste material, resulting in an enhancement of the nutrient composition of the plant material. It reduces the presence of anti-nutritional compounds and increases their bioavailability (Steudler et al., 2019). This process can enhance the digestibility of waste material (Özlü & Altop, 2023) and the bioavailability of nutrients (Güngör & Erener, 2023). In studies on fermentation, bacteria, fungi, or yeasts are typically preferred as inoculants, with the combination of two or more types of microorganisms being the preferred inoculant (Li et al., 2020; Saleh et al., 2021). This study investigated the effects of exogenous enzymes on the nutrient composition of fermented soybean meal in the solid-state fermentation method.

MATERIAL AND METHOD

The study was carried out in a 3 x 2 factorial design involving three fermentation periods (3, 5 and 7 days), two enzyme additions (yes or no) per period, and five replicates per group totaling 35 samples, which includes the control. The experimental layout is detailed in Table 1.

The soybean meal utilized was sourced from a local company, dried at 75 °C, and stored at 4 °C until needed. The microbial inoculant, *L. acidophilus* (ATCC 4356), was procured from the American Type Culture Collection (ATCC).

Prior to fermentation, the soybean meal was ground to 1 mm particle size and placed in the fermenter. Subsequently, each fermenter received 100 g of ground soybean meal and 500 ml of distilled water. To promote microorganism growth, a mixture of nutritional salt (glucose:urea:(NH4)2SO4:peptone:KH2PO4:MgSO4.7H2O = 4:2:6:1:4:1) was added. After sterilization at 121 °C for 15 minutes, 1 g of a composite enzyme (phytase, xylanase, and beta-glucanase) was included in each fermentation medium and sterilized with UV light.

Table 1. Plan of the research

		Days			
		0 days	3 Days	5 days	7 days
Enzyme	With enzyme		Fermented with enzyme for 3 days	Fermented with enzyme for 5 days	Fermented with enzyme for 7 days
	Without enzyme	Control	Fermented without enzyme for 3 days	Fermented without enzyme for 5 days	Fermented without enzyme for 7 days

L. acidophilus was cultivated in a shaking incubator at 30 °C and 120 rpm for 48 hours in MRS broth. Subsequently, 1 ml of the *L. acidophilus* culture (10^8 cfu/ml) was introduced into the sterilized fermenters. The fermenting samples were left at 30°C for the designated duration (3–5–7 days). Following fermentation completion, analyses for dry matter, ash, crude protein, crude fiber, and ether extract were performed based on Akyıldız's method (1984).

The data collected underwent analysis of variance using the GLM ANOVA/MANOVA procedure with a 3 x 2 factorial design (three fermentation periods, two enzyme additions), in Statistica (1984). Statistical significance ($P < 0.05$) indicated variations between groups, which were further examined using Tukey's HSD test at a significance level of $P = 0.05$ to pinpoint the differing groups.

RESULT AND DISCUSSION

The study concluded that the nutrient composition of soybean meal was positively influenced. Results were comparable to Altop et al. (2019). Crude protein level significantly increased (P<0.001). A fermentation time x enzyme interaction affected nutrient composition (P<0.001). Crude fiber, an anti-nutritional factor for monogastric animals, decreased (P<0.001). The highest crude protein level was in the sample fermented for three days without an enzyme (P<0.001). Feedstuffs' nutrient composition is positively impacted by solid-state fermentation (Wang et al., 2017; Altop et al., 2018). Li et al. (2020) found increased crude protein levels in soybean meal fermented with *L. acidophilus*, consistent with prior results due to microbial protein production.

The lowest crude fiber level was in the fermented for three or five days without an enzyme (P<0.001). The second lowest was in the sample five days without enzyme (P<0.001). Güngör et al. (2017) reported cherry kernels' crude fiber levels varied when fermented with different microorganisms. A relative increase in crude fiber rates may be due to microorganism-substrate incompatibility or decreased nutrients (carbohydrates). The highest ether extract level was in the seven days with enzyme, however same sample had lowest crude protein level (P<0.001).

CONCLUSION

Fermentation has been shown to improve the nutrient content of different agricultural wastes, such as soybean meal. This enhances the utilization of feed in diets and provides additional benefits through the probiotic effects of microorganisms. Recent research confirms these findings, showing an increase in crude protein levels, stable ether extract levels, and a decrease in crude fiber levels. The optimal fermentation period for soybean meal with *L. acidophilus* and without enzymes was found to be three days.

ABSTRACT

The aim of this study was (i) to evaluate the growth traits of buffalo calves [Live weight (LW), Chest girth (CG) Chest depth (CD), Chest width (CW), Withers height (WH), Rump height (RH) and Body length (BL)] in the 0-6 mo period and (ii) to investigate the effects of some environmental factors such as, body condition score (BCS), calving season, gender and parity on these traits. The study was conducted in 5 farms in the Samsun province, located in the Black Sea region in Türkiye. A total of 86 Anatolian buffalo cows and calves were selected. The body condition of the cows was scored subjectively at 15–20 d before calving. Based on the statements of the owner farmers, parity, calving seasons, gender and calf birth dates were recorded. Also, LW, CG, CD, CW, WH, RH and BL of calves were measured once a month for 6 mo. Data of evaluated variables were analysed using a general linear model procedure and t-test. The LW of the calves positively correlated with other growth traits. LW values of male calves were found to be higher than female calves at birth and 30 d. LW and BL values calves of cows with high BCS were higher than calves of those with low BCS at all growth periods. Except from birth, RH values calves of cows with high BCS were higher than calves of those with low BCS at other growth periods. Similarly, other growth traits were affected by BCS in different growth periods. Calving season affected the LW and CD values of calves at birth. At birth, the LW values of the calves of cows with parity of ≥5 were higher than the calves of cows with parity of 1. At the same period, the CG and WH values of the calves of cows with parity of 4 and ≥5 were higher than the calves of cows with parity of 1. It was concluded that parity, calving season, gender and BCS of the cow may affect the growth characteristics of calves at different growth periods.

INTRODUCTION

As in dairy cattle farms, the most important part of sustainable production in buffalo farms is successful calf management (Okuyucu and Erdem, 2018; Kharkar et al., 2019). Cows that are culled from the herd due to various reasons such as old age, low productivity and disease are replaced by young buffalo heifers and production continues with these animals. Therefore, raising healthy buffalo calves with high growth performance is directly related to profitable and sustainable production.

To evaluate the growth performance of calves, buffalo breeders and researchers focus on live weight (LW), which is one of the most important indicators of growth, because birth weight and LW are related to survival as well as adaptation (Alkoyak and Öz, 2022). Although this trait is considered as the first measure of growth performance, chest girth (CG), chest depth (CD), chest width (CW), withers height (WH), rump height (RH) and body length (BL) are other body traits used in determining growth performance. These body traits are used as indicator traits or selection criteria in breeding selection programs. Moreover, these traits allow the animals that do not reach the targeted average body measurements in certain growth periods to be identified and culling from the herd (Şekerden, 2010).

It has long been known that the growth traits of buffalos are affected by both genetic factors and non-genetic environmental factors. Environmental factors may adversely affect the actual growth potential of the animal, thereby reducing the accuracy of the selection program applied (Alkoyak and Öz, 2022). Therefore, environmental factors affecting yield traits should be carefully examined. Previous studies have emphasized that many environmental factors such as gender, parity, calving season and calving year have an effect on the growth traits of calves (Şekerden and Tapkı, 2003; Gupta et al., 2012; Hossein-Zadeh et al., 2012; Alkoyak and Öz, 2022). In a study conducted on Egyptian buffalo calves, El-Bramony et al. (2008) reported that the birth weight (BW) of female calves was lower than that of male calves. In the same study, it was determined that as the parity of the cow increased, the BW of the calf also increased. In the studies conducted on Anatolian buffalo calves (Erdem et al., 2015; Alkoyak and Öz, 2022), it was noted that the calving season had a significant effect on BW. Recent studies have focused on environmental factors such as parity, calving season and gender affecting the growth traits of buffalo calves (Şekerden and Tapkı, 2003; Gupta et al., 2012; Hossein-Zadeh et al., 2012; Alkoyak and Öz, 2022). To our knowledge, there is no information on the effects of dry period BCS of the cow on the growth traits (LW, CG, CD, CW, WH, RH and BL) of calves in addition to these environmental factors. Our hypothesis was that environmental factors such as gender, cow’s BCS, calving season and parity had an effect on the growth characteristics of calves in the 0-6 growth period.

The aim of this study was (i) to determine the correlations between LW and some growth traits (CG, CD, CW, WH, RH and BL), (ii) to evaluate the growth traits of buffalo calves in the 0-6 mo period and (iii) to investigate the effects of some environmental factors such as, body condition score (BCS), calving season, gender and parity on these traits.

MATERIAL AND METHOD

All the experimental procedures were performed according to the guidelines and approved by the local Ethics Committee of Ondokuz Mayis University (Permit No: 2018/21).

This study was conducted in five commercial dairy buffalo farms in the Bafra district of Samsun, where buffalo herds are densely populated,Türkiye. These farms were selected within a 15 km radius of Bafra district to facilitate data collection and body trait measurement. A total of 86 Anatolian buffalo cows and female (n=35) and male (n=51) calves were used. Buffalo cows on the farms were (i) housed in semi open free stall barns and (ii) fed a total mixed ration consisting of meadow hay, maize silage, paddy straw and commercial concentrate. The buffalo cows were fed with the same feeds both during the dry period and the lactation period.

Body condition status of pregnant buffaloes was scored on a scale of 1 to 5 during the 15–20 d before birth (Singh et al., 2017). In this range, 5 scales were defined: Emaciated/poor: 1-1.5; Thin/moderate: 2.0-2.5; Average/good: 3.0-3.5; Fat: 4.0-4.5; Obese/ grossly fat: 5.0. After birth, each calf was housed with its dam for five days. Then, the calves were separated from their dams in the following days. The buffaloes were fed with the same feeds both during the dry period and the lactation period. The calves were group-housed (6 calves in each pen) for 6 mo. During the research, calf's birth dates, calf's gender, dam's parity and calving season were recorded.

Buffalo cows that completed the transition from colostrum to normal milk were milked once per day in the morning. During milking, the teat cups of the milking machine were attached to two teats of the cow, while the other two teats were reserved for feeding the calf. After milking, the calves were kept with their dams for feeding. From 2 mo to 6 mo after calving, three teats of each cow were milked, while the other teat was reserved for feeding the calf. The calves in this study were weaned at 6 mo. From 10 days, calves were fed meadow hay and concentrate ad libitum.

To determine the growth traits of newborns, farms were visited within 24 h after birth. Then, the LW of the calves were measured using a digital scale. The CG was determined with a tape measure and CD, CW, WH, RH and BL was measured with a measuring stick. The investigated growth traits were measured at birth, 30 d, 60 d, 90 d, 120 d, 150 d and 180 d.

To reveal the relationships between factors and variables in the current data, the calving season was examined in 4 groups (Autumn, Winter Spring and Summer). Also, the parity was classified as 1, 2, 3, 4, and 5≤. The cow's BCS was calculated and those below the mean were defined as the first group (Low: <2.27) and those above the mean were defined as the second group (High: >2.27). Data were analysed using SPSS. The normality and homogeneity of the data obtained on the body traits of the calves were checked using the Kolmogorov-Smirnov and Levene's tests ($p > 0.05$).

The effects of gender, calving season and parity on body traits (LW, CG, CD, CW, WH, RH and BL) at birth, 30 d, 60 d, 90 d, 120 d, 150 d and 180 d were investigated using the model below.

$$Y_{ijkl}: \mu + a_i + b_j + c_k + e_{ijkl}$$

Where Y_{ijkl} = an observed value of LW, CG, CD, CW, WH, RH and BL; μ = the overall mean; a_i= the effect of the gender of the calves (i = Female, Male); b_j = the effect of calving season (j = Autumn, Winter, Spring, Summer); c_k = the effect of the parity (k = 1, 2, 3, 4 and 5≤); and e_{ijkl}= the random error.

To determine the effects of BCS of the cow and gender on body traits (LW, CG, CD, CW, WH, RH and BL) at birth, 30 d, 60 d, 90 d, 120 d, 150 d and 180 d were analyzed using the t-test.

RESULTS AND DISCUSSION

In the present study, LW value of buffalo calves at birth (Figure 1a) was lower than several previously reported studies (Murrah buffalo calves, Barbosa et al., 2006; Egyptian buffalo calves, El-Bramony et al., 2008), but higher than others (Surti calves, Sorathiya et al., 2009; Anatolian buffalo calves, Erdem et al., 2022; Alkoyak and Öz, 2022). In the present study, the CG, CW, WH and RH values at birth (Figure 1) were consistent with the values reported by Erdem et al. (2022), but the CD and BL values were not consistent.

The LW value at 30 days of age was consistent with the results of the study conducted by Erdem et al. (2022), but was not consistent with the other body characteristics examined. Also, LW value of buffalo calves at 180 d was higher than several previously reported studies (Surti calves, Sorathiya et al., 2009; Murrah calves, Gupta et al., 2012). However, the LW value of Anatolian buffalo calves at 180 days of age was lower than that reported in another previous study (Çelikeloğlu et al., 2015).

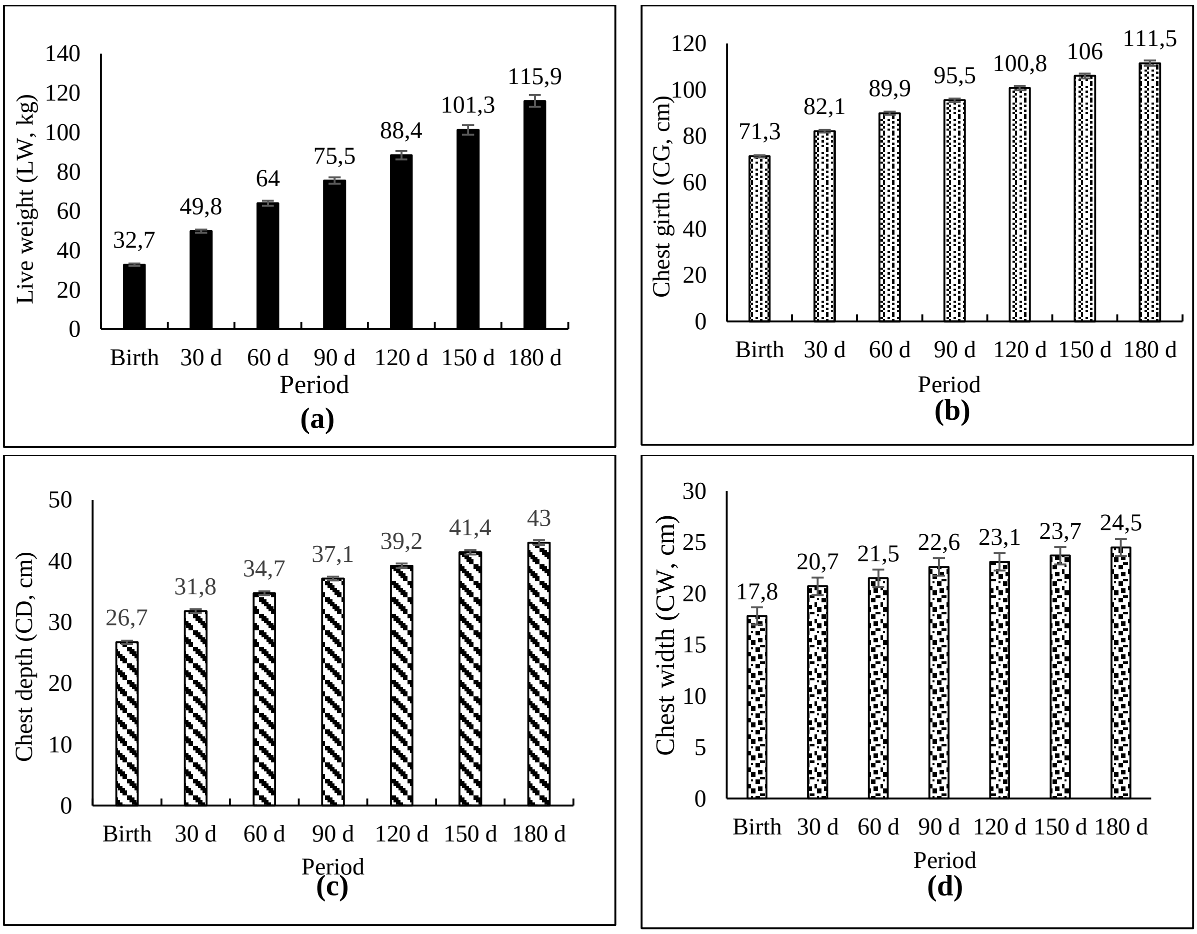

Figure 1. Mean values of live weight and body measurements of calves

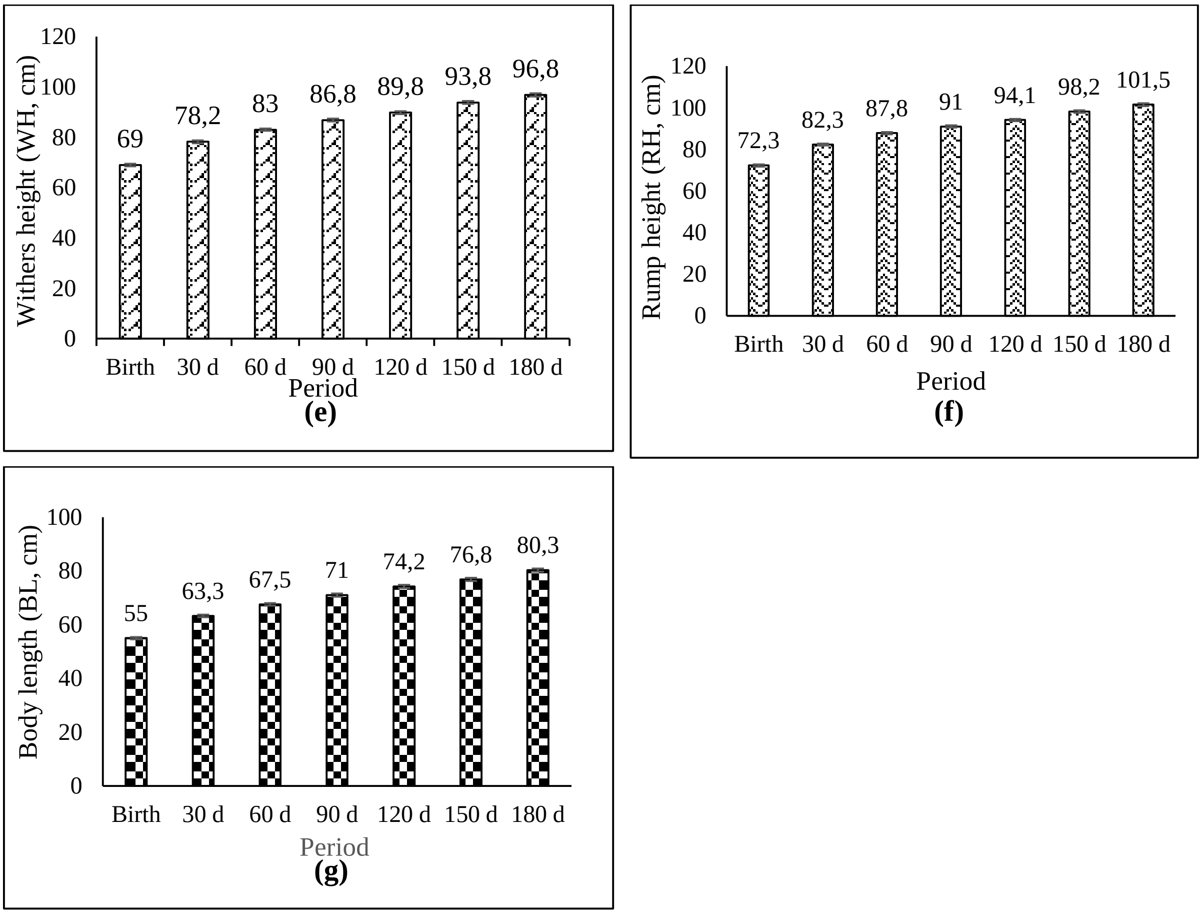

Figure 1. Cont.

In the present study, statistically significant positive correlation coefficients were determined between LW and other growth traits (Table 1).

Table 1. Correlation coefficients between live weight and some body traits

Periods	Body Traits					
	CG	CD	CW	WH	RH	BL
Birth	0.871 (p = 0.01)	0.478 (p = 0.01)	0.545 (p = 0.01)	0.707 (p = 0.01)	0.714 (p = 0.01)	0.639 (p = 0.01)
30 d	0.832 (p = 0.01)	0.472 (p = 0.01)	0.541 (p = 0.01)	0.684 (p = 0.01)	0.668 (p = 0.01)	0.499 (p = 0.01)
60 d	0.927 (p = 0.01)	0.787 (p = 0.01)	0.594 (p = 0.01)	0.735 (p = 0.01)	0.778 (p = 0.01)	0.599 (p = 0.01)
90 d	0.891 (p = 0.01)	0.793 (p = 0.01)	0.509 (p = 0.01)	0.779 (p = 0.01)	0.827 (p = 0.01)	0.684 (p = 0.01)
120 d	0.910 (p = 0.01)	0.820 (p = 0.01)	0.432 (p = 0.01)	0.760 (p = 0.01)	0.789 (p = 0.01)	0.766 (p = 0.01)
150 d	0.929 (p = 0.01)	0.802 (p = 0.01)	0.460 (p = 0.01)	0.835 (p = 0.01)	0.859 (p = 0.01)	0.699 (p = 0.01)
180 d	0.933 (p = 0.01)	0.769 (p = 0.01)	0.617 (p = 0.01)	0.829 (p = 0.01)	0.868 (p = 0.01)	0.801 (p = 0.01)

The effect of gender on LW values of buffalo calves at birth ($p = 0.048$) and 30 d of age ($p = 0.019$) was found to be significant, but this effect disappeared in the subsequent 60 d, 90 d, 120 d, 150 d and 180 d of growth periods (Table 2). During these growth periods, LW values of female calves were lower than males. The findings of the present study were consistent with previous studies on buffalo calves (Şekerden, 2010; Kul et al., 2018; Alkoyak and Öz, 2022). However, the effect of gender on other growth characteristics was statistically insignificant in all growth periods. The variation in LW values of female and male calves may have been caused by differences in physiological and/or endocrine systems (Alkoyak and Öz, 2022).

LW: Live weight; CG: Chest girth; CD: Chest depth; CW: Chest width; WH: Withers height; RH: Rump height;
BL: Body length

BCS is one of the important welfare assessment criteria that subjectively indicates the body fat reserves and nutritional status of the animal in all ruminants (Akdag et al., 2024). Therefore, BCS values in both lactation and dry period can affect milk yield, milk components (Akdag et al., 2024), fertility traits (Bezdíček et al., 2020), as well as the growth performance of calves. The mean BCS of cows (2.27) at the dry period was relatively low in our study. This shows that buffalo cows in the dry period were not fed adequately. Additionally, LW and other body traits of calves in some growth periods were affected by maternal BCS value in the dry period (Table 3). Calves of cows with high BCS had higher LW, WH and BL values at birth compared to those of cows with low BCS ($p = 0.027$). Similarly, calves of cows with high BCS had higher LW, WH and BL values at other growth periods compared to those of cows with low BCS. Except for the 180-d age period, calves of cows with high BCS had higher CG values compared to those of cows with low BCS in all other growth periods. Similarly, except for the 180-d age period, calves of cows with high BCS had higher WH values compared to those of cows with low BCS in all other growth periods. Also, except for the birth, calves of cows with high BCS had higher RH values compared to those of cows with low BCS in all other growth periods. Calves of cows with high BCS had higher BL values compared to those of cows with low BCS in all growth periods (Table 3). In a similar study conducted on Holstein cows and calves (Metin Kıyıcı, and Sarıaslan, 2023), as the BCS value of the cow increased, the BW and BL values of the calves also increased. The results of the present study were consistent with the findings reported by Metin Kıyıcı and Sarıaslan (2023). These results indicate that buffalo cows with good BCS values during the dry period have positive effects on the growth characteristics of the calves born. Therefore, it is thought that careful monitoring of the feeding and management practices and body condition of buffalos in the dry period can offer significant contributions to the performance of their calves during the growth period.

LW: Live weight; CG: Chest girth; CD: Chest depth; CW: Chest width; WH: Withers height; RH: Rump height; BL: Body length

Another environmental factor examined, the calving season, statistically affected the LW values of calves at birth ($p = 0.048$; Table 4). The LW values of calves born in winter were highest at birth. However, it was determined that the LW value was highest in calves born in the summer months at 60 days of age ($p = 0.018$).

The CD values were higher in calves born in summer than in those born in autumn and winter at birth ($p = 0.028$), 30 d and 60 d ($p < 0.001$). Also, the CD values were higher in calves born in summer (43.4 cm) than in those born in spring (40.2 cm) at 150 d ($p = 0.015$). The CW values were higher in calves born in autumn and winter than in those born in spring and summer at 30 d (Table 4). The CW value (20.5 cm) of calves born in spring was lowest at 60 d ($p = 0.001$). Also, the CW values were higher in calves born in summer and autumn than in those born in spring at 90 d ($p = 0.005$). Similarly, the calving season, statistically affected the WH values of calves at 60 d ($p = 0.001$), 90 d ($p = 0.002$), 120 d ($p = 0.032$), 150 d ($p = 0.040$). The calving season, statistically affected the RH values of calves at 60 d ($p < 0.001$), 120 d ($p = 0.004$), 150 d ($p = 0.009$). The BL value was highest in calves born in the summer months at 120 d ($p = 0.012$) and 150 d ($p < 0.001$). The BL value was higher in calves born in autumn than in those born in summer at 180 d. According to all the findings reported above, it is seen that the calving season affects the growth characteristics. Similarly, previous studies have reported that the calving season affects the LW values of calves at different age periods (Erdem et al., 2015; Alkoyak and Öz, 2022). The effects of the calving season on body characteristics can be explained by (i) their good use of pasture in spring and summer during the last days of pregnancy (Alkoyak and Öz, 2022), (ii) the difference in the vegetation period of the pasture (variation in the dry matter and other nutrient content of the pasture), (iii) and the change in the feeding profile in autumn and winter (variation in dry matter intake).

[a-c] Mean values in the same column with different superscripts differ ($p<0.05$); LW: Live weight; CG: Chest girth; CD: Chest depth; CW: Chest width; WH: Withers height; RH: Rump height; BL: Body length

In the present study, the effects of the cow's parity on the LW ($p = 0.031$), CG ($p = 0.047$) and WH ($p = 0.030$) values of the calf at birth were remarkable findings (Table 5). At birth, the LW values of the calves of cows with parity of ≥5 (35.3 kg) were higher than the calves of cows with parity of 1 (30.4 kg). The results of the previous study on buffaloes were consistent with the findings of the present study (Uğurlu, et al., 2016; Kul et al., 2018). At the same period, the CG values of the calves of cows with parity of 4 (72.8 cm) and ≥5 (72.4 cm) were higher than the calves of cows with parity of 1 (68.6 cm). Similarly, the WH values of the calves of cows with parity of 4 (70.7 cm) and ≥5 (70.4 cm) were higher than the calves of cows with parity of 1 (66.2 cm). In summary, it was determined that as the parity of the cows increased, the LW, CG and WH values of the calves at birth increased. These results can be explained by changes in physiological factors that support the productive performance of buffalo cows as they reach their mature equivalents (do Nascimento Rangel et al., 2014).

CONCLUSIONS

It was concluded that the environmental factors examined affected the LW and body traits of calves at different growth periods. Controlling the negative effects of these environmental factors by improving rearing and feeding conditions is important in terms of increasing the growth performance of buffalo calves. Eliminating the effects of these environmental factors will increase the success rate of future selection programs aimed at improving the growth performance of buffalo calves.

ABSTRACT

In ancient times, wheat was first cultivated on the hills above the Tigris river, and it is known that emmer and siyez wheat were among the first crops grown in this region. The history of Siyez wheat used in this study dates back to 12,000 years ago, according to some sources. In Turkey, it is grown with traditional agricultural methods in narrow areas, especially around Kastamonu, Sinop and to a limited extent in the provinces of Çankırı, Çorum, Bilecik, Kayseri, Erzincan, Tekirdağ, Kocaeli, Edirne and Kars. Studies on the nutrient requirements of Siyez wheat are insufficient. The aim of this study was to determine the iron, zinc and phosphorus fertilizer requirements of the crop during its cultivation on calcareous soils. The experiment was carried out under greenhouse conditions with different doses of phosphorus (0 and 4 kg P_2O_5 da^{-1}), zinc (0, 4, 8, 16 mg Zn kg^{-1}) and iron (0, 4, 8, 16 mg Fe kg^{-1}). According to the results obtained, the average plant height was between 82.67-102.44 cm, the number of spikelets was 21.33-29.00 p/pod, the length of spikelets was 2.90-4.03 cm, the biomass yield was 18.42-25.08 g/pod and the grain yield was 4.55-6.47 g/pod. When grain yield (g/pot) was evaluated, there was a significant increase in yield with the P0Fe16Zn4, P0Fe4Zn8, P1Fe8Zn4 and P1Fe0Zn16 treatments. Leaf and grain Fe concentrations ranged between 33.9-88.7 and 24.3-55.1 mg kg^{-1}, leaf and grain Zn concentrations ranged between 31.4-69.8 and 48.9-109.9 mg kg^{-1}, leaf and grain P concentrations ranged between 0.13-0.20 and 0.27-0.39%, leaf and grain K concentrations ranged between 0.54-0.66 and 0.38-0.42%. According to the statistical analyses, significant differences were observed between Fe and Zn application doses ($P<0.01$). The Fe*Zn combination was also statistically significant at $p<0.01$ level. According to the results of the study, if there is sufficient amount of phosphorus in the soil, 1 kg Fe /da and 2 kg Zn /da application can be recommended and if there is insufficient amount of phosphorus in the soil, 4 kg P /da, 2 kg Fe /da and 1 kg Zn /da application can be recommended.

Keywords: Zinc, iron, phosphorus, calcareous soil, siyez(einkorn) wheat

INTRODUCTION

One of the most important interventions to minimize nutrient deficiencies in humans in developing countries is the selection and development of plant genotypes that contain high concentrations of micronutrients in the edible parts. At present, half of the world's population

is suffering from micronutrient deficiencies, especially Fe and Zn (Welch and Graham, 1999). Zn and Fe deficiency causes serious health problems such as immune system disorders, poor physical growth, impaired mental and cognitive development, and anemia (Welch and Graham, 1999; Hotz and Brown, 2004). Developing countries widely consume cereal-based foods as their primary source of calories. However, the concentration and bioavailability of Zn and Fe in cereal seeds are naturally low. Welch and Graham (1999) reported that cereal grains are the major source of Fe and Zn for people in developing countries, but the intakes do not satisfy their mineral demands. Therefore, an increase in the total amount and bioavailability of Zn and Fe in food crops is an important necessity. Due to the high prevalence of Fe deficiency in humans, increasing the concentration of Fe in food is a major global concern (Aciksoz et al., 2011). Iron deficiency is the most common cause of anemia throughout the world. According to a recent report based on the WHO database, approximately 1.6 billion people are affected by anemia (McLeon et al., 2009). The improvement of both iron concentration and bioavailability in cereal grains is therefore a major challenge and a high priority research area (Cakmak et al., 2010). Due to the high rate of decomposition of Fe into unavailable forms when applied to calcareous soils and the low mobility of Fe in the phloem, soil and/or foliar Fe fertilization is less effective than Zn fertilization for grain enrichment (Cakmak, 2008). Zinc deficiency has been identified as a major risk factor for human health worldwide. According to the World Health Organization (WHO, 2002) report on the risk factors responsible for the development of disease and illness, "Zn deficiency" is ranked 11th among the top 20 most important disease factors (Hotz and Brown, 2004).
In this study, compared to wild and cultivated wheat varieties such as *T. dicoccon* and *T. dicoccoides*, *Triticum monococcum* was found to be a much more promising genetic donor for micronutrients (Cakmak et al., 2000). In recent years, the trend toward low-impact and sustainable agriculture, coupled with increasing interest in the nutritional components of food, has led to the rediscovery of many forgotten crops, including siyez (einkorn). Today, traditional einkorn is cultivated in mountainous regions of Turkey, the Balkans, southern Italy, southern France, Spain, and Morocco. However, yields are relatively low compared to bread wheat varieties (Loje et al., 2003). In Turkey, einkorn (Iza/Siyez) and emmer (kaplıca/chatalsiyez/gernik/kavılca) are still grown in limited areas in the poor highlands of the Western Black Sea region, which extends from the western end of the Kızılırmak delta to the east of Adapazarı and Bilecik, reaching 2000 m above sea level in the west (Kan et al., 2015). Siyez (T. *monococcum*) is a diploid species. It derives from its wild relative, wild siyez (*T. baeoticum*). Southeast Anatolia is believed to have first grown it (Diamond, 1997; Heun et al., 1997; Nesbit and Samuel, 1998; Lev-Yadun et al., 2000). Siyez common wheat, also known as einkorn wheat (*Triticum monococcum ssp. monococcum* L.) in foreign sources, is suitable for organic farming, and compared to bread wheat, it is often more disease-resistant and drought-tolerant. It is also rich in starch, fibers, minerals, and secondary plant compounds (Arzani et al., 2017; Nesbitt and Samuel, 1996). It has been reported that up to 30% of the world's total land area is composed of calcareous soils, the availability of iron in the soil is significantly reduced as a result of precipitation of inorganic Fe^{+3} due to high soil pH, and iron deficiency inhibits the growth and yield of most crops in calcareous soils (Ohwaki et al., 1997); it has been reported that about 50% of agricultural soils in our country are deficient in Zn (Eyüpoğlu et al., 1995), and this rate reaches up to 90%, especially in the region of Konya (Cakmak et al., 1996).

The aim of this study was to determine the appropriate fertilizer doses for Siyez wheat cultivation in Konya calcareous soils and increase grain Zn and Fe concentrations.

MATERIALS AND METHODS

In the study, siyez wheat obtained from the Agricultural Credit Cooperative of İhsangazi district of Kastamonu province as experimental plants and nutrient-poor calcareous soil were used. Four doses of iron (0-4-8-16 mg kg^{-1} Fe; Fe-EDDHA (6% Fe) form) and four doses of zinc (0-4-8-16 mg kg^{-1} Zn¸ $ZnSO_4.7H_2O$ form) were applied to the experimental plants. In a study conducted in a total of 64 pots with four replications under greenhouse conditions according to a randomized factorial plot experimental design. In addition, 4 kg N da^{-1} (in the form of AN (33%), and 2.5 kg K da^{-1} (in the form of K_2SO_4 (51% K_2O) fertilizers were applied to all pots before planting. The experimental soil was collected from a depth of 0–30 cm, sieved through a 4 mm sieve, and filled into the pots by weighing (7 kg of soil pot^{-1}) as an oven-dried basis. 15 wheat seeds were planted in each pot. After 15 days of emergence, the plants were thinned out, leaving 10 plants in each pot. The pots were watered daily and the soil was irrigated to keep the soil at field capacity, and the pot placement was changed regularly every week so that the pots could benefit from temperature and sunlight homogeneity. Flag leaf samples were collected from all plants at the end of the 6-month growth period, and these leaves were stored for elemental analysis after preliminary preparation. The Siyez wheat plants were harvested at the end of the 227-day (7.5-month) growth period, after grain formation and ripening were completed. Wet and dry plant weights and grain weights of plants in each pot were determined individually. Leaf samples and above-ground parts of harvested plants were dried in an oven at 65^0C for 48 hours, weighed, and then ground. Flag leaf samples taken from the pots during the heading period and grain samples taken at harvest time were subjected to wet digestion with H_2SO_4 and H_2O_2 after pre -treatment (Kacar and Inal, 2010). The contents of P, K, Zn, and Fe (Bayraklı, 1987) were determined in the obtained filtrates. In the calculation of crude protein in the grain, the nitrogen value in the grain was calculated by multiplying it by a factor of 6.25. In addition, the soil used in the pot experiment was analyzed for fertility, and the results are presented in Table 1.

Statistical analysis of the values obtained as a result of the research, it was carried out with the Minitab 18 Statistical Software package program. All data (Fe, Zn, and Fe*Zn interactions) were subjected to the Tukey's multiple comparison test to determine the statistical significance of the treatment effects. Group means were compared using the least significant difference option with $p \leq 1\%$ and $p \leq 5\%$, as shown in the tables with the lettering.

Table 1. The analysis results of experiment soil

Parameters	Results	Commentary	Literature of analysis method
pH (1:2.5 soil:water)	7.45	Neutral	(Richards, 1954)

RESULTS AND DISCUSSIONS

According to the results of the analysis of variance on the effects of different doses of iron and zinc fertilizers applied on grain and leaf N, P, K, Fe, and Zn concentrations of Siyez wheat, applied Fe doses showed a significant effect on leaf N, K, Fe, Zn concentrations and grain P, Fe, Zn concentrations ($p<0.01$) (Table 2). The applied Zn doses showed a significant statistical effect on leaf N, Fe, and Zn concentrations and grain N, protein, and K, Zn concentrations ($p<0.01$). When the Fe*Zn interaction was analyzed, the effect on the concentrations of N, K, Fe, Zn in the leaves and N, protein, Fe, Zn in the grain was also statistically significant at the $p<0.01$ level.

When the mean values of fertilizer applications were examined (Table 3), increasing doses of iron significantly increased grain Fe, Zn, and leaf K and Fe concentrations compared to the control ($p<0.01$). However, it significantly and negatively affected grain P concentration compared to the control ($p<0.01$). In general, the Fe16 dose showed the highest values among these parameters. Iron fertilization (Table 3) had a positive effect on grain micronutrient concentration. K, Zn, leaf Zn, and Fe concentrations were significantly and positively affected by increasing zinc fertilization ($p<0.01$). Zinc fertilization significantly increased the grain's Zn concentration. Grain Zn concentration increased significantly compared to the control, particularly at the Zn16 (89.91 mg kg^{-1}) dose. The Zn8 (0.42%) dose had the highest K content in grains ($p<0.01$).

The leaf and grain N concentrations of Siyez wheat showed significant differences with the combined effect of Fe and Zn treatments. The grain N concentration ranged from 1.58 to 1.83%, while the leaf N concentration ranged from 0.45 to 0.76% (Figure 1). The values of grain protein content varied between 10.44 and 11.14% (Table 3). According to a study, the average value of protein content in the grain was 14.4% (Atar and Kara, 2017). In their study, which also used siyez wheat under Canadian conditions, Dorval et al. (2015) reported that the protein content of all varieties varied between 14.2 and 15.4%. Erdoğan (2023) studied siyez wheat grown in Bursa with different N doses and found that the average protein content ranged from 9.51 to 11.37 percent. The highest values were found with N doses of 20, 10, and 15 kg N/ha. Another study reported a variation in the protein content of siyez wheat from 13.49 to 19.01% (Demirel, 2013).

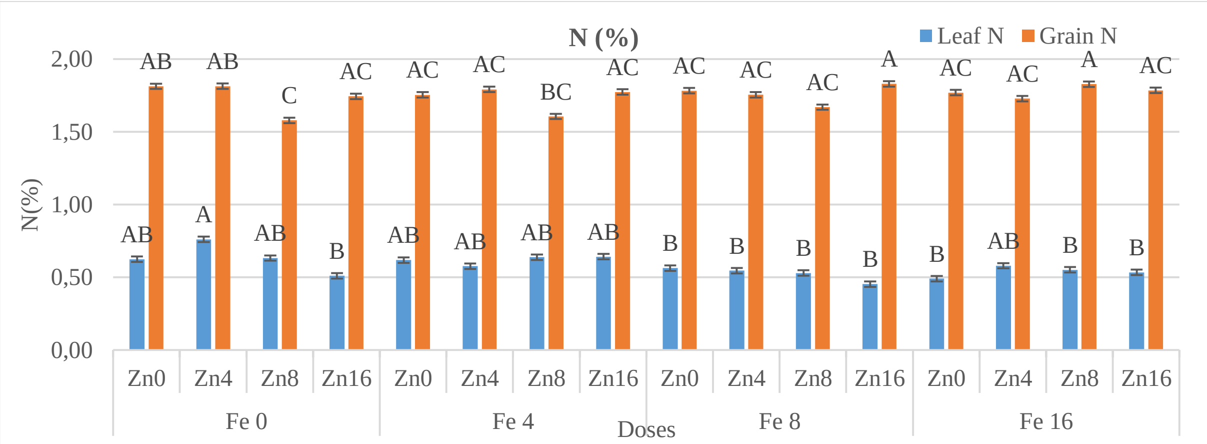

Figure 1. Effect of Fe and Zn applications on grain and leaf N concentration (%) of siyez wheat (Different letters at the columns show significant differences at $p < 0.01$ for applications).

The addition of Fe and Zn to Siyez wheat (*Triticum monococcum*) resulted in a change in the grain P concentration from 0.27 to 0.39% and the leaf P concentration from 0.13 to 0.20% (Figure 2). We observed the highest grain P concentration at the Fe0Zn8 (0.39%) and Fe0Zn16 (0.37%) doses, and the highest leaf P concentration at the Fe0Zn0 (0.19%) and Fe4Zn8 (0.20%) doses. When the results are compared with the literature, the average amount of P in Siyez wheat samples was 0.52% (Suchowilska et al., 2012), the average amount of P in grains was 0.54% (Erba et al., 2011), and the average P in grain was 0.48% (Zengin, 2015), which was in the range of 0.35-0.63%. Furthermore, Zencirci et al. (2021) found the highest concentration of P to be 5687 mg/kg.

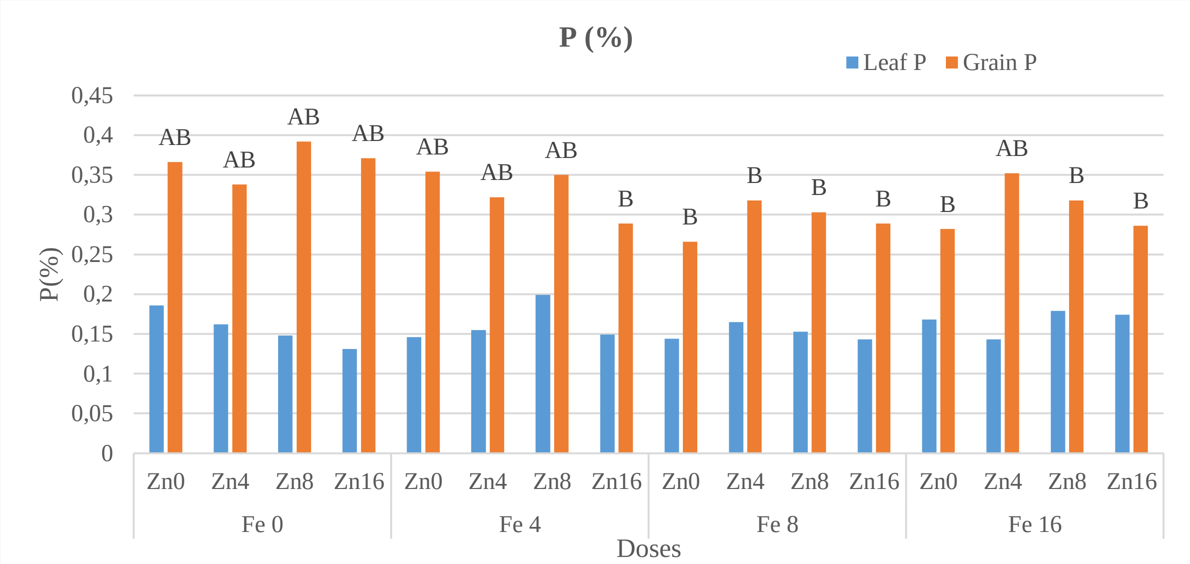

Figure 2. Effect of Fe and Zn applications on grain and leaf P concentration (%) of siyez wheat (Different letters at the columns show significant differences at $p < 0.01$ for applications)

The grain K concentration was lowest at Fe8Zn0 (0.38%) and highest at Fe0Zn8 (0.42%) (Figure 3). The leaf K concentration ranged from 0.54 to 0.66%, with the Fe16Zn8 (0.66%) and Fe16Zn16 (0.65%) doses exhibiting the highest K concentration. When the results were compared with the literature, the average K concentration of Siyez wheat was 0.39% (Abdell-All et al., 1995); in another study it ranged from 0.39 to 0.47% with an average of 0.43% (Suchowilska et al., 2012), and the highest K concentration (565 mg/kg) was found in Siyez grains from Kastamonu İhsangazi (population 4) (Zencirci et al., 2021). The highest potassium content in siyez wheat treated with biochar was 2.45% (Çığ et al., 2021), and in another study it was reported to vary between 0.22-0.62% with an average of 0.46% (Zengin, 2015).

Fe treatments ($p<0.01$) and Fe*Zn interaction ($p<0.01$) had a statistically significant effect on grain Fe concentration, while Fe and Zn treatments ($p<0.01$) and Fe*Zn interaction ($p<0.01$) had a statistically significant effect on leaf Fe concentration (Figure 4). The lowest Fe concentration in the grain was 24.3 mg kg^{-1} at the Fe0Zn16 dose, while the highest value was 55.1 mg kg^{-1} at the Fe16 Zn4 dose. Leaf Fe concentration ranged from 33.9 to 88.7 mg kg^{-1}. The highest leaf Fe concentrations were observed at Fe16Zn8 (88.73 mg kg^{-1}) and Fe16Zn16 (63.98 mg kg^{-1}).

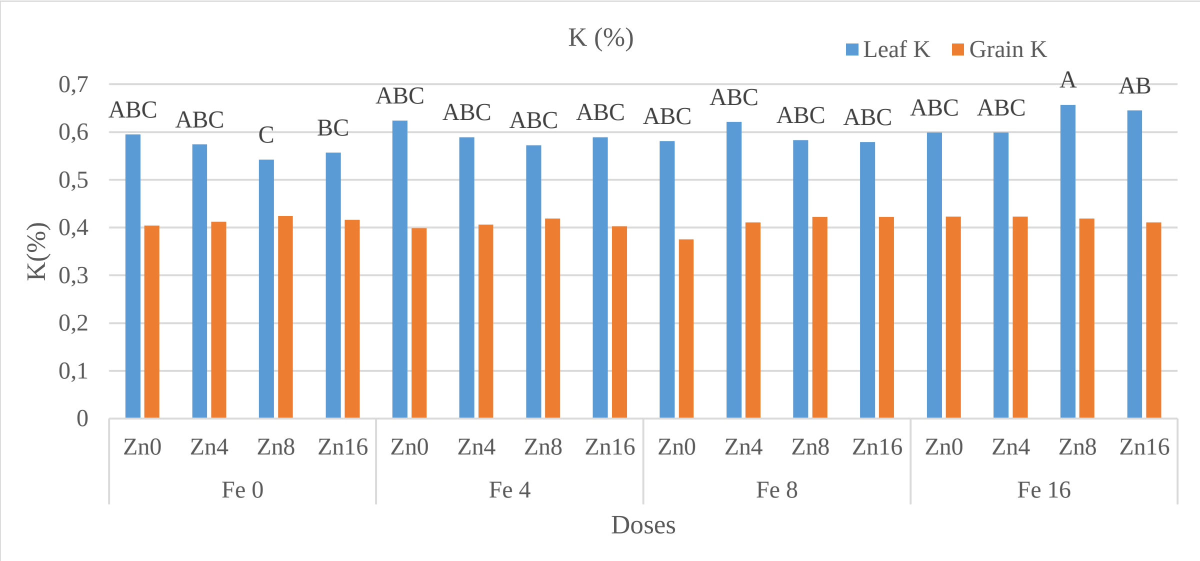

Figure 3. Effect of Fe and Zn applications on grain and leaf K concentration (%) of siyez wheat (Different letters at the columns show significant differences at $p < 0.01$ for applications)

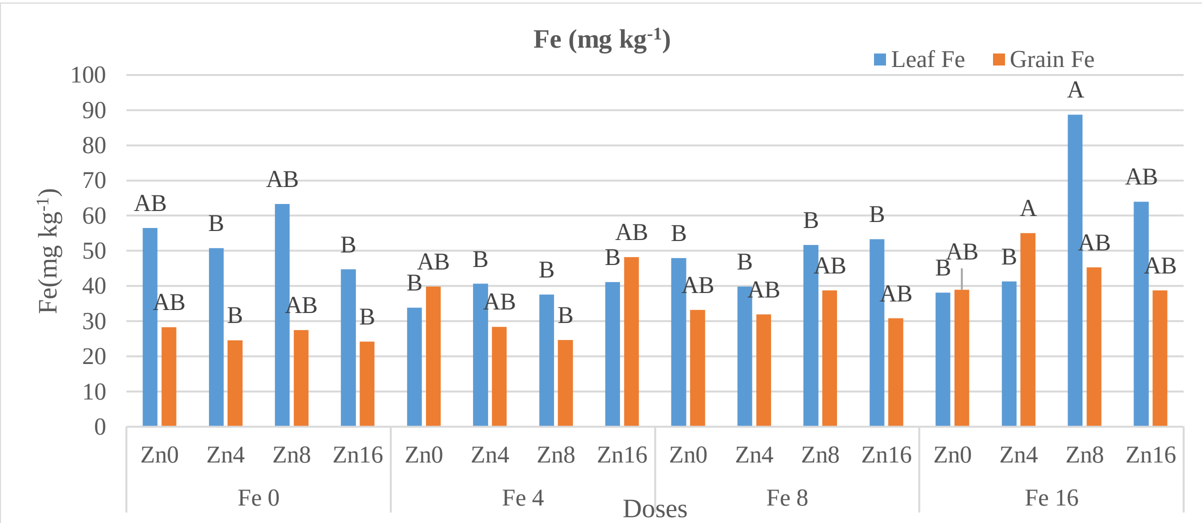

Figure 4. Effect of Fe and Zn applications on grain and leaf Fe (mg kg^{-1}) concentration of siyez wheat (Different letters at the columns show significant differences at $p < 0.01$ for applications)

There were statistically significant changes in the amount of Fe in the grains ($p<0.01$) and the amount of Fe in the leaves ($p<0.01$) after Fe treatments ($p<0.01$). There were also statistically significant changes in the amount of Fe in the grains and leaves ($p<0.01$) at Fe*Zn interaction(Figure 4). The lowest Fe concentration in the grain was 24.3 mg kg^{-1} at the Fe0Zn16 dose, while the highest value was 55.1 mg kg^{-1} at the Fe16 Zn4 dose. Leaf

Fe concentrations ranged from 33.9 to 88.7 mg kg^{-1}, with the highest observed at Fe16Zn8 (88.73 mg kg^{-1}) and Fe16Zn16 (63.98 mg kg^{-1}).

When the results compare with the findings of previous studies on *Triticum monococcum* wheat, Suchowilska et al. (2012) reported that the Fe concentration of T. *monococcum* wheat varied between 32 and 62 mg kg^{-1}, Cakmak et al. (2000) reported that the Fe concentration in T. *monococcum* wheat samples varied between 34 and 85 mg kg^{-1}. Erba et al. (2011) reported an average of 52.3 mg kg^{-1}, and Zengin (2015) reported that grain Fe concentration was between 24.19-44.43 mg kg^{-1}. Fe content in 54 different siyez samples grown in the Adana region in 2003-2004 in the mountainous and plain areas was found to be between 32 mg kg^{-1} and 61 mg kg^{-1} in the mountainous area and between 35 mg kg^{-1} and 85 mg kg^{-1} in the plain area (Ozkan et al., 2007). In addition, Siyez wheat from Kastamonu İhsangazi (Population-4) was reported to have the highest Fe content (59.32 mg kg^{-1}) (Zencirci et al., 2021).

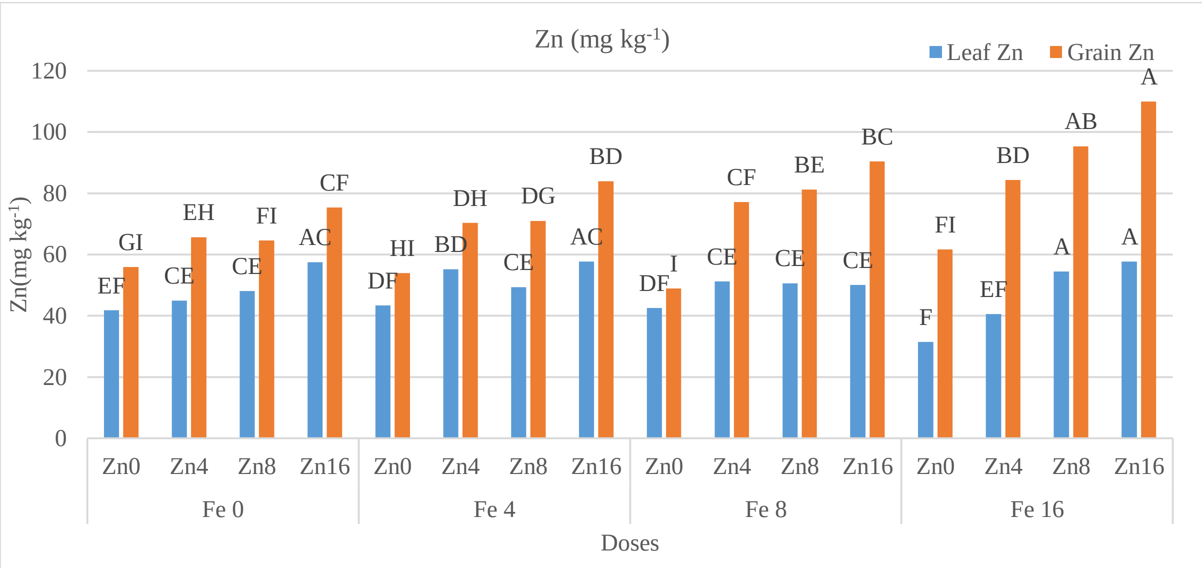

Figure 5. Effect of Fe and Zn applications on grain and leaf Zn (mg kg^{-1}) concentration of siyez wheat (Different letters at the columns show significant differences at $p < 0.01$ for applications)

The effects of Fe, Zn treatments, and Fe*Zn interaction ($p<0.01$) on the Zn concentration in the grain and leaves were found to be statistically significant (Figure 5). The lowest grain Zn concentration was 48.9 mg kg^{-1} at the dose of Fe8 Zn0, while the highest value was 110.0 mg kg^{-1} at the dose of Fe16 Zn16. In general, as Fe and Zn doses increased, the concentration of Zn in the grain increased significantly. Leaf Zn concentration varied between 31.5-57.8 mg kg^{-1} and the highest leaf Zn concentrations were observed at Fe16Zn8 (69.84 mg kg^{-1}) and Fe16Zn16 (65.62 mg kg^{-1}) doses. According to various studies, the amounts of Zn reported by Ozkan et al. (2007) for 54 different *Triticum monococcum* wheat cultivars were between 36 mg kg^{-1} and 76 mg kg^{-1} in dry matter.

Suchowilska et al. (2012) reported Zn contents of 33-68 mg kg^{-1} in 12 different siyez wheats. Cakmak et al. (2000) reported 29-89 mg kg^{-1} in 13 different siyez varieties, Bálint et al. (2001) reported 33.9-41.8 mg $kg^{-1,}$ Gabrovska et al. (2002) had an average of 42 mg kg^{-1}, Erba et al. (2011) 59.6-87.4 mg kg^{-1}, Zencirci et al. (2021) had the highest 74.68 mg kg^{-1}, and Zhao et al. (2009) reported that it was between 20.1-27.8 mg kg^{-1}. These values are parallel and even higher than the data from our research. The Zn concentration in the grain increased with Zn fertilizer application. It was observed that the average leaf Zn contents obtained in our study were sufficient considering the limits established for the concentration of Zn (mg kg^{-1}) in the vegetative parts of wheat plants (deficient <15, sufficient 15-70, and excess >70 mg kg^{-1}) (Ibrikçi et al., 1994).

CONCLUSION

Since the exact amounts of pure macro and micronutrients used in the production of siyez wheat in our country are not available in different sources, in this study it was found that applying Fe and Zn fertilizers to siyez wheat had positive results both in determining the macro element concentration of the product and in increasing the micronutrient concentrations. The application of increasing doses of Fe and Zn fertilizers significantly increased the grain potassium and grain zinc concentrations. In the case of Fe and Zn deficiency in the soil, we recommend applying 1 kg Fe da^{-1} and 2 kg Zn da^{-1} fertilizer for siyez growth.

ABSTRACT

The nodulation potential of legume components in annual grass-legume forage mixtures was investigated. Pea and vetch sown alone (100%), in double mixtures with oat in the legume:grass ratio (70:30%), and in triple mixtures in the legume:legume:grass ratio (35:35:30%) were tested in a pot trial under semi-controlled conditions. Spring forage pea variety Crystal and spring vetch variety Obrazets 666 were used. Based on plant morphometry - root mass, nodule characteristics, some biometric indicators of nodule formation were calculated. Pea plants (100%) showed greater specific nodule-forming ability compared to vetch (100%). The same tendency was found for the mixtures with oat (70:30%). In the triple mixtures (pea-vetch-oat - 35:35:30%), the specific nodule-forming ability of both leguminous crops decreased, weaker for pea (5.22%) versus vetch (13.66%).

Keywords: pea, vetch, nodulation, mixtures

INTRODUCTION

The permanent climate changes occurred in recent decades posed a serious risk to agricultural crops, reducing both their productivity and the quality of the production (Aranjueloa et al., 2014). Climate change projections in Europe predict an increase in temperatures, a decrease in rainfall and a dramatic increase in the frequency of drought years. Agriculture and biodiversity are most vulnerable to the effects of climate change. The increasing frequency and duration of drought periods require adaptation of crops to the changed conditions, and greater efficiency of resource use (Lionello and Scarascia, 2018; Grillakis, 2019).

Growing of crops in mixtures is considered as a one of the ways to use resources more efficiently. Mixed cropping is more efficient than monocropping in terms of using environmental resources for plant growth and development (Sebastia et al., 2004; Mahapatra, 2011). They are longer lasting, more resilient and better able to withstand adverse conditions (Porqueddu et al., 2003; Peyraud et al., 2009). Each species in the mixture contributes to a different degree to increase productivity (Vasilev et al., 2005;

Albayrak et al., 2011; Vasileva and Vasilev, 2012a,b). Many studies have proven the higher productivity of mixtures compared to single crops (Turk, 2000; Odhiambo and Bomke, 2001; Glacomini et al., 2003; Elessesser, 2004; Vasilev, 2004; Malhi et al., 2004; Shiferaw et al., 2004; Shisaya, 2005).

Legumes are a desirable component in mixtures due to their nitrogen-fixing ability. Mixtures with legume component (-s) included in their composition are more productive and resistant. An advantage of grass-legume mixtures is the possibility of supplying the grass component with nitrogen from the legume (-s) through symbiotic nitrogen fixation (Nyfeler et al., 2005, 2006; Peeters et al., 2006; Pozdisek et al., 2011). The nitrogen obtained through this process is one of the main elements of sustainable agriculture, so the mixed cultivation of perennial grasses and leguminous species also has an important ecological aspect (Dita et al., 2006; Luscher et al., 2014; Kusvuran et al., 2014). In the case of mixed grass-legume crops, a part of the nitrogen is transferred from the legume to the corresponding grass component in the mixture. Although most of the fixed nitrogen is available to the leguminous crop, some is released into the soil and becomes available to the grass crop. Competition for soil nitrogen in mixed systems can have a beneficial effect on stimulating nitrogen-fixing processes.

The ability to supply the grass components in the mixture with nitrogen from the legume through symbiotic nitrogen fixation reduces or eliminates the need to use nitrogen fertilizers, thus helps to improve nitrogen nutrition of plants (Gil and Fick, 2001). In mixtures, the amount of nitrogen decreases, legumes receive more nitrogen from the air and are less competitive with grasses for soil nitrogen. On the other hand, at appropriate ratios with grass components, legumes are stimulated to fix more nitrogen (Sesitisch et al., 2002). After decomposition of nodule biomass by legumes, additional nitrogen becomes available to grasses (Li et al., 2015). After ploughing a red clover/grass ryegrass mixture mowed for silage, Ledgard (1991) found a residual effect of 63.0 kg N/ha for the following crop (wheat). The mowed and chopped biomass and left on the ground during the fallow period provides 80-160 N/ha of available nitrogen for the next crop after the grass-legume mixtures, and 160-260 N/ha after single legume crops.

Studies on the nodulating status of leguminous forage crops would be a contribution to the effective use of their symbiotic nitrogen-fixing potential to increase forage productivity.

In the present study, we investigated the potential for nodule formation of legumes in annual grass-legume forage mixtures - pea-oat (70:30%), vetch-oat (70:30%) and pea-vetch-oat (35:35:30%).

MATERIAL AND METHOD

A pot trial was performed with the next variants of the study: pea (100%), vetch (100%), pea-oat (70:30%), vetch-oat (70:30%), pea-vetch-oat (35:35:30%), repetition – fourfold. Pots with a volume of 5 l were used. Spring forage pea variety Crystal and spring vetch variety Obrazets 666 were used. Under laboratory conditions, after washing the root system of leguminous crops, the following parameters were determined: on the root mass: root mass length (cm), specific root length (length of the root mass/fresh weight of the root mass) (cm/g), fresh top mass weight (g/plant), weight of dry root mass (g/plant) (drying 60 ^{o}C); nodulation - the number of nodules on the main and lateral roots of the plants was counted by counting and recalculating to the number of nodules per plant; nodule weight (g/plant), specific nodulating ability(g nodules/g root mass), rate of nodule formation according to the formula of Nif Tal Project of the University of Hawaii (1979): Rate of nodule formation =(aX10)+(bx5)+(cx1)+(dx0)/total number of plants,

where a - plants with nodules located along the main root; b - plants with tubers located on the lateral roots, but closer to the main root; c - plants whose noduless are scattered along the roots; d - plants without nodules; of top mass: height (cm), fresh top mass weight (g/plant), dry top mass weight (g/plant) (drying 60 ^{o}C), top mass/root mass ratio (length), top mass/root mass ratio (weight). Pearson's simple linear correlation coefficient (r) was calculated and correlation dependences between the studied indicators were found. Minimum, maximum values, STDEV, CV% were defined.

RESULTS AND DISCUSSION

Both pea and vetch are high productive annual legume crops (Kosev et al., 2019; Vasileva et al., 2020a, 2020b). Data were analyzed in relation to the habit of the plants, and their ability to form nodules in the beginning of flowering stage was investigated. Based on the morphometry of the plants – top mass, root mass, nodule parameters, some biometric indicators of nodule formation were calculated.

In terms of root mass, the length varied from 8.2 to 11.4 cm (Table 1). The weight of fresh root mass in the double mixtures decreased slightly for pea plants and by 8.8% for those of vetch. In the triple mixtures, the reductions were significant for both legume crops and ranged from 19.61 to 20.18%.

Table 1. Root mass of pea and vetch in annual mixtures

Variants	Root mass			
	length	SRL	fresh weight	dry weight
	cm	cm/g	g/plant	g/plant
Pea (100%)	11.4	4.286	2.66	0.66
Vetch (100%)	10.2	3.377	3.02	0.79
Pea-oat (70:30%)	11.1	4.007	2.77	0.75
Vetch-oat (70:30%)	9.3	4.408	2.11	0.69
Pea-vetch-oat (35:35:30%)	9.1	3.776	2.41	0.66
Pea-**vetch**-oat (35:35:30%)	8.2	2.724	3.01	3.02
Max	11.4	4.408	3.02	3.02
Min	8.2	2.724	2.11	0.66
STDEV	1.24	0.629	0.35	0.94

Bolding refers to the respective crop in the mixture

The weight of the fresh root mass in the double mixtures decreased to 30.1% in vetch and remained almost unchanged in pea. However, an opposite trend was observed in the triple mixtures, where the weight of fresh root mass in pea decreased by 9.40% and did not change in vetch.

In terms of nodule formation, pea plants (100%) (16.1 nodules/plant) had the highest nodule formation capacity (Table 2), followed by vetch (100%) (14.5 nodules/plant). In mixtures, the tendency for greater nodule -forming ability of pea compared to vetch is maintained, as it is determined by the ratio with the grass crop. In the triple mixtures (pea-vetch oat - 35:35:30%), the nodule formation of both pea and vetch plants decreased by 5.22% and 13.66%, respectively. The data for specific nodulating ability were similar.

Table 2. Parameters of nodule biomass of pea and vetch in annual mixtures

Variants	Nodules		
	number/plant	weigth	SNA
		g/plant	cm/g
Pea (100%)	16.1	0.3365	0.1265
Vetch (100%)	14.5	0.3031	0.1003
Pea-oat (70:30%)	15.0	0.3135	0.1132
Vetch-oat (70:30%)	14.0	0.2926	0.1387
Pea-vetch-oat (35:35:30%)	13.9	0.2905	0.1205
Pea-**vetch**-oat (35:35:30%)	13.7	0.2863	0.0951
Max	16.1	0.3365	0.1387
Min	13.7	0.2863	0.0951
STDEV	0.90	0.0188	0.0163

Bolding refers to the respective crop in the mixture

According to the level of nodule formation, legumes are ranked as follows (Figure 1): for pea - pea (100%) (62), pea-oat (70:30%) (58), pea-vetch-oat (35:35: 30%) (52); for vetch - vetch (100%) (60), vetch-oat (70:30%) (50), pea-vetch-oat (35:35:30%) (49).

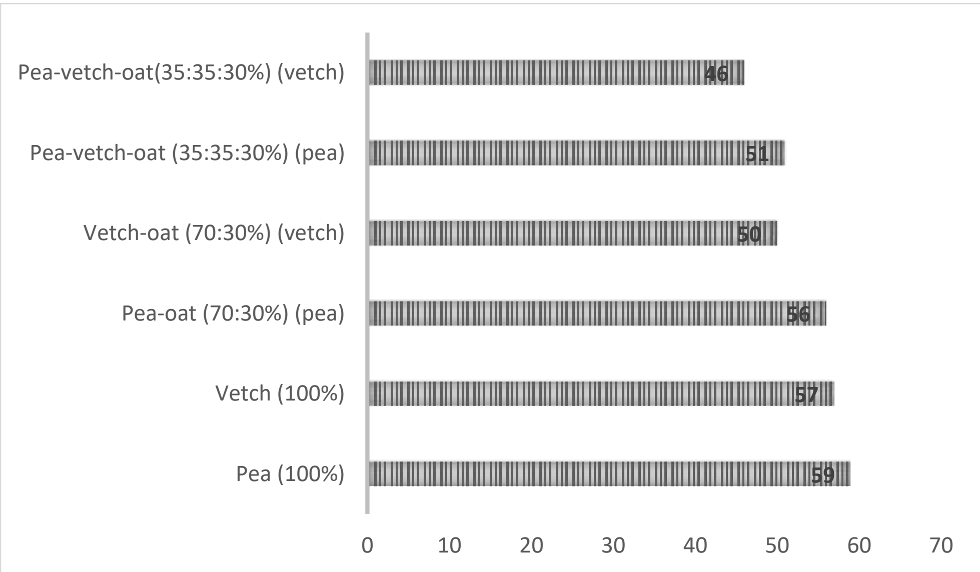

Figure 1. Nodule rate of pea and vetch in annual mixtures

Top mass height ranged from 48.6 to 55.9 cm (Table 3). In the triple mixtures (pea-vetch-oat - 35:35:30%) it decreased, respectively for pea up to 9.84% and insignificantly for vetchs (up to 3.57%).

Table 3. Top mass of pea and vetch in annual mixtures

Variants	Top mass		
	heigth	fresh weigth	dry weigth
	cm	g/plant	g/plant
Pea (100%)	55.9	9.30	2.34
Vetch (100%)	50.4	8.00	2.14
Pea-oat (70:30%)	51.2	8.99	2.31
Vetch-oat (70:30%)	49.8	7.68	2.02
Pea-vetch-oat (35:35:30%)	50.4	9.01	2.15
Pea-**vetch**-oat (35:35:30%)	48.6	7.56	1.99
Max	55.9	9.30	2.34
Min	48.6	7.56	1.99
STDEV	2.53	0.76	0.14

Bolding refers to the respective crop in the mixture

Some ratios between top mass and root mass (height, length, fresh and dry weight) of the plants were also determined, which ratios follow the trend established for the indicators themselves (Table 4).

Table 4. Top mass/root mass ratios of pea and vetch in annual mixtures

Variants	Top mass/Root mass		
	height/length	fresh weight	dry weight
Pea (100%)	4.904	3.496	3.545
Vetch (100%)	4.941	2.649	2.709
Pea-oat (70:30%)	4.613	3.245	3.080
Vetch-oat (70:30%)	5.355	3.640	2.928
Pea-vetch-oat (35:35:30%)	5.538	3.739	3.258
Pea-**vetch**-oat (35:35:30%)	5.927	2.512	0.659
Max	5.927	3.739	3.545
Min	4.613	2.512	0.659
STDEV	0.483	0.520	1.038

Bolding refers to the respective crop in the mixture

Some correlation dependences were also established between the studied indicators through the Pearson linear correlation coefficient (r) (Table 5).

A strong positive correlation was found between length of root mass and number and weight of nodules (r=0.9225), as well as between specific length of roots and specific nodule ability (r=0.9194).

A significant positive correlation was found between the height of the top mass and the specific length of the roots (r=0.5730), between the weight of the fresh top mass and the length of the root mass (r=0.7011), between the specific length of the roots and the number and weight of nodules (r=0.5157).

A moderate positive correlation was found between the height of the top mass and the specific nodulating ability (r=0.3901).

A weak positive correlation was found between specific nodulating ability and: fresh weight of top mass (r=0.2900), dry weight of top mass (r=0.1789), length of root mass (r=0.2560), number and weight of nodules (r=0.2459).

CONCLUSIONS

Data were analysed in relation to the habit of pea and vetch plants, and their ability to form nodules in pea-oat (70:30), vetch-oat (70:30%) and pea-vet-oat (35 :35:30%) mixtures. Based on plant morphometry – top mass, root mass, nodule parameters, some biometric indicators of nodulation were calculated. Pea plants (100%) (16.1 nodules/plant) were found to have the highest nodulating ability, followed by vetch (100%) (14.5 nodules/plant). In mixtures, the tendency for greater nodule-forming ability of pea compared to vetch was maintained, as it is determined by the ratio with the grass crop. In the triple mixtures (pea-vetch-oat - 35:35:30%), the nodule formation of both pea and vetch plants decreased by 5.22% and 13.66%, respectively.

A strong positive correlation was found between length of root mass and number and weight of nodules (r=0.9225), as well as between specific length of roots and specific nodule ability (r=0.9194).

A weak positive correlation was found between specific nodulating ability and fresh weight of top mass (r=0.2900).

ABSTRACT

Erinacea species is used in traditional medicine to treat rheumatic diseases.The aim of this study was to determine for the first time the chemical composition and antibacterial activity of essential oil from the fresh aerial parts of *Erinacia anthyllis* belonging to the Fabaceae family. The steam distilled oil was analyzed using gas chromatography techniques (GC-FID and GC-MS) using two different stationary phase columns (polar and non polar). Furthermore, antibacterial activity against various gram-positive and negative bacteria was determined by disk diffusion and microdilution. A total of 44 volatile substances were identified, accounting for about 98.22% of essential oils. The main components were phytol (9.26%), tricosane (8.62%). In addition, essential oils exhibit effect on all bacterial strains. The obtained inhibition zone ranged from 7mm to 21mm with the highest inhibition zone recorded for*Bacillus Sp* (21mm).*Erinacea anthyllis* essential oil has good antimicrobial activity against all tested pathogenic bacteria and may be used as a natural antimicrobial agent in the treatment of many infectious diseases.

Keywords: *Erinacea anthyllis;*antibacterial*;* essential oil; Batna; Algeria

INTRODUCTION

The Fabaceae family, known as Leguminosae, is a large and diverse family of flowering plants that includes over19000 species. It is one of the most economically important plant families, as many species are used for food, fodder, fuel and medicinal purposes.[1-2]
Several species within the Fabaceae family possess antibacterial proparties against a range of pathogenic bacteria, including *Escherichia coli*, *Salmonella*, *Staphylococcus aureus* and *Streptococcus* pyogenes.[3-7] The genus *Erinacea* belongs to the legume family , the tribe Genisteae, while is represented by a single species called *Erinacea anthyllis* Link or *Erinacea*

pungens Boiss.[8] *Erinacea anthyllis*, also known as blue broom, hedgehog plant, or rushy kidney vetch, is a species of flowering plant. It is a dwarf, spiny shrub that grows under 30cm tall and has erect branches terminating in sharp spines. The leaves are inconspicuous and the flowers are blue and purple. It is native to Spain and Algeria. Moreover, it is a rare and choice spiny legume.[9] *E anthyllis* is used in traditional medicine in Algeria to treat rheumatic diseases and as a honey source in the siroua region of Morocco.[10] *Erinacea anthyllis* contains a variety of secondary metabolites including polyphenols, flavonoids and steroids. Two new prenylated isoflavonoids named ErinasoneA and ErinasoneB were isolated from this plant, along with 19 known secondary metabolites. These two isoprenylated isoflavonoids have been found to have antioxidant and antibacterial activities.[11] There is no information about *E.anthyllis* essential oil in the provided search results. The retrieval results mainly provide information on taxonomy, morphology, habitat, and chemical composition of this plant. Therefore, in this study, the chemical constituents of essential oils extracted from the aerial parts of *E. anthyllis* were examined. In addition, the antibacterial ability against four common pathogens was also evaluated.

MATERIALS AND METHODS

Plant collection and identification

Stems, leaves, flowers of *Erinacea anthyllis* Link. were collected during the flowering stage in May 2022 from Batna, eastern of Algeria. Plant materials were authentically identified by Prof. Khellaf REBBAS, Department of Biological Sciences, University of M'sila. A voucher specimen (Number N°VAREAT5/22) was deposited at the Herbarium of VARENBIOMOL unit,Constantine, Algeria.

Extraction of essential oil

The fresh aerial part of *Erinacea anthyllis* (150 g) was subjected to steam distillation in a Kaiser Lang apparatus for three hours. The resulting oil (750 mg) was collected and dried over anhydrous sodium sulphate and kept at 4 °C until analysis. Oil yield is calculated based on plant weight.

GC-FID and GC-MS analysis

GC-FID essential oil components were analysed using a SCHIMADZU GC-2010 chromatograph equipped with Rxi-5ms capillary column (30 m * 0.25 mm, film thickness 0.25 µm). Helium was the carrier gas, at a flow rate of 1.44 mL/min. The oven temperature was maintained at 45°C for 10 min and then increased to 180°C at a rate of 3°C/min and maintained at 180°C for 5 min, then to 280°C at a rate of 5°C/min and maintained at 280°C for 5 min and finaly to 330°C at a rate of 10°C/min for 2 min. Injector and detector (FID) temperatures were set at 330 °C. Diluted samples (in dichloromethane) of 1 µL were injected in the split/splitless (30:1 split) mode GC-MS analysis was performed using GCMS-QP2010. The Mass selective detector was equipped with a capillary column Rxi-5ms capillary column (30 m * 0.25 mm, film thickness 0.25 µm). Helium was the carrier gas, at a flow rate of 1.44 mL/min. The oven temperature was maintained at 45°C for 10 min and then increased to 180°C at a rate of 3°C/min and maintained at 180°C for 5 min, then to 280°C at a rate of 5°C/min and maintained at 280°C for 5 min and finally to 330°C at a rate of 10°C/min for 2 min. For GC-MS detection, an electron ionization system with ionization energy of 70 eV, was used. Injector temperature was: 330°C. Diluted sample (in dichloromethane) of 1 μL were injected in the split/splitless (30:1 split) mode. Identification of oil components issued from capillary column was accomplished based on comparison of their retention index to those of literature and also comparison of their mass fragmentation patterns with those of databases. [12]

Antimicrobial assay

E.antyllis oil has been evaluated against four common pathogens, *Bacillus, Staphylococcus aureus*(ATCC25923), *Escherichia coli*(ATCC25922), *and Pseudomonas aeruginosa* (ATCC27853). To study antibacterial activity, sterile Muller Hinton agar medium was prepared in petri dishes, and yeast starch agar was inoculated separately into the medium alone.aseptically prepare four wells (6 mm in diameter) and add 80 □L of each extract prepared in DMSO to the wells. Plates were incubated at 37°C for 24 hours before the zone of inhibition was measured. At the end of the incubation period, the zone of inhibition was measured. [13]

Minimum inhibitory concentration determinations (MIC)

The minimal inhibitory concentration (MIC) , is defined as the lowest dose of antibiotic that inhibits observable bacterial growth after 24 hours of incubation. In this regard, the essential oil of *E. anthyllis* was diluted decimally with dimethyl sulfoxide (DMSO) and 10 μl of each dilution was pipetted into a sterilize paper disc (ø6 mm) placed in a petri dish. Petri dishes containing previously inculated Mueller-Hinton agar containing the culture of the bacteria to be tested, a negative control is also included in the test. The possible activity of the solvent against the bacteria to be tested is checked using a paper disc soaked in DMSO. The dishes were then incubated at 37°C for 24 hours. [14]

RESULTS AND DISCUSSION

Chemical constituents of essential oil

The steam distillation of *E. anthyllis* aerial part yielded a yellow essential oil with perfumery odour (0.35%, w/*w*). Identification of compounds was carried out using Target, Wiley 8, FFNSC1.2, NIST11, and Adams data bases.[12] These identifications were confirmed by linear retention indices (RI). As showen in Table 1, we detected 44 compounds representing 98.22% of the total composition. The main compounds were phytol (9.26%), tricosane (8,62%), □-thujone (7.66%), Artemesia ketne (6.64%), □□Muurolene (5.74%), 2-hexadecanone 6,10,14 trimethyl (6.22%) and Hexacosane (5.56%). Phytol and tricosane are two chemical compounds that are foundin many essential oils,including some varieties of lavender, lemongrass, and peppermint.Moreover, Bthujone is another compound that is found in some Fabaceae essential oils,including wormwood and sage. [15]

Phytol is a diterpene alcohol that is believed to have anti-inflammatory and antioxidant properties, and it is often used in the fragrance industry.[16] Tricosane is a straight chain hydrocarbon that is commonly found in plant waxes and has been used in some skincare products. [17] B-thujone is a monoterpene that is found in a variety of plants including sage.It is known for its psychoactive properties and has been used in some traditional medicines. [18]

E.anthyllis essential oils contain a complex mixture of constituents and thus have various antimicrobial properties, the bulk of this effect appears to come from oxygenated terpenoids, especially phenolic terpenes, phenylpropanes, and alcohols.

Antimicrobial activity

The antimicrobial potential of *Erinacea anthyllis* essential oil was assessed by the zone of inhibition of bacterial growth. The results in Table 2 demonstrated that essential oils have an effect on all bacterial strains. The zones of inhibition varied from 7mm to 21mm with highest zone recorded with *Bacillus Sp* (21mm).MIC values against *Echerichia coli*, *Staphylococcus aureus*,*Pseudomonas aeruginosa* and *Bacillus sp* are 1/4, 1/8,1/4,1/4 respectively.

Half-dilution of essential oils (Table 2) reduced the growth density of *Escherichia coli*, *Pseudomonas aeruginosa*, *Staphylococcus aureus* and Bacillus, but tested bacteria were resistant to 1/8 of the essential oil concentration, except *Staphylococcus aureus*. The concentrated oil exhibited high levels of activity against *Escherichia coli*, *Staphylococcus aureus*, *Pseudomonas aeruginosa*, and Bacillus, with inhibition diameters of 15 mm, 15 mm, 10 mm, and 21 mm, respectively, indicating that these bacteria are very sensitive. E. anthyllis essential oils had very small CMI values (1/4 and 1/8) for the tested microorganisms. These data are important for treating infections caused by these bacteria: *Staphylococcus aureus* is the leading cause of infection because of its virulence and ability to acquire antimicrobial resistance, causing serious problems for hospitals and healthcare professionals worldwide problem.[19] *Erinacea antyllis* essential oil has good antibacterial activity and may be used as a natural antibacterial agent in the treatment of various infectious diseases caused by Gram-positive and Gram-negative bacteria.

CONCLUSION

For the first time, the chemical composition of *E.anthyllis* essential oil and antibacterial activity were investigated. A total of 44 compounds were identified, accounting for 98.22%of the total oil.Good antibacterial effect of *Erinacea* essential oil has been observed, indicating its high potential as a new source of antibacterial agent. These effects can be traced back to their chemical constituents, such as phytol, tricosane, □□thujone,and □-Muurolene.

ABSTRACT

Located in the north of the Aegean Sea and at the entrance of Saros Gulf, Gökçeada is the largest island of Türkiye. The island is home to important freshwater resources and there are 2 dam lakes (Zeytinli and Uğurlu Dams), 3 ponds (Aydıncık, Şirinköy and Uğurlu Ponds) and a lagoon (Gökçeada lagoon). The aim of the current research was to assess the non-carcinogenic health risks of fluoride via daily human intake in water of natural – artificial lentic habitats of Gökçeada Island of Türkiye. 6 natural – artificial lentic habitats were selected on the island and water samples were collected during the dry – wet seasons of 2022 – 2023. The fluoride levels were measured by using spectrophotometric method and Estimated Daily Intake (EDI) and Hazard Quotient (HQ) of fluoride were calculated. As a result of this investigation, all the calculated HQ values both in dry and wet seasons in terms of all age groups were recorded as less than the critical limit of 1 with an annualy mean of 0.099 for infants, 0.703 for children, 0.496 for teenagers and 0.398 for adults.

Keywords: Gökçeada Island, Natural – Artificial Lentic Habitats, Health Risk Assessment

INTRODUCTION

Health risk assessment methods are being widely used all over the world in especially recent years. They are quite useful and effective tools in estimating carcinogenic and non-carcinogenic hazards, which may occur when people are exposed to certain toxicants (Ustaoğlu and Aydın, 2020; Tokatlı and Ustaoğlu, 2020; Tokatlı and Varol, 2021a; 2021b; Varol and Tokatlı, 2022; Tokatlı et al., 2022; 2023).

Gökçeada is the largest island in Türkiye with a surface area of 289.5 square kilometers and a coastline of 95 kilometers. Gökçeada, like all the islands in the Aegean Sea, has a volcanic ground and consists of rocks formed in the young geological period. The general geographical feature of the island is forest, maquis and olive groves and although, Gökçeada is generally suitable for all kinds of plant cultivation due to its fertile soil structure, olive groves are among the most important agricultural products of the island. In general, the continental climate is observed in the northern part of the island, and the characteristics of the Mediterranean climate are observed in the southern parts (Anonymous, 2022; http://www.gokceada.gov.tr/; https://www.gokceada.bel.tr/; https://www.kulturportali.gov.tr/).

The aim of the current research was to assess the non-carcinogenic health risks of fluoride via daily human intake in water of natural – artificial lentic habitats of Gökçeada Island of Türkiye.

MATERIALS AND METHODS

Water Collection

In this research, 6 natural – artificial lentic habitats (1 natural lake, 2 dam lakes and 3 artificial pons) located in the Gökçeada Island were selected. The coordinate information with the names of investigated freshwater ecosystems are given in Table 1. The topographic map of Gökçeada Island and selected locations are given in Figure 1. Water samples were collected in the summer season of 2022 (dry season) and the winter season of 2023 (wet season) with a telescopic water sampling device approximately 3 meters from the shore into the pre – cleaned polyethylene bottles.

Table 1. Coordinate information of selected stagnant water bodies

Name of Lentic	Station Code	GPS-North	GPS-East
Gökceada Lagoon	L1	40.133	25.956
Zeytinli Reservoir	R1	40.176	25.863
Uğurlu Reservoir	R2	40.138	25.713
Aydıncık Pond	P1	40.147	25.925
Şirinköy Pond	P2	40.114	25.772
Uğurlu Pond	P3	40.140	25.737

Figure 1. Topographic map of Gökçeada Island and selected locations

Health Risk Assessment

In the current research, population was divided into four age groups based on their physiological and behavioural differences as follow: infants (< 2 years old), children (2 – 6 years old), teenagers (6 – 16 years old) and adults (> 16 years old). The daily exposure to fluoride was calculated in these four different groups by using the equation 1. Hazard Quotient (HQ) describes the non-carcinogenic risk of fluoride and it was calculated by using the equation 2 (Yousefi et al., 2018). A lower value of HQ than 1 reflects a negligible risk of non-carcinogenic effects and a higher value of HQ than 1 reflects an important health risk and a significant risk of severe fluorosis may be present.

$$EDI = \frac{Cf \ x \ Cd}{Bw} \tag{1}$$

$$HQ = \frac{EDI}{RfD} \tag{2}$$

EDI: Estimation of fluoride consumption – daily (mg/kg/day)

C_f: Fluoride level in the investigated drinking water samples (mg/L)

C_d: Mean daily water intake (L/day) (the mean water consumption rates in infants, children, teenagers and adults were 0.08, 0.85, 2 and 2.5 L/day, respectively)

B_w: Body weight (kg) (body weights of investigated groups were considered 10, 15, 50 and 78 kg, respectively)

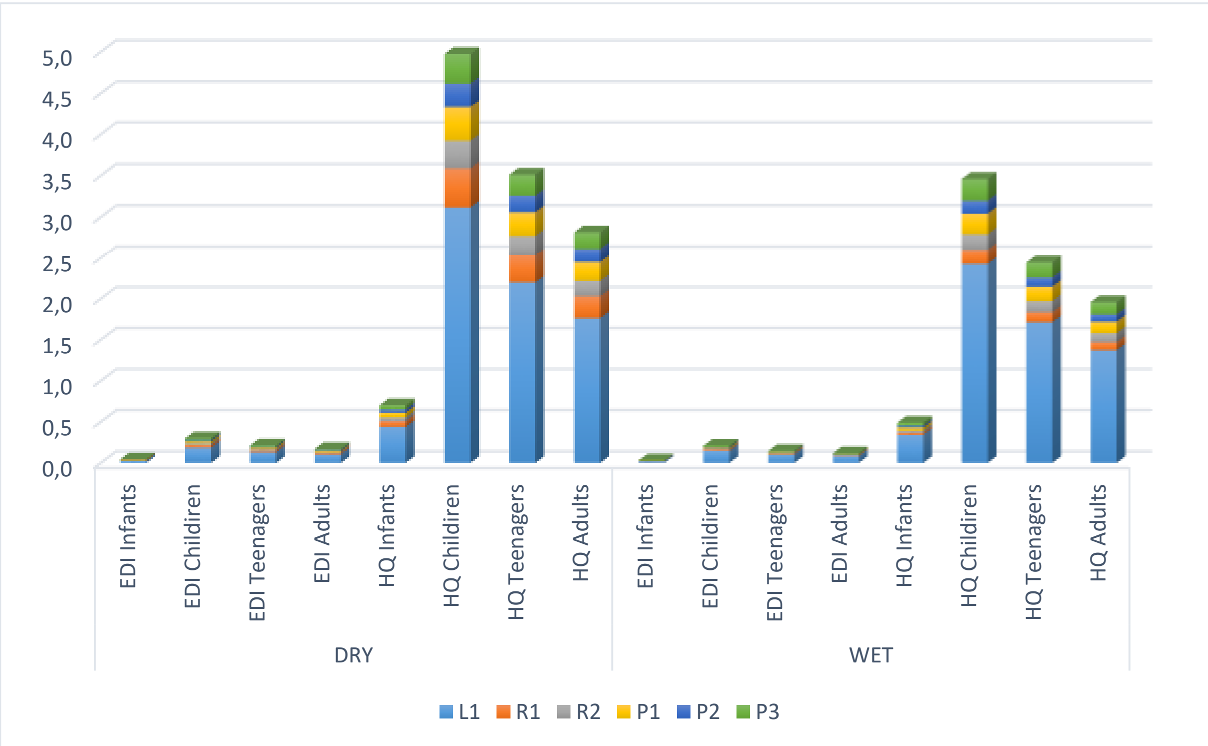
RfD: Reference dose (mg/kg/day) (it is 0.06 mg/kg/day for fluoride (EPA, 1992)).

RESULTS AND DISCUSSION

Spatial – temporal EDI – HQ values for the investigated different populations of consumers in water of natural and artificial lentic habitats of Gökçeada Island are given in Figure 2.

The average EDI values for fluoride in infants, children, teenagers and adults were recorded as 0.007, 0.050, 0.035 and 0.028 respectively in the dry season, while they were 0.005, 0.035, 0.024 and 0.020 respectively in the wet season. The average HQ values for fluoride in infants, children, teenagers and adults were recorded as 0.117, 0.829, 0.585 and 0.469 respectively, while they were 0.081, 0.577, 0.407 and 0.326 respectively in the wet season. The EDI and HQ risk rankings among the investigated different age groups were found as follows: children > teenagers > adults > infants in both dry and wet seasons in general.

In numbers of investigations on the assessment of health risks associated with fluoride in water conducted in many different countries confirmed that the children are at the chronic health risk due to the intake of fluoride in drinking water (Gao et al., 2013; Narsimha et al., 2018; Dehghani et al., 2019; Qasemi et al., 2020; Tokatlı et al., 2022; 2023). In the current research, as similar with the literature data, group of children were found as the riskiest age group for the health risk due to the intake of fluoride in water of natural and artificial lentic habitats of Gökçeada Island.



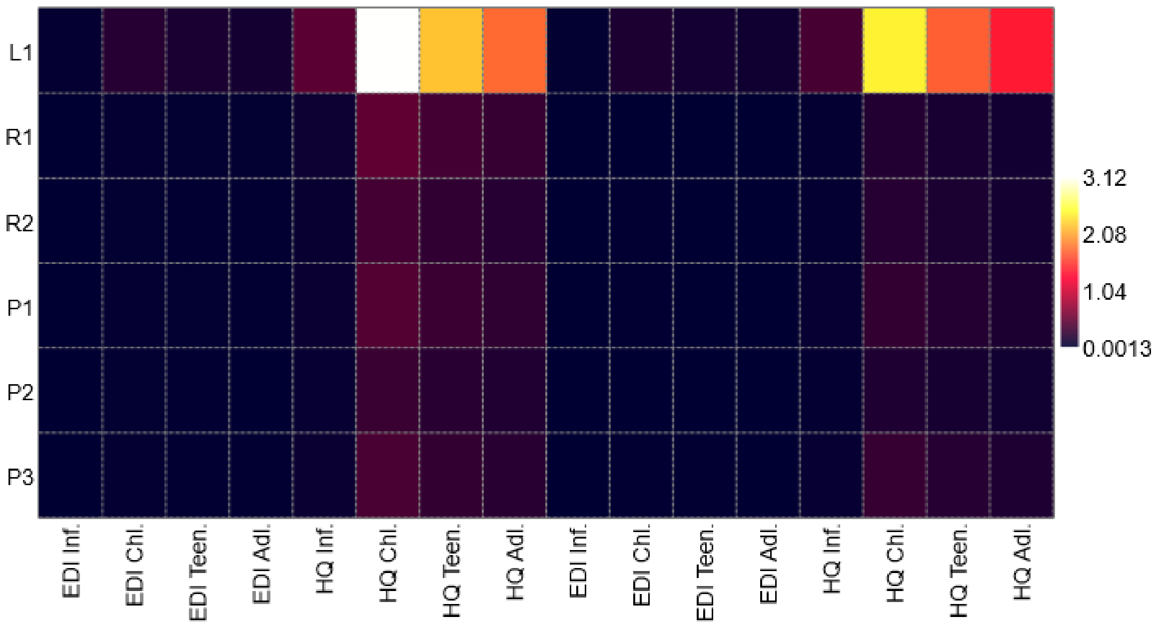


Figure 2. Spatio – temporal EDI – HQ values of different water consumers

CONCLUSIONS

In the current research, the non-carcinogenic health risks of fluoride via daily human intake in water of 6 lentic habitats located in Gökçeada Island of Türkiye were investigated. As a result of this study, the detected HQ values of all age groups were found as less than the critical limit of 1 and the risk rankings among the investigated different age groups were found as follows: children > teenagers > adults > infants in general. It was also determined that EDI and HQ values were significantly decreased in all the investigated natural and artificial lentic habitats during the rainy season.

ABSTRACT

Gökçeada, a district of Çanakkale, is the largest island in Türkiye. It is one of the rare islands in the world whose drinking water resources are sufficient to meet its own needs. There are 2 dam lakes, 3 artificial ponds and a lagoon on the island, which may use its fresh water resources for both drinking and irrigation. The aim of this research was (1) to determine the spatial – temporal variations of fluoride accumulations in water of stagnant water bodies located in the Gökçeada Island of Türkiye and (2) to evaluate the data in terms of dental health of the local people. 6 stagnant water bodies were selected on the island and water samples were collected during the dry – wet seasons of 2022 – 2023. The fluoride concentrations were measured by using spectrophotometric method. According to the results of this study, the fluoride accumulations were varied from 0.166 – 3.300 mg/L. It has been also noted that, the fluoride contents of water bodies decreases approximately 1.5 times during the rainy season, in general.

Keywords: Gökçeada Island, Stagnant Water Bodies, Fluoride Accumulations

INTRODUCTION

Fluoride is an essential element and it has a critical importance on the dental health. One of the main sources of fluoride intake is drinking water, but foods, drugs and industrial exposure are also among the entryways to the human body (Andezhath et al., 1993; Güner et al., 2016; Tokatlı and Güner, 2018; Onur et al., 2019; Onur and Tokatlı, 2020; Tokatlı et al., 2022; 2023).

Gökçeada, which has a very rugged landform due to its location on a volcanic ground, is one of the rare islands in the world whose drinking water resources are sufficient to meet its needs. When compared in terms of fresh water resources, it ranks first among the islands in the Aegean

Sea and fourth in the world. Gökçeada, which has 4 other ponds other than Zeytinli Dam Lake, may use its fresh water for both drinking and irrigation. Although Zeytinli Dam was built as a small dam, it provides most of the island's drinking water. There is a lagoon named as Salt Lake located in the northwest of the island. This lagoon was formed by the evaporation of the sea and condensation on land again and it is very important for natural life as it is located on the migration routes of migratory birds (Anonymous, 2022; http://www.gokceada.gov.tr/; https://www.gokceada.bel.tr/; https://www.kulturportali.gov.tr/).

The aim of this research was to determine the spatial – temporal variations of fluoride accumulations in water of stagnant water bodies located in the Gökçeada Island of Türkiye and to evaluate the data in terms of dental health of the local people.

MATERIALS AND METHODS

Water Collection

In this research, 6 stagnant water bodies (1 natural lake, 2 dam lakes and 3 artificial pons) located in the Gökçeada Island were selected. The coordinate information with the names of investigated freshwater ecosystems are given in Table 1. The topographic map of Gökçeada Island and selected locations are given in Figure 1. Water samples were collected in the summer season of 2022 (dry season) and the winter season of 2023 (wet season) with a telescopic water sampling device approximately 3 meters from the shore into the pre – cleaned polyethylene bottles.

Table 1. Coordinate information of selected stagnant water bodies

Name of Lentic	Station Code	GPS-North	GPS-East
Gökceada Lagoon	L1	40.133	25.956
Zeytinli Reservoir	R1	40.176	25.863
Uğurlu Reservoir	R2	40.138	25.713
Aydıncık Pond	P1	40.147	25.925
Şirinköy Pond	P2	40.114	25.772
Uğurlu Pond	P3	40.140	25.737

Figure 1. Topographic map of Gökçeada Island and selected locations

Fluoride Analysis

Fluoride levels of stagnant water bodies of Gökçeada Island were determined with spectrophotometric method by using a "Hach Lange DR 3900 Spectrophotometer" with a wavelength range of 320 – 1100 nm and "Hach Lange LCK 323 Cuvette Test" with a measure range of 0.1 – 2.5 mg/L (https://tr.hach.com/).

RESULTS AND DISCUSSION

Fluoride accumulations in water of stagnant water bodies of Gökçeada Island are given in Figure 2 as GIS based distribution maps and spatial – temporal variations of fluoride levels are given in Figure 3.

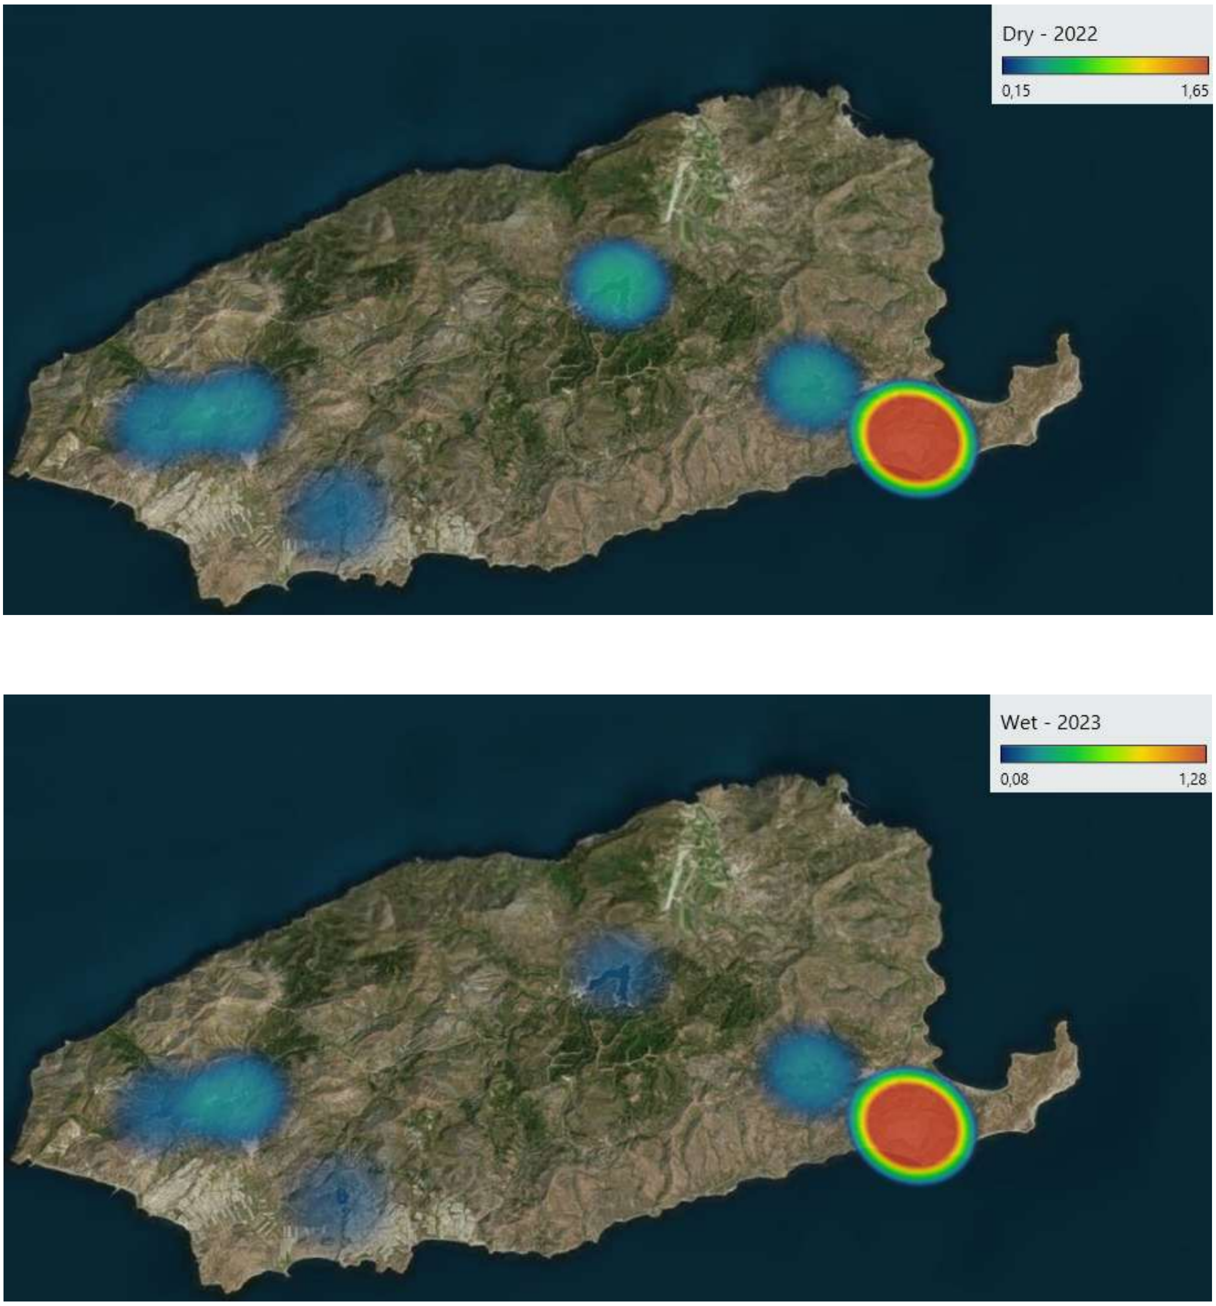

Figure 2. Fluoride levels of stagnant water bodies in dry (up) and wet (down) seasons (mg/L)

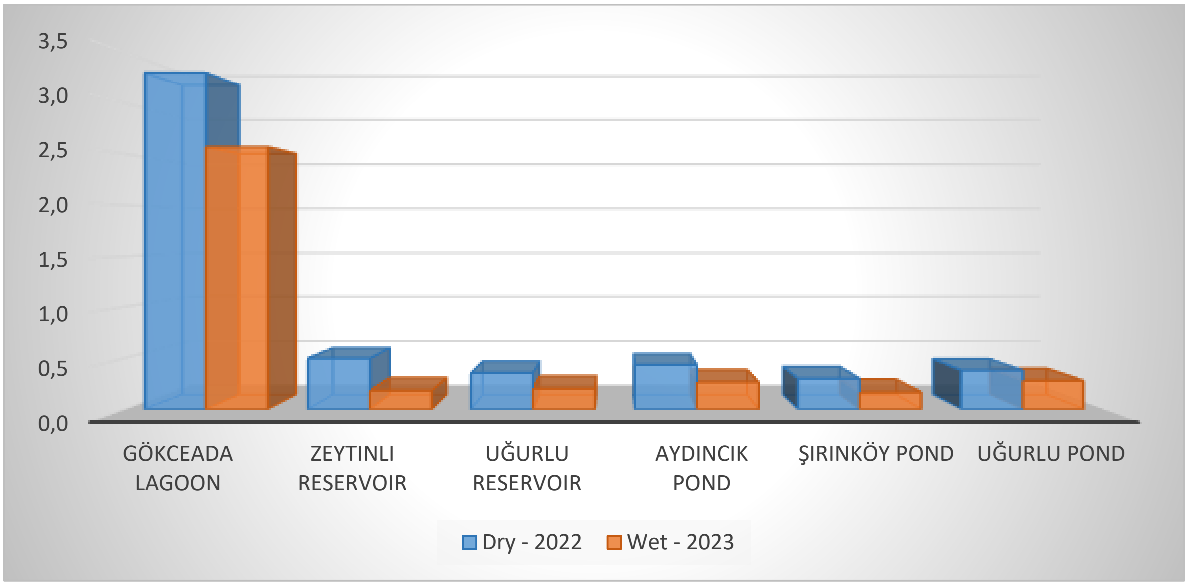

Figure 3. Spatial – temporal fluoride accumulations of stagnant water bodies (mg/L)

The fluoride accumulations in water of stagnant water bodies of Gökçeada Island varied from 0.300 mg/L (Şirinköy Pond) – 3.300 mg/L (Gökceada Lagoon) with a mean value of 0.878 mg/L in the dry season, while they were varied from from 0.166 mg/L (Şirinköy Pond) – 2.570 mg/L (Gökceada Lagoon) in the wet season with a mean value of 0.611 mg/L (Figure 3).

Although fluoride, which may easily get deposited in teeth, has a special importance in terms of especially dental health. It may have also quite adverse health effects on human depending on the content and consumption (Ayoob and Gupta, 2006; GómezHortigüela, 2013; Taghipour et al., 2016; Tokatlı et al., 2022; 2023). Drinking water is a direct source of fluoride exposure and urban water with optimal fluoride levels has preventive effect on body health and especially dental caries. However, exposure to fluoride more than optimal level may result in fluorosis that is an important dental health problem (Güner et al., 2016; Tokatlı and Güner, 2018; 2020; Jannat et al., 2022; Din et al., 2024). In the current research, the concentrations of fluoride in water of all the investigated stagnant water bodies located in the Gökçeada Island were ranged from 0.166 – 3.300 mg/L and fluoride levels of all the investigated 5 stagnant water bodies used as drinking water were within the acceptable limit of 1.5 mg/L for drinking (except Gökceada Lagoon – not used as drinking water) specified by TS266 (2005), EC (2007) and WHO (2011).

CONCLUSIONS

In the current research, spatial – temporal variations of fluoride accumulations of fluoride in water of 6 stagnant water bodies located in the Gökçeada Island of Türkiye were investigated. As a result of this study, the fluoride accumulations were varied as 0.300 – 3.300 mg/L in the dry season and 0.166 mg/L – 2.570 mg/L in the wet season. It was also determined that fluoride levels in waters were significantly decreased in all the investigated stagnant water bodies during the rainy season.

ABSTRACT

Immunity is crucial for protecting organisms from diseases and harmful substances. Vertebrates and insects have immune systems with different molecular mechanisms. Vertebrates, like humans, have innate and adaptive immunity. The innate response offers immediate, nonspecific defenses, including physical barriers like skin and mucous membranes, along with cellular and humoral responses involving various immune cells and soluble components. On the other hand, adaptive immunity entails highly specialized responses mediated by T and B cells that form memories against specific infections. However, insects, such as *Galleria mellonella* model rely heavily on their innate immune system for defense. This system, which includes physical barriers, cellular reactions, and humoral components, responds to invading pathogens in a quick and nonspecific manner. Cellular defenses in insects include nodulation, phagocytosis, encapsulation, the respiratory burst in which free radicals are generated, and humoral defense mechanisms such as prophenol oxidase, antimicrobial peptides, and coagulation. Furthermore, molecular pathways like Imd (Immune deficiency), mTOR, and JAK-STAT are critical in coordinating insect immune responses. These pathways control a variety of immunological processes, including pathogen identification, signal transduction, and immune effector synthesis. Understanding the complex molecular mechanisms of insect immunity is critical not only for understanding the underlying principles of host defense, but also for practical applications like pest control and disease management. Insights into insect immunity would led light to develop new drugs by crippling of insect immune system by immunosupressive innovative drugs such as eicosanoid (immune meditor molecules in insects) biosynthesis inhibitors for combating insect-borne diseases in human and agricultural pests while limiting environmental effects.

Keywords: Immune Response, Insects, *Galleria mellonella*, Immunosupressive Drugs

INTRODUCTION

The immune system in living organism’s functions as a mechanism of defence that is complex and essential for survival and adaptation (Parkin and Cohen, 2001). It includes both innate and adaptive components that develop over time to protect against infections and infections, parasitism, and harmful interactions (Danilova, 2006). Immunity also involves the identification and elimination of foreign genetic material through various mechanisms, including the restriction-modification and CRISPR-Cas systems (Zakrzewska and Burmistrz, 2023). Initiation of immune responses is facilitated by phagocytic macrophages that detect bacterial surfaces and secrete cytokines and chemokines to provoke inflammation and recruit additional immune cells (Arango and Descoteaux, 2014). The evolution of the immune system is closely linked to the broader evolutionary narrative of life on Earth, ranging from the origin of prokaryotic organisms to changes in multicellular size and the development of adaptive immune responses in vertebrates (Cooper and Alder, 2006). In summary, the immune system in living organisms is crucial for maintaining the integrity and homeostasis of organisms, emphasising the importance of these complex evolutionary processes.

Innate Immunity in Vertebrates

The innate immune system in vertebrates is the primary line of defence against pathogens. This immune system functions as a physical barrier as well as cellular and humoral responses (Kasamatsu, 2013). Since physical barriers such as skin and mucosa are the first points of contact with danger, epithelial cells that prevent infection here are extremely important. Mucus formed by epithelial cells secretes substances such as perspiration and saliva, creating a potential defence mechanism against pathogens (Gallo and Hooper, 2012). It acts as natural killer cells and these tissues have added an important feature to the innate immune system by exerting microcidal effects against viruses and gaining memory cell properties with interleukins 12 and 18 (Kyndra, 2022). The cellular response needs to produce interferons and pro-inflammatory cytokines to fight viral infections and interferon lambda is crucial in antiviral immune responses (Liu et al., 2024). To understand these immune mechanisms, it is crucial to study the innate immune system of vertebrates in the evolutionary process (Kasamatsu, 2013).

Insects have strong immune systems that include physical and more different immune responses against pathogens (Zhou et al., 2024). Since insects do not have an innate immune system like vertebrates, they show different immune responses to survive against pathogens (Hoffmann and Hetru, 1992). In the insect immune system, humoral immunity has a very important influence on the metabolic adaptation and behaviour of insects (Nunes et al., 2021). In insect immunity, haemocytes, phagocytosis, nodulation and encapsulation processes play an important role in cellular and humoral responses (Marmaras and Lampropoulou, 2009). These responses are interconnected in insect immunity. While haemoxides affect humoral factors, they form a strong defence system against pathogens. When insect immunity is viewed from a broad perspective, the immune system of insects is sensitively tuned for survival and adaptation to various environmental conditions.

Adaptive Immunity in Vertebrates

Adaptive immunity in vertebrates is mainly determined by the primary functions of T and B cells in the formation of immunological memory. T and B lymphocytes undergo extensive genetic regulation to produce a variety of antigen-specific receptors that enable recognition of many pathogens. Following initial exposure to an antigen, these cells undergo proliferation as well as differentiation, leading to the formation of long-term memory lymphocytes that can respond quickly and effectively upon subsequent exposure to the same pathogen (Yang et al., 2021). The development of memory T cells is modulated by many different factors, including the balance between memory formation and immunoregulation, which can influence the outcome of infectious diseases, cancer and autoimmune diseases (Kurtz and Franz, 2003). Similarly, the process of memory formation, particularly in B cells, is complex and requires strategic choices regarding the specificity and affinity of immune receptors, which are vital for maintaining effective long-term immunity (Netea et al., 2019). It is also effective in generating immediate responses at barrier sites to enable tissue-resident B cells to provide defence (Cancro and Tomayko, 2021). In short, the memory-forming ability of the adaptive immune system is vital for the persistent survival in vertebrates against a variety of pathogens.

Comparison Between Vertebrate and Insect Immune Systems

The immune systems of vertebrates and insects have both similarities and differences. In Vertebrates, lymphocytes and immunoglobulins are highly functional, indicating the presence of both innate and adaptive immunity (Melillo et al., 2018). In contrast, insects rely solely on innate immunity to combat pathogens, using cellular and humoral mechanisms such as phagocytosis, secretion of antimicrobial peptides and activation of signalling pathways, including Toll and similar pathways (Simona and Jean-Luc, 2016). Whereas vertebrates with adaptive immunity function as lymphocytes equipped with specific antigen receptors, invertebrates, including insects and jawless vertebrates, have shown immune responses similar to adaptive immunity, thus challenging the traditional categorisation of immune systems (Shaochun et al., 2014). Moreover, while arthropods exhibit a wide variety of immune components with some elements resembling those found in vertebrates, such as Toll-like receptors, they also exhibit distinctive features such as significant gene duplication and variability in immune receptors (William et al., 2014). These observations underline that the immune systems of various animal taxons are more complex and have evolved in different directions in the evolutionary process and that there are diverse immune systems.

Insect Immune System

Insects show an immune system that encompasses both physical and humoral defence mechanisms. The first line of defence against pathogens is formed by physical barriers, including the trophic matrix and chitinous exoskeleton (Ulrich et al., 2022). Cellular defence mechanisms such as nodulation, phagocytosis, encapsulation and respiratory blast play a crucial role in the identification and inactivation of invading microorganisms (Hoffmann, 2003). The humoral immune response is primarily driven by the antimicrobial peptides (AMPs) and the prophenol oxidase pathway, which work to eliminate pathogens and facilitate blood clotting (Li et al., 2024; Ulrich et al., 2022). Recent research has underlined the complex nature of these immune responses, showing that the environmental factors can greatly influence their efficiency (Moure et al., 2022). Moreover, the interplay between various immune pathways, including the production of reactive oxygen species and associated signalling pathways, underlines the adaptive properties of insect immunity (Hoffmann, 2003; Ulrich et al., 2022) This overarching strategy enables insects to effectively counter a variety of pathogens, underlining their evolutionary success in immune defence.

Immune Response of Insect in Term of *Galleria mellonella*

G. mellonella displays a diverse immune system response. In recent years, there has been a large number of studies focusing on the immune mechanisms of this model organism. Larvae infection with *Pseudomonas entomophila* activates immune-related genes and defence strategies in a dose-dependent manner, leading to antimicrobial activity in the haemolymph (Jakub et al., 2023). While ink injections promote hemocyte mobilisation, lemongrass essential oil and citral have been found to inhibit this process (Kyndra et al., 2022). The melanisation process plays an important role in the immune response, as melanin encapsulation shows antifungal properties against Cryptococcus neoformans and other fungal pathogens (Trevijano and Zaragoza, 2018). *G. mellonella* is a very valuable model to research host-pathogen interactions and to evaluate therapies such as antimicrobial photodynamic therapy that are effective against various pathogens (Chastain et al., 2022). These observations emphasise the importance of *G. mellonella* in the study of immune responses and its potential for various biological applications.

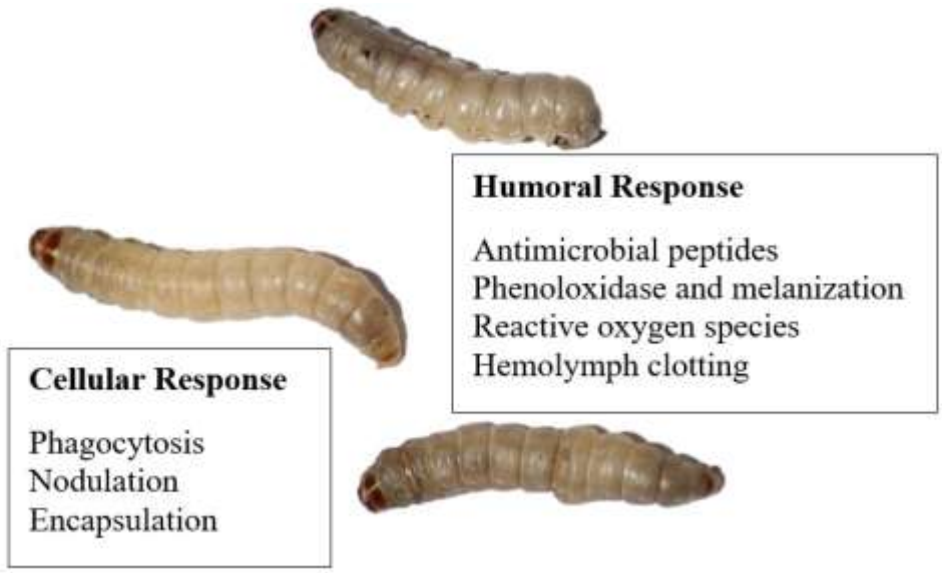

Figure 1. *G. mellonella* immune response (The photograph of the *Galleria mellonella* 7th stage larva was taken by our team).

Pathways in Insect Immunity

Insect immunity is regulated by several critical molecular pathways, in particular the Imd, mTOR and JAK-STAT pathways. The Imd pathway is crucial for generating immune responses against Gram-negative bacteria, as it triggers the synthesis of antimicrobial peptides (AMPs) through specific receptors that detect pathogen-associated molecular patterns (Lovett and Leger 2017; Ulrich et al., 2022). The evolutionarily conserved JAK-STAT pathway is important in modulating immune responses against various pathogens, including viruses and fungi, by mediating cytokine signalling and enhancing immune cell differentiation (Xiang-Yi et al., 2023; Krishnakumar and Kannan, 2020). Furthermore, the mTOR pathway is involved in cellular growth and metabolism and influences immune responses by integrating signals from both nutrients and pathogens (Kurtz and Franz, 2003). Collectively, these pathways contribute to a strong immune response; however, pathogens have evolved strategies to circumvent these defences, which has led to ongoing research into the intricacies of insect immunity and the influence of non-coding RNAs on these pathways ((Kurtz and Franz, 2003; Ulrich et al., 2022). However, gaining insight into these interactions is vital for formulating new approaches to enhance insect resistance to pathogens.

Applications of Insect Immunity Research

Research in the field of insect immunology has significant potential for the development of pest control methods, management of agricultural diseases and the creation of immunosuppressive pharmaceuticals. A comprehensive understanding of the mechanisms underlying insect innate immunity, including the functions of antimicrobial peptides (AMPs) and immune signalling pathways, could lead to the development of novel pest management strategies. For example, the distinctive immune responses observed in aphids offer potential targets for environmentally friendly pest control by exploiting their natural defences against various pathogens and parasites (Yang et al., 2021) Furthermore, the identification of AMPs as natural antimicrobial agents provides valuable opportunities to support food safety and improve agricultural productivity (Moure et al., 2022). In addition, investigating the immunomodulatory roles of non-coding RNAs could pave the way for the creation of immunosuppressive drugs that could have applications in both agricultural and medical fields (Lovett and Leger, 2017). In summary, integrating insect immunity research into practical applications offers promising prospects for sustainable agricultural practices and improved health outcomes (Moure et al., 2022; Lovett and Leger, 2017).

CONCLUSIONS

Understanding the immune mechanisms of vertebrates and insects reveals the diversity and specialisation of their defence strategies. Vertebrates, like humans, have both innate and adaptive immune systems, allowing for immediate, non-specific responses mediated by T and B cells and highly specific, long-lasting immunity. In contrast, insects such as *G. mellonella* rely primarily on an evolved innate immune system. This system includes physical barriers, cellular defences such as phagocytosis and encapsulation, and humoral responses such as antimicrobial peptides and the prophenol oxidase pathway. Key molecular pathways such as Imd, mTOR and JAK-STAT play important roles in regulating insect immune responses, including pathogen recognition, signal transduction and production of immune effectors. By delving deeper into the complexities of insect immunity, we are not only improving our understanding of the fundamentals of host defence, but also paving the way for innovative applications in pest control and disease management. Targeting the insect immune system with immunosuppressants such as eicosanoid biosynthesis inhibitors offers a promising approach to combat insect-borne diseases and agricultural pests. This strategy has the potential to minimise environmental impacts while effectively reducing the prevalence of these challenges. Therefore, continued research on insect immunity is essential to develop new and sustainable solutions to global agricultural and health challenges.

ABSTRACT

Eicosanoids are a large class of compounds known as intercellular signaling molecules derived from fatty acids with 20 carbon atoms. Eicosanoids were discovered in vertebrates as physiolohical mediators in the 1960s, and were shown to be present in insects in the 1980s. In both vertebrates and invertebrates, eicosanoids play important roles in the immune system as well as normal physiological roles such as digestion, reproduction and nervous system functions and also were secreted in pathophysiological process. Insects, unlike vertebrates, have an innate immune system and are not capable of developing adaptive immunity. The innate immune system of insects provides defense by forming physical barriers (integument, peritrophicmembrane), cellular and humoral immune responses and reactive free radicals (ROS and nitrous oxide radicals). Eicosanoids play a critical role in regulating and activating these immune responses via certain signal pathways. For example, prostaglandins and thromboxanes promote phagocytosis and respiratory burst against pathogens, while leukotrins and lipokines trigger inflammation and migration of immune cells. In conclusion, eicosanoids play a crucial role in the functioning of the insect immune system and are critical in defense against pathogens. Further research on the insect physiology and pathology of these molecules may offer new opportunities for insecticide development and pest control strategies. We foster to develop new drugs in term of agricultural insecticidal apporoaches by inhibiting eicosanoid biosynthesis in different tissue of insects by eicosanoid biosynthesis inhibitors (EBIs) such as Cyclooxygenases enzyme systems (COX-1 and 2), Lipoxygenases (LOXs), Epoxyeicosatrienoic acids (EETs) pathways in our laboratory.

Key Words: Eicosanoids, Insects, Immune Response, Eicosanoid Biosynthesis Inhibitors,

INTRODUCTION

One of the systems essential for the survival of organisms is the immune system, a defense system that protects against pathogens. This complex system has evolved over thousands of years to counter threats ranging from bacteria and viruses to fungi and parasites. Immune responses can be categorized into two major groups: innate or adaptive. Generally, organisms use mainly the rapid and non-specific mechanisms of the innate immune system to provide initial protection (Tunaz, 2004).

Insect Immunity

Insects have a highly effective innate immune system, although they lack the antibody-mediated adaptive immunity of vertebrates. This system, which has evolved over millions of years of evolution, is divided into two main branches: humoral and cellular immunity. Humoral immunity includes the production and secretion of antimicrobial peptides (AMPs) into the hemolymph (circulating fluid). These peptides, such as cecropins, atakins and defensins, show broad activity against bacteria, fungi and even viruses (Gillespie et al., 1997). Cellular immunity reacts by direct interaction between circulating hemocytes and pathogens (Strand and Pech, 1995). The main cellular responses include phagocytosis, nodulation, encapsulation and melanization (Strand and Pech, 1995).

Phagocytosis, the import and digestion of small-sized invaders into cells, is a fundamental defense mechanism that has been conserved throughout evolution (Stuart and Ezekowitz, 2005). Insect hemocytes, acting like mammalian macrophages, enclose pathogens in specialized compartments called phagosomes and enzymatically degrade them (Pearson et al., 2003). A more complex cellular process, nodulation, occurs when the numbers of invaders become too large for hemocytes to handle as a single cell (Satyavathi et al., 2014). In this process, hemocytes aggregate around invaders to form nodules that melanize and are isolated from the rest of the organism. Encapsulation similarly targets larger invaders, such as parasitoid eggs that are too large to be phagocytosed (Carton et al., 2002). Hemocytes form multilayered capsules around invaders, effectively isolating them from the organism. Melanization, a crucial process in both nodulation and encapsulation, involves the phenoloxidase (PO) enzyme system (Cerenius et al., 2008). This enzyme catalyzes the production of melanin, a toxic pigment that both physically encapsulates invaders and produces cytotoxic and cytotoxic products that contribute to their elimination (Nappi and Christensen, 2005). The insect immune system, including these mechanisms, is a very effective defense system against pathogens.

Insect And Mammalian Immunity

Although the innate immunity of insects and mammals has some differences, there are striking similarities, particularly in the components of humoral immunity (Sheehan et al., 2018). Both systems depend on the recognition of pathogen molecules by specialized receptors (Akira et al., 2006). Activation of these receptors triggers signaling cascades leading to the production of effector molecules, including AMPs, in both systems (Imler and Zheng 2004). For example, the Toll pathway in insects and the Toll-like receptor (TLR) pathway in mammals activate the transcription factor NF-κB, which plays an important role in regulating the expression of immune genes (Silverman and Maniatis 2001). This homology links to the IMD pathway in insects and the TNF-α pathway in mammals, both of which also activate NF-κB (Kleino and Silverman 2014).

Despite these similarities, insect and mammalian immunity also shows striking differences. Most obviously, insects do not have antibody-mediated adaptive immunity. While vertebrates have B and T lymphocytes that can establish highly specific and long- term immune responses, insects have defenses based only on innate immunity (Flajnik and Kasahara 2010). This lack of adaptive immunity is compensated for by the extraordinary diversity of insect AMPs and the production of thousands of unique receptors by alternative spilicing, such as DSCAM, thereby broadening the spectrum of pathogens that can be recognized (Schmucker et al., 2000). Furthermore, while mammalian melanization is primarily involved in skin pigmentation and UV protection, insect melanization plays a crucial role in innate immunity as described above (Brenner and Hearing, 2008, Nappi and Christensen, 2005). Finally, insect AMPs are primarily produced in adipose tissue, whereas mammalian AMPs are usually produced locally by cells at the site of infection (Bozzaet al., 2011, Zhang et al., 2021).

HEMOLYMPH AND HEMOCYTES

Hemolymph is the circulating fluid that circulates in hemocele. It is in direct contact with the tissues. It is composed of hemocytes and plasma. The main functions of hemolymph are transport, storage and immunity. (Chapman 1998). The functions and structures of some hemocytes are listed below.

a. The prohemocyte: a stem cell. Other hemocytes are derived from prohemocytes. They are small cells with a small volume of cytoplasm. In many insect species, prohemocytes are located in the hematopoietic organs. A lower percentage are located in circulating hemolymph.

b. The granulocyte: contains a large number of granules. They are phagocytically active. After being activated by incoming impulses, granulocytes release granule contents into the surrounding environment. Garnulocytes are the most common type of hemolymph detected in Lepidopterans.
c. The plasmatocyte: are cells characterized by a high volume of cytoplasm that adheres strongly to surfaces. Plasmatocytes have been detected in lepidopterans. However, in some insect groups, including the genus Anopheles and Aedes, they have not been detected significantly.
d. The oenocytoid: it is a hemocyte that displays phenoloxidase activity. However, it does not show adhesion properties.

e. The spherule: cells with large spherules in the cytoplasm. They are responsible for the synthesis of cuticle components. (Chapman 1998).

Table 1. Similarities between insect hemocytes and human neutrophils (Browne et al., 2013).

	Hemocytes	Neutrophils
Phagocytosis	Lectin-mediated	Lectin-mediated
ROS	$O_2^{\cdot-}$, H_2O_2, $NO^{\cdot}$	$O_2^{\cdot-}$, H_2O_2, $NO^{\cdot}$
Degranulation	Yes	Yes
AMPs	Peroxynectin, transferrin, lysozyme, defensin	MPO, transferrin, lysozyme, defensin
Receptors	TLRs, B-1,3-glucan, IL-IR	TLRs, B-1,3-glucan, IL-IR
Transcription factors	NFκB, IκB	NFκB, IκB
Cascades	IMD, JNK, JAK-STAT	IMD, JNK, JAK-STAT
Kinases	p38 MAPK, ERK, PKC, PKA	p38 MAPK, ERK, PKC, PKA
Neutrophil extracellular nets (NET)	NET-like structures present	NETs present

EICOSANOIDS

Eicosanoids are molecules formed by enzymatic oxygenation of arachidonic acid and other 20-carbon polyunsaturated fatty acids. Eicosanoids are involved in many areas in the cell where they are synthesized. The main eicosanoids are leukotrienes, thromboxanes, prostacyclin, prostaglandins, lipoxins and hepoxylins (Stanley et al., 2009, Tunaz et al., 2018).

It has been reported that eicosanoids are involved in the formation of the immune response against bacteria in insects (Miller et al., 2005). Many studies with eicosanoid inhibitors have reported that eicosanoids are involved in insect immunity against infections (Stanley and Miller, 2006; Satyavathi et al., 2014, Tunaz et al., 2018).

Synthesis of Eicosanoids

Eicosanoid synthesis starts with the hydrolysis of arachidonic acid from the plasma membrane by Phospholipase A2. Hydrolyzed arachidonic acid is catalyzed to eicosanoid by 3 potential pathways. The first of these pathways is the cyclooxygenase pathway, which results in the formation of prostaglandins. Examples of prostaglandins are thromboxanes and prostacyclins. Another pathway is the lipooxygenase pathway. At the end of this pathway, a large group of eicosanoids are synthesized. This group includes leukotrienes, lipoxins, hepoxylins, peroxy-fatty acids and hydroxy-fatty acids. The last pathway is the cytochrome p450-epoxygenase pathway. As a result of this pathway, epoxyeicostrienoic acids are formed (Stanley et al., 2009).

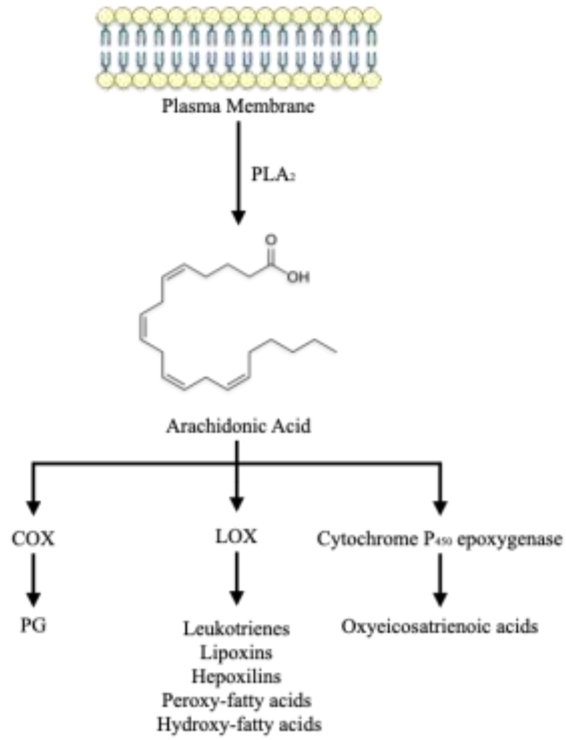

Figure 2. Eicosanoids synthesis. PLA_2: Phospholipase A_2, COX: cyclooxygenase, LOX: lipoxygenase, PG: prostaglandin.

CONCLUSIONS

Eicosanoids are molecules that enzymatically synthesized from polyunsaturated fatty acids by oxygenation reactions. They plays critical roles in several processes in insect immunity. These processes include migration of hemocytes, phagocytosis, synthesis of antimicrobial peptides. Studies have shown that these processes are affected when COX inhibitors, one of the enzymes responsible for eicosanoid synthesis, are used (Stanley-

Samuelson et al., 1991). Similarly, Shrestha and Kim in 2008 showed that prophenoloxidase activity is controlled by eicosanoids. In another study with eicosanoid synthesis inhibitors, it was observed that hemocyte migration was affected in a dose-dependent manner (Merchant et al., 2008). In addition, it has been shown the role of eicosanoids in the immune response to viral infections in *G. mellonella* (Büyükgüzel et al., 2007). Eicosanoids are also associated with the IDM and Toll pathways. Both pathways lead to the biosynthesis of eicosanoids by activating PLA2. In this case, eicosanoids have been shown to play an active role in cellular and humoral immunity (Satanley and Kim 2019).

ABSTRACT

Lactic acid bacteria include several genera, the majority of which are represented by *Lactobacillus*. They are currently the focus of a great deal of research due to their potential in various biotechnological applications. They have demonstrated their ability to produce antimicrobial agents such as lactic acid, hydrogen peroxide, and bacteriocins, which may act synergistically against filamentous fungi.

These properties of *Lactobacillus*, particularly their antimicrobial potential, raise important questions linked to the production of antifungal agents, bio-preservation and the fight against fungal deterioration. These issues are of fundamental importance in diverse fields such as agriculture, biotechnology, food industry and more.

In our experiment, we have demonstrated the antifungal activity of four lactic acid bacteria isolated from camel and goat milk, designated L1, L2, L3, and L4, against four phytopathogenic fungal strains (*Aspergillus niger*; *Phytophtora infestans*; *Penicilium spp*; et *Endosporium spp*). This evaluation was carried out using different levels of concentrations of the bacterial supernatant, namely 0.25, 1, 1.75, and 2.5 µl/ml.

Our strains showed strong antifungal activity, even at low concentrations, with a significantly different effect from one strain to another. All four supernatants had a significant effect against *Penicillium spp*, *A.niger*, and *P.infestans*, with an antifungal index between [43.33 - 63] %, [38.46 - 61.54] %, and [35.56 - 55.56] % respectively. Furthermore, the best antifungal activity against *Endosporium spp* was obtained by strains L4 and L1 with inhibitory effects equal to 38.24% and 26.47%.

These results provide a clear idea of the antimicrobial potential of *Lactobacillus* strains, which represent an alternative to some antifungal agents used in different fields (agriculture, biotechnology, …etc).

Keywords: *Lactobacillus*, filamentous fungi, antifungal activity, agriculture, biotechnology.

INTRODUCTION

Lactic acid bacteria (LAB) are a diverse group of microorganisms, predominantly represented by the genus Lactobacillus, that have garnered significant attention in recent years for their versatile applications in biotechnology. These bacteria are known for their ability to produce various antimicrobial substances, including lactic acid, hydrogen peroxide, and bacteriocins, which can work synergistically to inhibit the growth of filamentous fungi. The antimicrobial properties of Lactobacillus not only highlight their potential as natural preservatives but also raise critical questions regarding their role in antifungal agent production and bio-preservation strategies across multiple sectors such as agriculture and the food industry.

In this study, we explore the antifungal capabilities of four specific Lactobacillus strains isolated from camel and goat milk, designated L1, L2, L3, and L4. These strains were tested against four phytopathogenic fungal species: *Aspergillus niger*, *Phytophthora infestans*, *Penicillium spp.*, and *Endosporium spp.* The experimental design included varying concentrations of bacterial supernatants to assess their efficacy in inhibiting fungal growth. The results demonstrated notable antifungal activity across all strains, particularly against *Penicillium spp.*, *A. niger*, and *P. infestans*, suggesting that these LAB could serve as effective biocontrol agents in combating fungal deterioration in various applications. This research underscores the potential for Lactobacillus strains to offer sustainable alternatives to synthetic antifungal agents in diverse fields.

Materials and Methods

Strains Used:

- Four *Lactobacillus* strains (L1, L2, L3, L4) were selected from the collection at the Laboratory of Biology of Microorganisms and Biotechnology (LBMB), University of Oran.

Strain Revivification:

- The bacterial strains were revivified in skim milk and MRS broth at 30°C, **Figure 1.**

Figure 4: Revival of lactic strains.

Fungal Strains Tested:

- Four phytopathogenic fungal species were studied: *Aspergillus niger*, *Phytophthora infestans*, *Penicillium spp.*, and *Endosporium spp*. The purification of fungal species was carried out by a series of subcultures, which consists of transferring a part of the mycelium of each colony into a PDA box and then incubating it for 3-5 days at 28°C. The identification used is based on the combination of macroscopic and microscopic observations **(Engelkirk et al., 2011):**
- • Macroscopic observation is based on the cultural characteristics observed with the naked eye.
- • Microscopic observation is based on the morphological characteristics of mycelium and spores **(Griensven, 2000),** and was evaluated by the adhesive tape technique **(chabasse et *al*., 1999)** which consists of pressing on the surface of the colony using a small piece of transparent tape, then stuck to a glass slide covered with lactophenol cotton blue and observed under a microscope.

Antifungal Activity Testing:

- The antifungal activity of the Lactobacillus strains was assessed by introducing their supernatants into melted PDA medium at 45°C (**Soliman et Badeaa, 2002**), **Figure 2.**
- Different concentrations of the supernatants (100, 400, 700, 1000 µl) were tested.
- The plates were incubated at 28°C for five days.
- The antifungal activity was calculated using the formula: I = {Dt - Da}/{Dt}×100

Where I is the inhibition index, Dt is the diameter of the control colony, and Da is the diameter of the colony in the presence of the bacterial supernatant.

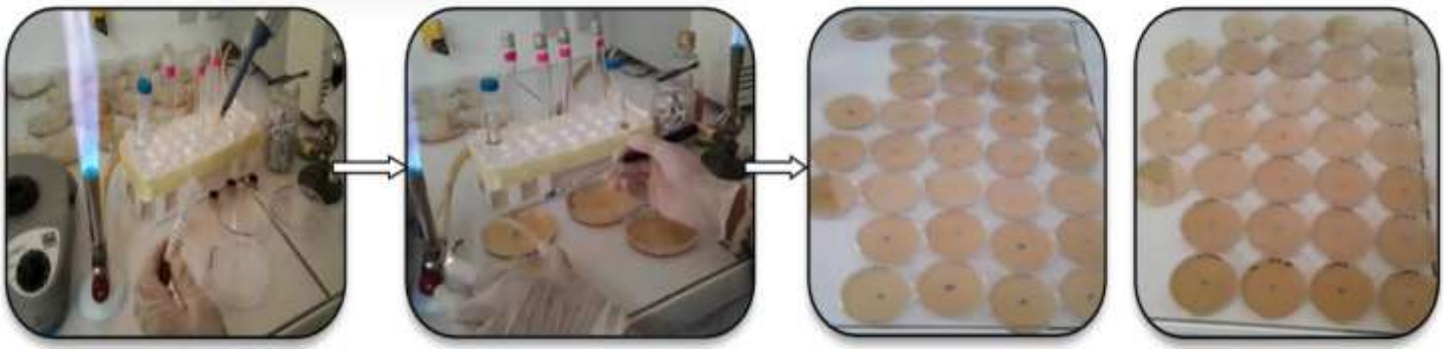

Figure 5: The realization of antifungal activity.

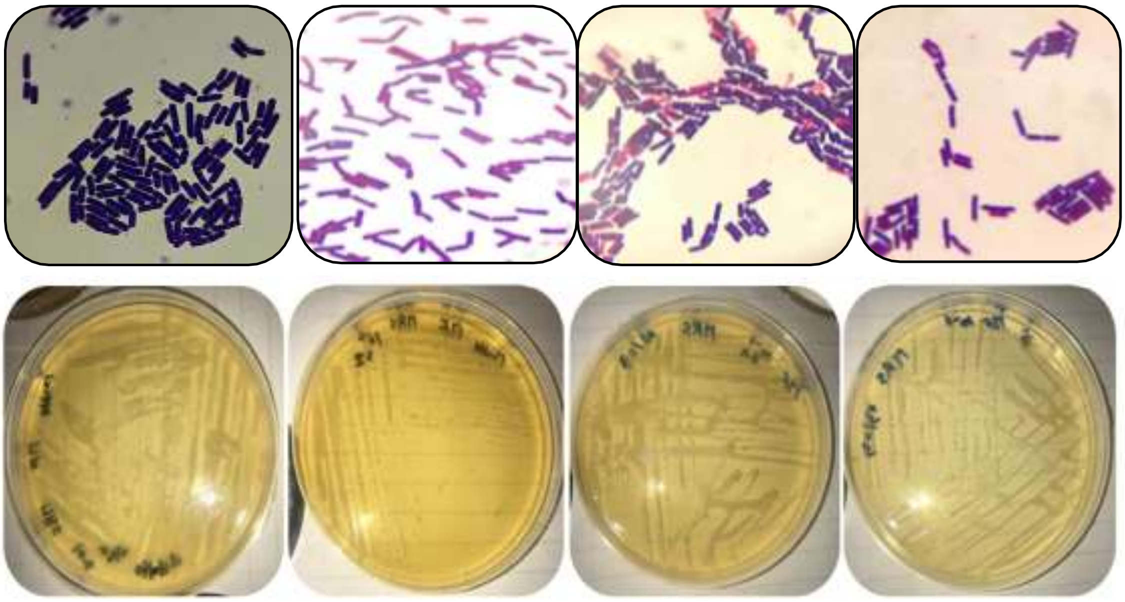
RESULTS AND DISCUSSION

Revivification and identification

Two types of observation were necessary to determine the purity of the bacterial cultures after subculturing. Macroscopic observation revealed that the colonies of the different strains have the same phenotypic characteristics, elongated shape with regular outline, whitish color and creamy appearance **(Figure 3).** Microscopic observation after Gram staining showed the shape and purity of the cells: the bacteria are Gram-positive rods, isolated or in pairs. Among the four strains examined, none of them showed catalase activity.



L1 L2 L3 L4

Figure 6: Macroscopic and microscopic appearance of lactic strains

Antifungal Activity

The results showed that the supernatant of the four Lactobacillus strains (SL1, SL2, SL3 and SL4) exhibited more or less significant antifungal activity depending on the strain and the different concentrations of the supernatant, **Table 2.**

Table 1: Effect of supernatants on the growth diameter of fungal strains.

Strains	Fungal strains	Growth diameter (mm) with different concentrations of supernatant (µl)				
		T	100	400	700	1000
SL1	*Penicillium spp*	30	18	17	16	14
	Aspergillus niger	39	30	30	19	15
	Phytophtora infestans	45	38	33	30	20
	Endosporium spp	34	31	30	29	25
SL2	*Penicillium spp*	30	21	16	14	11
	Aspergillus niger	39	31	30	25	23
	Phytophtora infestans	45	34	33	29	29
	Endosporium spp	34	32	30	30	28
SL3	*Penicillium spp*	30	22	20	19	16
	Aspergillus niger	39	35	30	25	24
	Phytophtora infestans	45	35	33	33	20
	Endosporium spp	34	34	32	32	30
SL4	*Penicillium spp*	30	22	20	19	17
	Aspergillus niger	39	33	30	30	22
	Phytophtora infestans	45	33	29	28	28
	Endosporium spp	34	29	25	24	21

All concentrations of SL1 supernatant cause a significant effect on *Aspergillus niger* and Penicillium spp by an antifungal index equal to 61.54% (50µl/ml) and 53.33% (50µl/ml) respectively. The antifungal index equal to 55.56% of the 50µl/ml concentration and 33.33% at 35µl/ml is considered the highest and rather significant for *Phytophtora infestans*. The lowest index is measured on *Endosporium spp* in the high concentrations: 26.47% (50µl/ml) and 14.71% (35µl/ml), **Figure** 4.

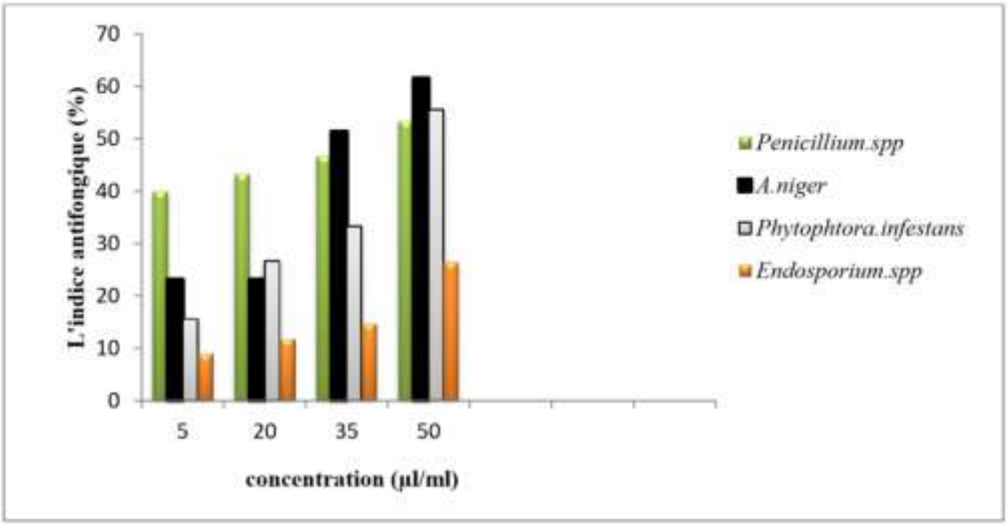


Figure 7: Antifungal effect of SL1 supernatant.

The best activity of the supernatant from the Lactobacillus 2 strain was obtained against *Penicillium.spp*, with an inhibition rate exceeding 63% at 50µl/ml and 53% at 35µl/ml. *Aspergillus niger* and *Phytophthora infestans* respectively give an antifungal index equal to 38.46% (50µl/ml) and 35.56% (50 and 35µl/ml). The supernatant of *Lactobacillus* 2 is weakly influential with high concentrations especially against *Endosporium spp* with an antifungal index equal to 11.76% (20 and 35µl/ml) and 17.65% (50µl/ml), **Figure 5**.

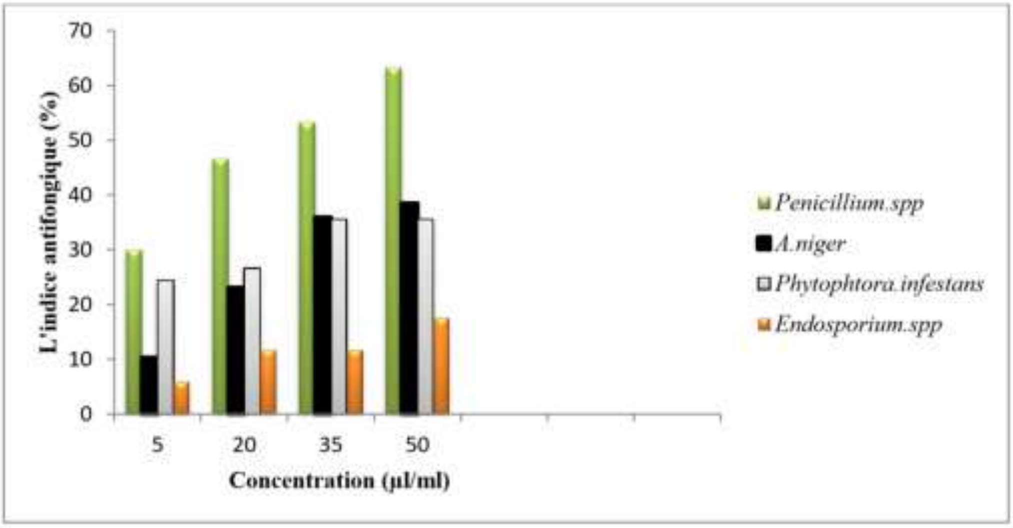

Figure 8: Antifungal effect of SL2 supernatant.

The analysis of the results illustrated in **Figure 6** allowed us to note that *Phytophthora infestans* is the most sensitive strain with respect to the SL3 supernatant with an inhibition rate equal to 55.56% (50µl/ml) and 26.67% (35µl/ml). The antifungal index in high concentrations (50µl/ml) reaches 46.67% for *Penicillium spp,* 38.46% for *Aspergillus niger* and greater than 35% for concentrations of 35µl/ml. No antifungal activity was detected on *Endosporium.spp* for low concentrations 5 and 20µl/ml.

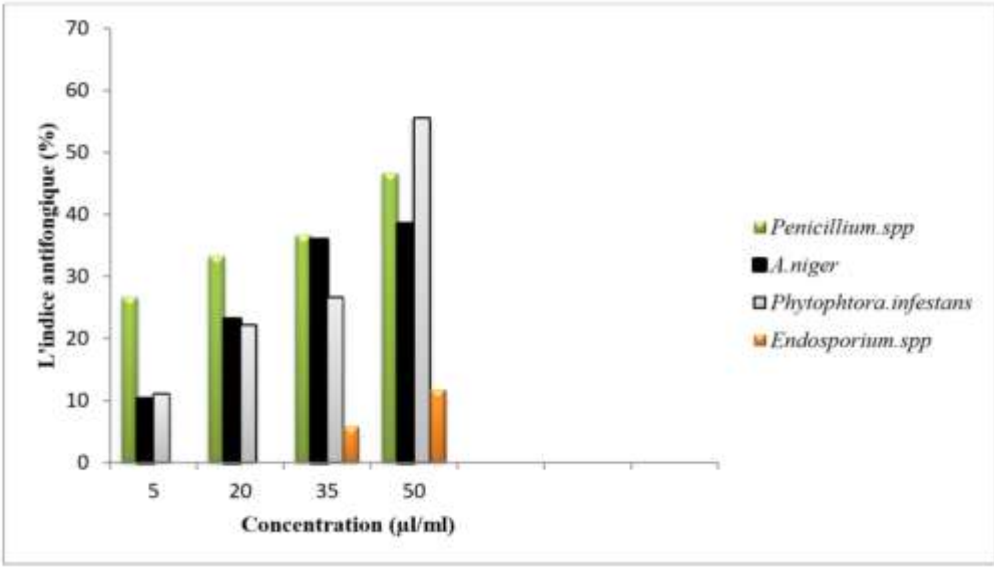

Figure 9: Antifungal effect of SL3 supernatant.

The observation of the histogram of **Figure** 7 relating to the antifungal effect of the supernatant SL4, shows that all the concentrations of the latter cause a significant effect on the four fungal strains with an antifungal index between 37.78% and 43.59% for the concentrations of 50µl/ml and between 23.08% and 37.78% for the concentrations of 35µl/ml. The antifungal index in the low concentrations is higher than 33% (20µl/ml) for *Penicillium spp* and *Phytophtora infestans* and higher than 23% for *Aspergillus niger* and *Endosporium spp.*

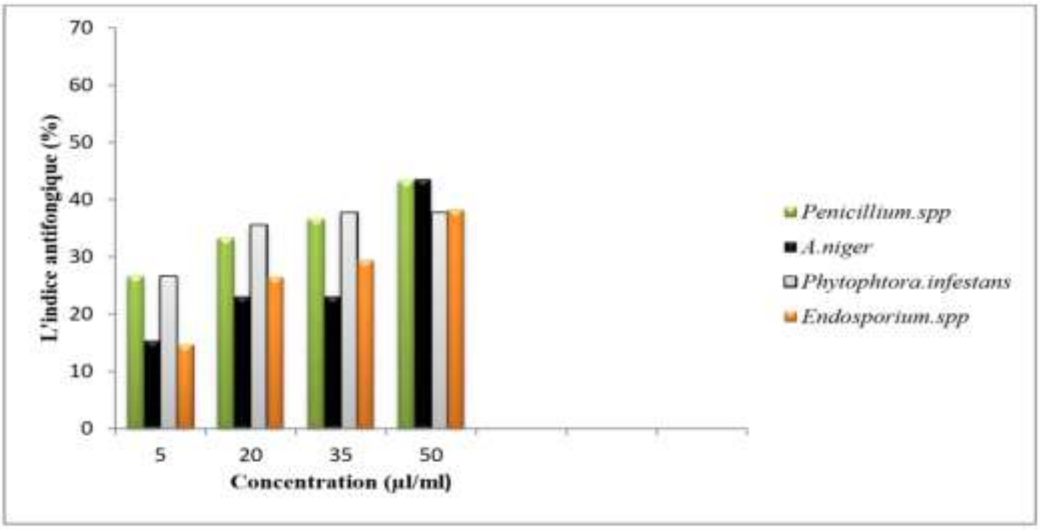

Figure 10: Antifungal effect of SL4 supernatant.

Lactic acid bacteria produce a wide range of compounds that could act synergistically against yeasts and filamentous fungi **(Magnusson et *al*., 2003). Cabo et *al* (2002)** suggested that the antifungal activity of lactic acid bacteria is due to a synergistic effect between lactic acid produced by the bacteria and acetic acid from the culture medium. Many studies have shown that lactic acid bacteria produce antifungal compounds that are different from organic acids, these compounds are difficult to isolate and characterize because of their low concentrations, chemical composition, being synergistically active molecules with low individual activity, or other unknown reasons **(Nes et *al*., 2011).** The majority of purified antifungal substances have been low molecular weight compounds such as: phenylacetic acid, cyclic dipeptides and short or medium chain fatty acids **(Schnürer and Magnusson, 2005).**

CONCLUSION

The results of this study demonstrate the significant antifungal potential of the four *Lactobacillus* strains (L1, L2, L3, L4) tested against common phytopathogenic fungi, including *Aspergillus niger*, *Phytophthora infestans, Penicillium spp,* and *Endosporium* spp. All strains exhibited notable antifungal activity, with varying degrees of effectiveness depending on the fungal species and the concentration of bacterial supernatants. The strains L1 and L4 showed the highest inhibition against *Endosporium spp*, indicating their strong antifungal properties. These findings suggest that *Lactobacillus* strains can serve as a promising alternative to conventional antifungal agents, offering a natural and effective solution for controlling fungal pathogens. This work highlights the potential for utilizing lactic acid bacteria in agricultural, biotechnological, and food preservation applications, contributing to the reduction of chemical fungicide use and combating fungal resistance.

ABSTRACT

Staphylococcus aureus is an important pathogen due to its serious human and animal health problems worldwide. It causes a wide variety of diseases, including skin and soft tissue infections, mastitis, osteomyelitis, bacteraemia, endocarditis, pneumonia, foodborne intoxication, and hospital- and community-acquired infections. Many disinfectants, including quaternary ammonium compounds (QACs) as active biocides, have been widely used for sanitization in the food industry, poultry processing facilities, veterinary medicine, hospitals and healthcare facilities, and environments that could promote the development of bacterial resistance to disinfectants. The aim of the present study was to investigate the susceptibility of *S. aureus* isolated from chicken meat to quaternary ammonium compound (QAC) disinfectants, including benzalkonium chloride (BKC) and cetylpyridinium chloride (CPC). The minimum inhibitory concentration (MIC) of these QACs against the chicken meat isolates of *S. aureus* was determined quantitatively using a broth microdilution method. The MIC values of BKC were ranged between 1 and 8 µg/ mL, while the MICs for CPC were ranged between 0.5 and 2 µg/ mL. Of the isolates, 53.8% were found to be resistant to BKC with MICs of over 2 µg/ mL. The results of this study demonstrated the antimicrobial efficacy of quaternary ammonium compounds BKC and CPC on *S. aureus* isolated from chicken meat, which could be useful for food processing and consumer health in preventing and controlling foodborne pathogens, including resistant bacteria.

Keywords: Quaternary ammonium compounds, Chicken meat, *Staphylococcus aureus*, Minimum inhibitory concentration, Broth microdilution method

INTRODUCTION

Staphylococcus aureus is a ubiquitous Gram-positive, nonmotile, and facultatively anaerobic bacterial pathogen associated with hospital- and community-acquired infections. It causes a wide variety of human diseases including skin and soft tissue infections, food poisoning, bacteremia, toxic shock syndrome, pneumonia and endocarditis (Götz et al., 2006; Bhunia, 2008; Bannerman and Peacock, 2011). *S. aureus* is often found on the skin, nares and mucous membranes of human and warm-blooded animals including all food animals (Götz et al., 2006; Bannerman and Peacock, 2011). *S. aureus* contamination is associated with foods including raw milk, milk products, puddings, pork sausage, ham, meats, fish, shellfish, salads and vegetables (Bhunia, 2008; Beier et al., 2021). Moreover, cross-contamination in food production chain can occur by food handlers or preparers, equipment, and contaminated food contact surfaces (Bhunia, 2008).

Antimicrobial resistance is the most serious clinical and public health problem around the world. The overuse or misuse of antimicrobial agents in humans, animals and plants has dramatically accelerated the emergence and spread of antimicrobial-resistant strains including methicillin-resistant *Staphylococcus aureus* (MRSA) (Götz et al., 2006; WHO, 2023). MRSA strains, as a serious and enduring threat to human health, are typically resistant to all beta-lactam antimicrobial agents, which are commonly used to treat infections (David and Daum, 2010; Bannerman and Peacock, 2011). Thus, the treatment of infections caused by these antimicrobial-resistant pathogens may be more difficult and expensive than infections caused by methicillin-susceptible *S. aureus* (MSSA) (David and Daum, 2010).

Quaternary ammonium compounds (QACs) have been used as common disinfectants in controlling bacterial growth in hospitals, healthcare settings, food industries, veterinary practices, and environments due to their broad-spectrum antimicrobial activities and surfactant properties (McDonnell and Russel, 1999; Bjorland et al., 2001; McBain et al., 2004; Wu et al., 2015). The antimicrobial activity of QACs corresponds with the side chain's hydrophobicity and demonstrates a maximum impact when the alkyl chain has 12 -16 carbon atoms. QACs inhibit spore growth but not the germination processes due to their sporostatic properties, (Marris, 1995; McDonnell and Russel, 1999; Mao et al., 2020). Among the QACs, benzalkonium chloride (BKC) and cetylpyridinium chloride (CPC) are two of the most frequently used QACs. BKC is a cationic surfactant with a broad-spectrum antimicrobial activity except for bacterial endospores. Its bactericidal effectiveness has been linked to a change in the permeability of the cytoplasmic membrane after the lipid bilayers in the cell membrane dissociate, allowing cell contents to leak out (Leggett et al., 2016; Maillard et al., 2022). CPC, a monocationic surfactant, has both hydrophilic and lipophilic properties derived from the chloride and cetylpyridinium cations, respectively (Lim et al., 2004).

The objective of this research was to investigate the antibacterial efficacy of quaternary ammonium compounds, including benzalkonium chloride and cetylpyridinium chloride, against the foodborne pathogen *S. aureus* using the broth microdilution method.

MATERIALS AND METHODS

Bacterial Isolates

In this study, thirteen *S. aureus* isolates from samples of chicken meat consisting of breast and leg parts identified in previous research (Özdemir, 2022) were tested. All isolates were identified using biochemical tests and PCR assays for the *S. aureus*-specific fragment (Sa442) and thermonuclease gene (*nucA*) (Brakstad et al., 1992; Martineau et al., 1998; Götz et al., 2006; Bannerman and Peacock, 2011). The isolates were identified in our earlier study (Özdemir, 2022) as methicillin-resistant *S. aureus* (MRSA) and methicillin-sensitive *S. aureus* (MSSA) utilizing the *mecA* gene (Milheiriço et al., 2007). Before the experiments were done, the isolates were cultured overnight in Brain Heart Infusion broth (BHI) (Merck, Darmstadt, Germany).

Quaternary ammonium compounds

Quaternary ammonium compounds (QACs) used in the present research included benzalkonium chloride (BKC) and cetylpyridinium chloride (CPC). These compounds were purchased from Sigma-Aldrich (MO, USA). Stock solutions of BKC and CPC were prepared and sterilized through a 0.45 µm membrane syringe filter (Sartorius AG, Goettingen, Germany). The tested concentrations for BKC ranged from 0.25 to 128 µg/mL and for CPC ranged from 0.5 to 256 µg/mL.

Examination of antimicrobial efficacy of quaternary ammonium compounds

The minimum inhibitory concentrations (MIC) of quaternary ammonium compounds (QACs) including benzalkonium chloride (BKC) and cetylpyridinium chloride (CPC) against the *S. aureus* isolates from chicken meat were determined using the broth microdilution method as described by the Clinical and Laboratory Standards Institute (CLSI, 2012; CLSI, 2022). Bacterial suspensions were prepared, and the turbidity was adjusted to the 0.5 McFarland standard. The suspensions were then diluted 1:100 in Mueller-Hinton (MH) broth to obtain final inoculum suspensions. The sterile U-bottom 96-well microtiter plates (Lp Italiana) were used. The microtiter plates were filled with MH broth with a two-fold concentration of QACs solution and 50 µl of the bacterial suspension (adjusted final inoculum density of 10^6 CFU/mL). *Staphylococcus aureus* ATCC 29213 was used as a quality control strain to determine MIC values in all experiments. The 96-well microtiter plates were incubated for 16-20 h at 37 ºC. The optical density (OD) was measured using a microplate reader (Thermo Electron Corporation, Vantaa, Finland) at 600 nm. The MICs of the isolates against the QACs were detected as the lowest concentration with no visible growth (Andrews, 2001; CLSI, 2012). The *S. aureus* isolates were categorized as resistant to BKC at MICs > 2 µg/mL and to CPC at MICs > 1 µg/mL. based on the comparison with the control strain (*S. aureus* ATCC 29213).

RESULTS AND DISCUSSION

Quaternary ammonium compounds (QACs) are known as cationic detergents with broad-spectrum antimicrobial properties (McDonnell and Russell, 1999; McBain et al., 2004). QACs such as cetylpyridinium chloride (CPC) and benzalkonium chloride (BKC), have been shown to have antimicrobial properties against a variety of pathogens, including foodborne pathogens, in earlier investigations (Lim et al., 2004; Wu et al., 2015; Mao et al., 2020; Beier et al., 2021). Table 1 summarized the minimum inhibitory concentrations (MICs) of BKC and CPC against the isolates of *S. aureus* from chicken meat.

Table 1. The minimum inhibitory concentration (MIC) of benzalkonium chloride (BKC) and cetylpyridinium chloride (CPC) against the *S. aureus* isolates from chicken meats

Disinfectants	Resistance (%)	Percentages of the isolates with MIC values (μg/ml)										
		256	128	64	32	16	8	4	2	1	0.5	0.25
BKC	53.8						**7.7**	**46.1**	30.8	15.4		
CPC	15.4								**15.4**	23.1	61.5	

The resistance levels of the isolates were determined by comparing their minimum inhibitory concentration (MIC) values to those of *S. aureus* ATCC 29213. *The MIC value of the isolate > 2 µg/mL for benzalkonium chloride (BKC) and > 1 µg/mL for cetylpyridinium chloride (CPC) was accepted as a resistant isolate. The percentages of the resistant isolates are displayed in bold font.*

Of the S. aureus *isolates used in this study, 53.8% showed BKC resistance (MIC > 2 µg/mL) and 15.4% exhibited CPC resistance (MIC > 1 µg/mL).* S. aureus *isolates (46.15%) had susceptible BKC MICs that ranged from 1-2 µg/mL.* Furthermore, it was determined that 84% of the isolates were susceptible to CPC, which had a range of 0.5 to 1 µg/mL (Table 1). Wu et al. (2015) noticed that the MICs varied based on the type of QACs and the species of bacteria. QACs, such as cetylpyridinium chloride and benzalkonium chloride, have antibacterial activity against foodborne and zoonotic pathogenic bacteria. They observed that Gram-positive strains, including *S. aureus* were extremely susceptible to QACs. All *S. aureus* strains isolated from swine feces were susceptible to *benzalkonium chloride* (at MICs < 30 µg/mL) and cetylpyridinium chloride. MIC values ranged from 0.5-1µg/mL for *benzalkonium chloride* and ranged from 0.0625-1µg/mL for cetylpyridinium chloride (Beier et al., 2021).

The determined MIC values of benzalkonium chloride and cetylpyridinium chloride (CPC) against the isolates, including methicillin-sensitive S. aureus *(MSSA) and methicillin-resistant* S. aureus *(MRSA) isolates, were represented in Figures 1 and 2. The MIC values of benzalkonium chloride (BKC) against the MSSA isolates (66.7%) ranged between 0.25 and 2 µg/mL. Furthermore, 33.3% of the MSSA isolates for BKC showed the MIC at higher concentrations (≥4 µg/mL) and were recorded as resistant. Remarkably, all MRSA isolates were found to be resistant to BKC (Figure 1).*

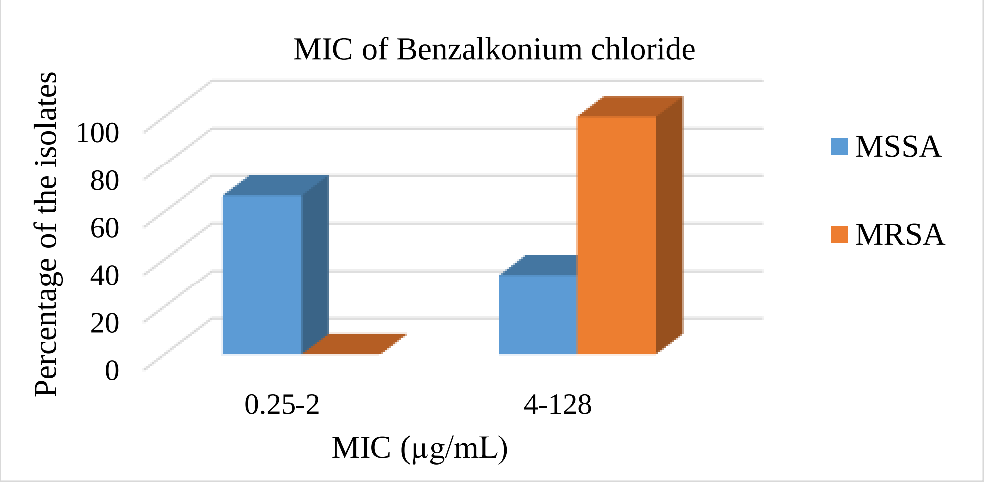

Figure 1. Distribution of MIC values of benzalkonium chloride in the MSSA and MRSA isolates. MSSA: Methicillin-sensitive S. aureus, *MRSA: methicillin-resistant* S. aureus.

Figure 2 demonstrates the MIC distribution of the cetylpyridinium chloride (CPC) in the MSSA and MRSA isolates. Of the MSSA isolates, 11.1% had MIC values of 2 µg/mL for cetylpyridinium chloride (CPC), whereas 88.9% exhibited MIC ranges of 0.5 and 1 µg/mL for CPC. Moreover, a MIC range between 0.5 and 1 µg/mL was found in 75% of the MRSA isolates, while 2 µg/mL was found in 25% of the MRSA isolates.

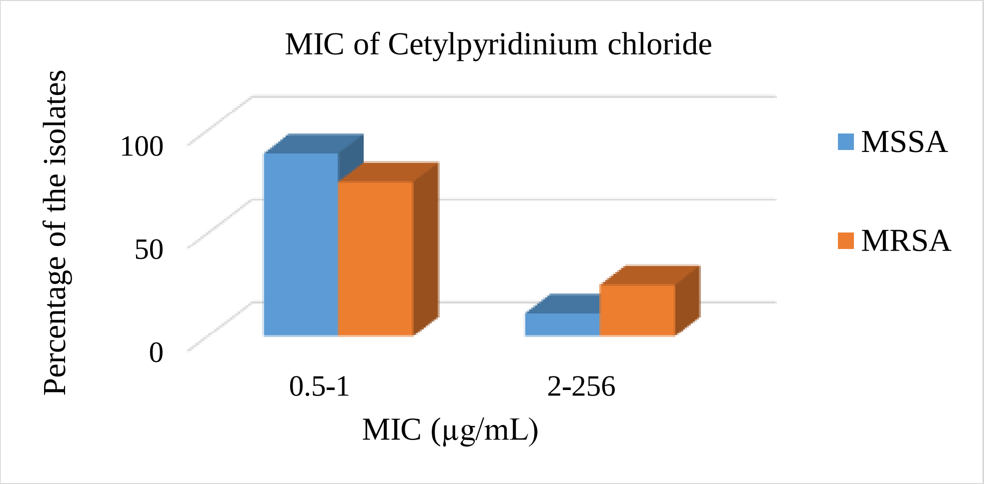

Figure 2. Distribution of MIC values of cetylpyridinium chloride *in the MSSA and MRSA isolates. MSSA: Methicillin-sensitive* S. aureus, *MRSA: methicillin-resistant* S. aureus.

Our results indicated that higher MIC values for the tested quaternary ammonium compounds were determined in MRSA isolates compared with MSSA isolates. As compared to MSSA strains, MRSA strains were found to be highly resistant not only to oxacillin and but also *benzalkonium chloride with MIC values* of *10 µg/ml in a previous study* (Akimitsu et al.,1999). *In contrast*, six MRSA strains displayed increased susceptibilities to disinfectants, including QACs, by Beier et al. (2021). Suller et al. (1999) investigated the susceptibilities of MRSA and MSSA strains to cetylpyridinium chloride. *They demonstrated that MICs of 2 or 4 µg/ml for MRSA were found to exhibit "low-level resistance" to cetylpyridinium chloride, but the MSSA strain had MICs of 1 µg/ml.*

CONCLUSION

This study showed the antibacterial activity of quaternary ammonium compounds (QACs), including benzalkonium chloride and cetylpyridinium chloride. They are widely used as disinfectants and sanitizers in variety of applications including food industry against the *S. aureus* isolates originated from chicken meat. The antimicrobial activity of every QAC varies according to their chemical properties and the type of bacteria.

ABSTRACT

Infections caused by antimicrobial-resistant and multidrug-resistant bacteria such as *Staphylococcus aureus* are the most common cause of mortality and morbidity worldwide. Antimicrobial therapeutic options against infections caused by resistant pathogens, such as methicillin-resistant *S. aureus* (MRSA), are frequently restricted. The clinical problems emphasize the crucial need for novel and effective antibacterial treatments. Nanoparticles (NPs) act as potential antimicrobial agents. They can penetrate the bacterial cell membrane, disrupt important molecular pathways, showing unique antimicrobial mechanisms. Therefore, the antibacterial effect of gold nanoparticles (AuNPs) on *S. aureus* isolates, including MRSA originating from chicken meat, was examined in this study. The antibacterial activity of chemically synthesized AuNPs (20 nm in size) against *S. aureus* isolates was carried out using the broth microdilution method. The minimum inhibitory concentrations (MICs) of AuNPs for the meat-associated isolates were determined at 500 µg/mL and higher. The results of this study present the susceptibility of the *S. aureus* isolates to AuNPs. Further studies are needed investigating the antibacterial activity and efficacy of different gold nanoparticle sizes and concentrations against resistant pathogens.

Keywords: Gold nanoparticles, *Staphylococcus aureus*, MIC, Antibacterial effect

INTRODUCTION

Antimicrobial resistance is becoming increasingly recognized as a major risk to global public health and development threats (WHO, 2023). The overuse and misuse of antimicrobial agents in humans, animals, and plants are primary causes in the development and spread of antimicrobial-resistant pathogenic bacteria (WHO, 2023; Berman et al., 2023). Bacteria that carry resistance genes can propagate either directly among human populations or indirectly by contaminating food, water, or other surfaces with sewage (Woolhouse and Ward, 2013). In particular, direct transmission of antimicrobial-resistant bacteria from food-producing animals to humans can occur from contact with animals and ingestion of animal products, especially when handled or improperly cooked (Woolhouse et al., 2015; Berman et al., 2023).

The emergence of certain bacteria that have developed high resistance to antimicrobials, such as methicillin-resistant *Staphylococcus aureus* (MRSA) and vancomycin-resistant

Enterococcus (VRE), are the most common bacteria in human infections (Gouyau et al., 2021; Moradi et al., 2023). Therefore, developing novel and potent antimicrobials for controlling these bacteria is a major priority (WHO, 2017; Sanchez-Lopez et al., 2020). For instance, recent studies have shown that specific metal nanoconstructs have antibacterial abilities that may be used to treat infectious diseases (Rai et al., 2009; Sanchez-Lopez et al., 2020; Gouyau et al., 2021).

Metal-based nanoparticles are the most widely utilized inorganic nanoparticles and exhibit a promising treatment for resistance to traditional antimicrobials. They do not only demonstrate efficiency against bacteria that have already achieved resistance, but also target a range of biomolecules weakened in the emergence of resistant strains, using completely different mechanisms of action from those described for conventional antimicrobials (Slavin et al., 2017; Sanchez-Lopez et al., 2020).

Gold nanoparticles (AuNPs) among the significant nanomaterials are of particular interest in the area of biomedicine and its uses due to their chemical, electrical, optical, mechanical, and thermal characteristics. These large potentials have raised the possibility of toxicity as a result of interactions with biological tissues and molecules (Pissuwan et al., 2011; Dykman and Khelbstov, 2012; Sani et al., 2021). Several investigations have reported the antibacterial activity of AuNPs against pathogenic bacteria, including *S. aureus* (Li et al., 2011a; Li et al., 2014; Elbehiry et al., 2019; Gouyau et al., 2021). AuNPs have great potential in diagnostic roles, food packaging, drug delivery, photothermal and radiation therapy, biosensing, gene therapy, as well as cancer diagnostics, enzyme fixation, cosmetics, and cell imaging (Pissuwan et al., 2011; Li et al., 2011b; Kong et al., 2017; Elahi et al., 2018; Paidari and Ibrahim, 2021, Sani et al., 2021).

Recently, there has been an increasing amount of research focused on the antibacterial properties of AuNPs, which makes them a good candidate for antibiotic complementation (Sanchez-Lopez et al., 2020; Sathiyaraj et al., 2021; Moradi et al., 2023). Therefore, in this study we aimed to investigate the antibacterial activity of AuNPs against *S. aureus*, which is responsible for food spoilage and foodborne illnesses.

MATERIALS AND METHODS

Bacterial isolates

This study used 13 *S. aureus* recovered from chicken meat samples (breast and leg parts) collected from various supermarkets and butchers. The *S. aureus* isolates from chicken meat were cultured in Tryptic Soy Broth (Merck, Darmstadt, Germany) and incubated overnight at 37 °C. Biochemical tests and PCR analysis for the *S. aureus*-specific genomic fragment (Sa442) and thermonuclease gene (*nucA*) have previously been employed to identify the isolates (Brakstad et al., 1992; Martineau et al., 1998; Götz et al., 2006; Bannerman and Peacock, 2011). Using the *mecA* gene (Milheiriço et al., 2007), these isolates were previously identified as methicillin-sensitive *S. aureus* (MSSA) and methicillin-resistant *S. aureus* (MRSA) using the *mecA* gene in our previous study (Özdemir, 2022).

Nanoparticles used in the study

The chemically synthesized AuNPs using sodium citrate had a 20 nm particle size and a concentration of 1 mg/mL. The tested concentration of AuNPs ranged from 500 to 0.9766 µg/mL.

Antibacterial activity of AuNPs against *S. aureus* isolates

The antibacterial activity of AuNPs against S. aureus *isolates, including methicillin-resistant* S. aureus *(MRSA), originated from chicken meat, was evaluated by the determination of minimum inhibitory concentration (MIC) and minimum bactericidal concentration (MBC), which were achieved by the broth microdilution method (CLSI, 2012; CLSI, 2022). Briefly,* bacterial cells were added to a final concentration of $1x10^6$ CFU/mL. Serial *two-fold dilutions (500-0.9766 µg/mL) were prepared in growth medium Mueller-Hinton broth (Merck, Darmstadt, Germany) in sterile 96-well U-bottom microtiter plates (LP Italiana). The MIC values of* Staphylococcus aureus *ATCC 29213 as a control strain was used in all experiments. After overnight incubation at 37°C, the MIC values of the isolates were determined by measuring the optical density (OD) at 600 nm using a microplate reader (Thermo Electron Corporation, Vantaa, Finland). The MIC is defined as the lowest test concentration of the agent at which bacterial growth is completely inhibited (Andrews, 2001).* The minimum bactericidal concentration (MBC) of *AuNPs* (500, 250 125, 62.5, 31.25 and 15.625 µg/mL) against *S. aureus* isolates were assessed on the Mueller-Hinton agar (Merck, Darmstadt, Germany) in this study. The microtiter plates were incubated at 37°C for 16-20 h. All experiments were performed in triplicate.

RESULTS AND DISCUSSION

The inappropriate and excessive use of antimicrobial agents in humans and animals accelerates the emergence and spread of antibiotic-resistant bacteria, especially multidrug-resistant bacterial pathogens. For instance, methicillin-resistant *S. aureus* (MRSA), one of the most common antibiotic-resistant bacterial pathogens, is resistant to antibiotic treatment and is considered an important threat to human health (Sanchez-Lopez et al., 2020; WHO, 2023). Antibiotic efficacy may be affected by the spread of these strains and their resistance genes. Consequently, there is an crucial need to find and develop novel approaches to fight antimicrobial resistance (WHO, 2017). Pharmaceutical firms involved in the development of non-traditional drugs, particularly those working in the nanotechnology sector, were interested by these new benefits and made investments in the creation of novel nanomaterials that have been shown to be promising agents against bacteria resistant to traditional antibiotics (Sanchez-Lopez et al., 2020).

In recent years, metal-based nanoparticles, including gold, silver, and copper, have shown promising results for combating various resistant microbes (Moradi et al., 2023). In this study, antibacterial effects of gold nanoparticles (AuNPs), 20 nm in size, against *S. aureus* isolates from chicken meat samples were tested by using the broth microdilution method. The values obtained for the minimum inhibitory concentration (MIC) and minimum bactericidal concentration (MBC) of the AuNPs against the isolates are presented in Table 1.

Table 1. MIC values of synthesized AuNPs against *S. aureus* isolated from chicken meat

Isolate	Methicillin Resistance	Au NPs	
		MIC[a]	MBC[b]
C1	MSSA[c]	500	>500
C2	MSSA	>500	>500
C3	MSSA	>500	>500
C4	MSSA	>500	>500
C5	MRSA[d]	500	>500
C6	MSSA	>500	>500
C7	MSSA	>500	>500
C8	MSSA	>500	>500
C9	MSSA	500	>500
C10	MRSA	>500	>500
C11	MSSA	>500	>500
C12	MRSA	500	>500
C13	MRSA	500	>500

[a]MIC, minimum inhibitory concentration (µg/mL); [b] MBC, minimum bactericidal concentration (µg/mL); [c]MSSA, methicillin-sensitive *S. aureus*; [d]MRSA, methicillin-resistant *S. aureus* harboring the *mecA* gene.

The antimicrobial effect of 20 nm AgNPs for the *S. aureus* isolates, including MSSA and MRSA, was found to be 500 µg/ mL and higher. The MIC range of the AuNPs was higher than 500 µg/ mL in 61.5% of the isolates. The image for MBC of AuNPs against the *S. aureus* isolate (C1) is demonstrated in Figure 1.

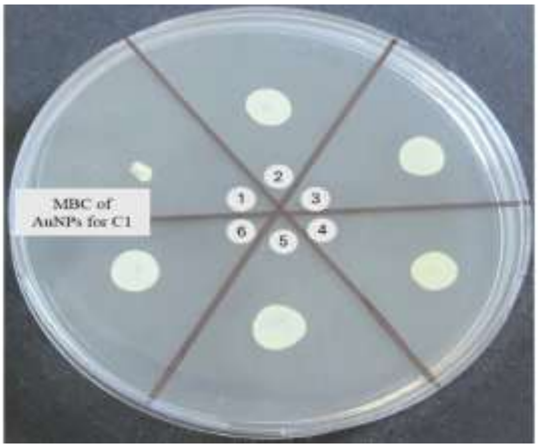

Figure 1. Representative image for the minimum bactericidal concentration (MBC) of AuNPs against *S. aureus* isolate (C1). The numbers 1, 2, 3, 4, 5, and 6 show compound concentrations of 500, 250, 62.5, 31.25, 15.625, and 7.8125 µg/mL, respectively.

In previous studies, the antibacterial activity of AuNPs against *S. aureus* strains was reported (Li et al., 2014; Shamaila et al., 2016; Elbehiry et al., 2019). In the work of Shamila et al. (2016), the antibacterial effects of different sizes of AuNPs were studied against different enteric bacterial human pathogens including *S. aureus* strains. The authors found that the MICs of gold NPs sized 7-34 nm were 3.92 µg/mL, whereas the MICs of gold NPs sized 20-40 nm were 3.98 µg/mL for *S. aureus*. They also reported that larger doses of gold NPs are required for the complete inhibition of *S. aureus* due to their thick peptidoglycan layer. Furthermore, AuNPs effectively inhibited the growth of a variety of multidrug-resistant bacteria, including MRSA (Li et al., 2014). On the contrary, Gouyau et al. (2021) in France revealed that chemically synthesized 12 nm gold nanoparticles had a weak antibacterial activity against the *S. aureus* tested.

CONCLUSION

Antimicrobial alternatives are often limited in treatment to prevent infections caused by antimicrobial-resistant and multidrug-resistant bacteria such as *S. aureus*. Therefore, there is a significant need for novel and effective strategies to combat antibiotic resistance to overcome clinical challenges. Nanoparticles have recently been investigated as potential antimicrobial agents for the treatment of antimicrobial-resistant bacterial pathogens. This study demonstrated the antibacterial activity of gold nanoparticles against the isolates of *S. aureus*, which may pose a potential threat to food safety and human health.

ABSTRACT

To discover new biocontrol agents beneficial to agriculture, researchers can explore natural and uncharted ecosystems as potential sources of novel agents for pharmacological and industrial applications. Microorganisms represent the most economically viable and biologically valuable sources for the production of biocontrol compounds. In this study, 42 samples of soil collected from Tifrit forest located in semi-arid region in Saida 34° 50′ 00″ north, 0° 09′ 00″ east (Algeria).The main objective of the study was to assess six *Streptomyces* isolates (T1, T4, T5, T6, T7, and T8) for their enzymatic activity (lipase, protease, amylase, and cellulase) by screening their activities on agar plates and showing a clear zone around the colonies. The isolates were subsequently characterized phenotypically, biochemically, and through PCR analysis and 16S rDNA sequencing. Examination of colony morphology, agar plate culture characteristics, and biochemical reactions suggested that the isolates belong to *Streptomyces* species. The results demonstrated that isolates T1, T4, and T5 exhibited lipase activity by hydrolyzing lipids in egg yolk agar. Also, all isolates displayed protease activity by digesting proteins in skimmed milk agar. Amylase production, indicated by starch digestion in starch casein nitrate agar, was not observed in any of the tested isolates. However, isolates T1, T5, T6, and T8 demonstrated cellulase activity by hydrolyzing cellulose in carboxy methyl cellulose (CMC) agar. Molecular characterization of these isolates was conducted, which included genomic DNA extraction, 16S rRNA gene amplification, and sequencing to confirm the specific *Streptomyces* strains. Genomic DNA was extracted from *Streptomyces* isolates, followed by PCR amplification using Streptomyces-specific primers (RI7F/RI8R and AM45F/AM47R) and universal bacterial primers (27F/1492R) targeting the 16S rRNA gene. All isolates (T1, T4, T5, T6, T7, and T8) produced single PCR bands of approximately 438 bp, 940 bp, and 1480 bp when using RI7F/RI8R, AM45F/AM47R, and 27F/1492R primers, respectively. These results showed the presence of bacterial 16S rRNA and specifically the conserved 16S rRNA region of *Streptomyces* species in all the isolates. The isolates were sequenced using the 27F/1492R primers. BLASTn analysis of the 16S rRNA gene sequences identified isolates T1, T4, T5, and T6 as *Streptomyces aegyptia*, with identity percentages of 99.91%, 99.71%, 99.64%, and 96.7%, respectively. However, isolates T7 and T8 were identified as *Lysinibacillus fusiformis* and *Umezawaea beigongshangensis*, with identity percentages of 99.86% and 99.71%, respectively. The 16S rRNA sequences of these isolates were aligned with similar sequences from the GenBank database, and a phylogenetic tree was constructed. This tree demonstrated that isolates T1, T4, T5, and T6 formed a cluster within the Streptomyces group, while isolates T7 and T8 branched separately, consistent with their identification as belonging to different genera. The findings highlighted the significant potential of these indigenous Algerian forest soil microorganisms, particularly in the discovery of novel enzymes, underscoring their relevance for industrial applications. This research emphasizes the diversity of the microbial population in Algerian soil and the importance of exploring such natural reservoirs for biotechnological advancements.

Key Words: Algerian soil, Enzymatic activity, *Streptomyces*, Tifrit forest.

INTRODUCTION

The actinobacteria phylum stands out as one of the main producers of biologically active substances, used in various fields such as medicine, industry and agriculture **(Genilloud 2017; Trabelsi et al. 2016)**. Actinomycetes, Gram-positive filamentous bacteria, are known to produce a wide range of enzymes for commercial use **(Al-Dhabi et al. 2019)** . In particular, *Streptomyces* species are considered as micro-organisms of great industrial importance due to their ability to generate different enzymes **(Magda et al. 2012, Sarmiento-Vizcaíno et al. 2022)**. Enzymes of microbial origin are particularly prized in the industrial sector because of their remarkable stability, productivity and availability. They are also cost-effective and their production methods are environmentally friendly **(Oumaima and Faouzi 2023)**. From an industrial point of view, their practical and ecological nature makes them even more popular **(Ferreira, Azzoni, and Freitas 2021)**. *Streptomyces spp*. including *S. griseus, S. clavuligerus, S. thermoviolaceus, S. rimouses, and S. thermovulgaris*, which are known for their production of various proteases, exploit both simple and complex molecules as sources of nutrients **(Al-Dhabi, Mohammed Ghilan, and Arasu 2018)**. *Streptomyces* species also secrete a variety of extracellular enzymes. These *Streptomyces* generate extracellular proteases, the production of which is closely linked to sporulation and the formation of aerial mycelium **(Arasu et al. 2019)**. The enzymes most commonly produced by *Streptomyces* species include protease, chitinase, amylase, lipase, xylanase, cellulase and laccase **(Oumaima and Faouzi 2023)**.The extracellular enzymes produced by *Streptomyces* have significant potential to replace the toxic chemicals used in various industries. However, the adoption of these alternatives has not yet been given a wide platform in developing countries. This study was carried out to identify new *Streptomyces* strains capable of producing extracellular enzymes. This research project focuses on exploring the biotechnological potential of six *Streptomyces* strains isolated from Algerian forest soils, highlighting their reservoir of genetic and metabolic diversity for enzyme production. Assessing the enzymatic capacities of these strains is a central objective of this study.

MATERIALS AND METHODS

Isolation of actinomycetes from soil

Soil samples were systematically collected from Tifrit forest, located in Saida city, western Algeria. The collection was performed utilizing the Pochon and Tardieux technique, ensuring consistency in sampling. All samples were extracted from a depth of 15 cm and subsequently dried under aseptic conditions **(Idris Khodja et al. 2023)**. The agar medium dilution method was used for the isolation of actinomycete strains. Samples were diluted in successive series to 10^{-5}, then an aliquot of 0.1 ml was deposited on the surface of starch-casein-nitrate (SCNA) agar medium, enriched with nalidixic acid (20 mg/l) to inhibit the growth of Gram- negative bacteria, and nystatin (50 mg/l) to inhibit the development of fungi **(S.Loqman 2009)** all plates were incubated at 28°C for 5 to 10 days at a rate of three plate per dilution **(Songsumanus et al. 2011)**. Observable colonies formed on the plates were isolated and grown on the same medium, then incubated for a further 10 days. The isolates thus obtained were characterised based on their morphological and cultural properties. Before subculturing, *Streptomyces* isolates were inoculated onto GYM agar medium and stored at 4°C for three months **(Gacem et al. 2020)**. Isolated colonies were subcultured on International Streptomyces Project (ISP: ISP2-ISP7) agar media to obtain pure cultures. In accordance with the protocol of Shirling and Gottlieb (1966), the morphological, biochemical and physiological characteristics of the actinomycete isolates were determined **(Shirling and D. Gottlieb 1966)**. Six isolated colonies of actinomycetes (T1, T4, T5, T6, T7, and T8) were selected for their enzymatic activity (lipase, protease, amylase, and cellulase) by screening their activities on agar plates.

Morphological and physiological analysis of isolates

Macromorphology and cultivation characteristics

Morphological characterisation was carried out by examining the growth behaviour of isolates on different culture media: oat agar (ISP3), inorganic salt-starch agar (ISP4), glycerol-asparagine agar (ISP5), yeast extract-malt extract agar (GYM) and starch-casein agar (SCA). We carried out a visual assessment of characteristics such as the coloration of aerial and substrate mycelia, as well as the production of soluble pigments.

Scanning electron microscope observation

The scanning electron microscope (SEM) examinations were carried out in the laboratories of the Advanced Materials Research Centre at the University of Sharjah, United Arab Emirates.
The spore surfaces of active actinomycetes isolates were examined using a scanning electron microscope (SEM) at magnifications ranging from 5000X to 25000X. To prepare the samples, buffer was placed on 21-day cultures of each isolate grown on oat agar (ISP3). The buffer was then subjected to a sputter coating process using a Quorum Technology Mini Sputter Coater, with a target composition of gold (80%) and palladium (20%), for a duration of 2 minutes, resulting in the deposition of approximately 100 A° of coating material. The gold sputterer was operated at 1 kV, with a plasma current of 18 mA and a chamber pressure of 10-2 mbar. After the coating process, the samples were observed using a Tescan VEGA XM variable-pressure

SEM, with a maximum accelerating voltage of 30 kV. Images were viewed on a computer screen and an Oxford Instruments X-Max 50 EDS detector (system without LN2) with 125 eV resolution was used for further analysis. The surface structures of the spores were classified as smooth (sm), spiny (sp), warty (wa) or hairy (ha). We took a 5-micron and a 3-micron photo of each sample.

Preparation of *Streptomyces* spore suspension

The selected *Streptomyces* isolates were suspended in sterile polystyrene tubes containing 3 ml of distilled water, in order to obtain a spore suspension with a concentration of 10^7 spores/ml **(Bonaldi 2014; Shepherd et al. 2010)**.

Detection of amylase production

A 25µl volume of the spore suspension of pure actinomyces isolates was grown on starch-casein-nitrate agar (SCNA) and incubated at 28°C for 4 days. The plates were then flooded with an iodine solution and left for 30 minutes, before being washed with distilled water **(dos Santos et al. 2012)**. Bacterial colonies producing amylase show a light zone against the black colour of the coloured starch.

Detection of proteolytic activity

A 25µl volume of the spore suspension of pure Actinomyces isolates was inoculated onto agar plates containing skimmed milk casein (Himedia, India) and incubated at 28°C for 4 days. The appearance of thinning zones around the colonies revealed proteolytic activity of the isolates, indicating hydrolysis of the casein **(Sharmin et al. 2005)**.

Detection of lipolytic activity

A 25µl volume of the spore suspension from the pure isolates was streaked onto egg yolk agar plates containing Baird-Parker agar base (Oxoid, UK) supplemented with 50% egg yolk emulsion (Mast Diagnostics, UK). The dishes were then incubated at 28ºC for 4 days **(Magda et al. 2012)**. The appearance of light zones around the colonies indicates lipolytic activity of the isolates, resulting from hydrolysis of the lipids present in the egg yolk.

Detection of cellulolytic activity

A 25µL volume of a spore suspension of pure isolates was inoculated onto agar plates containing carboxymethyl cellulose (CMC), followed by incubation at 28°C for 4 days. After incubation, the plates were flooded with 0.1% Congo red solution and left in contact for 15-20 minutes, then rinsed with 1 ml NaCl solution and incubated at 4°C overnight. The formation of clear zones around the colonies, in contrast to the red colour of the non-hydrolysed medium, revealed the cellulolytic activity of the isolates, indicating the hydrolysis of cellulose **(Saratale et al. 2014)**.

Genomic Sequencing

Genomic DNA from isolates was extracted using the Promega Wizard® Genomic DNA Purification Kit from Promega, USA, following the manufacturer's instructions designed for Gram-positive organisms. The quality and quantity of the DNA obtained were assessed by 1% agarose gel electrophoresis and NanoDrop (Thermo Fisher Scientific). A 1 ml aliquot of a 7-day-old culture was transferred to an Eppendorf tube and centrifuged at 13,000 rpm for 2 minutes. After removal of the supernatant, the cells were resuspended in 480 µl of 50 mM EDTA. After homogenisation, the mixture was incubated at 37°C for 30-60 minutes, followed by centrifugation at 13,000 rpm for 2 minutes. Next, 600 µl of nuclear lysis solution is added, and the cells are carefully resuspended by pipetting. The DNA is then purified according to the manufacturer's instructions, using the Wizard® Genomic DNA Purification Kit.

PCR primers specific to actinomycetes

Two sets of primers were used in this study for the molecular identification of actinomycetes producing the most active metabolites. The first series (AMF and AMR) had the following sequences:
AM45F_5‘-GTG AGT CCC CAG ATC ACC CCG AAG-3’ and AM47R_5‘-GTG GGC AAT CTG CCC TTG CAC TCT-3’ respectively, and amplified a Streptomyces-specific target sequence of 438 bp. The second sets R17/R18 (R1) had the following sequences:
R17_5‘-GTGAAAGCCCGGGGCTTAAC-3’ and R18_5'-CACCACCACAAGGGGCA, respectively, they amplified a Streptomyces-specific target sequence of 438 bp. The third sets (Actino-F (AO1) and Actino-R (AO2)) had the following sequences:
2- FC27_5‘-AGA GTT TGA TCC TGG CTC AG-3’ and RC1492 _5‘-TAC GGC TAC CTT GTT ACG ACTT-3’, respectively, and amplified a specific region within the 16S rRNA of actinomycetes with a size of 1,490 bp. The primers were synthesised by Invitrogen Life Technologies (USA).

Amplification of 16S rRNA gene fragment

The reaction mixture for PCR amplification was prepared in a volume of 25 µl containing the following: Actino-F; 10 µM, Primer Actino-R; 10 µM, Hot Start 2X Taq master mix (BioLabs, New England), template DNA and Nuclease-Free water (BioLabs, New England) was used to bring the reaction volume to 25 µl. A similar mix was used for the other two primer sets.
PCR amplification was performed in thin-walled, nuclease-free 0. 2 ml thin-walled nuclease-free PCR tubes (Treff Lab, Switzerland) using the iCycler thermal cycler (Bio-Rad, USA) programmed as follows: Initial denaturation at 95 ˚C for 30 seconds, followed by a second denaturation at 95 ˚C for 30 seconds, annealing at 55 ˚C (for (Actino-F (AO1) and Actino-R (AO2)) for 40 seconds, extension at 68˚C for 1:30 min for 30 cycles and further extension at 68˚C for 5 minutes.

Finally, tubes were stored at 4 ˚C for direct use, or stored at -20 ˚C until use. The program was run for all primers in a similar manner, but only changing the annealing temperature for each set of primers, with the annealing temperature for the R17/R18 set (R1) being 64 ˚C and for the set (AMF and AMR) being 62 ˚C.

Electrophoresis and photography

The presence of DNA in the PCR products was verified by a standard electrophoresis procedure using 2% (w/v) agarose gels (PROMEGA, USA) and detected by ethidium bromide (EB) staining (Acros Organic, USA) at a final concentration of 0.5µg/ml. Electrophoresis was performed at 100 volts for 40 minutes. The size of PCR products was estimated using a 1 Kb DNA ladder (Promega, USA). Gels were visualised and photographed using Gel Doc-It-310 (Imaging System, UVP-USA).

Sequencing

ExoSAP-IT treatment

The ExoSAP-IT treatment begins by adding 1 µl (variable depending on the product) of PCR product, 2 µl of ExoSAP-IT reagent and 4 µl of NFW (nuclear free water) to a labelled PCR tube. The PCR tubes are then centrifuged using a mini-centrifuge for a few seconds to collect any drops on the walls. The tube was then incubated at 37°C for 15 minutes, followed by 15 minutes at 80°C by placing it in the PCR machine and running it through the ExoSAP-IT programme.

Sequencing reaction cycle

After the incubation period, two PCR tubes are labelled for each sample; one with the unknown sample number followed by the letter F and the other with the unknown sample number followed by the letter R. To both tubes, 7 µl of the ExoSAP-IT-treated sample from the previous step, 4 µl of forward primer (1uM/ul), 4 µl of reverse primer (1uM/ul), 2 µl of BigDye sequencing buffer and 1 µl of ready-to-use premix are added. Some NFW (nuclease-free water) is added to reach a total volume of 20 µl.
The PCR tubes are centrifuged using a mini-centrifuge to collect the drops on the sides, then placed in the PCR machine and run using the Cycle Sequencing PCR program with the BigDye terminator v3.1 sequencing kit. Finally, the samples are stored at -20°C until the next step.

Sequence clean-up

To completely remove excess terminations, ethanol/EDTA precipitation was performed. Sequencing reactions were precipitated in 96-well reaction plates by first removing the plate from the thermal cycler and wringing it out briefly and then adding 2 µL of 125 mM EDTA and 2 µL of 3 M sodium acetate to each well, ensuring that the solutions reached the bottom of the wells. Next, 50 µL of 100% ethanol was added to each well, and the plate was sealed with foil tape and mixed by inverting four times before incubating at room temperature for 15 minutes.

The plate was centrifuged at 4°C and 1650 rpm for 45 minutes using a Beckman Allegra 6A centrifuge equipped with a GH-3.8A rotor. After centrifugation, 70 µL of 70% ethanol was added to each well, followed by rotation at 4°C and 1650 xg for 15 minutes. Finally, the samples were resuspended in injection buffer, covered with aluminium foil and stored at 4°C. The next step should be carried out immediately after centrifugation, or the plate should be centrifuged for a further 2 minutes before proceeding. Once the cleaning process was complete, the samples were placed in a 96-well optical reaction plate and cycled for two hours on the sequencer to obtain the corresponding chromatograms. Bioinformatics analysis and identification were then carried out.

RESULTS AND DISCUSSION

Morphological, cultural and physiological characterisation of selected isolates

According to the results obtained, the ISP, GYM and CSA culture media proved effective for isolating actinobacteria from forest soils. The following figures show the cultural and morphological characteristics of the selected isolates:

Figure 1: Morphological characteristics of the isolates T1, T4, T5, T6, T7, T8 (on ISP3 plates) from left to right

Figure 2: Morphological characteristics of the isolates T1, T4, T5, T6, T7, T8 (on CSA plates) from left to right

Figure 3: Morphological characteristics of the isolates T1, T4, T5, T6, T7, T8 (on GYM plates) from left to right

Microscopic observation results

Microscopic examination revealed that all isolates had a branched filamentous structure, which may or may not be segmented, and sometimes fragmented. This morphology clearly associates them with actinomycetes.

After being grown on ISP3 medium at 28°C for 21 days, micromorphological examination of strains T1, T4, T5, T6, T7, T008, using a scanning electron microscope, revealed spaces between the spores and made it possible to visualise the distinctive sporophores of *Streptomyces*.

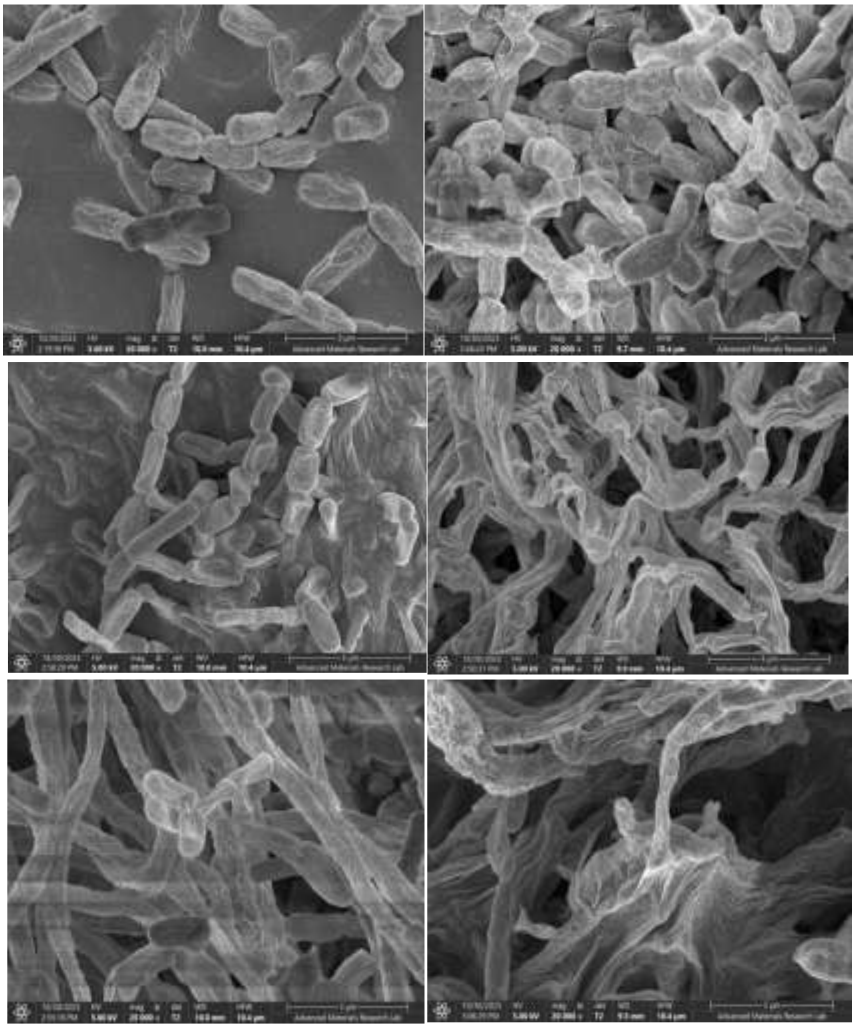

Figure 4: Spore surface morphology of isolates T1, T4, T5, T6, T7, T8 visualized by SEM at 10,000 from left to right

Lipase-producing actinomycetes

Microbial lipases are attracting growing interest as a result of rapid advances in enzyme technology **(Magda et al. 2012)**. They are now the third most widely marketed enzyme in terms of sales volume, after proteases and amylases **(Hasan, Shah, and Hameed 2006)**. In our study, the formation of clear zones around the colonies testifies to the lipolytic activity of the isolates, revealed by the hydrolysis of lipids. Of the six isolates evaluated, isolates T001, T004 and T005 showed significant lipase activity, confirmed by the digestion of lipids present in egg yolk agar, resulting in the appearance of clear zones around their colonies. In contrast, isolate T008 showed no lipase activity.

Figure 5: Assessment of lipolytic activity (clear zone around strains T1, T4 and T5, no zone around T8)

Protease-producing Actinomyces

Actinomycetes are major producers of proteases, enzymes essential to many biological processes. Among the various proteases they secrete, some play a key role in critical extracellular processes linked to their development. These processes, regulated by specific inhibitors, lead to the degradation of the biomass of the substrate mycelium, thereby promoting aerial growth and sporulation **(Chater 2016)**. The presence of clear zones around the colonies indicates proteolytic activity of the isolates, due to the hydrolysis of casein. Of the isolates tested, T1, T4, T5, T6, T7 and T8 showed protease activity by degrading the protein present in skimmed milk agar, which generated clear zones around their colonies.

Figure 6: Evaluation of proteolytic activity (clear zone around strains: T1, T4, T5, T6, T7 and T8)

Amylase-producing Actinomyces

Amylase-producing bacterial colonies were characterised by the formation of clear zones on starch agar. However, none of the isolates tested showed signs of amylase production, as evidenced by the absence of clear zones around colonies on starch, casein and nitrate agars.

Cellulase-producing Actinomyces

Bacterial colonies producing cellulase can be distinguished by the formation of clear zones on carboxy-methylcellulose (CMC)-stained agar. Of the isolates tested, T001, T005, T006 and T007 showed cellulolytic activity by degrading CMC, as evidenced by the presence of clear zones around their colonies on the CMC plates.

Figure 7: Evaluation of cellulosic activity (clear zone around strains: T1, T5, T6 and T7)

Molecular characterisation of isolates

Isolates were subjected to molecular characterisation involving genomic DNA extraction followed by Nanodrop spectrophotometric analysis. The results obtained for each isolate, including the optical density ratio (A260/280) and DNA concentration (ng/µl), are presented in the table below.

Table 1: Nanodrop results for each isolate

Isolates	Density A260/280	Concentarion ng/µl
T1	1.83	14.5
T4	1.52	11.6
T5	1.81	67.7
T6	1.87	141.5
T7	0.97	1.6
T8	1.71	14.9

Phyolgenetic Tree

MEGA version 7.0 was applied to generate a phylogenetic tree using the Neighbor-Joining method **(Saitou and Nei 1987)**. Bootstrap sampling, with 1000 replications, was used to estimate branch confidence values **(FELSENSTEIN 1985)**.

Figure 8 presents a phylogenetic analysis based on 16S rRNA sequences, highlighting the evolutionary relationships between the isolates studied. This analysis revealed that isolate T1 has a close genetic affinity with *Streptomyces aegyptia*, suggesting a common evolutionary lineage and significant genetic similarity. Similarly, isolate T4 showed a genetic relationship with a *Streptomyces sp*. strain, indicating its taxonomic membership of the wider *Streptomyces* genus. In addition, isolate T5 showed significant genetic similarities with *Umezawaea beigonoshangensis*, underlining its potential taxonomic association with this species. In addition, isolate T6 shares genetic characteristics with another *Streptomyces sp*. strain, further strengthening its taxonomic classification. Genetic analysis revealed that isolate T7 shares genetic similarities with *Lysinibacillus sp*, further clarifying its taxonomic categorisation within this bacterial genus. Finally, isolate T8 showed genetic affinity with *Umezawaea endophytica,* suggesting a significant evolutionary link between these two distinct isolates.

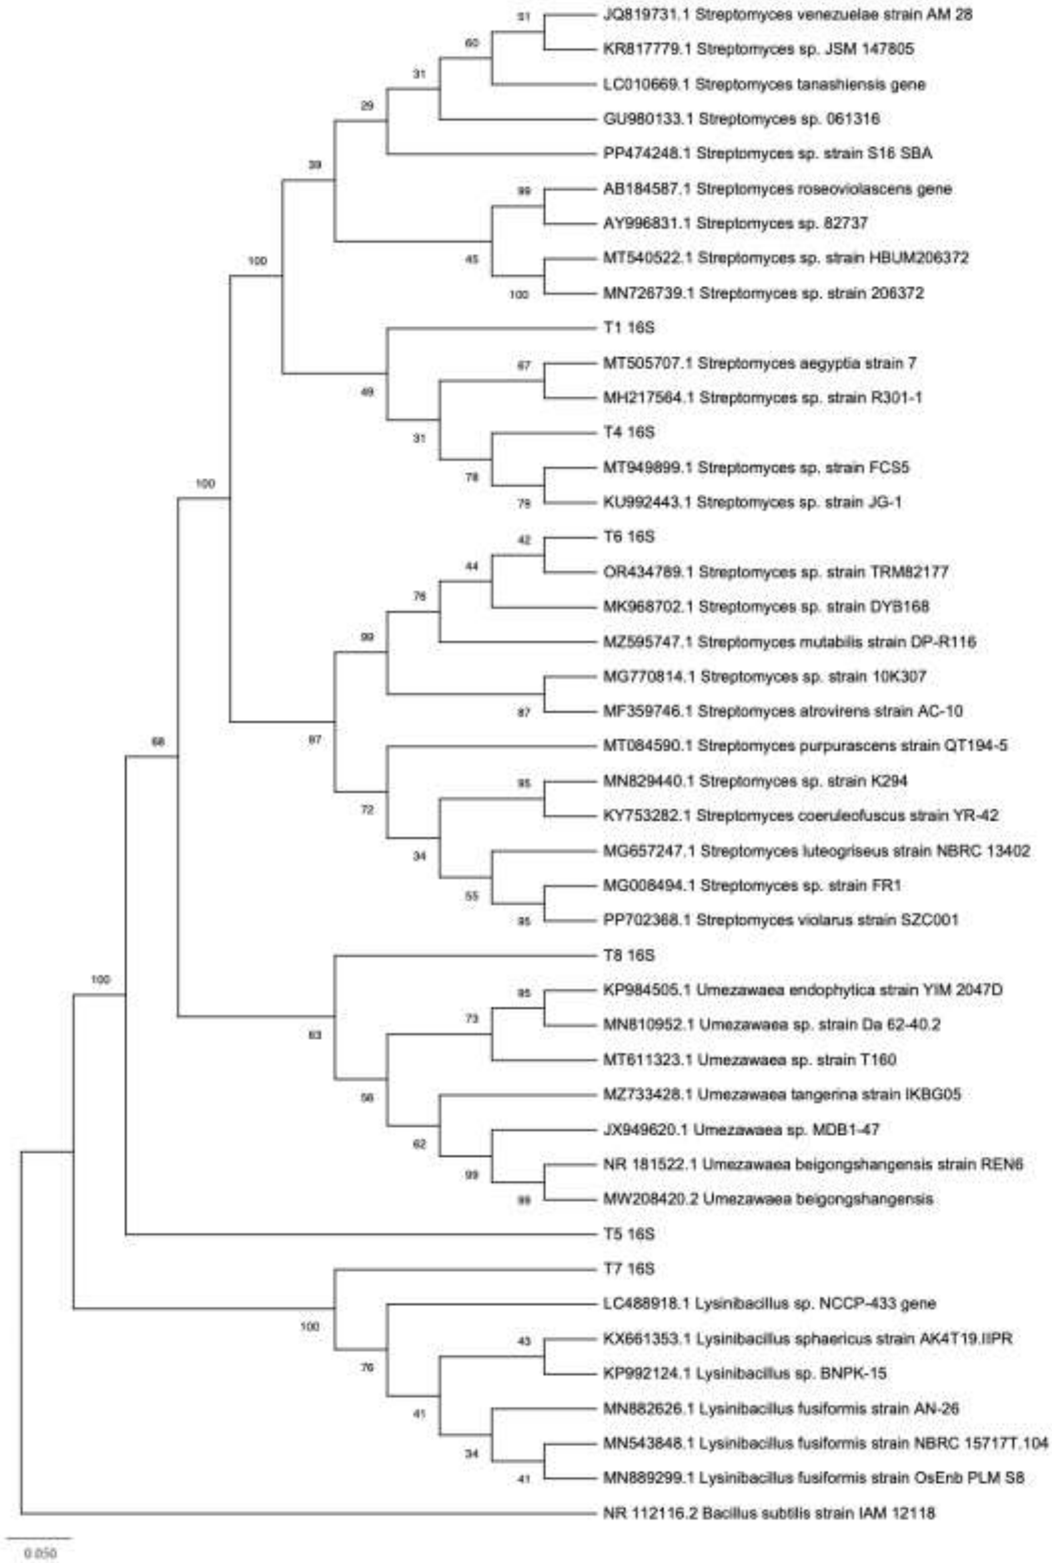

Figure 8: Phylogenetic tree constructed by the neighbour-joining method using blast results

CONCLUSION

Following in-depth analysis and characterisation of the *Streptomyces* isolates in this study, a number of significant results were obtained. The isolates showed a remarkable variety of colony morphologies and aerial mycelium colours, reflecting their intrinsic diversity. In addition, some samples showed significant production of soluble pigments. Detailed examination of the sporophores revealed distinct structures among the isolates, highlighting their heterogeneity.
In addition, assessment of hydrolytic enzyme production revealed significant variation in enzyme activities among isolates, with lipase, protease and cellulase activities detected in varying combinations. It should be noted that none of the isolates showed the ability to synthesise amylase. DNA analysis and the construction of a phylogenetic tree for molecular characterisation revealed genetic relationships and potential evolutionary lineages between isolates. This phylogenetic analysis revealed affinities with established species within the *Streptomyces* genus as well as with other bacterial groups, shedding light on their taxonomic classification.
This study highlights a promising enzymatic activity in actinobacteria isolated from unexplored forest soil in a semi-arid region of Saïda in western Algeria. Further exploration of the enzymatic activities, genetic characteristics and identification of metabolites that can be synthesised by these isolates could provide valuable information for applications in biotechnology, agriculture and pharmaceuticals.

ACKNOWLEDGEMENTS

We would like to thank the team of researchers and technicians in the biotechnology laboratories of the Department of Applied Biology at the University of Sharjah (United Arab Emirates). We would also like to thank Professor Nouar Tabet, Dean of the Faculty of Science, and Dr Hussein Alawadi, Director of the Advanced Materials Research Centre at the University of Sharjah, for their invaluable assistance.
The authors declare that there is no conflict of interest.

Comfrey (*Symphytum officinale* L.) has a centuries-old tradition as a medicinal plant. Today, multiple randomized controlled trials have demonstrated the efficacy and safety of comfrey external preparations. In recent years, significant research has focused on evaluating the chemo-biological profile of comfrey. The aim is to broaden the medicinal applications of this genus to encompass new pharmacological uses and to discuss the toxicological effect of comfrey oral and dermal preparations considering pyrrolizidine content. Nevertheless, to date there are no previous report on volatile organic compound profile using gas chromatography coupled with mass spectrometry. According to the European Union herbal monograph, *Symphytum officinale* L., radix herbal preparation should be prepared using ethanol 65% (*V/V*) as extraction solvent. Prepared in this way, the liquid extract was tested for Volatile organic compounds profile, dynamic viscosity, pH value and antiradical activity. Using gas chromatography coupled with mass spectrometry, a total of 22 compounds were identified: Ethyl 3-(N-butylacetamido) propanoate, C-methyl-scyllo-inositol and lanosterol most abundant one. Conversely, 65% ethanolic extract allantoin content was under the limit of detection. The kinematic viscosity of the obtained extract was 2.25 ±0.06 mm^2/s while pH value was 6.55. Antiradical activity, measured with the DPPH test was 59.96 ±0.45%. In conclusion, the 65% ethanolic extract prepared according to European Union herbal monograph standards showed low levels of allantoin, indicating a deviation from traditional expectations while at the same time, the extract demonstrated a wide range of volatile organic compounds and high antiradical activity, suggesting potential therapeutic benefits beyond its traditional uses.

Keywords: comfrey; allantoin; volatile organic compounds

INTRODUCTION

Comfrey (*Symphytum officinale* L. is a perennial herbaceous plant *Boraginaceae* family. It has characteristic pale purple flowers and long rough leaves (Melnyk et al., 2024). Comfrey has developed a spindle-shaped branched root, which is considered the most valuable part of the plant. Allantoin is the most significant pharmacologically active constituent in comfrey root, which accounts for 0.6-0.8% of the dry weight (Araujo et al., 2012). Besides allantoin, roots contain mucous polysaccharides (29%), fructose and glucose, phenolic acids like rosemary acid (up to 0.2%), chlorogenic acid (0.012%), caffeic acid (0.004%), α-hydroxide of caffeic

acid, glycopeptides, amino acids, and vitamins and minerals. Allantoin and Rosmarinic acid are usually considered as key compounds responsible for its bioactivities but other responsible compounds and molecular mechanisms have yet to be fully investigated (Staiger, 2012; Savić et al., 2015).
Comfrey root has been part of traditional medicine due to its analgesic and anti-inflammatory activity for centuries (Kucera et al., 2018). Today, multiple randomized controlled trials have demonstrated the efficacy and safety of comfrey external preparations with the purpose of repairing damaged tissue. This mechanism involves three stages: inflammation, proliferation, and remodeling, which occur gradually and dynamically (Araujo et al., 2012). Formulations prepared from the comfrey root are well-established and marketed in more than 10 countries. Mostly, those formulations are marketed for osteoarthritis and blunt injuries in the form of gels and emulsions (Staiger, 2012). Moreover, comfrey root formulations have been evaluated as safe and effective alternatives to topical non-steroidal anti-inflammatory drugs (Smith et Jacobson, 2011). On the other hand, comfrey root is well known for its toxic pyrrolizidine content (0.013-1.2%). Many studies have reported hepatoxicity, carcinogenicity and mutagenicity in the acute/chronic ingestion of pyrrolizidine-containing plants. Regarding the safety of comfrey preparations, even when they are intended primarily for topical application, the primary focus lies in the presence of pyrrolizidine alkaloids, which have the ability to be absorbed through the skin and subsequently activated metabolically (Frost et al., 2014). Therefore, many studies focus on the evaluation of the content of pyrrolizidine alkaloids while data on the content of other compounds are very limited. Trifan et al. (2018) stated that comfrey root preparations distributed on the European market are usually delivered from cultivars that do not contain pyrrolizidine alkaloids, or those formulations are prepared with root extract from pyrrolizidine alkaloids-depleted material. Therefore, there is a need for chemical evaluation of other compounds present in comfrey root in order to broaden the medicinal applications of this genus to encompass new pharmacological uses and to discuss the toxicological effect. The physical and chemical properties of comfrey extract can help to understand bioactive compounds' release properties and skin permeability properties. Furthermore, the physic-chemical properties of comfrey root extract can serve as a determination factor for internal and external purposes of comfrey root.

MATERIALS AND METHODS

Extraction procedure

Comfrey extracts are prepared in accordance with the "European Union herbal monograph" using maceration during 2 weeks, the ratio of solid to liquid was 1/10 g/ml with ethanol in water solution (0-60% V/V). After extraction, extracts were centrifuged (5000 rpm, 5min) filtered through filter paper and stored until analysis.

Viscosity and pH value of extract

The viscosity of extracts was measured using a Micro-Ubbelohde viscometer (DIN 55 350) immersed in a 21 °C water bath. Every sample was measured in three parallels and the results are expressed as the mean value.
The pH value was determined using a Mettler Toledo pH meter. Every sample was measured in three parallels and the results are expressed as the mean value.

Determination of antiradical activity

The previously described spectrophotometric method (Jakobek et al., 2007) with DPPH (2,2-diphenyl-1-picrylhydrazyl) was used to evaluate antioxidant activity. Namely, the extracts were filtered through a nylon filter pore size of 0.4μm and diluted to a concentration of 1 mg/ml using methanol. Measurement solutions were prepared with the addition of 1.2 ml of extract and 0.5 ml of 0.2 mM freshly prepared DPPH solution. All the measurements were done in triplicate at the wavelength of 517 nm.

Allantoin determination

The content of allantoin was determined using the colorimetric method described by Borchhers (1977). Al the measurements were done in triplicate at the wavelength of 520 nm.
Allantoin presence was confirmed using LC-MS/MS with multiple reaction monitoring (MRM) Agilent Ultivo triple quadrupole mass spectrometer system, with following conditions: Eluent: water: acetonitrile start: (90%:10%) than increasing the acetonitrile concentration from 10% to 20% in 2 minutes, then increasing the acetonitrile to 90% in 2.5 minutes., holding 90% acetonitrile for 0.3 minutes. The measurement time was 5 minutes. The temperature of analysis was set at 25 °C. The injection volume was 1uL.

GC-MS Analysis

10 of extract μL was transferred to a closed chromatographic vial and evaporated on a heating plate. Using a gas-tight syringe gaseous sample was analyzed using a Bruker 436-GC gas chromatograph coupled with Bruker SCION SQ (single quadruple, electron ionization) mass spectrometer (Durham, UK). The estimations were duplicated. The column (BR-5 ms; 0.25 nm × 30 m, df = 0.25 μm) operated at the following temperature regime: 50 °C (2 min) at the temperature rate increase of 10 °C/min up to 170 °C (0 min), then at 25 °C to 280 °C (5 min). Sample separation was set for 1:20, helium was used as the carrier gas. The flow of the mobile phase was 1.0 mL/min, and ionization energy was 70 keV. Scanning was done in the 50-500 m/z range. Chromatographic signals have been identified by comparing them to mass spectra from the National Institute of Standards and Technology's 11 collection. The area under particular chromatographic peaks was determined using a computer program installed in the chromatograph.

RESULTS AND DISCUSSION

The physic-chemical properties of comfrey extracts prepared with different ethanolic solutions are shown in Table 1. All obtained extracts had a characteristic aroma and dark brown color. pH value was in the range 4.65-6.55. The lowest pH value had extract prepared with 5% ethanol while the highest pH value was obtained with 65% ethanol. Similar values were obtained in a study (Araujo et al., 2012) where a pH value of 6.20 for commercial extract and of 6.90 for laboratory-prepared samples were determined. On the other hand, Chen et al. (2018) obtained something higher pH values using (7.15) using green extraction techniques. The obtained data in Table 1 suggest that all extracts were in accordance with the European pharmacopeia specification. Moreover, they were under the ideal range (4.5-7) for cosmetic preparations stability. Dynamic viscosity was in a range from 2.23 to 10 mm^2/s following a linear increase of water content in a solvent. These phenomena are probably related to higher allantoin and polysaccharide solubility in water than in ethanol. Generally, cosmetic formulations with lower viscosity are considered as better lubricant and better moisturizers.

Table 1: Dynamic viscosity and pH value of comfrey root extracts

Extract	%EtOH	pH value	Dynamic viscosity (mm^2/s)
1.	65.00	6.55 ±0.06	2.25 ±0.06
2.	45.00	6.49 ± 0.04	6.11 ±0.15
3.	25.00	6.45 ±0.11	6.77 ±0.41
4.	5.00	4.65 ±0.01	8.55 ±0.12
5.	0.00	6.28 ±0.01	10.00 ±0.1

According to Table 2, the antioxidant activity of obtained extracts was in the range from 30.39% (water extract) to 92.89% (45% *v/v* EtOH). Other studies also evaluated the antioxidant activity of comfrey root extract. Savić et al. (2015) found that the antioxidant activity of comfrey root extract (concentration of 0.15 mg/cm^3) is above 80% and it is slowly increased with increasing concentration. Simultaneously, the antioxidant activity of the allantoin standard compound was evaluated. It was shown that Allantoin in concentrations up to 0.15 mg/cm^3 doesn't possess antioxidant activity. On that account, allantoin is not responsible for antioxidant activity. Probably antioxidant activity is caused by the phenolic compound present in the extract. Evaluating results from Table 2 it was shown that water extract had the lowest antioxidant activity due to water polar properties which favor extraction of allantoin and pectin. Božić et al. (2019) compared different solvents (water, methanol, dichloromethane) in the extraction of antioxidants from comfrey root. Water extract (concentration 33 µg/mL) had an antioxidant activity of 8.33 methanolic extract (concentration of 167 µg/mL) had an antioxidant activity of 10.23% while dichloromethane extract did not possess antioxidant activity. In this study, allantoin content was determined in concentrations up to 16.96 mg/g. Water extract had the highest content of allantoin while with an increase of ethanol percentage, allantoin content decreased. According to the European Union herbal monograph, *Symphytum officinale* L., radix herbal preparation should be prepared using ethanol 65% (*V/V*) as extraction solvent. Conversely, 65% ethanolic extract allantoin content was under the limit of detection indicating a deviation from traditional expectations. Since the used colorimetric method is robust, this was re-evaluated by LC-Ms analysis where founded results were confirmed.

Table 2: Antioxidant activity and allantoin content of comfrey root extracts

Extract	%EtOH	% DPPH	Allantoin content (mg/g)
1.	65.00	59.96 ±0.45	0
2.	45.00	92.89 ±0.05	7.17 ±0.25
3.	25.00	91.35 ±0.50	12.90 ±1.03
4.	5.00	77.32 ±0.24	14.87 ±2.00
5.	0.00	30.39 ±3.28	16.96 ±0.55

Since 65% ethanolic extract had very low allantoin content (under the limit of detection) this extract was further evaluated for volatile organic compounds. Using gas chromatography coupled with mass spectrometry, a total of 21 compounds were identified (Figure 1): beta-d-Lyxofuranoside, O-nonyl-, C-methyl-scyllo-inositol and lanosterol most abundant ones (Table 3).

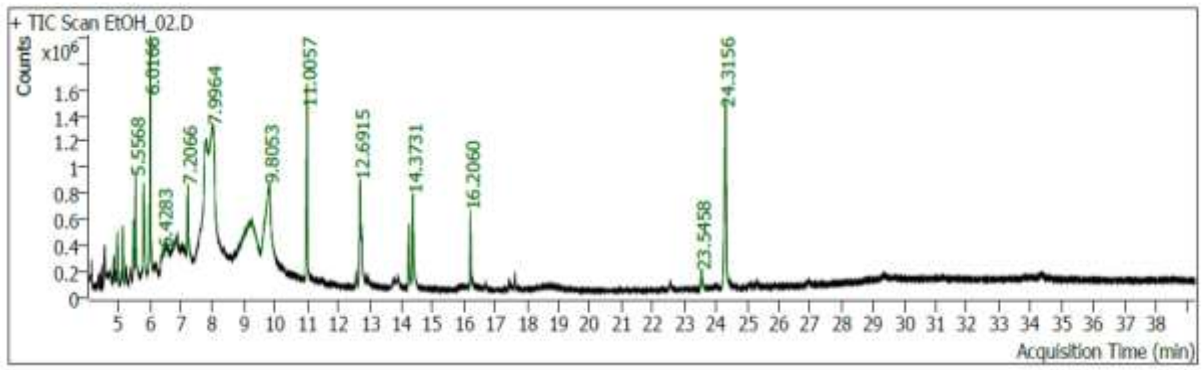

Figure 1: GC/MS chromatogram of 65% ethanolic extract of comfrey root

The largest group were **heterocyclic compounds (**Table 3**)**: Indolizine, Pyrimidine, 6-oxo-5-acetyl-4-hydroxy-1,6-dihydro-, 4H-Pyran-4-one, 2,3-dihydro-3,5-dihydroxy-6-methyl and 4-Hydroxy-2-mercapto pteridine, followed by **fatty acids and derivatives**: n-Hexadecanoic acid, 9,12-Octadecadienoic acid (Z,Z)- and Glycerol-1-monostearate, **Alcohols and derivatives**: 1,3-Dibutoxy-2-propanol, Scyllo-Inositol, 1-C-methyl- and Helindicine, **Carboxylic acids and derivatives**: Carbamic acid, 1,3,5-Pentanetricarboxylic acid and 3-Deoxy-d-mannoic lactone. From the detected compound two 2,5-Dimethylfuran-3,4(2H,5H)-dione and 5-Hydroxymethylfurfural) were **furans and furan derivatives.** Phenols are compounds that have a hydroxyl group (-OH) directly attached to an aromatic hydrocarbon group. The compounds categorized as **phenols and their derivatives** are: Catechol and 4-Vinylbenzene-1,2-diol**. Sterols and triterpenoids** are large, complex molecules that play vital roles in cell membrane structure and function. The compounds detected in comfrey, included in this category are: beta-Sitosterol **and** Lanosterol. Other detected groups were **Thiols** (tert-Nonyl mercaptan) and **sugars and sugar derivatives (**beta-d-Lyxofuranoside, O-nonyl-).

Table 3. GC-MS profile of comfrey root extract

No.	RT	Compound Name	Formula	%
1.	4.9823	2,5-Dimethylfuran-3,4(2H,5H)-dione	C6H8O3	1.51
2.	5.1465	Indolizine	C8H7N	1.87
3.	5.4903	Carbamic acid		1.41
4.	5.5568	4H-Pyran-4-one, 2,3-dihydro-3,5-dihydroxy-6-methyl	C6H8O4	1.66
5.	5.8114	Catechol	C6H6O2	3.74
6.	6.0166	5-Hydroxymethylfurfural	C6H6O3	6.65
7.	6.4283	tert-Nonyl mercaptan	C9H2OS	0.85
8.	6.8231	1,3,5-Pentanetricarboxylic acid	C8H12O6	0.96
9.	7.2066	4-Vinylbenzene-1,2-diol	C8H8O2	2.78
10.	7.7869	Pyrimidine, 6-oxo-5-acetyl-4-hydroxy-1,6-dihydro-	C6H6N2O3	8.43
11.	7.8548	1,3-Dibutoxy-2-propanol	C11H24O3	1.88
12.	7.9964	beta-d-Lyxofuranoside, O-nonyl-	C14H28O5	16.43
13.	9.2334	3-Deoxy-d-mannoic lactone	C6H10O5	8.78
14.	9.8053	Scyllo-Inositol, 1-C-methyl-	C7H14O6	12.13
15.	11.0057	n-Hexadecanoic acid	C16H32O2	6.03
16.	12.6915	9,12-Octadecadienoic acid (Z,Z)-	C18H32O2	3.40
17.	12.7283	beta-Sitosterol	C29H50O	2.3
18.	14.3731	4-Hydroxy-2-mercapto pteridine	C6H4N4OS	3.84
19.	16.2060	Glycerol-1-monostearate	C21H42O4	1.64
20.	23.5458	Helindicine	C15H23NO4	0.98
21.	24.3156	Lanosterol	C30H50O	11.83

beta-d-Lyxofuranoside O-nonyl was the dominant compound in 65% ethanolic extract. It possesses several bioactivities. It is a 7-beta-hydroxysteroid dehydrogenase inhibitor, Antiamyloid-Beta, Anti-TGF-Beta, Beta-2-Receptor-Agonist, Beta-Adrenergic receptor blocker, Beta Galactosidase inhibitor, Beta-Glucuronidase inhibitor and Aldehyde oxidase inhibitor (Perumal et al., 2021). The Aldehyde oxidase inhibitor role is vital for cosmetic formulations where those compounds oxidize electrophilic carbons of azaheterocycles, such as pyridine, pyrimidine, and pyridazine and increase solubility, decrease log P, and help to avoid cytochrome P450–mediated metabolism.

CONCLUSION

The evidence from this study suggests that the 65% ethanolic extract prepared according to European Union herbal monograph standards has low levels of allantoin, indicating a deviation from traditional expectations while at the same time, the extract demonstrated a wide range of volatile organic compounds and high antiradical activity, suggesting potential therapeutic benefits beyond its traditional uses. Therefore, future studies on the current topic are required to investigate other polar and non-polar compounds in comfrey root to broaden the medicinal applications of this genus to encompass new pharmacological uses.

ABSTRACT

Pet owners see their pets as a source of happiness. When they take care of their pets, they get rid of stress and start to feel better. Besides that, when they adopt a cat or a dog, pet owners take on various responsibilities, including feeding, sheltering, and regular veterinary check-ups. Pet owners like to take care of their pets by feeding them on time. However, the real challenge for most pet owners is feeding their pets when they are away from home, such as busy work schedules or business trips. For this reason, pet owners need an automatic pet feeder to solve the problem of feeding their pets. Especially pet owners who have more than one pet need the automatic pet feeder with high dry food capacity and the ability to dispense equal amounts of food. In this study, the automatic pet feeder designed to feed two dogs at the same time, which can be operated with both the solar energy and the power grid, is performed. The automatic pet feeder with two-way splitter basically consists of an ac-dc converter, 12 Volt photovoltaic (PV) panel, a solar battery charge controller, a battery group, digital timers, a DC motor, a DC motor controller, a sound system, 19 liter dry food reservoir and a food portion dispenser. If mentioned system is operated with the power grid, the ac-dc converter is used, but if it is operated with the solar energy, 12 Volt PV panel is used. With the design, the automatic pet feeder can be positioned both inside the house and in the garden. While it can be operated with the power grid when used indoors, it can be powered either by the solar energy or the power grid when used in the garden. Also, thanks to the battery group inside the automatic pet feeder, it is not affected by power outages or periods of time when the sun is not shining. The designed automatic pet feeder can be operated repeatedly in different time periods, 24 hours a day, 7 days a week, with digital timers. In addition, the amount of dry food to be given to pets at each meal can be easily adjusted by determining the rotation speed and rotation time of the food portion dispenser. Owing to its design, equal amounts of food are given to two dogs at the same time. Also, at each meal, the dogs are notified that it is time to eat with the music given by the sound system in the automatic pet feeder. As a result, this designed and implemented automatic pet feeder provides great convenience to pet owners as has a high dry food capacity, has a two-way splitter, can operated with both the solar energy and the power grid, and can easily adjust the number of meals and the amount of food. When pet owners are away from home, they do not need to ask anyone else for help to feed their pets by using this automatic pet feeder. In addition, pets are fed regularly.

Keywords: Automatic pet feeder, Grid-connected system, Off-grid solar system, Renewable energy

INTRODUCTION

The bond that humans establish with animals dates back to ancient times. Researches show that animals began to be domesticated by humans approximately 12 thousand years ago. Today, many people continue to share their homes, gardens with one or more pets. A pet is often considered a member of the family. Dogs and cats are the most popular pets (Sangvanloy and Sookhanaphibarn, 2020). Taking care of a pet affects people positively both emotionally, psychologically and physically (Liu, 2021). Studies have shown that people who care for pets can keep their blood pressure low and their heart rate controllable under stressful conditions. Therefore, owning a pet has been shown to reduce the change of heart disease and also reduce stress, thus improving performance. (Bembde et al., 2023).

One of the greatest happiness in human life is owning a pet. Some of the people who do not own pet also aim to have pet in the future. However, pets need to be cared for properly. When people adopt a cat or a dog, they take on various responsibilities, including feeding, sheltering, and regular veterinary check-ups. Since they are members of our family, it is an important task to feed them on time. To raise a healthy pet, each pet's food and feeding habits should be carefully examined. When pets are not fed on time, their health is directly affected (Vrishanka et al., 2021). Pet owners like to take care of their pets by feeding them on time. But nowadays, pet owners often face the situation of being away from home for long periods of time, such as busy work schedules or business trips, which causes pets not to be fed on time, irregular feeding, hungry etc. (Liu, 2021). For this reason, pet owners need an automatic pet feeder to solve the problem of feeding their pets.

One of the new approaches in pet feeding is automatic pet feeders. These devices will help pet owners take care of their pets. Automatic pet feeders can feed pets even if their owners are not at home. However, as the number of pets cared for in a household increases, automatic pet feeders on the current market may become insufficient. Both food capacity and providing equal amounts of meals emerge as problems. Additionally, pet owners can care for their pets not only at home but also in the garden. Therefore, automatic pet feeders must also be resistant to the external environment. In addition, people who care for their pets in the garden or in a rural area where there is no electricity need automatic pet feeders that can also work with solar energy, as they are environmentally friendly and can work independently of the power grid. Using this type of automatic pet feeders will help reduce greenhouse gas emissions and eliminate feeding irregularities of pets that may occur due to power outages in the power grid.

Especially in Türkiye, it is possible to use automatic pet feeders powered by solar energy. Türkiye is suitable for the use of solar energy since it is located between the 26th and 45th east meridians and the 36th and 42nd northern parallels (Kotcioğlu, 2011). Daily sunlight duration is nearly 5 hours in winter, 7 hours in spring, and 11 hours in summer months in Türkiye (Yüksel and Türkboyları, 2018). Therefore, Türkiye has a notable potential of solar energy and this potential is shown in Figure 1 (Kabalci et al., 2016). Colors of atlas show values of total annually average and solar energy potential is directly proportionate to region and notable amount of power could be acquired from solar energy in Türkiye.

Figure 1. Solar energy potential atlas of Türkiye (Kabalci et al., 2016).

In this study, the automatic pet feeder designed to feed two dogs at the same time, which can be operated with both the solar energy and the power grid, is performed. The automatic pet feeder with two-way splitter basically consists of an AC-DC converter, 12 Volt photovoltaic (PV) panel, a solar battery charge controller, a battery group, digital timers, a DC motor, a DC motor controller, a sound system, 19 liter dry food reservoir and a food portion dispenser. If mentioned system is operated with the power grid, the AC-DC converter is used, but if it is operated with the solar energy, 12 Volt PV panel is used. Thanks to the battery group inside the automatic pet feeder, it is not affected by power outages or periods of time when the sun is not shining. The designed automatic pet feeder can be operated repeatedly in different time periods, 24 hours a day, 7 days a week, with digital timers or manually. Thanks to its design, equal amounts of food are given to two dogs at the same time, accompanied by music.

MATERIAL AND METHOD

Study Area

Çanakkale is in the northwest of Türkiye and is located within the Marmara Region. Çanakkale has 12 districts and one of them is Ezine. Ezine's location is shown in Figure 2.

Figure 2. Ezine’s location in Çanakkale, Türkiye where the study is carried out

This study is realized in a detached house with a garden in Ezine. The feeding of two adult dogs kept in the garden is provided by the automatic pet feeder introduced in this study.

DESIGN AND REALIZATION OF THE PROPOSED SYSTEM

In this study, thanks to the two-way splitter structure of the proposed automatic pet feeder system, two dogs can be fed equal amounts of food every day. Additionally, depending on user preference, the proposed system can work with either the power grid or the solar energy.

Grid-connected Operation of the Proposed System

The grid-connected operation scheme of the proposed system is shown in Figure 3. As seen in Figure 3, the battery group is charged through the AC-DC converter and the charge control unit connected to the power grid. The battery group powers the control unit, and the control unit provides energy flow to the dc motor that rotates the food portion dispenser, either time-adjusted or manually. Additionally, the sound system plays music when the food is given.

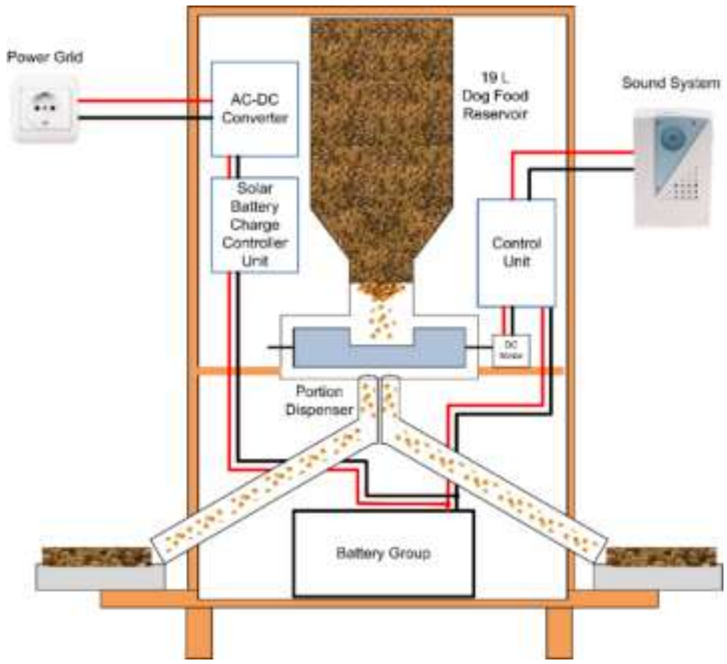

Figure 3. Grid-connected operation scheme of the proposed system

Off-grid Solar-powered Operation of the Proposed System

The off-grid solar-powered operation scheme of the proposed system is shown in Figure 4. As seen in Figure 4, PV panel charges the battery group with the solar charge controller. The battery group powers the control unit. The control unit provides energy flow to the DC motor that rotates the food portion dispenser, either time-adjusted or manually. The sound system plays music when the food is given.

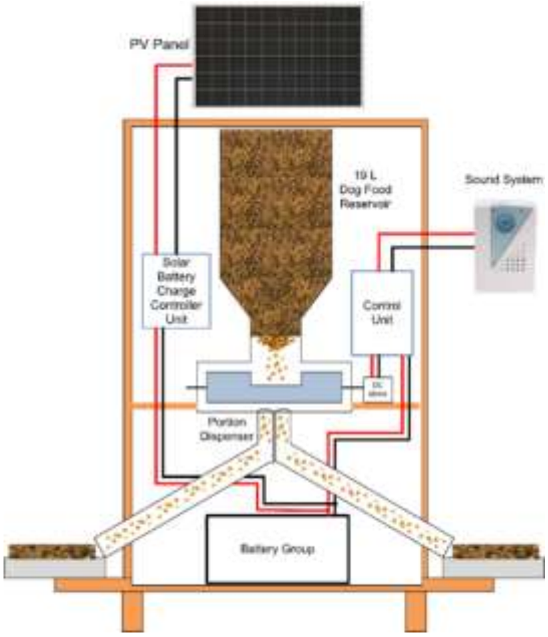

Figure 4. Off-grid solar-powered operation scheme of the proposed system

General Structure and Operation of the Proposed System

A photograph of the automatic pet feeder with two-way splitter is shown in Figure 5. The automatic pet feeder with two-way splitter basically consists of the energy source (power grid or 12 Volt PV panel), the AC-DC converter (only grid-connected operation mode), the solar battery charge controller, the battery group, digital timers, the DC motor, the DC motor controller, the sound system, 19 liter dry food reservoir and the food portion dispenser.

Figure 5. Photograph of the proposed automatic pet feeder

Depending on the user's preference, either the power grid or 12 Volt PV panel is used as the energy source in this study. The voltage value of the electricity used in houses in Türkiye is 220 Volt (rms value) and the frequency is 50 Hertz (Hz). One PV panel is preferred to be used in this study. This PV panel is rated at 12 Volt, 170 Watt. Characteristics of PV panel are expressed in Table 1.

Table 1. Characteristics of PV panel

Name	Rating
Panel Maximum Power	205 W
Peak Voltage	21.45V
Peak Current	9.6 A
Open Circuit Voltage	25.92 V
Short Circuit Current	9.9 A

The introduced system includes the AC-DC converter that is used only in grid-connected operation. The input voltage is 220 Volt AC and the output voltage is 13.8 Volt DC and output current 3,5 A DC.

The solar charge controller is used to regulate the flow of voltage and current from the PV panel to the battery group so that it can protect the battery group from damage due to overcharging. Some characteristics of the solar battery charge controller are shown in Table 2.

Table 2. Some characteristics of solar battery charge controller

Name	**Rating**
Rated Charge Current	10 A
Operating Voltage	12/24Volt auto sensing/auto switching
Control Method	Pulse width modulation (PWM) pulse-duration modulation charge mode
Working Temperature	-35ºC to +60ºC

Another important unit is the battery group. Batteries convert electrical energy into chemical energy for energy storage. In this study, the battery group consists of 6 valve-regulated rechargeable batteries connected in parallel. The capacity of each valve regulated rechargeable battery is 12 Ah, 12 Volt. Battery group of the automatic pet feeder is shown in Figure 6.

Figure 6. Battery group of the automatic pet feeder in use

An electric motor takes electrical energy and produces mechanical energy. Electric motors come in various ratings and sizes. In this study, 12 Volt DC motor is used to rotate the food portion dispenser. The specifications of the DC motor used are shown in Table 3.

Table 3. Characteristics of DC motor

Name	**Rating**
Operating Voltage	12 - 14,4 Volt
Speed	20000 RPM
Power	20 Watt

In the proposed automatic pet feeder, a sound system is used to notify dogs that it is time to eat. Photographs of the sound system are shown in Figure 7. In the construction of this sound system, a wireless doorbell with 24 melodies, a relay and a button are used. The wireless doorbell circuit is modified and transformed into a wired structure that works with a trigger signal. When the DC motor starts, the trigger signal comes to the sound system and the selected music plays. In addition, thanks to the added button, the selected music can be played manually at any time.

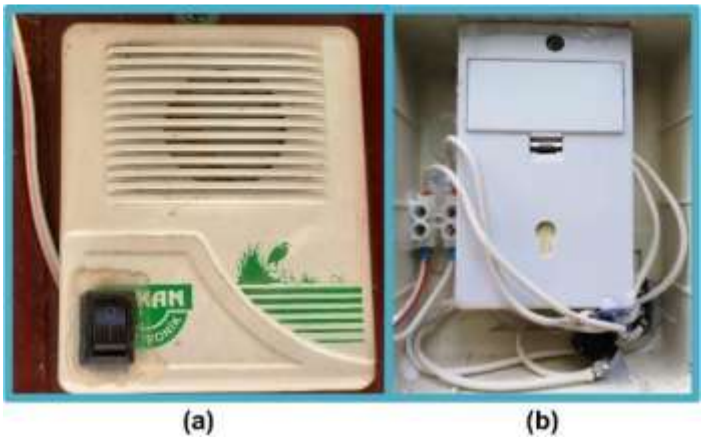

Figure 7. Photographs of the sound system in use

The parts of the automatic pet feeder related to food are the 19 liter dry food reservoir, the two-way splitter and the food portion dispenser. These parts are shown in Figure 8. The 19 liter dry food reservoir is made of a 19 liter plastic water bottle. The food portion dispenser mechanism is made of plastic water pipes of different sizes. The structure seen in Figure 8.b is connected to the shaft of the DC motor. When the shaft of the DC motor rotates, the food portion dispenser also rotates. As a result of this rotation, the dry food is put to the food bowls via two different paths by the two-way splitter.

Figure 8. (a) Photograph of two-way splitter, (b) Photograph of food portion dispenser
Proposed system's electrical connection and control unit are shown in Figure 9.

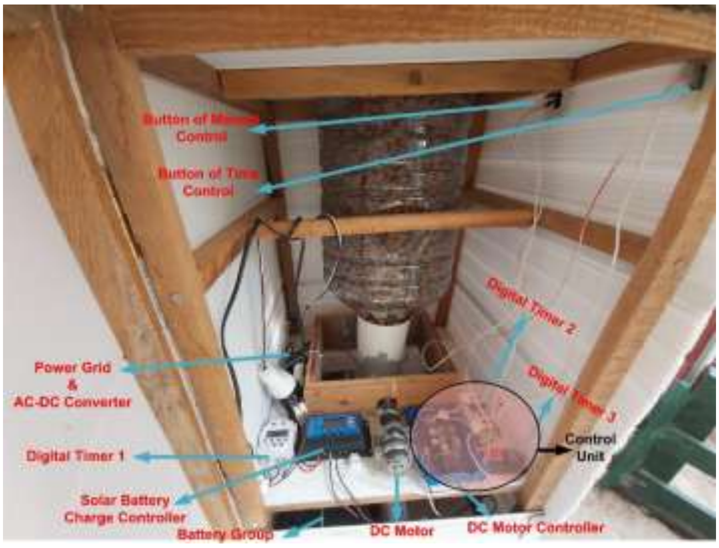

Figure 9. Photograph of proposed system's electrical connection and control unit

The operating steps of the proposed automatic pet feeder are as follows:

- The battery group is connected to the solar battery charge controller and the necessary settings of charge controller are made.
- In grid-connected operation, 220 Volt power grid voltage is converted to 13.8 Volt DC via the AC-DC converter. Then, the output of the AC-DC converter is connected to the solar battery charge controller via Digital Timer 1 (AC Type). Digital Timer 1 is used to set the time periods in which the battery group will be charged. Otherwise, the batteries will always be subject to charging.
- In off-grid solar-powered operation, PV panel terminals are directly connected to the solar battery charge controller. The AC-DC converter and Digital Timer 1 are not used in this operation.
- Terminals of the battery group are connected to the control unit. The control unit controls the operations of the DC motor and the sound system. The control unit consists of 5 elements. These are Digital Timer 2 (DC Type), Digital Timer 3 (DC Type), the DC motor controller, button of manual control and button of time control. When the button of manual control is pressed, equal amounts of food are given to both dog bowls. The button of time control turns the time adjusted operation on and off. A trigger signal is generated 24/7 with Digital Timer 2. Digital Timer 3 operates according to the trigger signal generated by Digital Timer 2 and determines how many seconds the DC motor will operate after the trigger signal arrives. The output of Digital Timer 3 is connected to the DC motor controller. The speed of the DC motor is adjusted with the DC motor controller. The amount of food to be given in each meal depends on the time set in Digital Timer 3 and the speed setting made in the DC motor controller.
- As soon as the DC motor rotates, a trigger signal is sent to the sound system and the previously specified music starts playing.
- With the rotation of the DC motor, the food portion dispenser starts to rotate and delivers equal amounts of food to the two dog food bowls in the specified time

As a result, the energy needs of the automatic pet feeder can be supplied from the power grid or the PV panel. Moreover, the two-way splitter structure works successfully. Thus, it can give equal amounts of food arranged in two food bowls at each meal, both time adjusted and manually.

CONCLUSIONS

The bond between humans and dogs dates back to a very distant past, and there are various positive effects that owning a dog brings to human life, such as relief from stress, security. However, pet owners undertake various responsibilities, such as regular feeding. Due to today's business life, it may not be possible to feed the dog regularly. Dogs are also negatively affected by this situation. To eliminate this negative situation, pet owners need automatic pet feeders.

In this study, the automatic pet feeder with the two-way splitter and powered by either solar energy or the power grid is introduced. This study is carried out in the detached house with a garden located in Ezine, Çanakkale, Türkiye. Since there is 19 liter dry food reservoir in the proposed system, the food needs of two dogs can be met with equal meals for days. Thanks to the battery group within the system, the feeding needs of the animals can be met 24 hours a day, 7 days a week. Successful results have been achieved using this proposed automatic pet feeder. Since dogs were fed regular and equal meals, their weight remained stable and they did not experience stress and unhappiness. Additionally, pet owners are able to continue their daily lives comfortably.

As a result, the energy needs of the pet feeder can be provided from the power grid or PV panel according to the user's preference. Additionally, the two-way splitter structure works successfully. Thus, it can give equal amounts of food arranged in two food bowls at each meal. Based on this system, designs can be created to feed more pets. By using solar energy in this study, it not only contributes to the reduction of greenhouse gas emissions but also enables the use of automatic pet feeders in places where there is no electricity.

Electronics and Automation Department, Ipsala Vocational School, Trakya University, Edirne, Türkiye

gorkemsen@trakya.edu.tr

ABSTRACT

Nowadays, most people keep pets in their homes or gardens to reduce the negative effects of daily life such as loneliness, stress, boredom and unhappiness. Especially with the pandemic period, there has been an increase in the number of people taking care of pets. Pet owners assume very serious responsibilities. The most important of these responsibilities are to feed pets regularly and meet their water needs. In order for pets to live a healthy and long life, they need to have a regular eating and drinking schedule like humans. However, no matter how much pet owners enjoy taking care of their pets, they may not be able to feed their pets regularly due to some reasons, such as today's busy work schedule or business travel. To eliminate this problem, pet owners need automatic pet feeders and water dispenser systems. Additionally, people who care for their pets in the gardens or in rural areas where there is no electricity, want to use automatic pet feeders and water dispensers powered by renewable energy. In this study, an off-grid solar-based automatic pet feeder and water dispenser that can provide dry food and water is introduced. The offered system has two main functions, namely feeding and water giving, and these functions can operate both manually and automatically in various time periods, 24 hours a day, 7 days a week. The automatic pet feeder and water dispenser basically consists of 12 Volt photovoltaic (PV) panel, a solar battery charge controller, a battery group, digital timers, a DC motor, a DC motor controller, a sound system, 19 liter dry food reservoir, a food portion dispenser, a water level control circuit, a solenoid valve and 38 liter water tank. The water dispenser is always active. The water level in the water bowl is detected through minimum and maximum water level sensors. When the water level drops to the minimum, water flow is provided from the 38 liter water tank to the water bowl through the solenoid valve until the water level reaches the maximum. Additionally, the pet feeder can provide equal portions of dry food at different times of the day. Each pet's feeding amount is different. For this reason, the rotation speed and rotation time of the food dispenser in the automatic pet feeder can be easily adjusted, allowing pets to be fed with the ideal amount of food. Furthermore, the automatic pet feeder provides music during each meal, signaling to the pet that it is time to eat. As a result, this introduced system which works with renewable energy, provides serious convenience to pet owners due to its features such as having high dry food and water capacities, adjusting the portion size of meals, providing regular pet feeding, and not being affected by power outages. By using the proposed automatic pet feeder and water dispenser, there will be no need to leave pets elsewhere to be fed and to ask for help from someone else.

Keywords: Automatic pet feeder, Automatic water dispenser, Off-grid solar system, Renewable energy

INTRODUCTION

Pets are tamed and fed by humans to turn them into animals with pleasant personalities. Pets that people keep most are dogs and cats. According to archaeological research, the first domesticated animals are thought to be dogs approximately 12,000 years ago (Harahap et al., 2022). Dogs are the most beloved pets in history and are one of the most common pets owned by people today, according to a recent study (Boateng et al., 2022).

Nowadays, many people share their homes and gardens with one or more dogs. Especially during the pandemic period, there was an increase in the number of people adopting dogs. Additionally, in today's generation, there are a significant number of people who want to own a dog (Koley et al., 2020). Currently, dogs are not only guardian animals, but also one of the owner's family members (Vania et al., 2016). By incorporating dogs into people's daily life routines, they provide physical, emotional and psychological benefits to people (Liu, 2021). Owning a dog meets a person's social needs and provides many other benefits, such as stress relief, boredom relief and responsibility training (Airikala et al., 2020). Additionally, some studies have shown that dogs can help treat children with developmental disorders such as autism (Harahap et al., 2022).

Even though owning a dog is one of the greatest joys in human life, it is not easy to raise a dog in practice because dogs need various care to stay healthy and happy (Harahap et al., 2022). Pet owners take on very serious responsibilities such as feeding, sheltering and regular veterinary check-ups. The most important of these responsibilities is to regularly feed the pets and meet their water needs (Koley et al., 2020). Since they are members of our family, feeding them on time and meeting their water needs is an important task. To raise a healthy dog, each pet's eating habits should be carefully examined. When pets are not fed on time, their health is directly affected (Vrishanka et al., 2021). However, no matter how much people love their pets, they may neglect to care for their pets in terms of providing food and water at equal intervals due to busy working lives, business trips or emergencies (Koley et al., 2020). For example, during the pandemic period, some pet owners were unable to care for their dogs because they were receiving health care in the hospital. As a result, it was observed that some dogs' reactions to their owners changed, and some dogs developed malnutrition. In some cases, dogs even died of starvation (Harahap et al., 2022). Therefore, pet owners need an automatic pet feeder to solve their pets' feeding problem.

Automatic pet feeders are devices that both save time for pet owners and ensure regular feeding of pets (Boateng et al., 2022). Automatic pet feeders can feed pets even if their owners are not at home. However, current automatic pet feeders on the market cannot meet the needs of every pet owner. It may be inadequate both in terms of food capacity and water capacity. In addition, pet owners can take care of their pets not only at home but also in the garden. Therefore, automatic pet feeders must also be resistant to the external environment. It is also important to meet the needs of pet owners in rural areas where there is no electricity. Hence, there is a need for solar-powered automatic pet feeders and water dispensers. The use of this type of automatic pet feeders and water dispensers will help reduce greenhouse gas emissions and eliminate irregularities in the feeding of pets due to power outages in the power grid.

Türkiye is suitable for the use of solar energy because it is located between the 26th and 45th eastern meridians and the 36th and 42nd northern parallels (Kotcioğlu, 2011). Daily sunlight duration in Türkiye is approximately 5 hours in winter, 7 hours in spring, and 11 hours in summer (Yüksel and Türkboyları, 2018). Therefore, Türkiye has an important solar energy potential and this potential is shown in Figure 1 (Kabalci et al., 2016). So, it is possible to use solar-powered automatic pet feeders and water dispensers in Türkiye.

Figure 1. Türkiye's solar energy potential atlas (Kabalci et al., 2016).

In this study, the off-grid solar-based automatic pet feeder and water dispenser that can provide dry food and water is introduced. The offered system has two main functions, namely feeding and water giving, and these functions can operate both manually and automatically in various time periods, 24 hours a day, 7 days a week. The automatic pet feeder and water dispenser basically consists of 12 Volt photovoltaic (PV) panel, a solar battery charge controller, a battery group, digital timers, a DC motor, a DC motor controller, a sound system, 19 liter dry food reservoir, a food portion dispenser, a water level control circuit, a solenoid valve and 38 liter water tank. This introduced system which works with renewable energy, provides serious convenience to pet owners due to its features such as having high dry food and water capacities, adjusting the portion size of meals, providing regular pet feeding, and not being affected by power outages.

MATERIAL AND METHOD

Study Area

Located within the borders of the Marmara Region, Çanakkale is located in the northwest of Türkiye. In addition, just like Istanbul, it has lands on both Asian and European continents. Neighboring provinces of Çanakkale are Edirne, Tekirdağ and Balıkesir. Çanakkale has 12 districts and one of these districts is Ezine, whose location is shown in Figure 2. This study is realized in an approximately three-acre olive grove in Ezine. The regular food and water needs of a dog living in this agricultural estate where there is no power grid are met by the solar-powered automatic pet feeder and water dispenser introduced in this study.

Figure 2. The location of Ezine, Çanakkale in Türkiye where the study is carried out

DESIGN AND REALIZATION OF THE PROPOSED SYSTEM

In this study, the automatic pet feeder and water dispenser that works with solar energy, independent of the power grid, and meets a dog's regular food and water needs is made.

Structure of the Automatic Water Dispenser

The general scheme and photographs of the automatic water dispenser part of the proposed system is shown in Figure 3 and Figure 4, respectively.

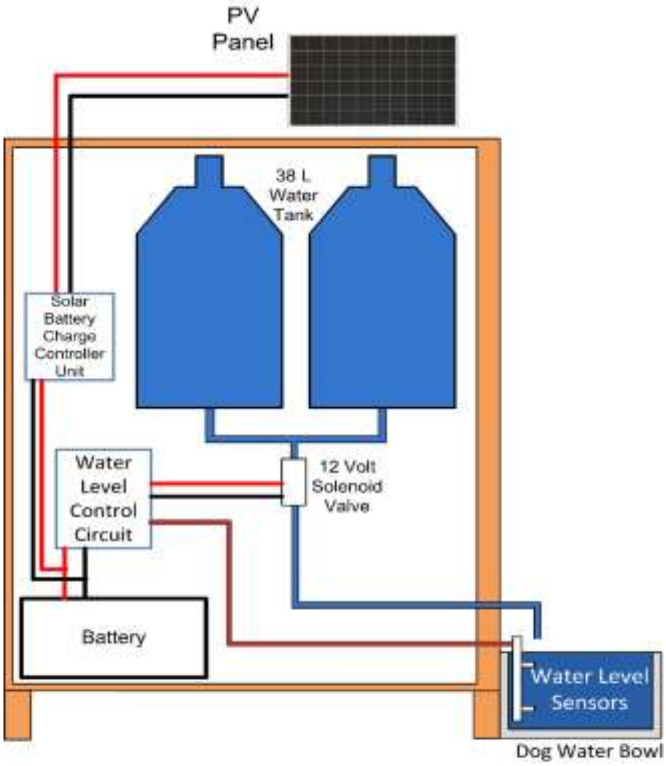

Figure 3. Off-grid solar-powered operation scheme of the automatic water dispenser

Figure 4. Photographs of the proposed automatic water dispenser

As seen in Figure 3, the structure of the automatic water dispenser consists of 12 Volt PV panel, the solar battery charge controller, the battery group, 38 liter water tank, the solenoid valve, water level sensors, the water level control circuit and dog water bowl.

Structure of the Automatic Pet Feeder

The general scheme and photographs of the automatic pet feeder part of the proposed system is shown in Figure 5 and Figure 6, respectively.

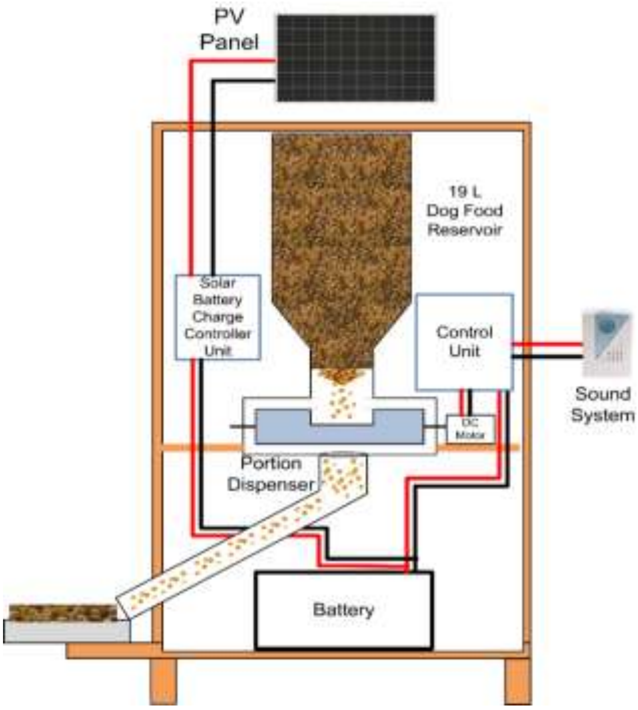

Figure 5. Off-grid solar-powered operation scheme of the automatic pet feeder

Figure 6. Photographs of the proposed automatic pet feeder

As seen in Figure 5, the structure of the automatic pet feeder consists of 12 Volt PV panel, the solar battery charge controller, the battery group, digital timers, the DC motor, the DC motor controller, the sound system, 19 liter dry food reservoir and the food portion dispenser.

General Structure and Operation of the Proposed System

Overall scheme of the proposed system is shown in Figure 7 and photograph of the proposed system is demonstrated in Figure 8, respectively.

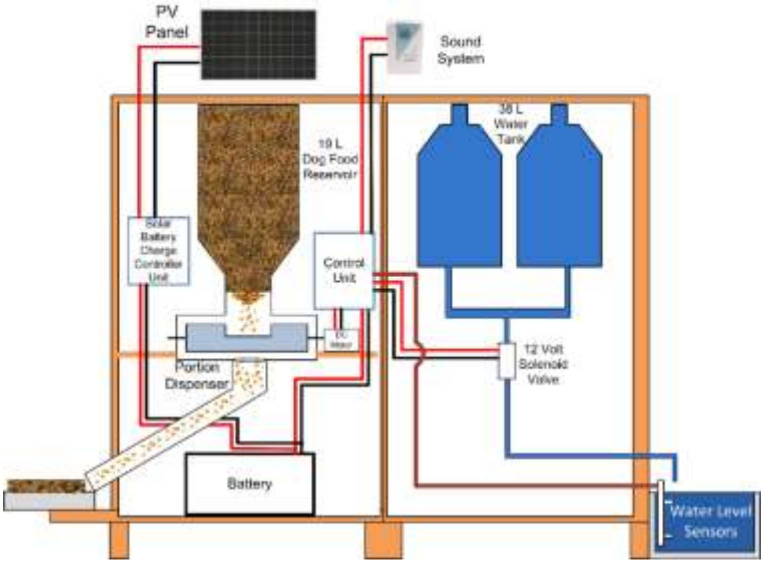

Figure 7. Overall scheme of the proposed system

Figure 8. Photograph of the proposed automatic pet feeder and water dispenser

As seen in Figure 7 and Figure 8, the introduced system consists of 2 parts that perform 2 separate functions. These are feeding and water giving, and these functions can operate both manually and automatically in various time periods, 24 hours a day, 7 days a week.

In this study, 12 Volt, 170 Watt PV panel is used. Characteristics of PV panel are presented in Table 1.

Table 1. Characteristics of PV panel

Name	Rating
Panel Maximum Power	205 W
Peak Voltage	21.45V
Peak Current	9.6 A
Open Circuit Voltage	25.92 V
Short Circuit Current	9.9 A

The solar charge controller is used to regulate the flow of current and voltage from PV panel to the battery group. Thus, it can protect the battery from damage due to overcharging. Some characteristics of the solar battery charge controller are presented in Table 2.

Table 2. Some characteristics of solar battery charge controller

Name	Rating
Rated Charge Current	20 A
Operating Voltage	12/24Volt auto sensing/auto switching
Control Method	Pulse width modulation (PWM) pulse-duration modulation charge mode
Working Temperature	-35ºC to +60ºC

The battery group is very important in solar-powered systems. In this study, the battery group consists of 3 deep cycle gel batteries connected in parallel. The capacity of each gel battery is 12Volt, 100Ah. Battery group of the automatic pet feeder is shown in Figure 9.

Figure 9. The battery group of the solar-based automatic pet feeder and water dispenser in use

In this study, 12 Volt DC motor is used and the task of this motor is to rotate the food portion dispenser. The characteristics of the DC motor are presented in Table 3.

Table 3. Characteristics of DC motor

Name	Rating
Operating Voltage	12 - 14,4 Volt
Speed	20000 RPM
Power	20 Watt

In the automatic pet feeder and water dispenser, the sound system is used to inform the dog that it is time to eat. Photographs of the sound system are shown in Figure 10. In the construction of mentioned sound system, a wireless doorbell with 24 melodies, a relay and a button are used. The wireless doorbell circuit is modified and transformed into a wired structure. Thus, the sound system works with a trigger signal. When the DC motor starts, the trigger signal comes to the sound system and the chosen music plays. In addition, thanks to the added button, the chosen music can be played manually at any time.

(a) (b)

Figure 10. Photographs of the sound system in use

The parts of the proposed system related to food are 19 liter dry food reservoir, the one-way splitter and the food portion dispenser. These parts are shown in Figure 11. The dry food reservoir is made of 19 liter plastic water bottle. The food portion dispenser mechanism is made of plastic water pipes of different sizes. The structure seen in Figure 11.b is connected to the shaft of the DC motor. When the shaft of the DC motor rotates, the food portion dispenser also rotates. As a result of this rotation, the dry food is put to the dog food bowl.

(a) (b)

Figure 11. (a) Photograph of one-way splitter, (b) Photograph of food dispenser

The parts of the proposed system related to water are 38 liter water tank, 12 Volt solenoid valve, water level sensors, dog water bowl. These parts are shown in Figure 12.

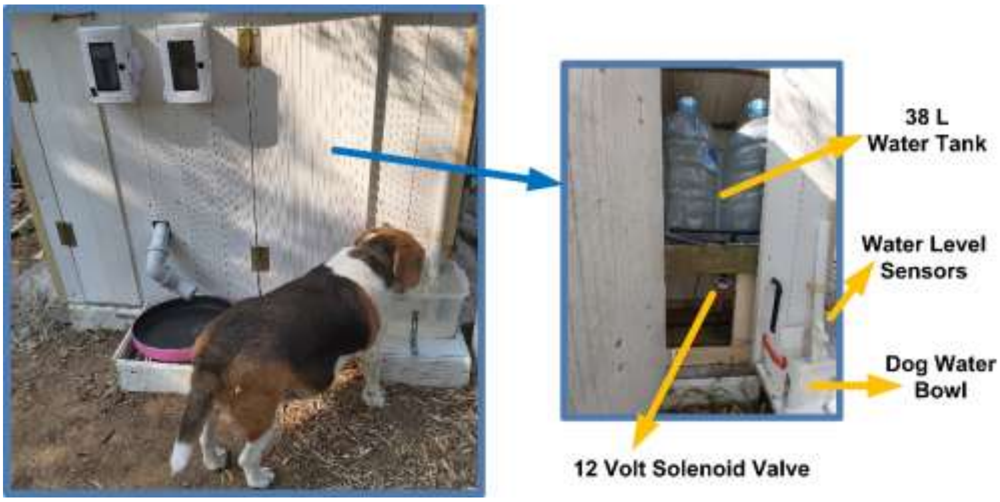

Figure 12. Photograph of the parts of the proposed system related to water

The control unit controls operations of the DC motor, the solenoid valve and the sound system. The control unit consists of 7 elements. These are Digital Timer 1, Digital Timer 2, the DC motor controller, the button of manual control, the button of time control, the button of manual water supply and the water level control circuit. The button of time control turns the time adjusted operation on and off. The pet feeder can give food at any time with the button of manual control. Also, water can be poured into the dog water bowl at any time with the button of manual water supply. The control unit is shown in Figure 13.

Figure 13. Control unit of the automatic pet feeder and water dispenser

The operating steps of the proposed automatic pet feeder and water dispenser are as follows:

- The battery group is connected to the solar battery charge controller. The necessary settings of charge controller are made.
- PV panel terminals are directly connected to the solar battery charge controller.
- The battery group is charged with solar energy during the day.
- Terminals of the battery group are connected to the control unit. For operation of the DC motor, trigger signals are generated 24/7 with Digital Timer 1 or button of manual control. Digital Timer 2 operates according to the trigger signal generated by Digital Timer 1 and determines how many seconds the DC motor will operate after the trigger signal arrives. The output of Digital Timer 2 is connected to the DC motor controller. The speed of the DC motor is adjusted with the DC motor controller. The amount of food to be given in each meal depends on the time set in Digital Timer 2 and the speed setting made in the DC motor controller.
- When it's time to eat, the food portion dispenser starts to rotate and delivers dry food to the dog food bowl. As soon as the DC motor rotates, the trigger signal is sent to the sound system and the previously chosen music starts playing.
- Minimum and maximum water level data received from the dog water bowl are sent to the water level control circuit. This circuit provides energy flow from the battery group to the solenoid valve when the water level in the dog water bowl is minimum. As a result, water flows from 38 liter water tank to the dog water bowl. When the water level in the dog water bowl reaches the maximum level, the water level control circuit cuts off the energy of the solenoid valve. Thanks to this mode of operation, water is constantly available within the maximum and minimum water levels set in the dog water bowl. Additionally, water flow into the dog water bowl can be achieved by manually energizing the solenoid valve without using the water level control circuit.

As a result, the energy needs of the automatic pet feeder and water dispenser can be supplied from PV panel. Moreover, the automatic pet feeder with one-way splitter structure and automatic water dispenser work successfully both time adjusted and manually.

CONCLUSIONS

Regular eating food and drinking water is so important for pets like human beings. If pet owners are with their pets, the pets do not have any problems with food and water since the pets are under constant supervision. However, pet owners cannot be with their pets all the time for different reasons. As a result, problems such as irregular nutrition and insufficient water consumption arise. To eliminate these problems, pet owners need automatic pet feeders and water dispensers. Moreover, pet owners are looking for systems powered by renewable energy.

In this study, the automatic pet feeder and water dispenser powered by solar energy is introduced. This study is carried out in an approximately three acres of olive grove in Ezine, Çanakkale, Türkiye. Since there is no power grid in the specified agricultural land, a dog's water and food needs are met regularly with the proposed system. With the using of this system, the pet owner is able to continue his daily life without experiencing stress.

As a result, it is confirmed that the need of energy in the automatic pet feeder and water dispenser can be met from solar energy. The proposed pet feeder is a suitable solution to meet the food and water needs of all pets. In addition, both the food and water capacity of the proposed pet feeder and the PV panel and battery capacity can be easily determined according to the need. Therefore, the use of the proposed pet feeder will be beneficial for both pets and pet owners.

ABSTRACT

The moisture content of the paddy plant after harvest is over 20%. This moisture content is not suitable for storage and processing. Therefore, the paddy plant needs to be dried. Approximately 600-1000 kg of paddy is harvested from an average of one acre of field. Drying must be fast for paddy harvested in large areas. Drying machines are used for this purpose. There are fixed or portable drying machines for paddy drying. These machines perform the moisture removal process by transferring hot air to the product with the support of a heat source. The paddy moisture removal process must be done at a certain time so that it does not damage the product. Therefore, the drying process of the machines is controlled. Various energy sources are used to provide hot air while drying with hot air. While it is possible to use energy sources such as electricity and fuel oil, they are less preferred due to the cost parameter. Drying can be done by burning coal or organic fuels efficiently. In this study, the structure and drying principles of paddy drying machines will be discussed. In addition, the energy sources used in these machines will be discussed.

Keywords: Paddy Drying, Energy Sources, Dryer Machine

INTRODUCTION

Rice, consumed by almost half of the world's population, is a basic need, source of nutrition and income. When the paddy is ripe, the ears are cut, and the grain consists of the caryopsis and the husk surrounding it without sticking to it and the inner husk. The product whose husk, that is, the husk, is not peeled is called paddy, the product that has only undergone the peeling process is called brown rice or cargo rice, and the final product that has undergone the peeling and polishing process is called rice. While 55-60% of rice is obtained during the processing of paddy, 15-20% is husk, 8-10% is bran, 7-8% is broken, 2% is damaged rice and 2% is obtained as grain product. (Taşlıgil & Şahin, 2011).
Rice (Oryza sativa L.) is a plant species from the Poaceae family and is an important export crop grown widely around the world. This plant is the only herbaceous warm climate plant cultivated in tropical and temperate water, they breathe and grow and develop using the dissolved oxygen in the water. Rice has the ability to grow in salty and alkaline soils, which is an important feature that distinguishes it from other plants and offers the potential to expand agriculture and increase productivity. (Öztürk & Akçay, 2010). The moisture content of the

products harvested from the field at 25-20% moisture should be reduced to 12-14% for storage and processing conditions. (Dizlek, 2014).

The agricultural sector includes a wide area with technological developments in food production worldwide, product flexibility and a perspective of expanding change. At this point, the emergence of continuous development requires the continuous renewal and development of the drying process in the rice sector. Because climate conditions, agricultural techniques and consumer expectations are constantly changing. Innovative solutions are constantly being sought in areas such as the development of new varieties, making drying processes more energy efficient, expanding automation and reducing environmental impacts. (Aydin & Güllü, 2007). Sustainability targets such as making waste management more effective in paddy drying systems should be set. It is important to minimize environmental impacts, protect natural resources and leave a healthier and safer world for future generations.
For a long time, it has been aimed to increase efficiency by using different techniques and resources in many parts of the world. Correct application of drying techniques protects the quality and consumability of grains while also minimizing product losses. In this study, the techniques used for drying paddy and the machines produced using these techniques will be discussed.

MATERIAL AND METHOD

Drying, dehumidification is the process of removing excess moisture from the product, a heat and mass transfer process. Heat transfer occurs from the product to the environment by convection, conduction or combinations. This transfer process from the product to the environment is affected by external factors such as the temperature of the drying environment, the humidity of the air, the type of product, the air flow rate and direction, and is also affected by internal factors such as the moisture content and temperature of the product. While external parameters affect the first stage of drying, internal parameters control the drying speed after reaching the critical moisture value. (Mengeş, 2005).
Common drying techniques in the agricultural industry and for food safety are listed below.

Drying Techniques

Air drying technique;

Cereals are drying in open areas using sunlight and natural ventilation. This method can be low-cost, but depends on weather conditions and the width of the drying area. The natural drying method in the sun can be effective in certain conditions, but it faces a number of technical limitations. In this method, the product exposed to direct sunlight creates uncertainty in the drying process. Lack of control in this process prolongs the drying time and creates uncertainty in the process of reaching the desired moisture level. In addition, the relative humidity level of the air may not be suitable for the product to be dried to reach the specified moisture level.(Suresh et al., 2023).

Mechanical drying;

Mechanical dryers blow hot air into the grains to remove moisture. This method is controlled and the air temperature and speed can be adjusted, thus providing fast and effective drying. There are many different machines in the industry for mechanical drying, with different capacities and different types of fuels. Zhang et al. (2022), analyzed the effects of different drying methods on the bursting rate, taste value and appearance quality to evaluate the quality of paddy rice in his studies. As a result of the analyses, a quality index system was used to comprehensively evaluate the quality of paddy rice. With the gray relational analysis method, the gray relational degree obtained when the moisture content was 24.4% during the drying process was determined as 0.996. These results show that the mechanical drying method gives the best result in terms of paddy rice quality.(Gummert, 2012).

Indirect drying technique;

Grains are dried not directly with hot air, but by the principle of heat conduction. Heat first heats a conductive surface and drying occurs by transferring the heat from this surface to the grains. Many studies have been conducted using different sources on indirect drying techniques. In a study conducted among solar drying techniques, El-Sebaey et al. (2023), observed that the indirect method resulted in higher quality products than other techniques. In Vitázek and Tirol (2008)'s study, they evaluated the performance of a closed grain dryer by measuring the temperature on the body surface with thermovision images and using the heat conduction principle.

Direct drying technique;

It is a technique in which grain products are dried by exposing them to direct heat or hot air flow (Babić et al., 2007). With this method, the products are placed directly into the dryer and heat or air is applied directly to the surface of the products, allowing the moisture to evaporate. Since heat or air comes into direct contact with the product surface, it provides rapid drying. One of the Italian Pedrotti Rice Dryer models used in this study uses special combustion chamber funnels to ensure that every calorie produced by the burners enters the product directly without heat loss with direct drying. The presence of heat distribution saves fuel. (Pedrotti, 2023).

Each drying method can work most effectively under certain conditions and requirements. Therefore, when choosing the right drying system, attention should be paid to the type of product to be used, its quantity and moisture content. In addition, the technologies used in rice drying depend on factors such as regional climate conditions, resource availability, access to technology and local production traditions. These differences significantly affect the sustainability, efficiency and quality of rice production. For example, Southeast Asia (SEA) contributes almost 20% to global rice production. (Nguyen-Van-Hung et al., 2019). In the Mekong River Delta of Vietnam, over 45% of rice is dried using mechanical dryers (Hung et al., 2013), in other regions (Filipinler, Myanmar) this rate drops to 5-10% or even below 5%. (Tado et al., 2015).

Drying techniques other than natural resources require a source for thermal energy. These sources can be electricity, natural gas, diesel, coal and other fossil fuels.

Drying Machines

There are several different types of machines used in the industry for drying paddy rice. These are flat bed, fluidized bed, rotary bed dryers. These machines are mostly found in factories. The most commonly used ones are vertical dryers that are operated mobile in the field or anywhere desired after harvest.

Flatbed dryers

Flatbed dryers (FBD) are used to dry paddy rice by spreading it on a flat bed. Some provide thermal energy from solar energy or natural air currents, while others use electricity, natural gas or paddy husk to provide energy. Figure 1 shows a picture of a flatbed dryer.

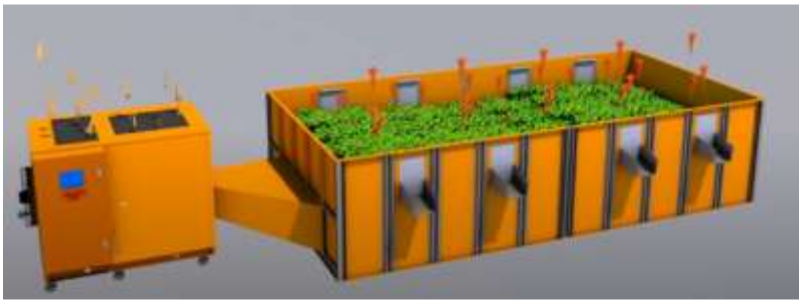

Figure 1. Flatbed Dryers

The rectangular bed of the flat bed founder is generally selected fine wire for air permeability (Syariffuddeen et al., 2020). After the drying air is heated, it is delivered to the grain pile by the fans and this process continues until the desired dem balance is achieved. FBD consists of three basic components, the oven to produce heat energy, the automation system for control, the fans to provide air flow and circulation, and the drying chamber. Flatbed dryer models vary depending on the air movements and direction. Models are available as single-direction (upward) air flow, double-direction (up and down) air flow (Hung et al., 2019).

Fluidized Bed Dryers

In fluidized bed dryers, the paddy is filtered in high-speed air currents. This filtration allows the paddy to dry quickly. These types of dryers are generally used on an industrial scale. An example of a fluidized bed dryer is given in Figure 2.

Figure 1. Fluidized Bed Dryers

In the fluidized bed system, air is pressurized with a fan inside the machine. The pressurized air passes through the perforated sheet and affects the product, affecting the gravitational force enough to suspend the grains. The aim here is to ensure that the product behaves like a fluid material (Kurtuluş, 2007). It has a wide range of uses, including processing, drying, cooling, agglomeration and granulation. (Ravi et al., 2023).

Rotary Bed Dryers

It is a type of dryer that tries to dry by moving it with a rotating drum. Heat and air flow distribute the grain evenly in the cylinder while drying it. It takes a certain amount of paddy, removes the paddy when the drying process is completed and makes a new load. Circulation is provided by continuous mixing during the process. The paddy pile is mixed homogeneously by shaking at a constant speed. This shaking process helps to balance the moisture accumulated on the surface of the paddy grains. (Firouzi et al., 2017). Energy is obtained by using fuels such as LPG, coal, husk, diesel. An example of a rotary bed dryer is given in Figure 3.

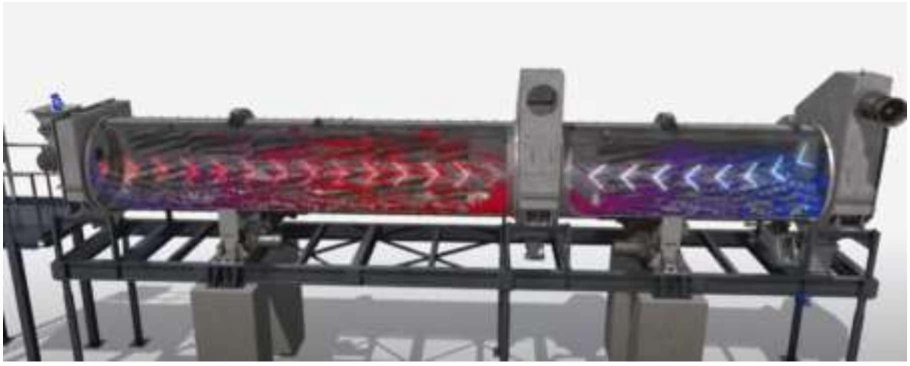

Figure 2. Rotary Bed Dryer

The leaves placed inside provide forward movement. In some dryers, a cooling process is performed as seen in the figure. This process is used to cool the grain after the drying process is completed and to quickly bring it back to ambient temperature. The air fan or cooling fan can also be called a cooling fan, which blows cold air to the material inside the rotating drum. This cold air prevents the product moisture from being reabsorbed. It also provides safe working conditions by preventing high temperatures that may occur inside the drum after the drying process.

Vertical Grain Dryer

Vertical grain dryers are other machines used to dry grains such as paddy, sunflower, corn. The vertical dryer is a mobile storage type system that sends the heat generated in the boiler to the heating chamber where the central helix is located via a low-pressure fan and presses it into the product at a certain pressure range from there, thus reducing the moisture of the product. Drying is done by changing the places of the product on the outside and the product that dries faster with the hot air spread from the inside to the outside, thus providing a homogeneous mixture. There is an 11 kW 1500 rpm feeding helix in the drying section of the vertical dryer. This helix conveys the paddy discharged into the hopper to the dryer. The main helix with a 22 kW 1000 rpm motor located in the center of the dryer carries the product from bottom to top in the dryer, thus providing drying. In addition, there is a 2.2 kW 1500 rpm motor dust fan outside the dryer, the fan increases efficiency by removing the garbage and grass in the paddy from the dryer. Since the garbage coming from the field with the product is wet like the paddy, it prolongs the drying period. Some producers clean the garbage in the paddy by sifting before drying. This is a necessary step because some factors such as moisture content changes and low drying temperatures during the process between harvest and storage put agricultural products under thermal and mechanical stress. Insufficient or no pre-treatment causes the drying period to be extended and causes excessive energy consumption. The dryer section of the general type of mobile vertical drying machine is given in Figure 4. The capacity starts from 5.5 tons and will dry 200 tons (daily) of paddy depending on the product type. The dryer used in this study has a 56m3 paddy chamber of approximately 31 tons. The basic points to be considered when choosing a dryer are to reach the maximum drying speed and to provide minimum energy consumption in obtaining the product with the desired properties. (Gungor & Ozbalta, 1997). The main factor is to use the heat in the dryer in the optimum way. The heat transfer varies according to the type of dryer, but it is a combination of transport, conduction and radiation. Many studies have been done and applied to determine the most suitable drying method. The drying method that increases energy efficiency and reduces environmental impacts without losing product quality is aimed (Kovacı et al., 2019).

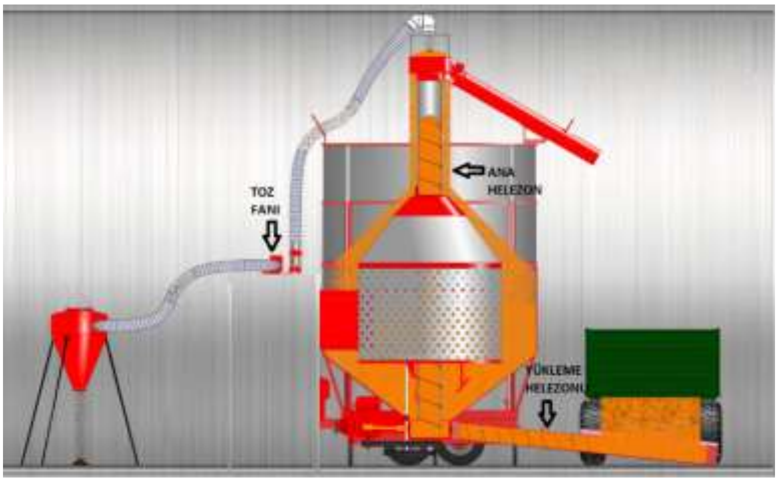

Figure 3. Vertical Grain Dryer

Drying machines generally do not operate with full energy efficiency due to inadequacies in theoretical calculations. Factors affecting energy efficiency can be listed as inadequate thermal insulation, drying methods that are not suitable for the product and environment, and poor quality energy sources (Jangam & Law, 2010). Increasing fuel costs and global warming have led to the most basic approach of recycling heat sources, thus energy efficiency can be greatly increased (Chua et al., 2010).

Examination of Fuels and Energy Resources

In this study, the thermal energy coming to the drying room is also provided by the energy released in the boiler. The energy of the boiler is approximately 700,000 kCal/hour. The product moisture entering the drying room with 1% moisture removal process per hour is realized within 6-12 hours depending on the outside air temperature and humidity rate. 45,000m3 of hot air at 65°C per hour is given into the dryer.
In paddy processing operating on an industrial scale, drying systems operating with coal, fuel oil, LPG fuels are used. The common point of these systems is to dry the paddy using high temperature and air flow. Fuel oil, which is widely used abroad as fuel, has led many drying facilities to turn to the coal-fired drying system, which is a more economically sustainable alternative, due to the energy consumption strategy based on import in our country, and the abnormal price increase arising from fluctuations in exchange rates.
Currently, fossil fuels are limited in terms of resources worldwide. These resources are rapidly depleting and cause environmental problems such as carbon dioxide emissions. Renewable energy sources and recyclable waste sources create a sustainable system.

Coal

The quality of coal depends on factors such as the amount of carbon in its organic matter and its moisture level. High carbon content directly affects the energy production potential of coal. Coal is divided into different classes according to the amount of carbon it contains. Generally, coal types are classified as "peat", "lignite", "hard coal" and "anthracite" according to their carbon content. Peat has a low carbon content (60% and below), while lignite has a medium carbon content (around 70%). Hard coal has a higher carbon content (80-90%), while anthracite is the type of coal with the highest carbon content (over 90%). High carbon content increases the combustion efficiency of coal, reduces the amount of coal used in energy production and thus minimizes environmental impacts. In addition, low moisture content increases the transportability and storability of coal. Therefore, quality standards and carbon content are decisive factors in the coal industry, because they directly affect the efficiency and environmental impacts in energy production processes. (Gunn et al., 2024).

Among coal types, anthracite, which ranks highest in terms of energy density, has a calorific value ranging from 7,300 to 8,000 kcal/kg and is used especially in industry and iron and steel industry. Second in line is hard coal, which has a calorific value ranging from 4,500 to 7,500 kcal/kg. A type of coal that is widely found around the world, hard coal has an important position among solid fuels. Although lignite constitutes approximately one third of the total world coal reserves, it is generally preferred in the power generation sector, namely thermal power plants, instead of heavy industry due to its low calorific value and high ash and moisture content. The calorific value of this brown coal, also known as lignite, is below 5,700 kcal/kg. Finally, peat is among the coal types that have completed their formation. Peat, which has an average calorific value below 2,600 kcal/kg, is generally found in humid regions. (Enerji & Bakanlığı).

Although our country is rich in coal deposits, a large part of its energy needs are provided from abroad, which causes risks in sustainable development and demand security. Although almost all of the existing conventional energy resources are available, only 30-31% of the total primary energy consumption is obtained from local resources. The low amount of energy obtained from own resources shows that a large part of the energy supply is based on imported energy resources. Turkey has approximately 2.1% of the world's coal reserves, and a significant part of these reserves consists of lignite. (MTA, 2023). Therefore, high energy fuels should be selected to provide the boiler energy and reach the moisture balance of the product within the specified time. In Turkey, this energy is reached with imported coal with high calorific value. Imported coal guarantees a lower calorific value of 7000-7800 Kcal//kg. This imported coal is burned approximately 40-50 kg to reduce the moisture content of paddy rice by 1% per hour. This value may vary depending on the conditions. Air temperature is also important among the factors affecting the total capacity and drying time. For example, since the air temperature drops at night, more energy needs to be produced, which means burning more coal.

Fuel oil

Fuel oil, the refining process involves the separation of crude oil into its different components through the thermal process of distillation. This process separates the components obtained from crude oil according to their boiling points. Fuel oil is produced during the distillation process, especially at temperatures between 250°C and 350°C. This temperature range is based on the evaporation and condensation properties of the various components in the crude oil. Fuel oil is a middle distillate product obtained at this stage of distillation and is generally used in various industrial applications such as industrial heating and power generation.

In grain drying plants, diesel fuel is usually stored and transported in large storage tanks. This gives plant operators the flexibility to provide fuel for long periods of operation. In terms of energy efficiency, for example, Pedrotti Grain Dryers, for a moisture range change of 28%-14%, the total kg of water to be evaporated per tonne is 163. The amount of water required to evaporate this water is 15l/tonne - 800Kcal/Kg H2O per tonne. In contrast, for a moisture range change of 24%-14%, the total kg of water to be evaporated per tonne is 116. The amount of water required to evaporate this water is 12l/tonne - 880Kcal/Kg H2O per tonne. The use of diesel fuel can cause emissions during the combustion process. These emissions can negatively affect air quality and have environmental impacts. It can often be more expensive than other types of fuel. However, the high energy density and efficiency of diesel fuel can reduce the total energy costs during the grain drying process (Pedrotti, 2023).
When evaluating the use of diesel fuel in vertical grain dryers in terms of energy values, it is very important to consider several factors. Studies have shown that diesel fuel consumption for drying grain varies depending on the moisture content of the grain pile and the efficiency of the dryer (Kuznetsov et al., 2023)
Direct combustion type burners are more common in diesel fuels. Specially designed combustion chamber funnels are used to ensure that every calorie is delivered to the crop without heat loss. Figure 5 shows the working method of a direct combustion type burner. Although burners provide advantages in terms of efficiency, their prevalence is not equal among countries due to the high cost of fuel. The high cost of diesel fuel in Turkey directs consumers to other cheaper alternatives.

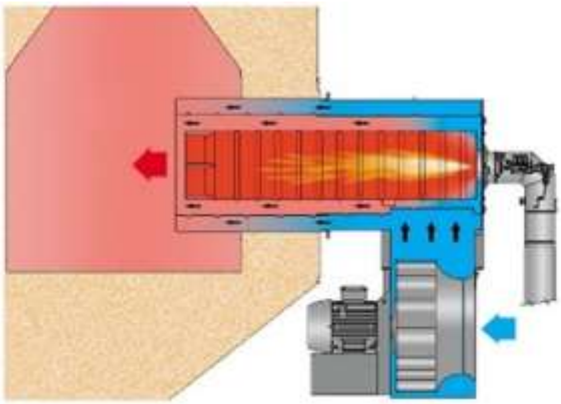

Figure 4. Direct Combustion Type Burner (Pedrotti, 2023)

Rice Husk

Husk is an important by-product of the rice industry and can be used as fuel in various industrial processes. When used as fuel, the technical properties of husk should be taken into account. Factors such as the combustion behavior of husk, the composition of gases formed during combustion and combustion efficiency are important.
Paddy husk can be considered as an alternative fuel due to its high silicon content. Although these husk are considered as waste after paddy production, they have various uses and new areas of use are being investigated. Paddy husk has a calorific value of 3000kCal/kg. The

chemical composition of burnt husk is approximately 70% SiO_2 (Martinez et al., 2006). In addition, if we look at the energy obtained by burning the husk, the energy obtained per kilogram varies between 2.6MJ and 7.5MJ (Steven et al., 2022). The flue gas formed as a result of husk combustion constitutes approximately 14% of CO_2, which is considered a greenhouse gas. The ash content contains a large amount of silicon. The combustion properties of husk determine its usability as a fuel. These properties include factors such as the moisture content of the husk, its calorific value, its ash content and the emission profile of the gases formed during combustion. In addition, the physical properties of husk are also important, because the fuel must burn homogeneously during the combustion process and the combustion chamber must be used effectively. The advantages of using husk as a fuel include being a renewable resource, low cost and contributing to waste management. However, the combustion properties and technical requirements of husk should be taken into consideration. Therefore, suitable combustion systems and designs should be developed for the use of husk as a fuel. In this way, the potential of husk, which is a rice husk fuel, can be evaluated more effectively. In addition, it is important to use this product to reduce zero waste and environmental pollution. (Akyol et al., 2016).

Other Fuels

Grain dryers can utilize a variety of fuel sources to operate efficiently. Common fuels include LPG, coal, wood, coconut shells, and solar energy. LPG and coal are traditional fuel sources used in industrial continuous flow grain dryers (Dębowski et al., 2021) . Wood, especially in the form of firewood or sawdust, is a common fuel source for grain dryers in countries such as Brazil. (Lima et al., 2017), (Quequeto et al., 2022), (Resende et al., 2022). Coconut shells have also been investigated as an alternative heat energy source for grain dryers (Dermawan et al., 2022). In addition to traditional fuel sources, renewable energy sources such as solar energy are also being evaluated to power grain dryers. In addition, connecting energy sources such as solar energy are also being evaluated to power the dryers (Jiang et al., 2010). In addition, studies are being carried out to reduce power cuts and energy savings through the use of electrophysical (Sjechlad et al., 2019). These disruptions are focusing on the development of new improvements to optimize energy consumption in dryers and minimize concentration effects (Sjechlad et al., 2019).

CONCLUSIONS

Rice harvested from the field with more than 20% moisture needs to be dried. This process needs to be done quickly, with minimal damage to the product. Different methods have been developed according to the incoming moisture structure and the place of use. Air drying, mechanical drying, indirect drying and direct drying techniques have been developed to remove water from the product. Drying process has been carried out by developing machines that work with these techniques. Flat bed, fluidized bed, rotary bed and vertical grain dryers have been developed considering the conditions such as the incoming grain type and the place of operation. Drying is provided by giving hot fluid to the product in these machines. Rice is in high humidity after harvest. It is important to remove this moisture quickly. Vertical mobile grain dryers that farmers can use have been developed for this purpose. An energy source is required for drying in these mobile machines. Fuel types used in grain dryers vary from traditional sources such as LPG and coal to alternative sources such as wood, coconut shells, pellets and renewable sources such as solar energy. When drying paddy rice harvested from the field with moisture above 20%, fuel selection can affect the efficiency, cost-effectiveness and environmental sustainability of the grain drying process.

ABSTRACT

Researchers who use artificial intelligence techniques in their studies have carried out academic studies by specifically incorporating machine learning, which is a sub-branch of this field, into their studies. In these studies, stereotyped algorithms in machine learning were generally used. The algorithms, models and methods used have tasks such as regression, classification, clustering and dimensionality reduction. Related studies vary depending on the area used and the needs. In this study, data about the algorithms, models, methods and usage amounts used in the publications published between 2019 and 2023, where the concept of machine learning is available in the DergiPark database, were processed and tables regarding the usage amounts were made, and a detailed comparison was made about how frequently the algorithms, models and methods were used in which areas. The method used in this study is to search for the specified keyword from the DergiPark database, download articles related to machine learning, scan them one by one, and record the algorithm numbers. Data were collected in three main areas: science, social and health. Science and social sciences are also divided into subfields. 692 articles were scanned: 273 articles in science, 259 articles in social sciences, and 160 articles in health sciences. 39 of these studies belong to the agricultural field. The algorithms used in studies in the field of agriculture are mainly of the supervised learning type, and deep learning has an important place in this field. The aim of the study is to shed light on which machine learning method can be used more efficiently for researchers in this field.

Keywords: Artificial Intelligence, Machine Learning, Agriculture, Data, Statistic

INTRODUCTION

Machine learning is not only an important decision tool for agriculture but also siding decisions on crop classification, performance on clustering crops, what crops to grow and what to do while supporting farms and villages around the country also detecting disease in plants, exploring smart agriculture, optimizing water management system and energy [1][2][3][4]. Several machine learning algorithms have been applied to support this field of prediction research. Machine learning methods, which are based on statistics, eliminate the limitations of statistical methods in analysis and provide researchers from all fields with the opportunity to perform more comprehensive and flexible analyses in today's abundance of data. But statistic ought to promote data of what artificial intelligence methods used in academy especially in agriculture. Today, the development of technology and the rapid increase in data sizes have caused different concepts to enter artificial intelligence field. These concepts vary according to their use cases and using frequencies. The penetration of information and communication technologies into almost every area of life and rapid technological developments trigger an increase in data sizes and types. For this reason, processing data is becoming more and more important every day to obtain meaningful and useful information from among data piles. In data analysis, statistics, which is the science of interpreting data and basing it on evidence, can limit researchers and be inadequate in the face of large-scale data sets. Although statistical methods are used in many fields, the concept of machine learning, which is based on statistical methods in data analysis, has emerged and enables process and analysis of different types of large-scale data, both structural and non-structural. Although machine learning and statistics serve similar goals, there are differences between them. Statistics, as a branch of science that examines the relationships between variables, analyzes the data set with various calculations and summarizes the findings, and generalizes the results obtained from the sample for the data mass. In this work, statistic helped us for making sense of where machine learning methods used. A literature review was conducted to create this study. A total of 692 sources written in Turkish and English including conference proceedings, articles published in DergiPark between 2019 and 2023, were examined. In the searches made on the DergiPark search engine, the keywords "Makine Öğrenmesi" were used and the results were scanned and sources that were found suitable for the study were examined. Figure 1 shows framework of survey.

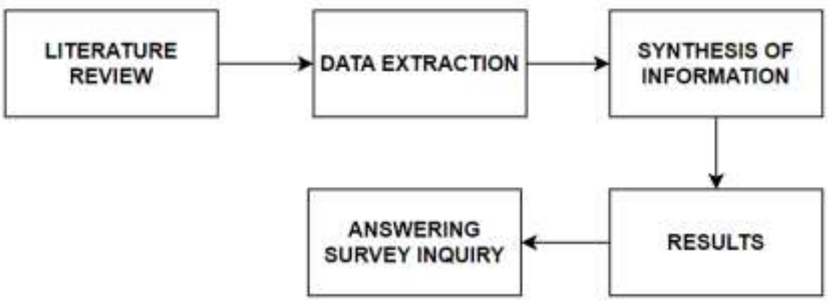

Figure 1. Framework of survey’s mechanism

MACHINE LEARNING

Machine learning, a sub-branch of artificial intelligence, uses statistics and computer processing power to detect patterns in complex data and make rational decisions [5]. Machine learning algorithms use a variety of statistical, probabilistic, and optimization methods to learn from past experiences and detect useful patterns in large, unstructured, and complex data sets.

In summary, machine learning is the modeling of systems that make inferences and predictions from data using statistical and mathematical operations, using computers [6]. Machine learning algorithms are divided into 3 groups according to the way they learn from data: Supervised, unsupervised and reinforcement learning. Supervised learning is a learning method that is performed by knowing what the results of the data inputs used in the algorithms will be when creating machine learning models. In other words, in this learning method, the input (Independent variables) and output (Dependent variable) are known. The outputs are the labels of the data. This type of learning is used in classification and regression algorithms. Unsupervised learning is a learning method in which the labels, that is, the classes, of the data are not known and models are created according to their similar features. In this learning method, there is only input. The algorithm creates the model without labels. Clustering and dimensionality reduction are examples of unsupervised learning. Reinforcement learning is the creation of a model by exposing and training an actor to the concepts of reward and punishment as a result of his actions. Optimization algorithms can be given as examples of this learning method. Deep learning is a form of learning that aims to make sense of the whole data with the help of layers of artificial neural network architecture created by taking the human brain as an example, taking into account the relationships of small pieces of data with each other.

Artificial Neural Networks

Artificial neural networks are a machine learning algorithm that mimics the idea of the working principle of the human brain. In this architecture, units called neurons process inputs according to the weights in the neurons and provide an output. Artificial neural networks are an excellent fault-tolerant and very fast architecture when processed in parallel. It extracts significant information from small relationships in the data [7].

Boosting Algorithms

Boosting algorithms are used in classification and regression architectures to improve the performance of the algorithm. This is done by updating the weights in each iteration. The process continues until the quality of the algorithm is optimized [8].

Convolutional Neural Networks

Convolutional neural networks are a special type of artificial neural networks. This architecture, which is generally used in image processing, is also used in natural language processing such as text processing. The most important feature of this architecture is that it allows the information to be used and summarized in the most efficient way with the help of the image grid structure [9].

Decision Trees

Decision trees are algorithms used in machine learning for classification tasks. They generally work with the divide and conquer logic. They can extract and reveal elements in large databases [10].

K-Means

The K-means algorithm is an unsupervised machine learning algorithm that clusters and classes unlabeled data based on Euclidean distance [11].

K Nearest Neighbor

K Nearest Neighbor is a supervised machine learning and data mining algorithm used in classification problems with its easy implementation and remarkable performance. The algorithm is the process of determining the closest input that is like the formed classes [12].

Linear Regression

Linear regression is a regression machine learning algorithm that consists of one dependent and one independent variable that is created as needed in models with ongoing continuous data [13].

Logistic Regression

Logistic regression is a supervised learning algorithm used in classification. The aim of the algorithm is to optimize a 2-class space and give appropriate outputs [14].

Naïve Bayes

Although it does not show much accuracy in real-world applications, it is a machine learning algorithm used in naive bayes classification, whose working logic is that the probability of an event occurring depends on the probability of any other event occurring [15].

Principal Component Analysis

Principal component analysis, namely, is an information extraction algorithm that works by changing the positions of the axes in the plane according to the situation in order to reveal important information in the data set on a certain plane [16].

Random Forest

Random forest is a powerful machine learning algorithm used in classification problems where the judgment of multiple decision trees is used in cases where there are unobservable variables in the environment [17].

Recurrent Neural Network

Recurrent neural network, as its name suggests, is a deep learning architecture used in situations where repetitive data is the issue. Repetitive data refers to structures such as time series and text data [18].

Sequential Minimal Optimization

The Sequential Minimal Optimization algorithm is a machine learning algorithm used specifically to improve the performance of support vector machines [19].

Support Vector Machines

Support vector machines are a popular algorithm that is often mentioned among classification algorithms, especially in cases where binary classes are present. The flexibility in the algorithm has made it possible to adapt to many situations. In this way, it plays an important role not only in binary classification but also in other classifications [20].

SOME STUDIES CONDUCTED IN DERGİPARK

Agricultural product pattern detection was performed in the Çivril-Baklan Plain within the borders of Çivril, Baklan and Çal districts of Denizli province, using 2020 Sentinel-2 satellite images and the python-based open source Eo-Learn library within Light Gradient-Boosting algorithm [21].

Tree Seed Algorithm is applied to clustering problems and the obtained results are compared with the traditional methods widely used in clustering process. It has been shown that Tree Seed Algorithm provides better search locally and globally thanks to its exploration and processing characteristics and can reach better results than the results achieved by traditional clustering methods [22].

The impacts of some environmental element on the weaning weights of Awassi lambs were examined as prediction was made by the regression decision tree method, that is one of the machine learning algorithms [23].

River flow data from consecutive flow monitor stations in the Eastern Mediterranean Basin and Seyhan Basin located on the same river routeing were used. In the literature, there are various previous step numbers in the input parameters as time series, and it was determined that the inputs of 6 months and earlier did not create much difference in the results compared to the previous model evaluations [24].

ANFIS method, one of the machine learning methods, was used to estimate the amount of sunflower production. To increase the finding out ability of the ANFIS model, the membership function numbers of the input variables were determined with the K-means algorithm [25].

Genotype yield estimates were made using regression-based algorithms within machine learning methods, using yield information of the genotypes used in the 2018 barley breeding program, collected from 12 different locations in 24 genotypes with 4 replications [26].

A deep feature extraction and machine learning based method was developed to detect diseases on plant leaves. To test the proposed method, 726 images of walnut leaves and a two-class dataset were collected. Feature extraction was performed on the images with DarkNet53 and ResNet101 models. The obtained features were combined, and the most weighted features were selected with the ReliefF algorithm. The selected features were classified with the SVM algorithm [27].

Data from 54 calves, 70% of which is the training set and 30% of which is the test set, was used with the artificial neural network. Illative of the analysis, the highest correct classification rate of diseased and healthy calves was calculated using the artificial neural network method [28].

Performance of 3 distinct algorithms for machine learning was measured from raisin images and morphological features extracted from these resulting images [29].

Histogram Based Gradient Augmentation and Support Vector Machine were applied in regression analyses for yield estimation [30].

Models for predicting soil moisture, which plays an important role in agricultural practice, were introduced. The accuracy of these models was compared using the coefficient of determination and the mean square error. The data acquired from the system enhanced for 55 days is used to train and test the models. The algorithms of multiple linear regression, polynomial regression, support vector regression, decision tree regression and random forest regression were used for estimation [31].

A convolutional network model was built from ground up and it was trained to conduct the required detection of plant diseases in the given set of classes. It was showed that the model has better classification capability than previous models [32].

The aim was to model the drying behavior of an organomineral fertilizer, which is one of the most important problems in the agricultural industry. Not only regression, but also the performances of multilayer perceptron and long short-term memory models were investigated. As a regression method, exponential function was used. In addition, Gaussian regression based on artificial neural network with covariance kernel function was also investigated [33].

The use of multitemporal Polarimetric Synthetic Aperture Radar images in the classification of agricultural products was investigated and the classification performances of machine learning algorithms used for this purpose were compared. Although the highest classification accuracy was obtained with the Light Gradient-Boosting Machine algorithm, it was observed that the difference between it and the random forest algorithm was not statistically significant [34].

In order to determine the land cover change in Kocaeli province due to urbanization and agricultural activities within the framework of dynamic change determination according to LandCover 2.0 standards, multi-temporal Sentinel 2 satellite images were used to comparatively evaluate the performance of four different data reduction - classification method combinations, namely, Location Index-Random Forest, Principal Component Analysis-

Random Forest, Location Index-Regression Tree and Principal Component Analysis-Regression Tree [35].
An approach based on the Faster Local-Convolutional Neural Networks model of deep learning has been proposed for the identification of cattle based on their facial images. As a result of experimental studies conducted on the test dataset, a classification performance of 98.44% accuracy has been achieved [36].
Classification was performed using a publicly available dataset containing 5 flower classes consisting of 4317 flower images, using deep learning methods and feature selection methods together [37].
The Dynamic Water Budget model modeled the basin rainfall-runoff relationship, which the conceptual rainfall-runoff model simulated through various parameters, more reliably in both calibration and validation periods compared to the Support Vector Regression based machine learning model [38].
The performances of the new generation ensemble learning algorithms XGBoost and LightGBM in the classification of agricultural products were compared. This performance comparison was made based on both model accuracy and processing time. Our experimental results concluded that the LightGBM method is superior to the XGBoost method in the classification of agricultural products [39].
Models were developed to estimate the breast diameter using the stump diameter value of stone pine, an important forest tree species, to be used within the administrative borders of the Izmir Regional Directorate of Forestry. The equations defining the relationship were obtained using the regression analysis method. The data set consists of measurement values obtained from 266 sample trees [40].
An image processing system was designed to discriminate among two different raisin varieties cultivated in Turkey. The collected images were applied to different pre-processing steps and 7 feature extraction morphological operations were conducted using image processing techniques. Using logistic regression, multilayer perceptron and machine learning with support vectors, models were constructed, and performance measurements were made [41].
The classification of apricot kernels as bitter and sweet was done using image processing and machine learning algorithms. The results obtained using seven different machine learning algorithms were compared [42].

ALGORITHMS ACCORDING TO USE CASE

The algorithms used in the studies vary according to their tasks and the type of data set. Recently popular deep learning architecture and support vector machines, which are frequently used in classification problems, have come to the forefront in terms of frequency of use. Classification is a type of supervised learning used especially when product and soil diversity come to the fore. They were followed by regression algorithms. Regression architecture has come to the fore in problems where various hybrid algorithms are used. Regression was used in problems where water regimes and production tracking were made according to years. Collecting and classifying agricultural data is not an easy task. For this reason, unsupervised learning methods used in machine learning cope with this task. In the studies in this article, clustering algorithms were used, although in small numbers. Figure 2 shows usage tasks according to the types of mentioned algorithms. Figure 3 shows distribution of machine learning methods used in studies conducted in the field of agriculture between 2019 and 2023 in DergiPark according to their count of use.

Figure 2. Usage tasks according to the types of mentioned algorithms

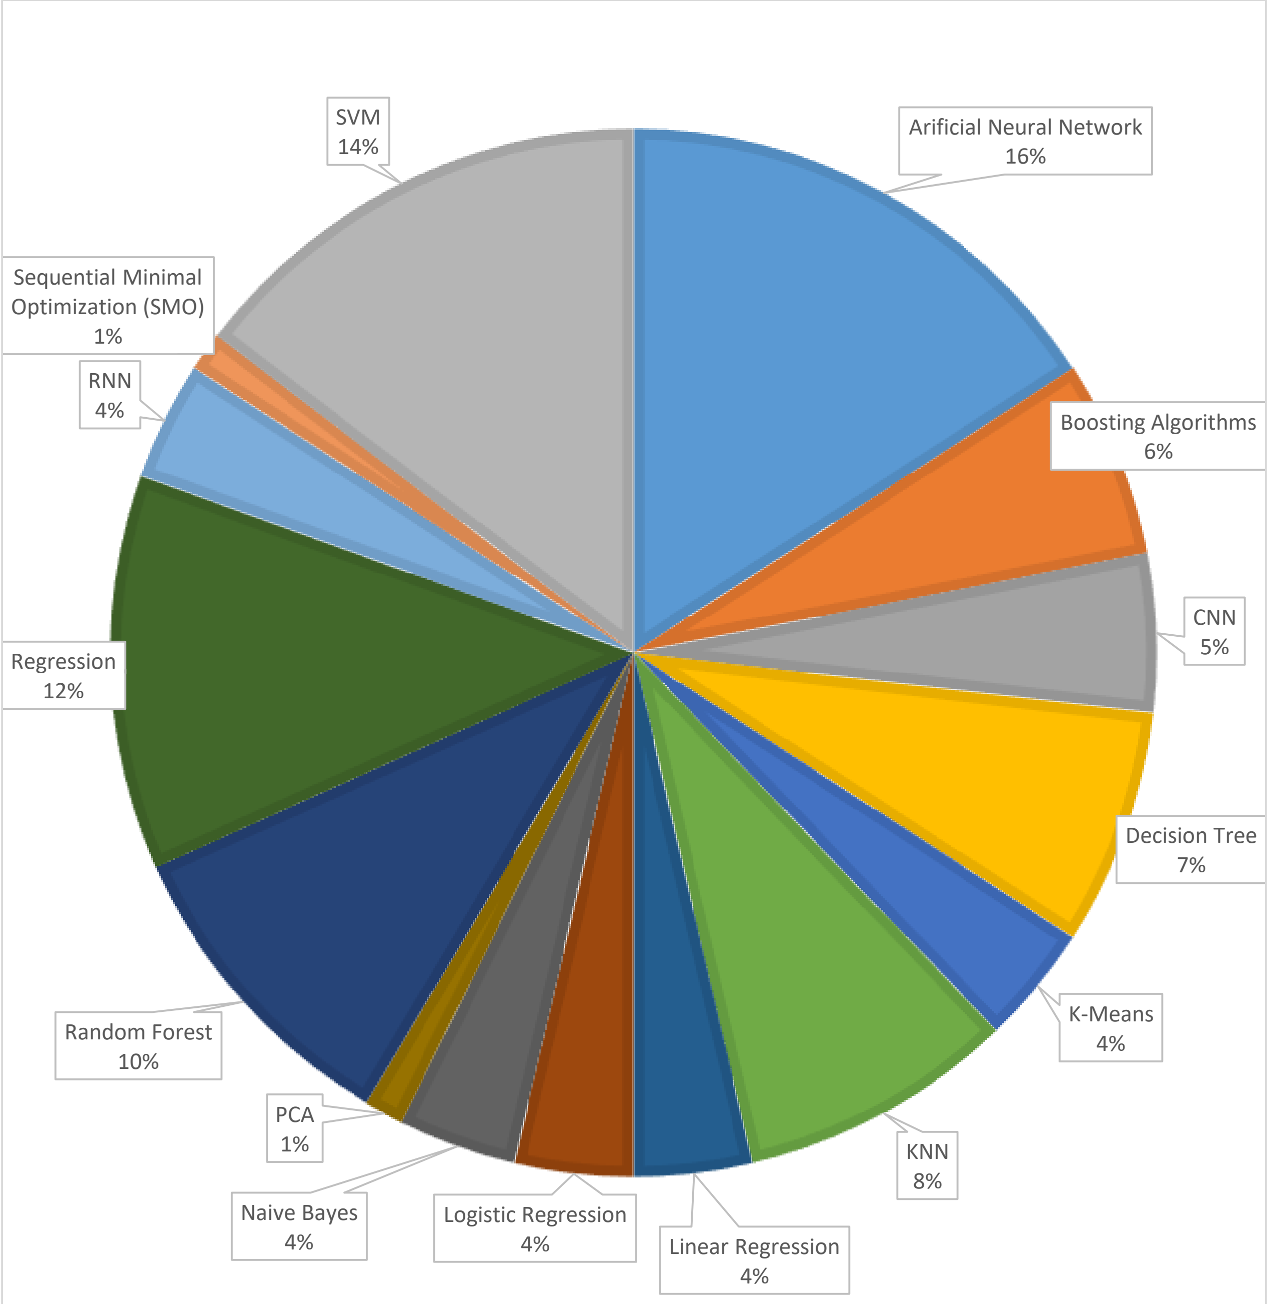

Figure 3. Distribution of Machine Learning Methods Used in Studies Conducted in the Field of Agriculture Between 2019 and 2023 in DergiPark According to Their Count of Use [21], [22], [23], [24], [25], [26], [27], [28], [29], [30], [31], [32], [33], [34], [35], [36], [37], [38], [40], [41], [42], [43], [44], [45], [46], [47], [48], [49], [50], [51], [52], [53], [54], [55], [56], [57], [58], [59]

CONCLUSION

In the study, it was seen that 95% of the methods used in the field of agriculture fall into the supervised learning class. Only 5% of them worked in this field using unlabeled data. The reason why supervised learning methods are preferred depends on the type of problem selected, the performance and consistency criteria being significantly higher in these machine learning methods, and the type of data used. In future, with arrival of 5G and IoT technologies to Turkey machine learning should be utilized much more effectively in agriculture. It will impact the economy of the country.

ABSTRACT

In the field of machine learning, the sequential processing technique used especially in natural language processing and the attention mechanism, which has become popular recently, direct the sector and the world of informatics. These two techniques have become even more important with their transformer and space state model architectures. Space state models also appear in finance, signal processing, and control systems. The strong prediction of the converter architecture and its resistance to long-term dependency when used, as well as the dynamic operation and speed of the space state models depending on the variables of the system, play a major role in this regard. Although these architectures are important in the field of natural language processing, they have also been used in science where sequential processing is important, such as bioinformatics. In this study, technical information about the architectures and the studies in the literature are given by comparing these two architectures, which are used in many fields.

Keywords: Machine Learning, Transformers, Space State Models, Sequential Processing

INTRODUCTION

Natural Language Processing (NLP) stands as a pivotal technology in the realm of computer science and artificial intelligence, aiming to bridge the communication gap between humans and machines by enabling computers to evaluate, interpret, and generate human language. Its significance spans various fields, underlining its versatility and critical role in advancing human-computer interaction. In the domain of natural language understanding, NLP facilitates the comprehension of complex language structures, allowing for the extraction of insights and actions, which is essential for artificial intelligence applications. This understanding is foundational for tasks such as text classification, named entity recognition, and language modeling, showcasing NLP's ability to parse and make sense of human language in a way that computers can process [1]. Machine translation exemplifies another vital application of NLP, breaking language barriers by translating text or speech from one language to another. This capability not only enhances communication across different language speakers but also supports global accessibility of information, making it indispensable in today's interconnected world [2], [3]. NLP is crucial for, healthcare, finance, and agriculture, among other fields, demonstrating its broad utility in understanding and responding to human and system interactions [4]. Overall, the significance of NLP across natural language understanding, machine translation, and sentiment analysis underscores its role in automating and enhancing interactions between humans and machines. By processing and generating human language, NLP not only facilitates more natural communication with computers but also supports decision-making and strategy development across diverse sectors[5].

Recent advancements in language processing, powered by deep learning, have been significantly influenced by the introduction and evolution of Transformer models. These models, originally developed for natural language processing (NLP), have revolutionized the field by leveraging self-attention mechanisms to process variable-length input sequences in parallel, capturing long-range dependencies more effectively than previous architectures[6]. This capability has led to their dominance in almost all NLP tasks, despite occasional errors that necessitate ongoing refinement and adaptation in industrial applications. Transformers have not only excelled in traditional NLP tasks but have also found applications in bioinformatics, particularly in proteomics, where they are used to predict protein properties from sequenced proteins, bridging the gap between the vast number of sequenced proteins and those with known properties[7], [8]. This application is part of a broader computational revolution in biology, where Transformer models are used to improve predictions and understandings of protein characteristics, including post-translational modifications. Beyond biology, Transformer models have been adapted for remote sensing image analysis, replacing conventional convolution operators with self-attention mechanisms to capture long-range dependencies in very high-resolution (VHR), hyperspectral (HSI), and synthetic aperture radar (SAR) imagery[9], [10]. This adaptation underscores the versatility of Transformer models across different domains. In the clinical domain, Transformer-based models have been applied to extract and structure information from radiology reports, outperforming previous deep learning models based on artificial neural networks (ANN) and convolutional neural networks (CNN)[11]. Additionally, the development of specialized models like TIS Transformer demonstrates the potential of deep learning techniques, originally designed for NLP, to learn the semantics of biological processes such as translation initiation site determination, further advancing our understanding of the proteome[12]. Moreover, the hardware acceleration of Transformer models addresses the computational challenges posed by their large size and the intensive memory requirements, showcasing significant improvements in latency and energy consumption over traditional deep neural network accelerators. This technological advancement supports the broader adoption and application of Transformer models across various fields. Finally, the transformative potential of Transformer language models (TLMs) extends to business and societal applications, where they are poised to enable new research topics and applications in information systems (IS), offering superior performance for a wide range of tasks and applications. This broad applicability and ongoing innovation underscore the significant impact of Transformer models on the field of deep learning and language processing.

Encoder-decoder architectures paired with attention mechanisms, as exemplified in Transformer models, and State Space Models (SSMs) represent two distinct methodologies for modeling sequential data. The former is composed of an encoder and a decoder that operate by processing input sequences in a sequential manner and generating output sequences with concurrent attention mechanisms, rendering them well-suited for applications such as machine translation. Conversely, SSMs explicitly characterize temporal dependencies through the formulation of hidden state evolution equations, showcasing proficiency in tasks like time-series analysis. Encoder-decoder architectures center on the acquisition of contextual information and the independent processing of input-output pairs, whereas SSMs prioritize the representation of temporal dynamics and sequential dependencies, often necessitating training techniques such as maximum likelihood estimation or Bayesian inference. These disparities underscore the unique capabilities of each approach in managing various forms of sequential data and diverse application domains. General features of the two architectures are shown in Figure 1.

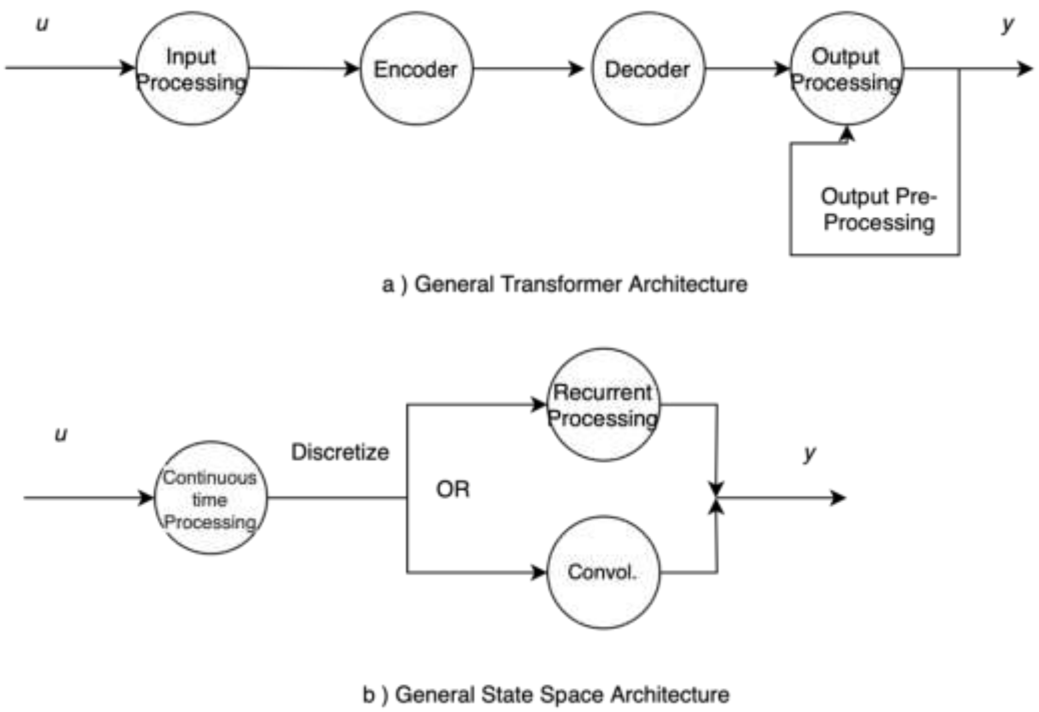

Figure 1. General structures of Transformers and State Space Models

BACKGROUND

In language processing, powered by deep learning, have seen significant contributions from the development and application of State Space Models (SSMs). These models have demonstrated state-of-the-art sequence modeling performance, challenging traditional sequence models like RNNs, CNNs, and even Transformers in some aspects. The introduction of the S4 model, which utilizes a HiPPO matrix for effectively managing long-range dependencies, marked a pivotal advancement in the use of SSMs for deep learning layers, showcasing their potential in handling complex tasks involving temporal sequences [13]. Despite their linear scalability with sequence length, which is a notable advantage over the quadratic scaling of Transformers, SSMs initially faced challenges in hardware utilization and expressivity in language modeling tasks [14]. To bridge the expressivity gap between SSMs and attention mechanisms in language modeling, new SSM layers like H3 have been proposed. These layers are designed to enhance the model's ability to recall earlier tokens and compare tokens across sequences, thereby improving performance on synthetic language tasks and coming close to matching Transformers on benchmarks like OpenWebText[15]. Furthermore, advancements in training efficiency, such as the introduction of FlashConv, have significantly improved the speed of SSM-based models, enabling them to outperform Transformers in certain scenarios [16]. Deep learning's impact on natural language processing (NLP) extends beyond SSMs, with neural network-based methods setting new performance benchmarks across a range of tasks, including speech recognition, language modeling, and semantic parsing [17]. The integration of deep variational Bayes filters and probabilistic modeling with SSMs has further enhanced the ability to learn complex, latent Markovian state space models, enabling unsupervised learning and identification of intricate patterns in data. Moreover, the exploration of deep neural network language models (DNN LMs) has shown promising improvements over traditional single-layer neural network language models (NNLMs), capturing higher-level discriminative information that contributes to more effective language models [18]. End-to-end models based on deep neural networks, including recurrent neural networks (RNNs) and attention-based encoder-decoder RNNs, have also gained popularity for their ability to process spoken language without the need for time alignment between input and output sequences, presenting a viable alternative to hybrid HMM-DNN systems [19]. In summary, the recent advancements in language processing enabled by deep learning, particularly through the development and application of state space models, have significantly pushed the boundaries of what's possible in NLP, offering improvements in efficiency, expressivity, and overall performance across a variety of tasks [20].

The advancements in sequence modeling through the introduction of the Mamba and Jamba algorithms, as inferred from the provided contexts, focus on addressing the limitations of traditional State Space Models (SSMs) and enhancing their performance in various sequence modeling tasks. One significant improvement is the development of models that efficiently handle long-form video understanding by selectively focusing on informative image tokens, thereby enhancing accuracy and reducing memory requirements. This approach, exemplified by the Selective S4 (S5) model, demonstrates a novel way of adaptively selecting image tokens to model long-term spatiotemporal dependencies more efficiently and accurately[21]. Similarly, advancements in language modeling have been made by addressing the expressivity gap between SSMs and attention mechanisms, with new SSM layers designed to recall earlier tokens and compare tokens across sequences, thereby closely matching the performance of attention-based models [22]. Further, the integration of Hamiltonian Monte Carlo (HMC) sampling with Sequential Monte Carlo (SMC) methods in nonlinear SSMs represents a significant leap in reducing model complexity and improving the adaptability to the local geometry of latent space. Additionally, the Sparse Modular Activation (SMA) mechanism introduces a way to dynamically activate sub-modules in neural networks, optimizing computation and memory usage during sequence modeling [23]. Moreover, the application of SSMs to machine translation highlighted the necessity of incorporating attention mechanisms to address S4's limitations in summarizing full source sentence. These advancements collectively underscore a trend towards more efficient, accurate, and flexible sequence modeling techniques, potentially indicative of the theoretical contributions of the Mamba and Jamba algorithms in enhancing selective state space models.

COMPARATIVE ANALYSIS

Transformers and State Space Models (SSMs) have been pivotal in advancing sequential modeling, each demonstrating unique strengths and limitations across various tasks. Transformers, renowned for their self-attention mechanism, have significantly impacted fields like speech recognition and natural language processing (NLP), outperforming Recurrent Neural Networks (RNNs) in accuracy and efficiency for sequence-to-sequence tasks such as automatic speech recognition. Their ability to approximate sequential relationships has been theoretically validated, showcasing their adaptability to different types of sequence modeling applications[24]. However, the quadratic computational cost associated with their attention mechanism poses limitations for processing long sequences [13]. On the other hand, SSMs, originally designed for continuous signals, excel in modeling long-range dependencies with sub quadratic runtime complexity, making them efficient for long sequences [25], [26]. Despite their scalability and efficiency, SSMs have struggled to match the performance of Transformers in language modeling tasks due to challenges in recalling earlier tokens and comparing tokens across sequences [27]. This gap is attributed to SSMs' underperformance in tasks requiring intricate local information processing, a domain where Transformers excel [28].

Recent advancements have aimed at bridging the gap between these models. The introduction of hybrid models, such as the Block-State Transformer (BST) and SPADE, combines the strengths of both SSMs and Transformers, leveraging SSMs for efficient long-range contextualization and Transformers for local sequence representation. These hybrid models have shown promising results, outperforming traditional Transformer architectures in language modeling perplexity and demonstrating superior speed and efficiency. Furthermore, innovations like FlashConv and the H3 layer have improved SSMs' hardware utilization and their ability to recall and compare tokens, narrowing the performance gap with Transformers in language modeling tasks. In summary, while Transformers excel in processing complex local information with high accuracy, their efficiency diminishes with longer sequences. SSMs, optimized for long sequences, have evolved through hybrid models and algorithmic improvements, offering competitive alternatives that combine the best of both worlds.

When the characteristics of Transformers and SSMs are compared, the main areas of use are similar. However, the tokenization approach, which is frequently used in natural language processing, is not used in SSMs, which may be an advantage here. However, although SSMs were not originally designed for natural language processing, they are quite successful in sequential data processing. The general characteristics of the two methods are shown in Table 1.

Table 1. characteristics of the Transformers and State Space Models

Transformers	State Space Models
Designed for sequential data	Designed for modeling dynamic systems
Self-attention mechanism	Markovian or non-Markovian dependencies
Parallel computation	Sequential computation
Effective for long-range dependencies	Effective for capturing system dynamics
Requires tokenization of input data	No explicit tokenization necessary
Commonly used in NLP tasks	Widely used in control systems, finance, signal processing, etc.

DISCUSSION

In general, the areas where both methods are used are similar. However, the recently emerging strengths of SSMs are thought to offer potential, especially in the field of bioinformatics. Integrating State Space Models (SSMs) in sequential modeling within the bioinformatics domain can significantly enhance the analysis and prediction of biological sequences, leveraging the strengths of SSMs in handling long-range dependencies and complex data structures. The S4 and S5 layers, as discussed by Jimmy Smith, Andrew Warrington, and Scott W. Linderman, demonstrate state-of-the-art performance in long-range sequence modeling by combining linear SSMs with deep learning, which could be particularly beneficial for modeling the sequential nature of genetic information and protein structures[29]. These models, especially the S5 layer with its multi-input, multi-output SSM, offer a promising framework for bioinformatics applications by efficiently handling sequences with long dependencies [30]. The Bayesian framework for filtering and parameter estimation, as explored in various studies, addresses the challenges of incomplete and noisy observations common in bioinformatics data, such as gene expression time series [31]. This approach, which avoids particle degeneracy and exploits low-rank tensor structures, could be adapted for more accurate modeling of biological systems [32]. Sequential Monte Carlo (SMC) sampling, highlighted by Mario V. Wüthrich, provides a powerful tool for solving non-linear and non-Gaussian state space models, which are prevalent in bioinformatics due to the complex and stochastic nature of biological processes. The integration of SMC methods with state-space models offers a robust framework for sequential analysis in bioinformatics [33]. Furthermore, the development of new sequential learning methods that exploit low-rank tensor-train decompositions for joint parameter and state estimation under the Bayesian framework, as discussed by Yiran Zhao and Tiangang Cui, introduces scalable function approximation tools that could significantly benefit bioinformatics applications by providing accurate and computationally efficient solutions [34].

ABSTRACT

The estimation of ore resources in a deposit was traditionally done using conventional methods, but with the development of mining geostatistics from the 1970s onwards, geostatistical methods became favored. These geostatistical methods were applied to the Chaabat El Ballout deposit, for which a specific approach was proposed.The iron deposit of Chaabat El Ballout is located northeast of the city of Souk Ahras. This deposit belongs to the Sellaoua scales zone. Geological studies conducted as part of this thesis revealed a duplex structure. The estimation of iron resources was initially done using vertical geological cross-section methods by EREM. These resources were re-estimated using ordinary kriging geostatistical methods, taking into account the duplex structure. The variograms of the 'thickness of the mineralization-bearing horizon' (EHP) and the 'mineralization coefficient' (CM) show the same zonal anisotropy, where the major axis has a direction of N160° and the minor axis has a direction of N70°. Directional variograms in these two directions were adjusted using spherical models. The direction of the major axis of anisotropy corresponds to that of the thrust direction. The results of estimations using geostatistical methods were compared to those obtained by conventional methods. The large discrepancy between the resources estimated by conventional methods and those obtained by ordinary kriging is surely due to the discontinuity of the mineralization: The mineralization is regular in the horizontal plane but discontinuous in the vertical plane due to the duplex structure. The mineralization coefficient was calculated in the vertical plane and was taken into account for correcting the resource estimates. Thus, to optimize the estimation of ore resources in breccia-type deposits using geostatistical methods, it is necessary to consider mineralization coefficients that resemble a probability coefficient."

Keywords: Iron deposit, Geostatistical estimation, mineralization coefficient.

INTRODOCTION

The Chaabat El Balout iron deposit is located in the northeastern part of Algeria, 20 km northeast of the city of Souk Ahras (Fig. 1). It consists of several discontinuous bodies and is mined to meet the needs of the local industry. Hence, there is a need to characterize them geologically and to find optimal methods for resource/reserve estimation.

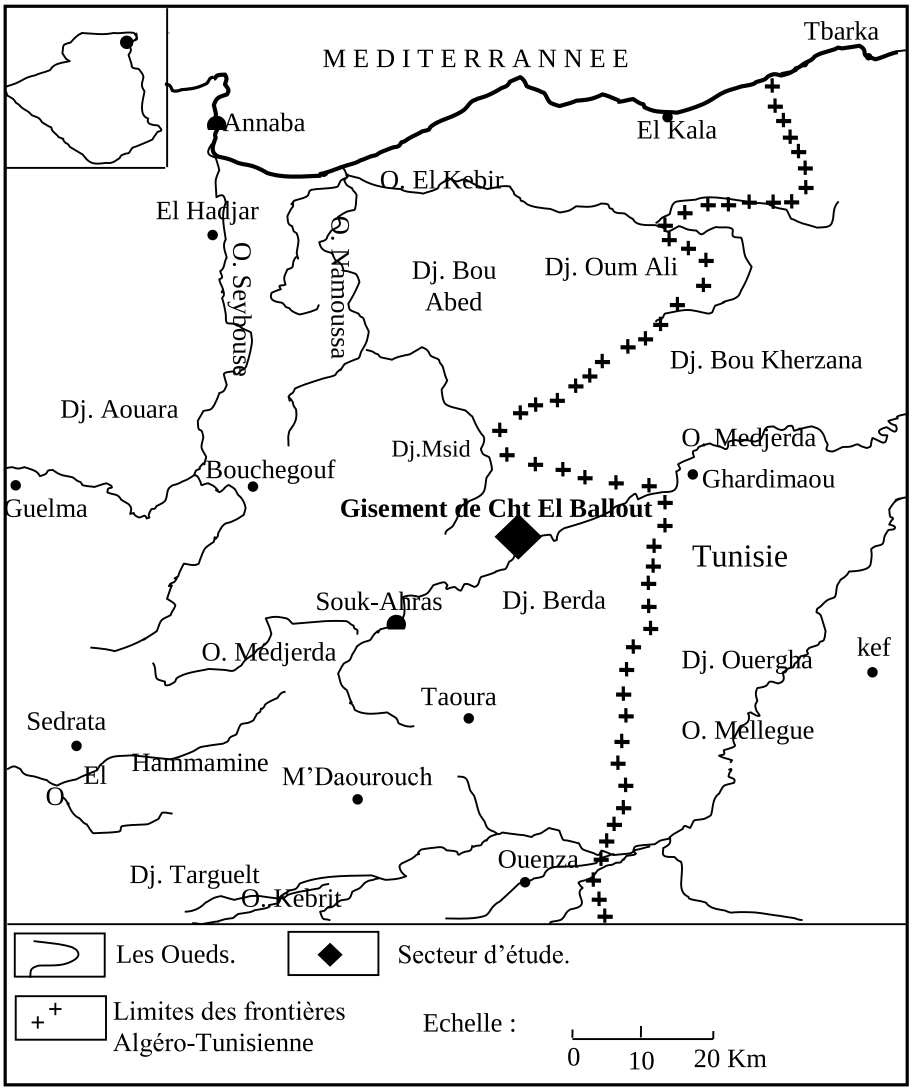

Figure 1. Geographical location of the Chaabet El Ballout iron deposit.

MATERIAL AND METHOD

The geological study of the region was conducted by David (1956), Kouzmine (1990), and Kriviakine et al. (1990).The deposit consists of upper Cretaceous age formations, lower Miocene and Quaternary. The ore body consists of a grinding zone with a thickness of 45 m and direction North West-South East (Fig. 2). This ore body plunges in depth with a dip of 30 ° to the southwest. The roof of this body is made of limestone while the wall is made up of sandstone and marl Miocene.

Geological cross-sections have been carried out, and among these sections (Fig.3), those conducted along the NW-SE direction show overlapping imbricate structures—duplexes (Boyer et al., 1982; Mitra et al., 1986).

These major thrusts generally correspond to detachment faults and are connected by several ramps—at least three—that define rock volumes (Fig. 3). In the Chaabet El Ballout deposit, the base of these duplex structures is composed of marls (Fig. 3). According to these cross-sections, the direction of the thrust is NW-SE, as proposed by Kriviakine et al. (1990). The variographic study was conducted using the Variowin software Pannatier (1996). The study was conducted on 240 core samples taken from 38 exploration holes. These samples were analyzed-On FeO, CaO, SiO_2.

The estimation of resources using the geostatistical method includes the following steps:

- Calculate the mineralization coefficient in the vertical plane.
- Calculate the thickness of the ore.
- Calculate the thickness of the mineralization-bearing horizon.
- Perform a 2D FeO variography.
- Kriging and, finally, resource/reserve estimation.

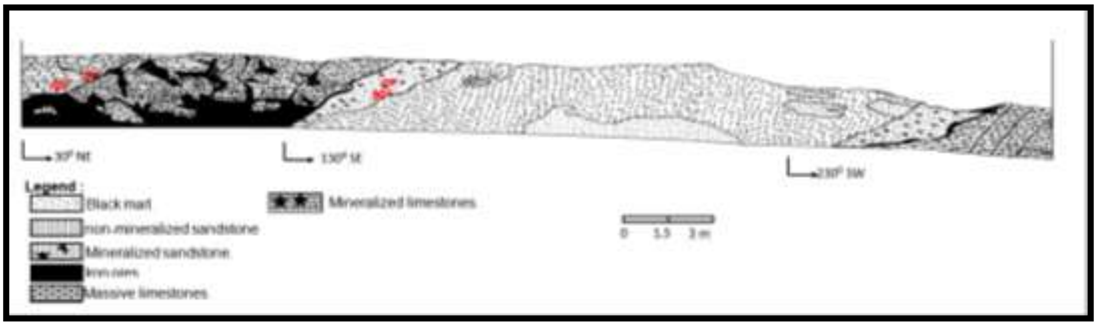

Figure 2. Geology career front bench N° :1020m.

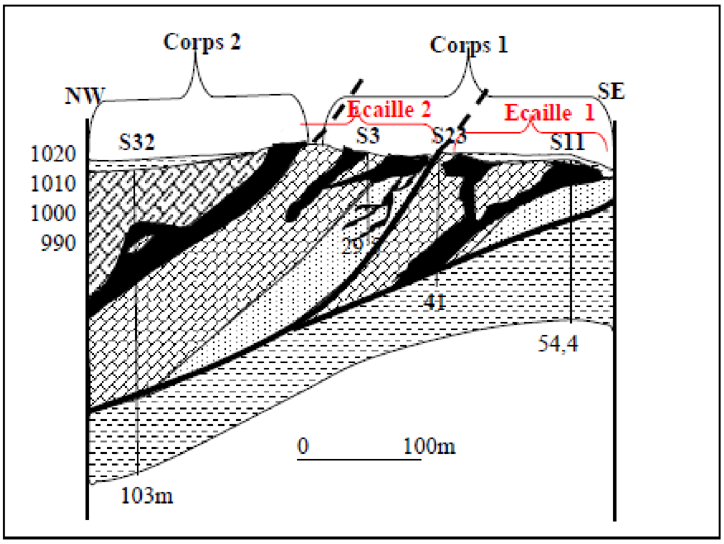

Figure 3. Geological cross-section along the NW-SE line

RESULTS AND DISCUSSION

The surface variograms (Fig. 4, 5) and directional experimental variograms of the regionalized variables—thickness of the mineralization-bearing horizon and mineralization coefficient (MC)—have been calculated and fitted (Fig. 6, 7) (Table 1).

The variograms of the thickness of the mineralization-bearing horizon(MBH) (Fig. 6) and the mineralization coefficient (Fig. 7) show zonal anisotropy, where the major axis is oriented N160° and the minor axis is oriented N70°.

Ordinary kriging was performed using the software Surfer08. Initially, the mean values of the regionalized variables EHP and CM, from 20x20m² surface blocks (Table 3), were kriged.

In the second phase, the mineralized thickness (MTH) was calculated using the following formula:
$MTH= MC_{krg}xTMTH_{krg}$

Where:

- MTH: The mineralized thickness of the (20x20m²) block;
- MCkrg: The kriged mineralization coefficient;
- TMTHkrg: The kriged total mineralized thickness.

- **Resource Estimation**

The estimation of iron ore resources for each block was done by multiplying the kriged variables MTH and CM by the block area (20x20m²) and the bulk density:
$Q_{minerai}$= MBH x CM x D x (20x20)
Given that MTH = MBH × CM, then Qore= MTH x D x (20x20)
Where:

- **D**: The bulk density.

At the Châabet El Ballout deposit, there are 5.6 million tonnes of mineralized rock containing 1.9 million tonnes of iron ore (Table 4).

- **Cartographie**

		Total=165	31.20	5595946.70			Total=165	12.29	1923822.60

CONCLUSIONS

The cross-sections show that the direction of the overlap is NW–SE, as proposed by Kriviakine et al. (1990). The grinding zone of the overlap (under the cover) may be confused with a stratiform layer.

The structural study of the deposit has clarified the orientation of the exploration profiles. These profiles should be perpendicular to the structure, thus oriented in the Southwest–Northeast direction.

The variograms for the thickness of the mineralization-bearing horizon (MBH) and the mineralization coefficient (MC) were fitted using spherical models. The direction of the major axis of anisotropy corresponds to the direction of the overlap.

At the Chaabet El Ballout deposit, there are 1.9 million tonnes of iron ore contained within 5.6 million tonnes of mineralized limestone, sandstone, and marl.

For optimizing the estimation of breccia ore resources using geostatistical methods, it is necessary to account for the mineralization coefficients, which are akin to a probability coefficient.

ENGINEERING PROPERTIES AND DETERIORATION OF IGNIMBRITES FROM WHICH KUŞKAYASI ROCK TOMBS WERE OPENED

Mustafa Korkanç

Niğde Ömer Halisdemir University, Faculty of Engineering, Department of Geological Engineering, Niğde, Turkey

Corresponding author e-mail: mkorkanc@ohu.edu.tr

ABSTRACT

The rock tombs subject to the research are in Karaatlı Town of Niğde Province Central District. There are 15 rock tombs located in the southwest of the town, 11 on the southern slope of the valley and 4 on the northern slope. The rock tombs, about which not much information can be found, were opened on ignimbrite rock masses, one of which is different from the others. The tombs located on the southern slope of the valley are more numerous, and the two-story large tomb is also located in this region. The rock tombs subject to the research continue to be subject to significant damage by treasure hunters, as well as deterioration caused by atmospheric effects. Block sample collection was carried out in order to determine the engineering properties of the ignimbrites where the tombs were found. Powder, fragment and core samples were prepared for various studies in the laboratory, and then the chemical, petrographic and geomechanical properties of the rock were determined. Due to the weak rock properties of tuff and ignimbrite type rocks and their easy excavation, there are many underground rock structures in Cappadocia region for different purposes. Rock tombs are also Late Roman Period structures and no research or definitions have been encountered other than their registration. In detailed research, the tombs opened in various sizes along the two slopes of the valley within the ignimbrites are empty and some of the tombs abandoned to neglect continue to be damaged by illegal treasure hunters every passing day. In order to provide a basis for studies to be carried out on the protection of such structures and their transfer to future generations, the engineering properties and deterioration of the rock in which the tombs were opened were tried to be determined within the scope of this study.

Keywords: Rock tomb, Ignimbrite, Petrographic properties, Engineering properties, Deterioration

INTRODUCTION

Rock tombs are known as tombs built for high-status individuals by many civilizations, in rock environments suitable for carving and processing. These structures are directly proportional to the development of the civilization. There are examples with very variable dimensions and aesthetic features in the world. No findings such as inscriptions or special reliefs that could help with dating were found in the examined rock tombs. There is no scientific study on the structures of the region so far. The engineering properties of the rock in which these tombs were opened constitute the subject of this study. Atmospheric weathering processes (such as freezing-thawing, wetting-drying and salt crystallization) primarily cause the crystals and minerals of the rock to decompose. As a result of the intense effects of these processes, different weathering types ranging from mm to m can develop. These effects can have more destructive results in rocks with low strength and high porosity properties such as tuff and ignimbrite. Especially in winter periods, such as Central Anatolia, the freezing of water and the expansion of its volume cause the existing intra-rock pores to increase (Fener and İnce, 2015). As this process progresses, cracks develop in the rock as a result of increasing pore volume, and integrity losses occur. In the studies on monuments and historical structures from past to present, weathering has been stated to be directly related to atmospheric actions (İpekoğlu et al. 2007; Korkanç 2013; Brimblecombe 2014), precipitation affecting the structure, groundwater (Sandrolini and Franzoni 2006; Fener and İnce 2015), petro-mechanics (Uchida et al. 2000) and hydraulics (Benavente et al. 2007) characteristics of the rock.

In this study, the rock material properties of the ignimbrites opened in the Karaatlı Rock Tombs, which are thought to belong to the Late Roman Period and about which no study has been done so far other than being registered, were investigated with laboratory and on-site non-destructive tests. It is expected that such studies will form the basis for future conservation studies.

MATERIALS AND METHOD

The rock tombs that are the subject of this study are in Karaatlı Town of Merkez District of Niğde Province. The rock tombs, which are also located in the southwest of the town, are located on two slopes of a valley. There are 15 tombs, 11 on the southern slope of the valley and 4 on the northern slope. There are kline inside these tombs that resemble each other. There are figures of dogs chasing mountain goats made with ochre in one tomb. There are holes like blind windows on the entrance doors of all of these rock tombs. Stylized human figures are carved in relief on the right and left of these doors (Niğde, 2007). The material properties of the rock unit where the tombs were opened were examined with Schmidt hardness hammer studies applied in the laboratory and on-site. Representative block samples were collected from the field for laboratory studies. Later, powder, fragment and core samples were prepared from these blocks according to the principles specified in ISRM (2007). According to the methods suggested in ISRM (2007) and TSE 699 (2009), dry and saturated unit volume weight, water absorption by weight, apparent porosity, capillary water absorption, P-wave velocity, Böhme wear repair and uniaxial pressure tests were performed in order to determine the geomechanical properties of the examined rock. In addition, the petrographic properties of the rock were determined by examining the prepared thin sections under optical microscope, and the main element contents were determined from the powder samples using the ICP-AES method.

The types of deterioration observed in the monument were classified according to the principles defined in ICOMOS (2008).

RESULTS AND DISCUSSIONS

Observations on rock tombs

Detailed field research has been conducted on the structure, which has no detailed research on it other than being registered in the literature. There are many underground structures in rocks such as tuff and ignimbrites, which are widespread in the Cappadocia region. These rocks were chosen because they are easy to process and on the surface. The rock tombs in the region have been opened in various sizes along the two slopes of the valley, and some of the tombs, which are empty and neglected, are still being destroyed by illegal treasure hunters. The rock tombs, about which not much information can be found, have been opened on ignimbrite masses, and one is different from the others. The other tombs have similar characteristics and are of similar sizes. The tombs on the eastern slope of the valley are more numerous, and the large tomb, which has two floors, is on the eastern slope.

Engineering properties of the ignimbrite samples

The main element contents of the examined samples were carried out with the ICP-AES method and the obtained results are presented in Table 1.

Table 1. Chemical composition of ignimbrites in the area where Kuşkayası rock tombs are located

Main element oxide (%)	SiO_2	Al_2O_3	Fe_2O_3	MgO	CaO	Na_2O	K_2O	TiO_2	P_2O_5	MnO	Cr_2O_3	LOI	Total
KA	74,16	13,43	1,30	0,23	1,79	3,57	3,85	0,20	0,06	0,05	<0,002	1,2	99,96

According to the obtained data, the SiO_2 contents of the ignimbrites collected from the region are relatively high. When examined in the total alkali-silicate diagram based on the chemical analysis data, it was determined that the ignimbrites were of rhyolitic composition.

Microscope examinations were made on two thin sections prepared on the collected ignimbrites sample and cracks and fractures were observed in these minerals where feldspar and plagioclase were observed as large phenocrysts, and opacifications were observed in places in the groundmass. For example, the ratio of phenocrysts in the first section is higher and their sizes are formed by relatively larger phenocrysts. The voids in the second section are relatively more than in the first section. The matrix ratio is higher than the grain ratio in both sections (Figure 1, Figure 2).

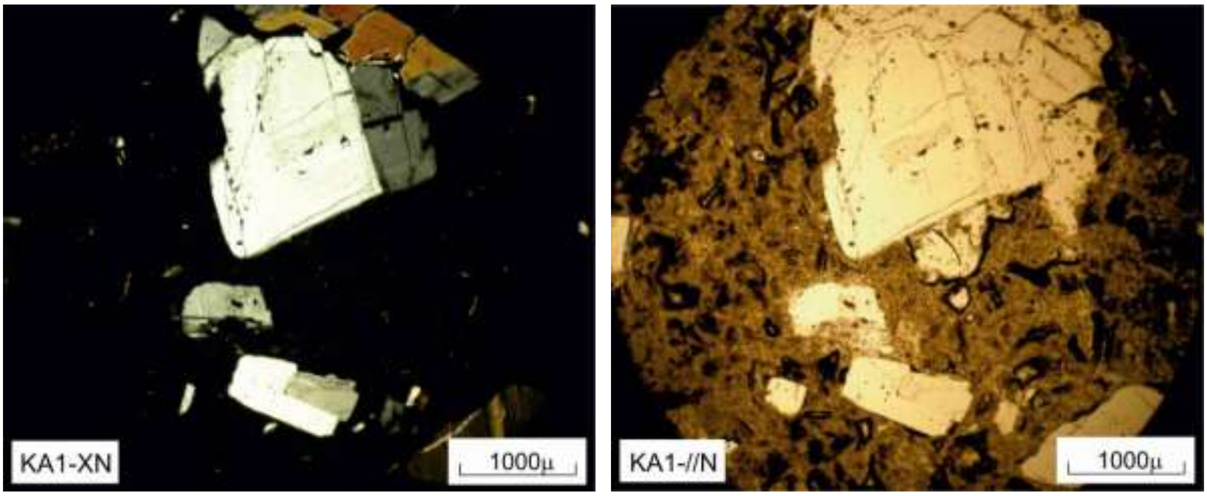

Figure 1. Microphotograph of sample no. KA a) Double-Nicol image, b) Single-Nicol image (magnification 4X)

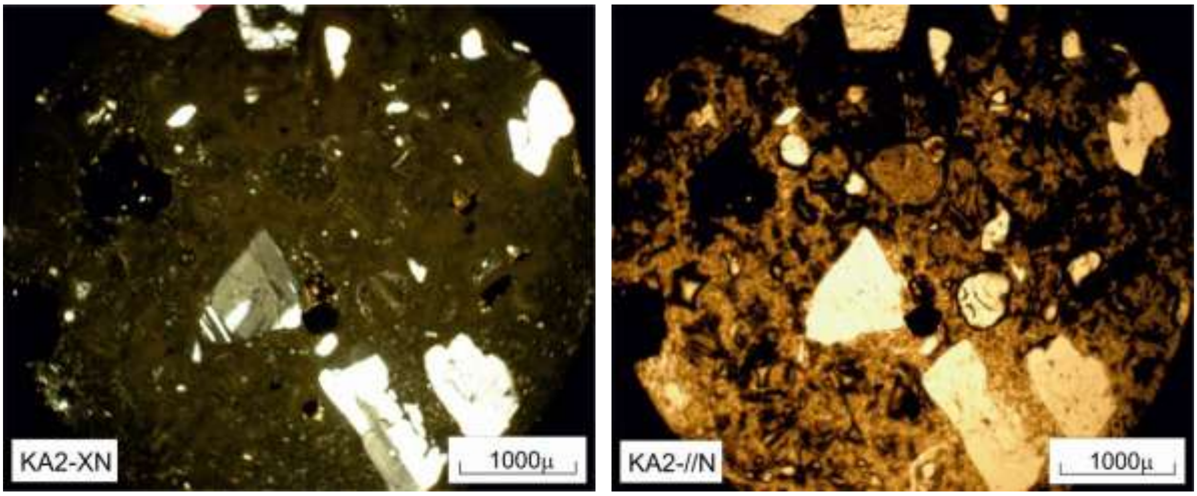

Figure 2. Another microphotograph of sample KA a) Double-Nicol image, b) Single-Nicol image (magnification 4X)

Opal-CT, Plagioclase (Plj.) and Feldspar (Feld.) minerals were observed in the examinations carried out by XRD method on powder samples prepared from blocks taken from the section where the rock tombs were excavated (Figure 3).

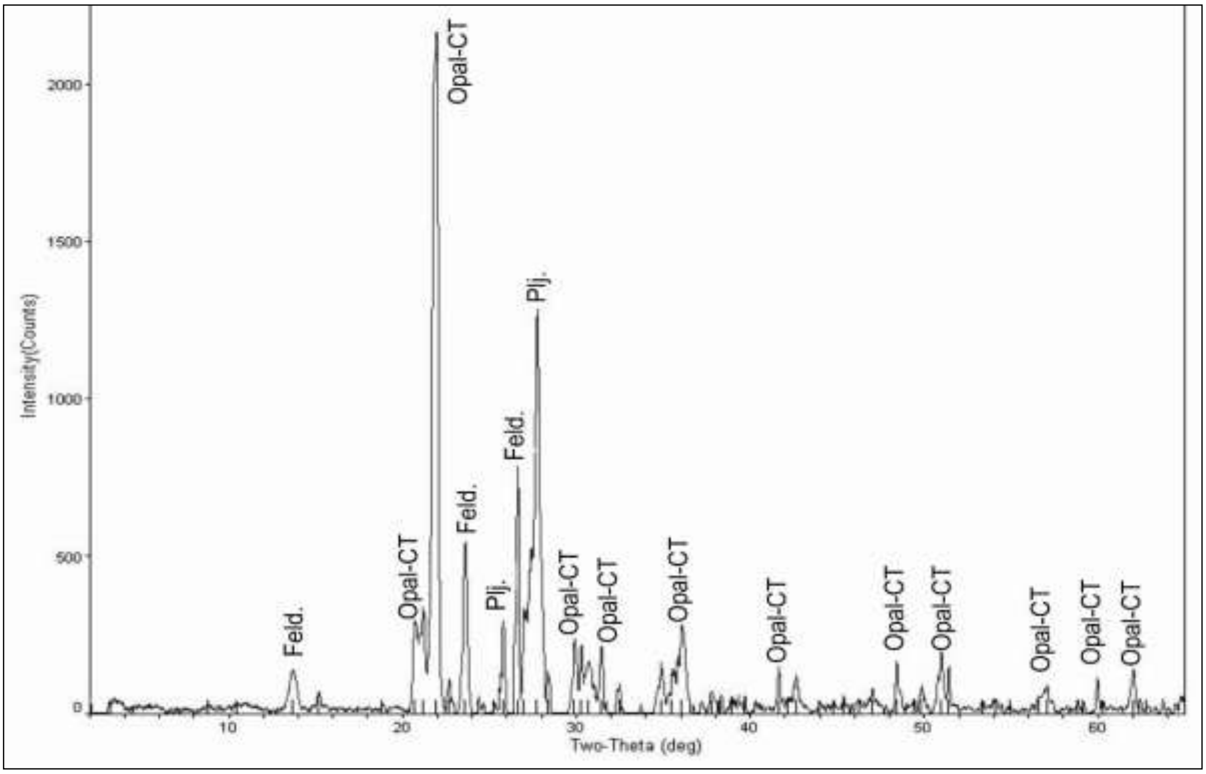

Figure 3. Diffractometer analysis results of the KA sample

In order to determine the engineering properties of the ignimbrites in the section where the rock tombs were opened, the data of dry and saturated unit weight, water absorption by weight, apparent porosity, P-wave velocity, stability index against dispersion in water as 2 cycles, capillary water absorption, Böhme surface abrasion and uniaxial compressive strength values and in-situ Schmidt hammer hardness measurements are presented below (Table 2 and Table 3).

K x10^{-5} (cm^2/sn)	5	9,27	10,25	9,73	0,43
ΔV (cm^3/50 cm^2)	3	34,20	35,00	34,73	0,46
σc (MPa)	3	26,0	34,2	29,4	43

The ignimbrites examined were classified as rocks with “very low unit volume weight” according to NBG (1985). Again, according to NBG (1985), when classified in terms of porosity, they are classified as “rocks with very high porosity”. According to the classification made according to the sonic velocity values obtained according to ISRM (1978), they were classified as rocks with “very low seismic velocity”. When the examined samples were evaluated according to their uniaxial compressive strength values according to ISRM (1981), they are in the “moderately resistant rock” classes (Table 13).

The obtained dry and saturated unit weight and values are relatively high, and the water absorption values are relatively low compared to other ignimbrites. The P-wave velocity and the resistance index to dispersion in water values are also relatively high. The abrasion losses of the examined sample are high compared to other rocks such as marble and limestone, and their compressive strengths are relatively low. The L-type Schmidt hardness hammer rebound performed on the field grave samples is presented below (Table 3).

Table 3. Schmidt hammer hardness index values measured from different areas in the rock tombs section.

Schmidt Hammer Hardness Index, SHV (L-type)					
Measurement location	**Number of Measurements**	**Min.**	**Max.**	**Average**	**S. Deviation**
Entrance portal of rock tomb no. 1	10	42	55	52,9	6,60
Entrance portal of rock tomb no. 2	10	44	56	53,1	5,80
Base section of rock tomb no. 2	10	37	56	50,3	7,00
Entrance portal of rock tomb no. 3	10	41	55	52,5	4,85
Entrance portal of rock tomb no. 4	10	43	54	48,5	5,20
Entrance portal of rock tomb no. 5	10	42	55	53,4	3,25
Entrance portal of rock tomb no. 6	10	42	57	53,6	4,50
Entrance portal of rock tomb no. 7	10	40	55	48,2	5,70
Entrance portal of rock tomb no. 8 (decomposition partially active)	10	32	40	33,8	3,70
Entrance portal of rock tomb no. 1 on the western slope of the valley	10	47	55	54,2	2,80
Entrance portal of rock tomb no. 2 on the western slope of the valley	10	40	54	52,5	4,80

The ignimbrites in the entire area were evaluated as "hard rock" and "very hard rock" according to the classification made according to Beer (1967) (Table 3).

Deterioration and suggestions observed on the stones where the graves were opened

Almost all of the rock tombs in the region, except for one, have similar characteristics. They were opened in ignimbrites that also spread at the same levels in the field. Those on the eastern slope of the valley are more in number. Some of the tombs, on which no detailed study has been conducted to date, have been destroyed by illegal treasure hunters. There are no protection measures in the region. Algae and moss formations were observed on the outer side of some rock tombs. In the section where the large rock tomb is located, superficial losses developed in the area intersected by the vertical cooling crack. In general, with the effects of surface decomposition, the rock mass is partially effective in a few cm of the outer part of the surface. No significant effect was observed in the other inner sections. Destruction due to human effects (graffiti) is quite high in some tombs, especially by illegal treasure hunters. It is thought that there will be a tourism potential due to the different characteristics of the rock structures in the region, depending on the archaeological evaluation, cleaning and protection measures taken. Images of the problems obtained from the field surveys conducted in the area where the rock tombs are located are presented below (Figures 4 - 6)

Figure 4. View of the destruction in the tombs and kline where there are two-storey kline that are different from the others.

Figure 5. Falls due to the intersection of cracks, graffiti due to human effects and illegal excavation areas

Figure 6. Effects of biological deterioration (development of lichens, moss and flowering plants)

CONCLUSIONS

Many underground structures have been opened in rocks such as tuff and ignimbrites, which are common in the Cappadocia region, due to their easy processing and being on the surface. Rock tombs in the region have also been opened in various sizes along both slopes of the valley, and some of the tombs, which are empty and neglected, are still being destroyed by illegal treasure hunters. Surface collapses have been observed in areas intersecting with discontinuities and are open to deterioration due to atmospheric effects. The effects of biological deterioration and destruction due to human effects (graffiti) in the area are quite high, especially in some tombs by illegal treasure hunters.

ABSTRACT

Stone heritages are important monuments that transfer the cultural traces of past civilizations to the present day. These monuments are subject to deterioration over time as a result of atmospheric effects, threatening the integrity of cultural heritage. Monuments built with rocks with particularly weak strength properties are more sensitive to atmospheric processes. In this study, the deterioration developments and damages that occurred in the monument carved into the pyroclastic rock located in the Şahmelik neighborhood of Develi district, Kayseri province were examined. For this purpose, the physical-mechanical properties of the rock and the in-situ deterioration developments were examined in the laboratory using non-destructive testing techniques (Schmidt hardness, P-wave velocity and IR thermography). According to the findings obtained from the study, the rock has low density, high porosity and high capillary water absorption. These features increase the sensitivity of the rock from which the monument is carved to atmospheric deterioration processes. With these features, planning of urgent restoration-protection works will be very important in transferring the monument to future generations.

Keywords: Şahmelik Tuff Rock Monument, Deterioration, Non-destructive testing techniques, Atmospheric processes, Kayseri.

INTRODUCTION

Atmospheric weathering processes (such as freezing-thawing, wetting-drying and salt crystallization) primarily reduce the bonding strength of minerals on the surface of rocks and cause flaking type development on the mm scale (Hatır, 2020). In the continuation of these processes, different weathering types ranging from mm to m scale may develop. Especially in rocks with low strength and high porosity properties, these effects can cause destructive results more quickly. In addition to high porosity values, high capillary water absorption properties cause more water to be stored in the rock. Especially in winter, the expansion of the volume of water by freezing causes an increase in the existing pores in the rock (Fener and İnce, 2015).

As this process progresses, the rock loses integrity as a result of the increased pore volume. In the studies on monuments and historical structures from past to present, weathering has been stated to be directly related to atmospheric actions (İpekoğlu et al. 2007; Korkanç 2013; Brimblecombe 2014), precipitation affecting to the structure, groundwater (Sandrolini and Franzoni 2006; Fener and İnce 2015), petro-mechanics (Uchida et al. 2000) and hydraulics (Benavente et al. 2007) characteristics of the rock.

In this study, the deteriorations developing in Şahmelik Tuff Rock Monument, where the destructive effects of atmospheric deterioration processes were most intensely observed in the region, were investigated. The deterioration developments in this monument built during the Byzantine period were investigated by laboratory and on-site non-destructive tests.

MATERIALS AND METHOD

In this study, the rock unit in which the Şahmelik Tuff Rock Monument was carved was investigated by laboratory and on-site non-destructive test studies. For laboratory studies, uniform rock blocks with dimensions of 30x30x25 cm were collected from the field. Then, cube samples with dimensions of 7x7x7 cm were prepared from these blocks according to the principles specified in TS EN 1936 (2010). Using cube samples, dry density and porosity values of the rock were determined by taking into account the methods recommended in TS EN 1936 (2010). Capillary water absorption value of the samples was determined according to the methods recommended in TS EN 1925 (2000). In order to understand the deterioration processes by evaluating the weathered and fresh properties of the rock together, non-destructive tests (Schmidt hammer hardness, Leeb hardness and P-wave velocity) were applied both in the laboratory and on-site. From these tests, the P-wave velocity value was determined according to the method recommended in ASTM E494 (2010). In determining the Schmidt hammer hardness (SHR) value, the method specified in ASTM D5873 (2014) was taken into account. In determining the Leeb hardness, the method recommended in İnce and Bozdağ (2021) was used.

In the study, only the IR thermography method applied on-site was used with the FLIR brand E5 model device. The types of degradation observed in the monument were classified according to the principles defined in ICOMOS (2008).

RESULTS AND DISCUSSIONS

Physical-Strength Properties of the Rock

The physical-strength properties of the rock unit in which the Şahmelik Tuff Rock Monument was carved are 1.01 g/cm^3, 38.15% and 1.81 km/s, respectively. According to NBG (1985), this rock is in the very high porosity class, while its density is in the very low class. For example, the capillary water absorption value is 652.5 g/m^{2}s^{0,5} and according to Snethlage (2005), it is in the highly absorbing rock class. From the fresh surface hardness values of the rock, Schmidt hammer was determined as 22 while Leeb was determined as 208.

Deterioration types observed in the monument

Atmospheric deterioration processes can develop in a very small area in rocks on the mm scale, or they can develop on the m scale and cause loss of integrity in monuments. In Şahmelik Tuff Rock Monument, many types of weathering were detected from m to m scale. The beginning of weathering developments is related to the presence of water penetrating the monument as capillary. The high water absorption characteristics determined in fresh rock allow the rock body to penetrate water, causing atmospheric weathering processes to work effectively. Especially the presence of water in the capillary region caused the matrixes in the rock body to decrease their ability to adhere to each other, causing differential erosion type (Figure 1). In addition, as seen in Figure 1, missing part type weathering was detected in some weak structural elements on the differential erosion region.

Figure 1. Differential erosion and missing part type deteriorations observed in the Şahmelik Tuff Rock Monument

The development of the differential erosion type observed in the capillary region throughout the monument to depths of approximately 80 cm affected the static balance of the structure and triggered the formation of cracks in the interior spaces (walls and piers) and on the upper covers (Figure 2). As a result of the increase in the stress differences created by the cracks observed throughout the monument, large-scale block ruptures occurred (Figure 3). These ruptures caused the collapse of the upper cover and the collapse of the walls, leaving the monument even more vulnerable to atmospheric degradation processes.

Figure 2. Crack type deteriorations observed in the monument

Figure 3. Block breaks caused by cracks

Non-Destructive Test Results

Non-destructive test measurements were carried out on-site to determine the deterioration developments in the monument. In the surface hardness tests on fresh rock, Leeb and Schmidt hammer values were determined as 208 and 22, respectively. In the Leeb measurements made on-site, it was determined that it varied between 103-125 in the differential erosion zones and 136-165 above this zone. Schmidt hammer hardness values were determined as 10-12 and 14-16 in the differential erosion zone and above, respectively. In both hardness tests, a decrease of approximately 50% was observed in the differential erosion zones compared to the fresh rock values. While the P-wave speed test was determined as 1.81 km/s in the laboratory, no value was obtained in the differential erosion zone in the on-site analyses. The P-wave speed values above this zone were measured between 1.05 and 1.34 km/s. The visual of the IR thermography method applied to determine the humidity and temperature distributions in the structure is given in Figure 4. When Figure 4a is examined, differential erosion type deterioration is observed in the capillary region of the interior carrier column. In addition, crack type deterioration is observed diagonally cutting the column. When Figure 4b is examined, it is determined that the temperature is lower in relation to humidity along the differential erosion and crack zone.

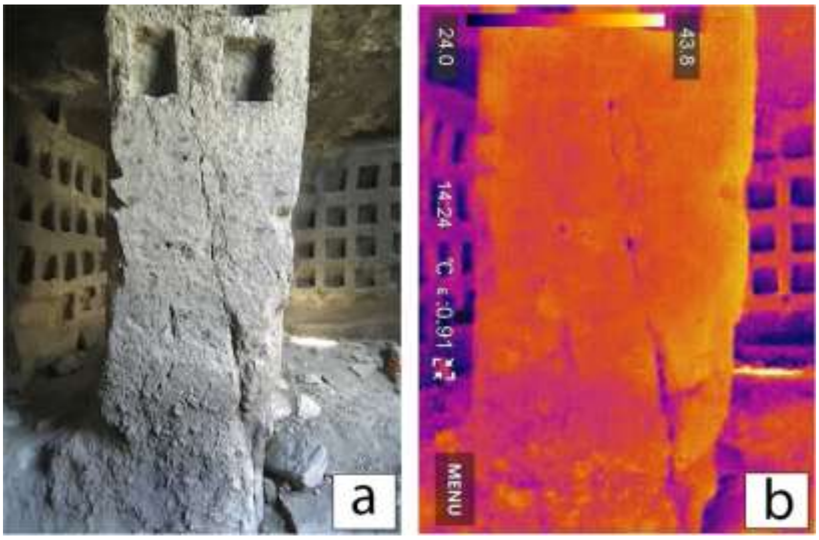

Figure 4. a) Interior image of the monument, b) IR thermography image

CONCLUSIONS

Rock properties play an important role in the deterioration of monuments built with stone. While rocks with high strength and low porosity are highly resistant to atmospheric effects, rocks with low engineering properties and high porosity are more sensitive to deterioration. In this study, deteriorations and structural problems in the Şahmelik Tuff Rock Monument, which was built on pyroclastic rock with low strength, high porosity and capillary water absorption properties, were examined.

- The structural integrity problems in the Şahmelik Tuff Rock Monument were triggered by differential erosion type deterioration developing in the capillary region due to the high water absorption properties of the rock.
- When the non-destructive tests applied in the laboratory and on-site were evaluated together, it was determined that the hardness values decreased by 25-50% compared to fresh rock. This decrease is the highest in the differential erosion region. In addition, the P-wave velocity value could not be obtained due to the excessive deterioration of this region.
- In the IR thermography images obtained from inside the structure, it was determined that the moisture content in the areas where differential erosion and crack type deterioration developed was also high.

ABSTRACT

Drought is a natural phenomenon characterized by a significant decrease in precipitation levels in a given region. This condition can lead to the desiccation of soil and water sources, as well as damage to vegetation and a decline in agricultural productivity. Droughts can arise from the interaction of various factors and typically have serious implications for ecosystems. Consequences may include water scarcity, food security issues, and economic losses. Consequently, drought represents a significant concern from both environmental and socio-economic perspectives. Global warming and climate change have led to more frequent and severe droughts worldwide, including in Turkey. Water resources and the agricultural sector are the most affected by droughts. In this study, drought analysis was conducted in Edirne province, located in the Thrace region of Turkey. Annual average rainfall, maximum temperature, minimum temperature, and average temperature data were used for analysis. Forty years of rainfall data (1984-2023) were analyzed. The Standardized Precipitation Index (SPI) and Reconnaissance Drought Index (RDI) methods were used for drought analysis. SPI and RDI values were calculated for 1-, 3-, 6-, and 12-month periods, and the severity, duration, and distribution of drought periods were determined separately for each station. Overall, examining the values calculated with SPI and RDI, it was observed that the years 1985, 1986, 1989, and 2013 were generally drought in the study area.
Keywords: climate, climate change, drought analysis, Edirne, RDI, SPI

1. INTRODUCTION

Climate change stands as one of the most pressing environmental challenges of our time, with its effects extending beyond mere temperature increases to significant alterations in precipitation patterns, thereby increasing the frequency and intensity of drought events. Drought, as one of the most prominent manifestations of climate change, is a complex phenomenon that needs to be addressed in both meteorological and hydrological contexts. Meteorological drought, initiated by a decline in precipitation, gradually evolves into hydrological drought, leading to reduced water resources and ecosystem degradation (Soğanci 2019; Kale 2021; Erişmiş 2023). Consequently, drought poses serious threats across various sectors, from agricultural production to water resources, endangering food security (Morán-Tejéda et al. 2012; Sharafati et al. 2019).

Drought analysis emerges as a crucial tool in understanding and managing the impacts of climate change. Methods such as the Standardized Precipitation Index (SPI), Standardized Precipitation Evapotranspiration Index (SPEI), and Reconnaissance Drought Index (RDI) are commonly used to evaluate drought conditions in specific regions. SPI measures deviations of precipitation over a given period relative to the normal distribution, while SPEI considers the balance between precipitation and evaporation in assessing drought conditions (Mohammed et al. 2020; Chisadza et al. 2023). Research has demonstrated the effectiveness of SPI and SPEI in assessing drought conditions and highlighting the adverse impacts of climate change. For instance, long-term drought analyses in the Meriç River Basin have detailed the impacts of climate change in the region (Erişmiş 2023), while studies in the Akarçay Closed Basin have illustrated the effects of temperature and precipitation anomalies on the hydrological cycle (Kale 2021). These analyses not only clarify the impacts of drought on agricultural production but also help understand farmers' responses to drought (Çuhadar and Atiş 2021; Kara and Yereli 2022). Additionally, these indices provide a comprehensive understanding of drought persistence and intensity, aiding in the development of necessary strategies for water resource management (Stagge et al. 2015).

Drought analysis goes beyond evaluating meteorological data, offering a broader perspective by incorporating future climate scenarios. For example, the work of Stagge et al. examines how indices like SPI, SPEI, and RDI change under climate change scenarios, underscoring their importance in assessing drought conditions (Stagge et al. 2015; Sharafi and Ghaleni 2022). Such studies are pivotal for identifying future drought scenarios and developing effective water management strategies.

Drought is not merely a natural disaster but also a socio-economic challenge. Losses in agricultural production threaten food security and may trigger migration in rural areas (Beden et al. 2020; Ekinci and Ökde 2021). In Turkey, developing strategies to combat climate change is of paramount importance in addressing these issues. The role of local governments is critical in this process, being key elements in combating climate change (Beden et al. 2020; Ekinci and Ökde 2021). In Turkey, developing strategies to combat climate change is of paramount importance in addressing these issues. The role of local governments is critical in this process, being key elements in combating climate change (Parlak 2022; Uysal 2022). Understanding the relationship between drought and climate change is essential for developing sustainable agricultural policies and water management strategies (Türkeş 2012).

In conclusion, climate change and drought analysis are complex issues that need to be addressed with their environmental and social dimensions. The use of indices such as SPI and RDI is crucial for evaluating drought conditions and mitigating their effects. Therefore, adopting a multidisciplinary approach in combating climate change is a critical necessity from both scientific and societal perspectives. Drought analysis plays a significant role in evaluating future climate scenarios and implementing effective measures.

Located in northwestern Turkey, Edirne is a critical region for agriculture and water resources management. Understanding the impacts of climate change in this region is vital for developing sustainable agriculture and water management strategies. In this context, meteorological drought indicators such as the Standard Precipitation Index (SPI) and the Reconnaissance Drought Index (RDI) are important tools for analyzing drought events in the region. This study aims to evaluate the impacts of climate change on meteorological drought in the Edirne region through SPI and RDI analyses. The findings will shed light on water management and agricultural planning strategies in the region and contribute to the development of measures to mitigate future drought risks. This study will be an important step towards achieving sustainable development goals in Edirne and similar regions.

2. METHOD

2.1. Study Area and Climate Data

Edirne, located in the northwestern part of Turkey, is a province rich in historical heritage. Geographically, Edirne is situated along the banks of the Meriç River, which serves as a significant water source for the region. This proximity to the river directly influences the area's climate and meteorological parameters. Edirne typically experiences a continental climate characterized by hot and dry summers, and cold and wet winters (Oruc 2021).

Covering approximately 1% of Turkey's total land area, Edirne's catchment area spans 6,279 km². The province is under the influence of a transitional climate between the continental and Mediterranean climates. The average annual precipitation in Edirne is 589.1 mm/m², while the annual average temperature is 13.7°C. These climatic characteristics play a crucial role in shaping Edirne's water resources and agricultural activities.
For the drought analysis of Edirne, meteorological data was sourced from the NASA POWER website. The analysis utilized observed data on annual average total precipitation, annual maximum temperature, annual minimum temperature, and annual average temperature. General information about the study area is provided in Table 1 and Figure 2.

Table 1. General Information About Meteorological Stations

Province	Latitude	Longitude	Altitude (km)	Year	P_{mean} (mm)	T_{min} (°C)	T_{max} (°C)	T_{mean} (°C)
Edirne	36.7411	35.143	0.39	1984 - 2023	563.765	7.826	19.617	13.336

Figure 1. Location Map of Edirne Province

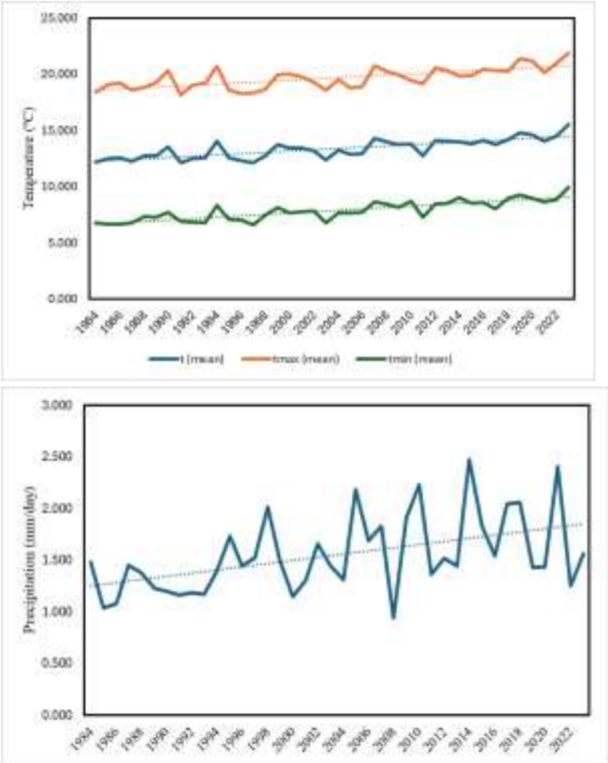

Figure 2. Temperature and Precipitation Graphs of Edirne Province by Years

2.2. Standard Precipitation Index (SPI)

The Standardized Precipitation Index (SPI) is an important tool used to assess meteorological droughts. Proposed by McKee and colleagues in 1993, this index measures the deviation of precipitation amounts from the normal distribution over a specific time period (typically 1, 3, 6, 12, or 24 months). SPI has been recognized by the World Meteorological Organization (WMO) as a reference index for drought monitoring and climate risk management. (Vicente-Serrano et al. 2012; Hao and AghaKouchak 2013). This index is obtained by dividing the difference between precipitation in a specific time period and the average precipitation by the standard deviation:

$$SPI_{i,j} = \frac{X_{i,j} - X_j^m}{\sigma_j} \qquad (1)$$

In Equation 1, $X_{i,j}$, represents the precipitation (mm) in month j of year i, X_j is the average precipitation (mm) for month j, and σ_j is the standard deviation of precipitation for month j. The SPI can be calculated for different periods (such as 1, 3, 6, 9, or 12 months).

The SPI (Standardized Precipitation Index) method assesses drought severity by calculating precipitation deficits for different time series during both wet and dry periods. Positive values calculated by this method indicate wet periods, while negative values represent dry periods. When calculating SPI, long-term precipitation data are fitted to a gamma distribution, and these values are then transformed into a normal distribution (Edwards and McKee 1997). This approach allows for consistent representation across different climatic conditions.

In drought assessment, a period where the index remains continuously negative is defined as a drought period. The month when the index first falls below zero is considered the onset of drought, and the month when it rises to positive values is regarded as the end of the drought (McKee et al. 1995).

2.3. Reconnaissance Drought Index (RDI)

The Reconnaissance Drought Index (RDI) is a tool developed for assessing meteorological droughts and is considered an effective instrument for analyzing drought conditions, especially in arid and semi-arid regions. RDI takes into account the water balance by using precipitation and potential evapotranspiration (PET) data, thus providing a more comprehensive evaluation of drought conditions (Waseem et al. 2016; Yisehak et al. 2021).

$$\alpha_k^i = \frac{\sum_{j=1}^{k} Pij}{\sum_{j=1}^{k} PETij}, i = 1\,(1)\,N and j = 1\,(1)\,K$$

P_{ij} and PET_{ij} represent the cumulative precipitation and potential evapotranspiration for the j-th month of the i-th year, respectively, and n is the total number of years of the available data.

$$RDI^i = \frac{Y^i - \bar{Y}}{\hat{\delta}_y}$$

Y^i represents the arithmetic mean, and Y denotes the standard deviation. In the case of applying the gamma distribution, the RDI can be calculated by fitting the gamma probability density function (PDF) to the given frequency distribution (Tigkas 2008; Tsakiris et al. 2008). For cumulative precipitation periods that may include zero values, such as short reference periods (e.g., monthly or 3-month), the RDI can be computed according to a composite cumulative distribution function that incorporates the probability of zero precipitation and the gamma cumulative probability

Table 2. Classification of Drought Conditions According to SPI and RDI

SPI or RDI Values	SPI or RDI Classification
X>2.00	Extremely Wet
1,99 – 1,50	Very Wet
1,49 – 1,00	Moderately Wet
0,99 – (-0,99)	Near Normal
(-1,00) – (-1,49)	Moderately Dry
(-1,50) – (-1,99)	Severely Dry
-2,00 ≤ X	Extremely Dry

3. RESULTS

3.1. Drought Analysis of Edirne

3.1.1. Drought analysis based on SPI

The temporal distribution of SPI values for 1-, 3-, 6-, and 12-month periods, calculated using monthly average precipitation data for Edirne from 1984 to 2023, is shown in Figure 3. According to Figure 3, the frequency of drought periods increases with the length of the period. The analysis reveals that the highest droughts for the 1-, 3-, 6-, and 12-month periods were observed in the years 2015, 2002, 1986, and 1985, respectively. The wettest periods occurred in the years 2014, 2021, 2010, and 2005, respectively.

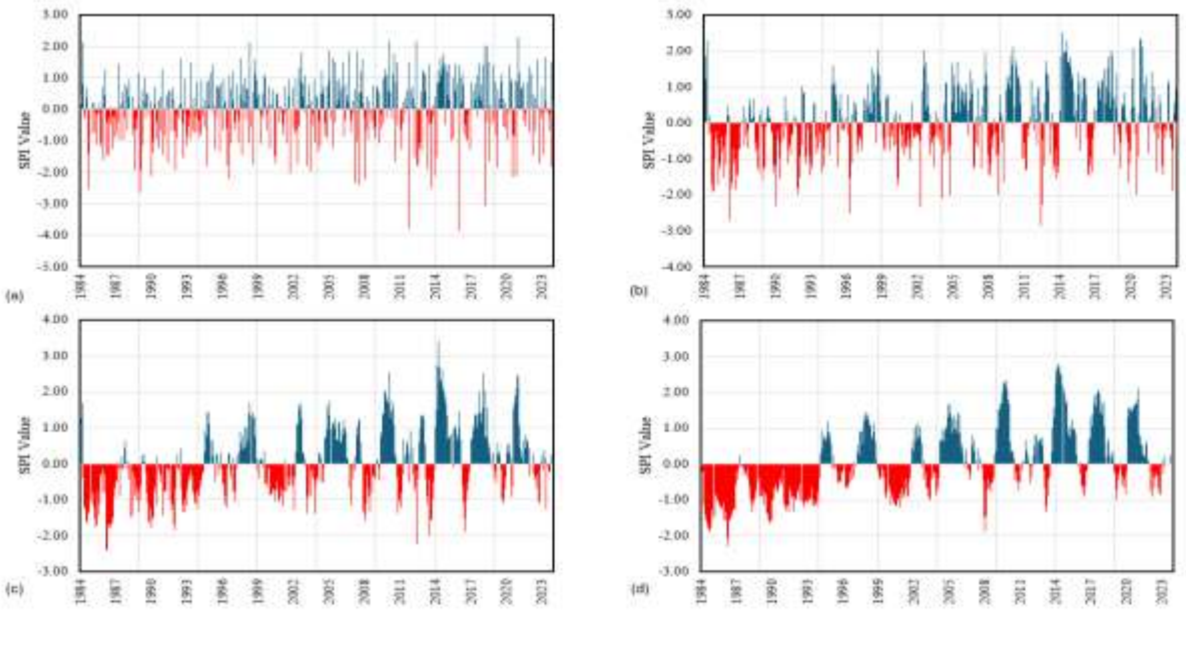

Figure 3. Temporal distribution of Edirne station SPI (a)SPI1 b)SPI3 c)SPI6 d)SPI12) values.

The SPI analyses revealed long-term drought periods over different time intervals. According to the SPI1 analysis, a 7-month drought period occurred from June 2016 to December 2016. The SPI3 analysis showed a drought lasting a total of 19 months from July 1984 to January 1986. The SPI6 analysis, which provides a longer-term assessment, identified a 40-month drought period from April 1984 to July 1987. The longest drought, as indicated by the SPI12 analysis, persisted for 92 months from May 1987 to December 1994. These data indicate that long-term droughts occurred at different intervals in the Edirne region, with drought conditions persisting significantly (Table 3). Additionally, it is observed that as the periods for SPI extend, there is an increase in the number of months affected by drought.

Table 3. Duration, severity and maximum occurrence values (SPI) of drought at Burdur station

.

Period	Time (Month)	Start	Finish	Pick Value	Pick Time
SPI1	7	Jun.16	Dec.16	-3.88	Dec.15
SPI3	19	Jul.84	Jan.86	-2.87	Jun-Aug.12
SPI6	40	Apr.84	Jul.87	-2.42	Mar-Aug.86
SPI12	92	May.87	Dec.94	-2.30	Mar.86-Feb.87

Figure 4 shows the percentage distribution of drought categories for SPI1, SPI3, SPI6, and SPI12 periods. The drought categories are classified as EW (Extremely Wet), SW (Severely Wet), MOW (Moderately Wet), MW (Mild Wet), MD (Mild Drought), MOD (Moderate Drought), SD (Severe Drought), and ED (Extreme Drought). In the SPI1 graph, the highest percentage is represented by the Mild Wet (MW) category at 39.2%, indicating that mild wet periods are more frequent in the short-term period. This is followed by the Mild Drought (MD) category at 30.2%. Extremely Wet (EW) and Extreme Drought (ED) periods have the lowest percentages, 1.3% and 3.1% respectively, suggesting that extreme conditions are less common during the SPI1 period.

In SPI3, the Mild Drought (MD) category stands out as the most common condition at 34.6%, followed by Mild Wet (MW) at 30.8%. Moderately Wet (MOW) and Moderate Drought (MOD) categories are observed at similar levels, 10.8% and 10.0%, respectively, while Extremely Wet (EW) and Extreme Drought (ED) periods are relatively lower at 2.3% and 1.9%.

For the SPI6 period, Mild Drought (MD) is the most prevalent condition at 38.1%, followed by Mild Wet (MW) at 27.9%. This suggests that drought conditions become more pronounced in longer periods. Moderate Drought (MOD) is third at

11.0%, while Extreme Drought (ED) is quite rare at 0.6%. Extremely Wet (EW) conditions are at 3.3% for this period.

In SPI12, Mild Drought (MD) has the highest percentage at 41.1%, indicating that long-term droughts significantly impact the region. Mild Wet (MW) is second at 26.7%. Extreme Drought (ED) is very low at 0.4%, and Extremely Wet (EW) is also low at 3.8%, suggesting that extreme conditions are rare over long periods.

Overall, SPI analyses show that drought conditions become more pronounced as the time period increases (from SPI1 to SPI12) and drought periods become more common. Mild Drought (MD) is the dominant category across all SPI periods, indicating that the region generally experiences mild drought conditions. The proportions of Extreme Drought and Extremely Wet conditions remain low, especially in longer periods, indicating that extreme conditions are less frequent. These data provide valuable insights into the general climatic dynamics of the Edirne region and are crucial for developing water resource management strategies.

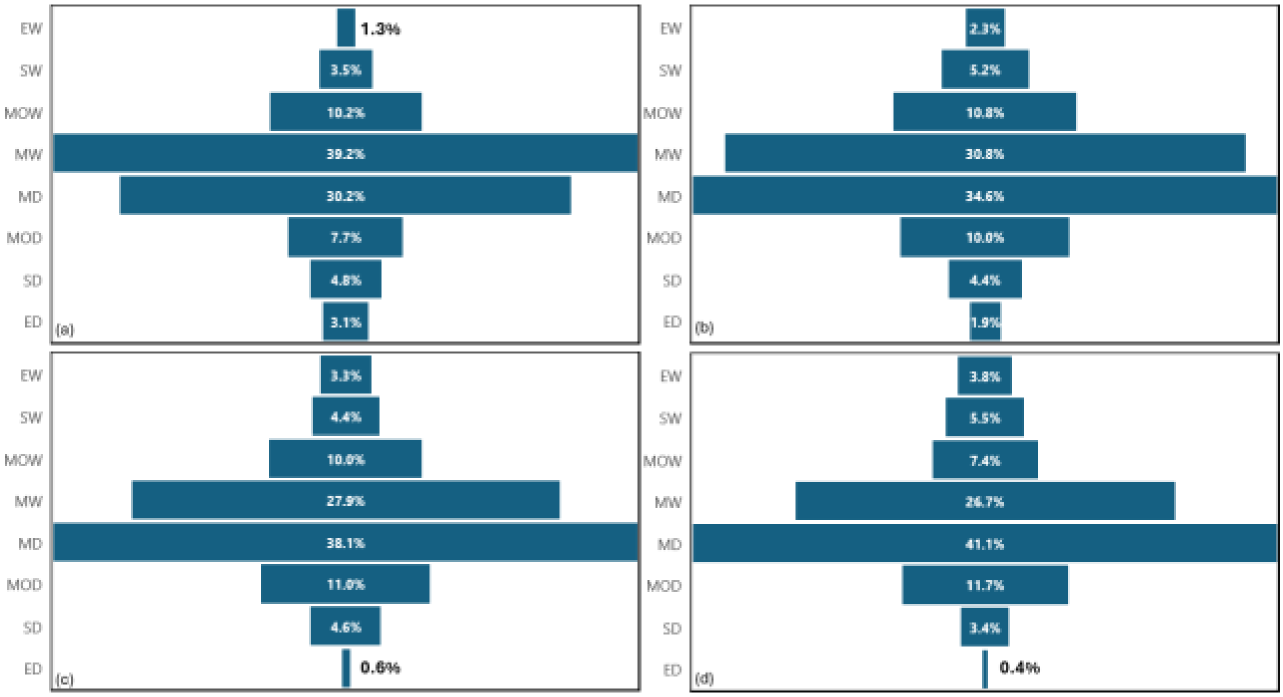

Figure 4. Occurrence percentages of drought classes (SPI) at Edirne station.

3.1.2. Drought analysis based on RDI

The temporal distribution of RDI values for 1-, 3-, 6-, and 12-month periods, calculated using monthly average precipitation data for Edirne from 1984 to 2023, is shown in Figure 5. According to Figure 5, the frequency of drought periods increases with the length of the period. The analysis reveals that the highest droughts for the 1-, 3-, 6-, and 12-month periods occurred in the years 1990, 1986, 1986, and 1986, respectively. The wettest period were experienced in the year 2014.

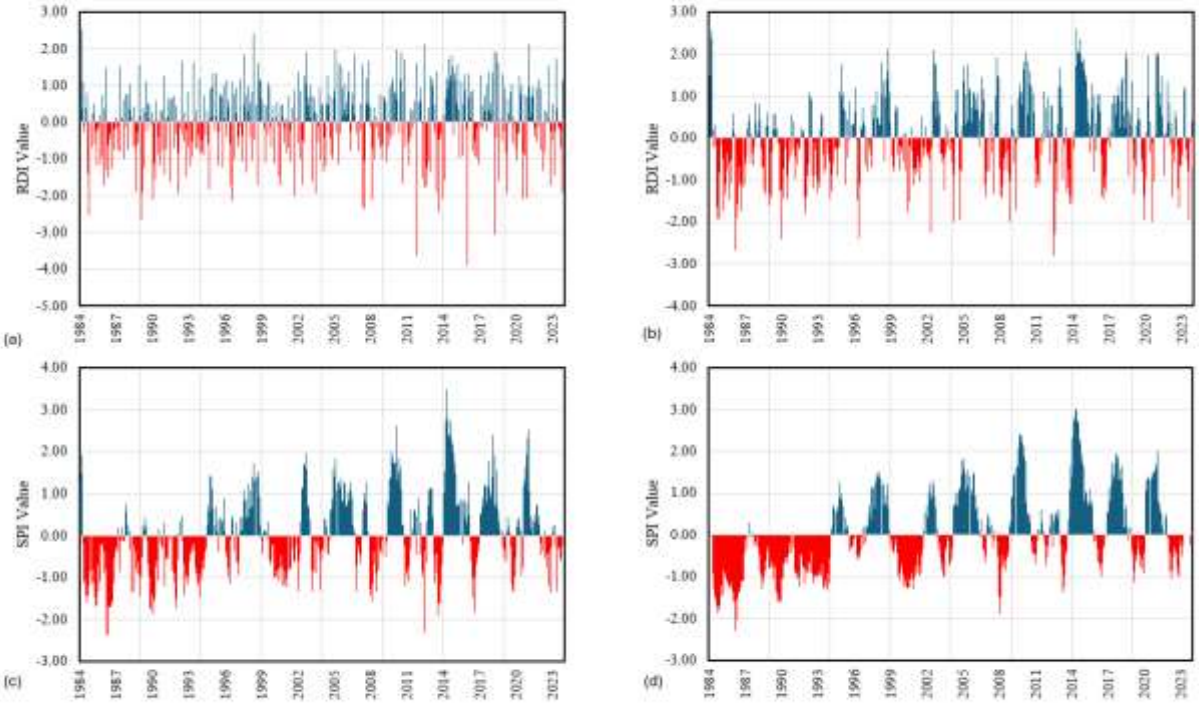

Figure 5. Temporal distribution of Edirne station RDI (a)RDI1 b)RDI3 c)RDI6 d)RDI12) values.

The RDI analyses clearly reveal the presence of long-term drought periods in the Edirne region over different time intervals (Table 4). According to the RDI1 analysis, a 7-month drought period occurred from June 2016 to December 2016. This indicates a short-term drought scenario, suggesting that seasonal effects triggered the drought conditions. The RDI3 analysis, on the other hand, points to a 15-month drought period from September 1989 to November 1990. This period extends beyond seasonal drought effects and indicates significant pressure on water resources on an annual basis.

Looking at the longer time frame of the RDI6 analysis, a 40-month drought period was identified from April 1984 to July 1987. This extended drought period could have serious impacts on both hydrological and agricultural activities, highlighting the importance of water management strategies. The longest drought, as indicated by the RDI12 analysis, encompasses a 51-month period from August 1987 to October 1990. This suggests that long-term droughts are also a significant threat in the region and underscores the necessity for long-term planning in water resource management.

Overall, RDI analyses show that as the periods extend, the number of months experiencing drought also increases. This situation indicates that drought events can span significantly longer periods rather than being short-term, necessitating comprehensive measures and strategies. These analyses provide a crucial foundation for measures against climate change and drought risks in the Edirne region.

Table 4. Duration, severity and maximum occurrence values (SPI) of drought at Edirne station.

Period	Time (Month)	Start	Finish	Pick Value	Pick Time
RDI1	7	Jun.16	Dec.16	-3.90	Dec.15
RDI3	15	Sep.89	Nov.90	-2.82	Jun-Aug.12
RDI6	40	Apr.84	Jul.87	-2.39	Apr-Sep.86
RDI12	51	Aug.87	Oct.90	-2.28	Mar.86-Feb.87

According to the RDI analyses, the distribution of drought conditions in the Edirne region varies significantly across different periods. In the RDI1 analysis, the most common drought categories are Medium Wet (MW) at 36.5% and Mild Drought (MD) at 31.9%. As the time period extends, there is a notable increase in the proportion of the Mild Drought (MD) category, which rises to 40.6% in the RDI12 analysis. This indicates that, particularly in long-term analyses, drought conditions become more moderately prevalent, with serious drought risks increasing over time (Figure 6).

On the other hand, more extreme drought categories such as Extreme Drought (ED) and Severe Drought (SD) remain at low percentages across all periods. For instance, in the RDI12 analysis, the percentage of Extreme Drought (ED) is only 0.4%, suggesting that extreme drought events are rare. The dominance of the Medium and Mild Drought categories indicates that drought risks in the region are more often characterized by long-term but less severe droughts. These findings are critical for the development of long-term water management and agricultural planning strategies in the Edirne region. The increasing prevalence of moderate drought conditions heightens the pressure on the region's water resources and underscores the importance of implementing effective drought management measures.

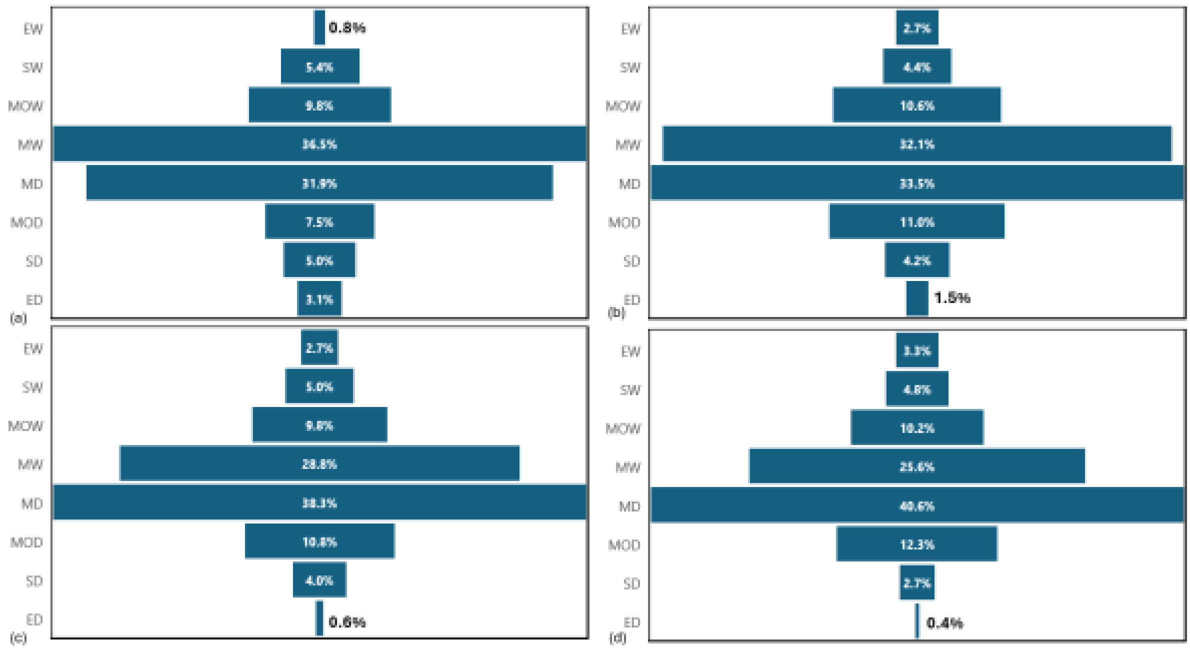

Figure 6. Occurrence percentages of drought classes (RDI) at Edirne station.

4. CONCLUSION

This study conducted meteorological and agricultural drought analyses for Edirne central district, located in the Thrace Region. To achieve this, average precipitation, and average minimum and maximum temperatures observed in Edirne from 1984 to 2023 were used to analyze meteorological and agricultural droughts. By applying the Standardized Precipitation Index (SPI) and the Reconnaissance Drought Index (RDI) methods to the data, the severity, magnitude, and distribution of dry and wet periods were determined for SPI and RDI values calculated for 1, 3, 6, and 12-month periods.

Upon examining the SPI results, it was observed that there were 7, 19, 40, and 92 dry months in Edirne during 1, 3, 6, and 12-month periods between 1984 and 2023, respectively. During the studied period, the maximum droughts in Edirne station for 1, 3, 6, and 12-month periods occurred in December 2015, June-August 2012, March-August 1986, and March 1986-February 1987, respectively.

Upon examining the RDI results, it was observed that there were 7, 15, 40, and 51 dry months in Edirne during 1, 3, 6, and 12-month periods between 1984 and 2023, respectively. During the studied period, the maximum droughts in the Edirne station for 1, 3, 6, and 12-month periods occurred in December 2015, June-August 2012, April-September 1986, and March 1986-February 1987, respectively.

Overall, examining the values calculated with SPI and RDI, it was observed that the years 1985, 1986, 1989, and 2013 were generally dry in the study area. The analyses indicated that the severity and duration of droughts have increased in recent years in the Edirne Basin, and agricultural droughts have also been observed alongside meteorological droughts.

To combat the devastating effects of drought in the Thrace Basin, an area significant for agricultural resources in our country, it would be beneficial to regularly monitor the variability in climate data and develop local policies that ensure the effective management of water resources. Additionally, identifying hydrological droughts and precipitation trends for the same region would provide a valuable resource for water management studies.

ABSTRACT

The effects of global warming not only alter hydrological systems but also exacerbate environmental issues such as drought and depletion of water resources. This situation increases pressure on water sources and causes harm to ecosystems, including water scarcity, erosion, and habitat loss. Particularly, the increase in frequency of extreme weather events further complicates the efficiency and sustainability of existing water resources. Therefore, water management and infrastructure planning require more sophisticated and knowledge-based approaches. Technologies such as remote sensing (RS), Geographic Information Systems (GIS), and Machine Learning (ML) can assist in making more efficient and robust decisions regarding the management of water resources and the selection of dam sites. These technologies can help optimize the utilization of current and future water resources and minimize environmental impacts. This, in turn, supports the sustainability of water resources and the development of more effective strategies to meet the water needs of communities. Consequently, advancements in satellite technology and computational power have expanded the capacity to manage various hydrological parameters and land characteristics. Conducting hydrological analyses through the integration of remote sensing and geographic information systems offers significant benefits in terms of both cost and time efficiency. In this study, according to DSI data, Sivas 4 September Dam, which decreased to 0 %in 2022, was examined in volumetric and spatial changes. Additionally, the correlation between annual temperature and precipitation levels and their impact on the water surface area of the dam was examined to identify the relationship between these variables.

Keywords: climate, climate change, global warming, monitoring, Satellite Imagery, Sivas

1. INTRODUCTION

Climate change is currently recognized as one of the most critical global challenges in terms of environmental sustainability and human health. The impacts of these changes are observed in various areas, such as rising temperatures, alterations in precipitation patterns, sea level rise, and the degradation of ecosystems. While reservoirs play essential roles in functions such as water management, energy production, and agricultural irrigation, increasing temperatures, shifting precipitation patterns, and heightened evaporation due to climate change negatively affect water levels in these reservoirs (Zhao and Gao 2018; Hou et al. 2022). Therefore, monitoring and assessing the effects of climate change have become more systematic and efficient through the use of modern technologies such as remote sensing and geographic information systems (GIS). Remote sensing, using satellite data, plays a crucial role in monitoring various parameters such as temperature variations, precipitation regimes, and changes in vegetation cover (Özdemir, 2023; Uslu et al., 2021; Softaoğlu, 2023; Roman et al., 2016; Binarti & Santoso, 2022).

Although freshwater lakes make up only 0.007% of the Earth's total water reserves, they account for 2.53% of the total freshwater reserves and are a crucial part of the water cycle (Shiklomanov, 1993). Lakes and reservoirs are the most accessible and usable water sources for human consumption and ecosystems. For this reason, observation stations have been established on lakes and reservoirs in many regions worldwide. However, field measurements require significant effort, time, and high costs, making it difficult to monitor many water sources in remote areas (Rahmani, 2021). Furthermore, while observation stations generally measure only water levels, the area and volume of water resources remain unmeasured. Monitoring both the surface area and volume of water resources is essential for understanding their responses to climate change on both regional and global scales (Jha et al., 2006). In this context, advancements in remote sensing and Geographic Information Systems (GIS) technologies have provided scientists with innovative approaches to monitor the surface areas and levels of water bodies (Cappelaere et al., 2003).

Numerous methods have been developed for the detection and extraction of water bodies from satellite imagery. One of the earliest studies in this field was conducted by Dolan et al. (1991), which examined the potential of satellite imagery in detecting water bodies. Gao (1996) emphasized the role of spectral bands in identifying water surfaces and demonstrated that these bands can lead to more accurate water body detection. The Normalized Difference Water Index (NDWI), developed by McFeeters (1996), has become a widely used method for water body identification. Braud and Feng (1998) explored the applicability of remote sensing techniques for monitoring water surfaces and noted that these techniques can play a significant role in water resource management. Frazier and Page (2000) compared different algorithms used for water body detection and identified the most effective methods. Xu (2006) demonstrated how satellite images can be utilized to calculate the surface areas of water bodies. Shen and Li (2010) examined the integration of remote sensing data in monitoring water bodies and provided recommendations on how this data can be used for water management. Feyisa et al. (2014) evaluated the effectiveness of various indices used to identify water surfaces and highlighted their importance as tools for monitoring water bodies. Water reflection has a lower value in near-infrared bands compared to land areas and is almost close to zero. This characteristic makes water bodies appear darker in satellite images, facilitating easier extraction (Raju et al., 2015). Shih (1985) demonstrated that the combination of bands from Landsat and other satellite sensors can be used to classify lake water surfaces. In this context, monitoring the surface areas of water resources using satellite images is of great importance for water management and environmental monitoring.

Remote sensing and GIS are also effectively utilized for monitoring and detecting changes related to climate change. Bhatt (2015) explained how these technologies can be used to determine the status of objects or phenomena across different time periods. Cuca (2017) emphasized the use of remote sensing to monitor the impacts of climate change on cultural and natural heritage, highlighting the importance of this data in the development of management strategies.
Climate change has significant impacts on water resources and dams. While dams play critical roles in water management, energy production, and agricultural irrigation, the rising temperatures, altered precipitation patterns, and increased evaporation rates resulting from climate change directly affect the water levels and functionality of dams (Null et al., 2013; Biglarbeigi et al., 2020). Marcé and colleagues examined the effects of climate change on water temperatures and emphasized the negative impacts these changes have on the ecological balance of dams (Marcé et al., 2010). Null and colleagues discussed how dams influence water temperatures and explored their potential to mitigate the effects of climate change (Null et al., 2013). Biglarbeigi and colleagues developed a model to assess the performance of dams under climate change scenarios, addressing changes in water levels and the challenges in water management, thereby contributing to the development of adaptation strategies (Biglarbeigi et al., 2020). Granados and colleagues analyzed the role of dam storage capacity in response to climate change and highlighted its impact on the reliability of water supply systems (Granados et al., 2021). Uysal and Doğan (2022) evaluated the effects of climate change on dam management and emphasized the importance of predicting future water flows.

The impacts of climate change on agriculture are better understood through remote sensing techniques. Uslu et al. (2021) used remote sensing and hybrid crop models to estimate crop areas and yields in Egypt, demonstrating how such studies provide valuable tools for assessing the effects of climate change on agricultural productivity. Özdemir (2023) utilized Sentinel-1 and Sentinel-2 satellite imagery to estimate above-ground biomass, examining its relationship with climate change. Similarly, Roman et al. (2016) analyzed the global distribution of water vapor using data from NASA's AIRS and EUMETSAT's IASI, highlighting the connection between this data and climate change. Binarti and Santoso (2022) used satellite imagery to analyze land cover changes associated with climate change. Such studies are crucial for identifying climate change vulnerabilities and assessing its impacts.

In conclusion, the detection and monitoring of climate change have become more systematic and comprehensive through the use of remote sensing and GIS technologies. These technologies are crucial for understanding the impacts of climate change and developing strategies to address these changes. Climate change has significant effects on dam water levels, water quality, and overall performance, posing challenges to water resource management. The adaptation of dams to climate change is vital for the development of water management strategies and the sustainable management of water resources.

The aim of this study is to examine the changes in the water surface area of the Sivas 4 Eylül Drinking Water Dam between 2013 and 2022. In this context, annual variations in the dam's water surface area were analyzed using Landsat 8 satellite data. The satellite images were processed on the Google Earth Engine (GEE) platform, and water surface area calculations were conducted. These analyses provide critical data for understanding the impacts of climate change on the dam and developing water management strategies. The study serves as a guide for the sustainable management of water resources in the Sivas region and adaptation to climate change.

2. MATERIALS AND METHODS

2.1. Study Area

The study focuses on the Sivas 4 Eylül Drinking Water Dam, located in the central Anatolian region of Turkey, near the city of Sivas. The dam plays a crucial role in meeting the drinking water needs of the Sivas region and also contributes to irrigation and flood control. Due to its importance for water resource management in the area, the Sivas 4 Eylül Dam is a vital part of the region's water infrastructure. The study area is characterized by a semi-arid climate, where water levels in reservoirs can fluctuate significantly due to variations in precipitation patterns and temperature, factors that are influenced by climate change. This makes the dam an ideal site for assessing the impacts of climate change on water surface area and developing adaptation strategies.

Sivas is characterized by its altitude exceeding 1,000 meters and expansive steppe areas. The city exhibits continental climate features, with hot and dry summers and cold, snowy winters (Dirican, 2017). The annual average temperature in Sivas ranges between 10-12 °C. During the summer months, temperatures typically rise to around 30 °C, while in winter, they can drop as low as -10 °C (Semerci, 2017).

In terms of precipitation, Sivas reflects the general climatic characteristics of Central Anatolia. The annual average rainfall ranges between 400-600 mm. Precipitation typically peaks in the spring and autumn months, while winter precipitation falls primarily as snow (Açık, 2018). These meteorological factors directly influence agricultural and livestock activities, shaping the region's economic structure.

2.2. Materiel

Effectively utilizing Landsat satellite imagery on the Google Earth Engine (GEE) platform to calculate the water surface area of a dam requires a systematic methodology. This process includes data acquisition, preprocessing, water body extraction, and area calculation. The first critical step is acquiring Landsat 8 satellite imagery, which is essential for water body analysis. Landsat 8, with its Operational Land Imager (OLI), provides high-resolution imagery, and its 12-bit precision and enhanced spectral capabilities make it a suitable platform for water body analysis (Chen et al., 2019; Chen et al., 2022). Accessing these images through GEE simplifies the processing of large datasets and offers various algorithms for analysis (Hu et al., 2022; Chen et al., 2022).

Preprocessing satellite images is essential for enhancing the accuracy of water body identification. Atmospheric correction is necessary to remove atmospheric interferences, and normalizing the data is important to ensure consistency across different images. The Tasseled Cap transformation can be used to derive brightness, greenness, and wetness components, which are critical for distinguishing water bodies from land (Shnain, 2021; Chen et al., 2020; Zhou et al., 2017). The application of the Tasseled Cap transformation is an effective method, particularly for achieving high accuracy in water body extraction (Shnain, 2021; Zhou et al., 2017).

Water body extraction can be performed using various indices. The Normalized Difference Water Index (NDWI) employs green and near-infrared bands to highlight water features while suppressing the reflectance of soil and vegetation (Duan et al., 2021; Zhang et al., 2023). Additionally, the Modified Normalized Difference Water Index (MNDWI) can be applied, which includes the shortwave infrared band, particularly useful in urban areas where built-up features may interfere with water identification (Zhang, 2023; Wu et al., 2021). To enhance the accuracy of water body extraction, machine learning algorithms, such as decision trees or neural networks, can be utilized. Research indicates that multilayer perceptron neural networks can significantly improve the extraction process (Liu et al., 2018; Li et al., 2022).

Once the water bodies have been successfully extracted, calculating the surface area is necessary. This is accomplished by converting the binary water mask (with water defined as 1 and non-water as 0) into a vector format, followed by calculating the area of the defined water bodies using geographic analysis tools within GEE (Stankova, 2023; Luo et al., 2022). Validation is essential to ensure the accuracy of the results; this can be done by comparing the extracted water area with on-site measurements or using high-resolution images for cross-validation (Li et al., 2023; Ullmann et al., 2020).

In conclusion, the integration of Landsat imagery with GEE provides a powerful tool for monitoring and calculating the water surface areas of dams. By following the outlined methodology, researchers can effectively utilize remote sensing technology, which is vital for collecting critical data on water resources. This information is highly valuable for sustainable management and environmental monitoring (Balcik & Ergene, 2016; Lamqadem et al., 2018).

3. RESULTS AND DISCUSSION

The water surface areas of the Sivas 4 Eylül Dam were extracted from satellite imagery from 2013 to 2022. The water surface areas and temperature values are presented in Figure 1. The total area of the lake's water surface varied from 3.99 km² to 0.59 km², with the minimum surface area recorded in 2022 and the maximum in 2013. The spatial and temporal changes in the water surface area of the Sivas 4 Eylül Dam are illustrated through thematic maps created in Geographic Information Systems (GIS) and presented in Table 1. During the monitoring period, fluctuations in surface area were observed over the years. The maximum increase in surface area, at 34.46%, occurred between 2019 and 2020, while the maximum decrease, at 38.75%, was noted in 2022.

The results indicate a significant declining trend in surface area between 2013 and 2022. By 2022, the reservoir had lost a substantial 85.14% of its water surface area compared to 2013. Throughout these years, the water surface area increased only once in a single year, but the overall trend has consistently been downward.

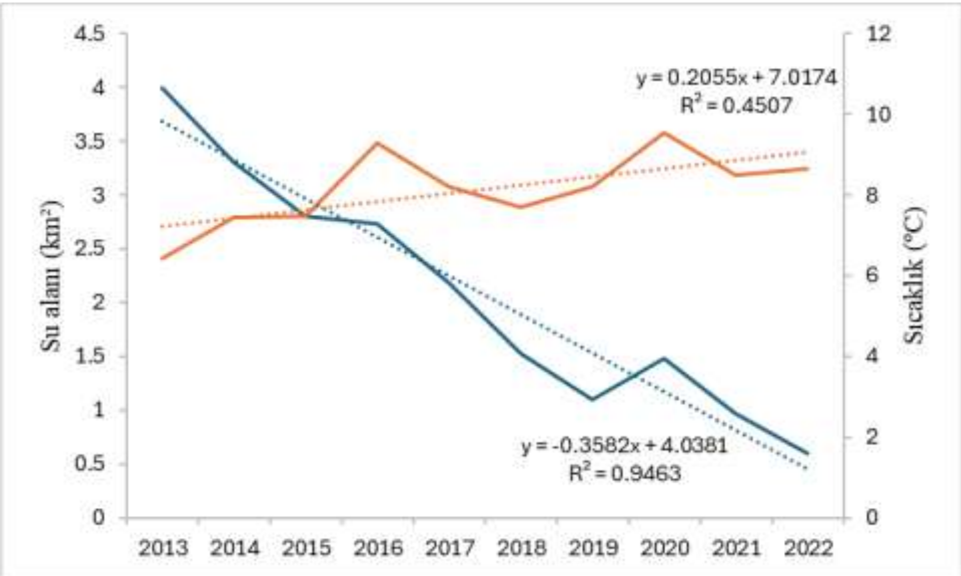

Figure 1. Water Surface Area and Temperature Values of Sivas 4 Eylül Drinking Water Dam by Year

The maps in Table 1 clearly depict the changes in the water body during the monitoring period from 2013 to 2022. These visual representations highlight the spatial dynamics and variations in water surface area over the specified years, providing valuable insights into the trends and fluctuations occurring in the Sivas 4 Eylül Dam.

Many studies have been conducted using remote sensing and Geographic Information Systems (GIS) techniques to monitor the water surface area of lakes and dams. Below are examples of various research efforts that have utilized remote sensing and GIS methodologies to track the water surface area of these bodies.

Duan et al. (2016) investigated the changes in the water surface area of Dongting Lake in China from 1980 to 2015. The study revealed a 30% reduction in the lake's area, which was associated with agricultural activities and climate change. Kumar et al. (2018) examined the changes in the surface area of Chilika Lake in India from 1990 to 2017. The research indicated a 20% decrease in the lake's area, linked to local climate conditions and human impacts. The authors emphasized the urgent need for conservation measures. Santos et al. (2020) analyzed the changes in the water surface area of the Amazon River in Brazil from 2000 to 2019, finding a 15% reduction associated with climate change and human activities. Niemeyer et al. (2022) studied the changes in the surface area of Lake Müritz in Germany from 1995 to 2021, reporting an 8% decrease related to climate change and human impacts. The authors suggested the development of ecosystem management strategies for the lake's conservation.

Table 1. Surface Area of the Sivas 4 Eylül Dam, Images, and Area Change Rates

Year	Map	Surface Area (km2)	Change Rate of Surface Area Compared with Initial Area (%)	Change Rate of Surface Area Compared with Previous Year (%)
2013		3.993	-	-
2014		3.304	-17.27%	-17.27%
2015		2.803	-29.79%	-15.14%

2016		2.729	-31.66%	-2.66%
2017		2.184	-45.30%	-19.95%
2018		1.521	-61.91%	-30.36%
2019		1.102	-72.41%	-27.59%
2020		1.481	-62.91%	+34.46%
2021		0.969	-75.73%	-34.58%
2022		0.594	-85.14%	-38.75%

In Turkey, Karakaya et al. (2018) examined the changes in the water surface area of Lake Eğirdir from 1980 to 2016. The study revealed a 30% reduction in the lake's area, attributed to climate change, agricultural irrigation, and human activities. Öztürk et al. (2019) assessed the changes in the water surface area of Lake Van from 1990 to 2018, noting a 25% decrease associated with climate change and water management issues. Akkaya et al. (2020) investigated the water surface area of Lake Sapanca from 2000 to 2020, finding an 18% reduction linked to local climate conditions and human impacts. Yılmaz et al. (2021) evaluated the changes in the surface area of Lake Manyas from 1985 to 2020, reporting a 40% decrease related to agricultural activities and climate change. Çelik et al. (2022) studied the changes in the water surface area of Lake Burdur from 1990 to 2021, observing a 50% reduction connected to climate change and human impacts. Kara et al. (2023) examined the surface area changes of Lake İznik from 2000 to 2022, finding a 22% decrease associated with climate change and water management issues. Şanlıyüksel Yücel and Yücel (2017) used remote sensing satellite imagery and unmanned aerial vehicles (UAVs) to determine the surface areas of mining lakes in abandoned coal mines in the Çan coal basin. The authors reported a decrease in the total surface area of all lakes from 2013 to 2014, with two lakes completely drying up. However, when these dried lakes were excluded from the calculations, the total area of the lakes was found to have increased. The reported decreases and increases in the total area of the lakes were attributed to both natural and anthropogenic processes such as erosion, precipitation, wind, mining activities, and water drainage into streams.

In this study, fluctuations in the surface area of the reservoir were observed during the monitoring period. The minimum area was calculated in 2022, while the maximum area was recorded in 2014. Additionally, the most significant decrease in surface area from one year to the next occurred in 2022, with a decline of 38.75%, while the largest increase was observed in 2020, at 34.46%. These changes may be related to climate shifts, including rising temperatures, decreasing precipitation, increasing evaporation, reduced surface runoff, and melting snow, as well as an increase in water consumption. Similarly, Kale (2017a) reported a rising trend in temperatures in Çanakkale, while another document presented by Kale (2017b) indicated that evaporation is expected to trend upwards in future periods. Furthermore, Ejder et al. (2016a) noted a decline in the annual flow of Sarıçay Stream, indicating a downward trend in flow. Similar downward trends due to climate change have been reported for other rivers as well. For instance, Ejder et al. (2016b) reported a decreasing trend in the flow of Kocabaş Stream. Kale et al. (2016a) documented a declining trend in the flow of the Bakırçay River, while Kale et al. (2016b) indicated a decrease in the flow of the Karamenderes River. Kale et al. (2018) also reported decreasing trends in the flows of the Tuzla, Büyük Menderes, and Gediz rivers. Kale and Sönmez (2018a) recorded a decline in the flow of Akkaya Stream, while Kale and Sönmez (2018b) noted a decreasing trend in Daday Stream's flow. Sönmez and Kale (2018) observed a significant reduction in the flow of the Filyos River.

As evident in the literature, climate change is often viewed as a driving force behind changes in water resource quantities. However, there are other factors affecting water resources aside from climate change, including human activities (Gao et al., 2011; Jackson et al., 2011; Zhou et al., 2015), agricultural practices (Dügel & Kazancı, 2004; Yercan et al., 2004; Kaçan et al., 2007; Durdu, 2010), excessive water consumption, and unsustainable water use. Contrary to popular belief, Turkey is not a water-rich country (Hisar et al., 2015). Therefore, water resources must be utilized sustainably.

CONCLUSION

The Sivas 4 Eylü Barajı supplies water for drinking, domestic use, agricultural, and other human activities. As the only dam within the basin, it holds significant importance. This study monitored spatial and temporal changes in the water surface area from 2013 to 2022, when a decline in water levels began, using remote sensing and GIS technologies. Satellite imagery provides historical data, and the integration of remote sensing and GIS techniques offers numerous advantages for tracking spatial and temporal changes.

Throughout the monitoring period, spatial decreases and increases in the reservoir's water surface were observed. These changes may be related to climate factors such as rising temperatures and evaporation, decreased precipitation patterns, excessive water use for drinking, domestic, or agricultural purposes, sediment transport, and losses from water leakage. Therefore, future studies should investigate the relationships between the water surface and other influencing factors.

Moreover, continuous monitoring is essential to support decision-making processes aimed at ensuring the sustainability of water resources in the Sivas 4 Eylü Barajı. This study also clearly validates the value of integrating remote sensing and GIS techniques to obtain better results from historical satellite imagery.

ABSTRACT

Nowadays, regional development, urbanization, and urbanization problems have become significant issues worldwide. Urbanization is increasing with the migration of the population from rural areas to cities, leading to the rapid growth of cities. However, this rapid urbanization also brings many problems. Regional development and urbanization are important factors in economic and social development. Due to the deterioration of urban areas, the concept of urban development has emerged. Urban development requires a regional approach that considers economic development, social participation, and environmental protection. Successful urban development requires an integrated approach to the different dimensions of urban life. This study focuses on the impacts of regional development on urbanization problems, the stages it undergoes, and its negative aspects.

Keywords: Regional development, Urbanization, Urbanization problems, Environmental protection

INTRODUCTION

Urbanization, especially in urban areas with inadequate social support and infrastructure, can lead to inequalities and health problems. Policies should focus on improving the socio-economic conditions of urban deprivation and promoting better health conditions. Urban growth is influenced by factors such as industrialization, infrastructure, and fiscal decentralization. Countries should reform their economic institutions, improve urban infrastructure, and promote industrial upgrading for sustainable urbanization. Regional disparities in urbanization should be addressed through the rational use of urban land as they threaten sustainable development (Ali & Varshney, 2012; Kuddus et al., 2020; Wei et al., 2023).

Urbanization encompasses the large-scale migration of people from rural to urban areas and the consequent alterations in urban landscapes. According to the United Nations in 2019, over half of the global population, approximately 4.2 billion individuals, resided in urban areas, a figure anticipated to swell to 6 billion by 2041 (United Nations, 2019).

Cities indeed hold diverse functions within societies. They serve as epicenters for technological advancement and economic prosperity for many nations, yet concurrently act as incubators for poverty, inequality, environmental risks, and communicable diseases (McMichael, 2000). The concentration of individuals in urban settings gives rise to various challenges, especially among low-income groups. For instance, numerous rural migrants relocating to urban slums bring along their families and pets, comprising both domestic animals and livestock. This influx of human and animal populations renders all migrants susceptible to prevalent infectious diseases, potentially establishing a cycle of urban transmission. Moreover, many low-income individuals in cities live in unregulated, harsh conditions, overcrowded areas near open sewers, and geographically hazardous areas such as slopes, riverbanks, and watersheds prone to landslides, flooding, or industrial hazards. All these factors contribute to the spread of infectious and non-infectious diseases, pollution, malnutrition, road traffic accidents, etc. (Alirol et al., 2011; Harpham & Stephens, 1991; Moore et al., 2003). The problems faced by low-income groups also impact other urban residents. As the trend of urbanization continues, this spillover effect increases, and the global dimension of these impacts becomes more pronounced as more of the world's population is affected (Alirol, 2011).

Urbanization gives rise to several significant health issues, including malnutrition, health conditions related to pollution, infectious diseases, inadequate sanitation and housing conditions, and associated health challenges. These problems directly impact individuals' quality of life and impose burdens on public health systems and resources (Kennedy, 2003).

Urbanization significantly impacts the nutritional health of impoverished populations negatively. Limited financial resources and elevated food costs in urban areas result in inadequate diets for the urban poor, leading to illnesses that cause reduced appetite and impaired nutrient absorption among affected individuals. Moreover, environmental pollution exacerbates malnutrition, and street food preparation under unhygienic conditions often leads to outbreaks of foodborne illnesses such as botulism, salmonellosis, and shigellosis (Kennedy, 2003). Urban dwellers also contend with overnutrition and obesity, which represent burgeoning global public health concerns. Obesity and related lifestyle conditions contribute to chronic ailments like cancer, diabetes, and cardiovascular diseases. While obesity predominates among affluent populations, international bodies have observed a surge in obesity rates among the middle class and the impoverished in recent years (WHO, 2000).

Low-income countries have populations suffering from protein-energy malnutrition (Nour, 2010), and the impact of micronutrient deficiencies on immune system development and function has increased susceptibility to infections (Tomkins & Watson, 1989; Schaible & Stefan, 2007). It is estimated that approximately 168 million children under the age of 5 are malnourished worldwide, with 76% of these children living in Asia (Ahmed et al., 1998). The World Health Organization is also concerned about an emerging obesity epidemic in poor countries, leading to non-communicable diseases such as diabetes, cardiovascular diseases, cancer, hypertension, and stroke (WHO, 2006).

Pollution is another significant factor contributing to deteriorating health conditions in urban environments. For example, the World Health Organization estimates that 6.5 million people died due to indoor and outdoor air pollution (11.6% of all global deaths), with about 90% of air pollution-related deaths occurring in low- and middle-income countries (WHO, 2016). Malnutrition and pollution also pave the way for the third major problem for urban populations: infectious diseases. Low-income individuals live in overcrowded conditions near open sewers and stagnant water, continuously exposed to health-threatening waste (Kennedy, 2003). Poor sanitation can lead to the transmission of helminths and other intestinal parasites. Pollution from overcrowded urban areas (e.g., CO2 emissions) contributes to local and global climate change, leading to direct health issues such as respiratory diseases, cardiovascular diseases, and cancers for both the wealthy and the poor.

National and international researchers, as well as policymakers, have investigated diverse strategies to tackle these challenges, yet the issues persist. For instance, research into solutions for mega-cities has been underway since the early 1990s. These studies have highlighted the importance of addressing pollution, electricity shortages, and dysfunctional infrastructure as primary endeavors. However, systematic attention to issues such as air pollution, urban water quality, traffic congestion, disaster management, and infrastructure remains lacking (Fuchs et al., 1994).

Urban centers do not expand in isolation; instead, they evolve in reaction to changing conditions (Thakur, 2002). Urban growth occurs as a consequence of population concentration in reaction to the accessibility of diverse amenities and services within the urban center. Furthermore, the urban populace is observed to be dispersed across settlements of differing magnitudes, ranging from small towns to metropolises, based on their functional significance (Pascione, 2001). Small towns may begin as villages, but due to increasing agglomeration economies, their nodality, functions, and services (both local and central) gradually transform them into urban centers over time (Verma, 2006). In the developing model, small and medium-sized towns grow more slowly in the early stages of urbanization compared to large cities, but in the later stage, small towns also grow as a result of congestion and overcrowding in large and medium-sized towns. Therefore, the growth of towns follows the urbanization cycle from small town, intermediate town, and primate city stages (Geyer & Kontuly, 1993). It is worth noting that the continuous increase in urban size is not sustainable. A decline in the growth rate occurs over the long term with the increasing size of urban centers (Mills & Becker, 1986). However, to benefit from the growth momentum, their natural growth must be allowed. In this scenario, achieving the optimal size of urban growth is challenging and ultimately, growth optimality will find its own level (Bhagat, 2005). The optimum level of growth depends on the urban center's capacity to provide all necessary amenities to the public fairly. High capacity increases the optimum level, while an influx of migrants beyond capacity puts excessive strain on the provision of basic amenities, leading to various urban problems.

Such a phase of over-urbanization engenders numerous challenges in urban centers. These include housing shortages, water scarcity, inadequate healthcare facilities, unemployment, escalating poverty and suicide rates, the proliferation of slums and informal settlements, the surge in beggars and homeless individuals, crime rates, including theft and kidnapping, traffic congestion, overcrowding, and atmospheric pollution, among others. These issues primarily stem from the continuous urbanization process observed in major cities (Verma, 2006; Mandal, 2000). This scenario reflects the peak growth of an urban center, after which a decline in urban expansion sets in. The necessity to alleviate such undesirable urban phenomena has prompted the emergence of urban planning. Urban planning is typically formulated with the objective of enhancing the aesthetics of the urban environment, making it more conducive to comfortable living, and addressing the well-being and welfare of inhabitants (Ali & Varshney, 2012). Regional development aims to enhance the economic, social, and environmental development levels of a country or region. However, urbanization can affect this process and cause some regions to develop more rapidly than others. Particularly in large cities, intense development can lead to increased economic and social inequalities between surrounding provinces and rural areas.

Urbanization also brings various problems. These include unplanned settlements, lack of infrastructure, traffic congestion, air and water pollution, housing issues, unemployment, inadequate social services, and rising crime rates. These issues negatively impact the quality of life for urban residents and contribute to the increase in environmental problems.

To address regional development and urbanization issues, various policies and strategies are being developed. These include urban planning, sustainable urban development, infrastructure investments, housing policies, equal distribution of job and education opportunities, environmental protection measures, and rural development support.

Sustainable urban development is particularly important for meeting the needs of urban residents while minimizing environmental impacts. In this context, it is necessary to develop public transportation systems, increase green spaces, ensure energy efficiency, and implement environmental planning practices.

Sustainable urban development represents an approach adopted to ensure that cities grow in an economically, socially, and environmentally healthy and balanced manner. This approach aims to meet the needs of current and future generations while focusing on the preservation of natural resources and minimizing environmental damage.

Sustainable urban development encompasses various dimensions

Economic Dimension: This aims to economically develop cities and ensure sustainable economic growth. Steps include increasing local employment opportunities, strengthening the labor market, and promoting sustainable economic activities.

Social Dimension: Sustainable urban development ensures social equity and justice. It involves meeting the needs of all urban residents, ensuring social participation, and facilitating access to housing and basic services.

Environmental Dimension: This ensures the protection of the environment and the sustainable use of natural resources. Measures include increasing energy efficiency, reducing greenhouse gas emissions, improving waste management, and preserving and increasing green spaces.

Measures for Sustainable Urban Development

Urban Planning: Adopting effective urban planning strategies to protect natural resources and preserve green spaces.

Transportation and Infrastructure: Developing public transportation systems, increasing bicycle lanes and pedestrian paths, and promoting environmentally friendly transportation systems.

Energy Efficiency: Increasing the energy efficiency of buildings and promoting the use of renewable energy sources.

Waste Management: Expanding recycling and waste reduction programs.

Green Spaces and Biodiversity: Increasing green spaces within cities and preserving biodiversity.

Sustainable urban development is a crucial strategy for achieving sustainability goals in cities and helps to leave a more livable environment for future generations.

Strategies for Effective Management

Collaboration and Policy Integration: Coordination among local, national, and international bodies is essential to develop comprehensive policies that address both urban and rural development needs. This includes integrated planning and resource allocation to ensure balanced growth.

Improving Rural Conditions: Investing in rural infrastructure, healthcare, education, and employment opportunities can reduce the pressure on urban areas by making rural living more viable and attractive.

Urban Planning and Sustainable Development: Implementing effective urban planning strategies to manage urban growth, promote sustainable development, and mitigate the negative impacts of rapid urbanization. This includes:

Developing efficient public transportation systems.

Ensuring adequate housing and basic services.

Promoting energy efficiency and the use of renewable energy sources.

Preserving green spaces and enhancing biodiversity.

Implementing robust waste management and recycling programs.

Addressing Urban Challenges: Governments should focus on tackling the issues that arise from rapid urbanization such as:

Alleviating traffic congestion through better infrastructure and public transportation.

Reducing pollution and improving air and water quality.

Enhancing public safety and reducing crime rates.

Providing adequate social services and healthcare facilities.

Ensuring access to education and employment opportunities.

RESULTS AND DISCUSSION

Regional development, urbanization, and urbanization problems have become serious global issues today. To effectively address these challenges, local governments, national governments, and international organizations must collaborate and develop sustainable solutions. This way, a more livable future can be built to enhance the quality of life for everyone and protect the environment.

Migration to urban environments will persist until conditions in rural areas improve. Considering the challenges posed by rural development, it seems unlikely that the underlying causes will be addressed in the near future. Therefore, governments and development agencies should prioritize adapting to the challenges of urbanization while striving to mitigate unplanned urbanization.

CONCLUSION

By adopting a holistic approach that includes improving rural areas and managing urban growth, we can create a more balanced and sustainable development model. Collaboration among all levels of government and international organizations is crucial for implementing these strategies effectively. This collective effort will help build a future where all individuals can enjoy a higher quality of life in a healthier environment.

ABSTRACT

In Algeria, several estimates indicate a decrease in rainfall ranging from 20 to 36% since the 1970s. The Tébessa region (Southeast Algeria) is part of the North Aurès region, in the Medjerda Mellègue watershed, with a semi-arid climate where precipitation is less than 400mm/year. Over the past twenty years, the region has experienced a very clear climate change that has led to significant impacts such as a decrease in river runoff and a decline in groundwater levels. This change was characterized by a hydro-pluviometric deficit evaluated at 30%, which had repercussions on all socio-economic activities in this region, especially on its agricultural development. Groundwater constitutes the main source of irrigation water for the plain. This study aims to assess the influence of climate change on groundwater quality. This evaluation was approached by the combined study of the evolution of two climatic parameters (precipitation and temperature) during the period (1986-2020), groundwater levels, and the physico-chemical parameters of groundwater. Thematic maps were developed using Geographic Information System (GIS) to identify the chemical facies of the waters, their quality, and their suitability for irrigation purposes. The results obtained showed that according to the sodium adsorption ratio and percentage sodium, more than eighty percent of the samples are suitable for irrigation. By exploring this data, we can gain a comprehensive understanding of the challenges and opportunities associated with water resources in Tebessa within the context of climate change.

Keywords: Climate change; Quality; Groundwater; Irrigation; GIS

INTRODUCTION

The quality of the water used for irrigation is an essential parameter for crop yield, maintaining soil productivity and protecting the environment. Thus, the physical and chemical properties of the soil, such as its structure (stability of aggregates) and its permeability, are very sensitive to the type of potentially exchangeable ions present in irrigation water.

The study region is one of the regions most vulnerable to climate variability (Laborde, 1993 and Meddi, 2009 - Boudjadja et al, 2003 - Ghenim et al., 2010 and 2013). Major factors on the availability, quality and quantity of water precisely for agriculture and on the productivity of crops over the coming decades.

Groundwater is the main source of irrigation water on the Tebessa Plain. The objective of our work is to assess the quality of groundwater and its suitability for irrigation in the face of climate change. The study of water chemism aims to identify the chemical facies of water, their quality, their origin and their suitability for irrigation

.

MATERIAL AND METHOD

The Morsott region is part of the North Auresian domain, of the Medjerda Mellègue watershed (figure 1). It is limited to the north by El aouinet, Bukhara and El meridj, to the south by Bir Dhab and Boulhaf Dyr, to the east by Ain Zerga, and to the west by Meskiana. The climate is characterized by the alternation of a hot and dry season and a cold and humid season. The hydrographic network is well developed and represented with small temporary watercourses with wide, well-developed valleys flowing into the Oued Chabro which flows upstream of the Oued Mellegue precisely to the south of the commune of El Aouinet.

The study region is part of the North Auresian domain, of the Medjerda Mellègue watershed, is characterized by a semi-arid climate where precipitation is less than 400mm / year.). It has experienced a decrease in rainfall, a decrease in the runoff of rivers and the drop in piezometric levels of groundwater reserves (UNDP. 2009), and for the last 30 years the region subject to a rainfall deficit estimated at 25-30% (FAO 2008) .This rainfall deficit is reflected on all socio-economic activities in this region, especially on its agricultural development.

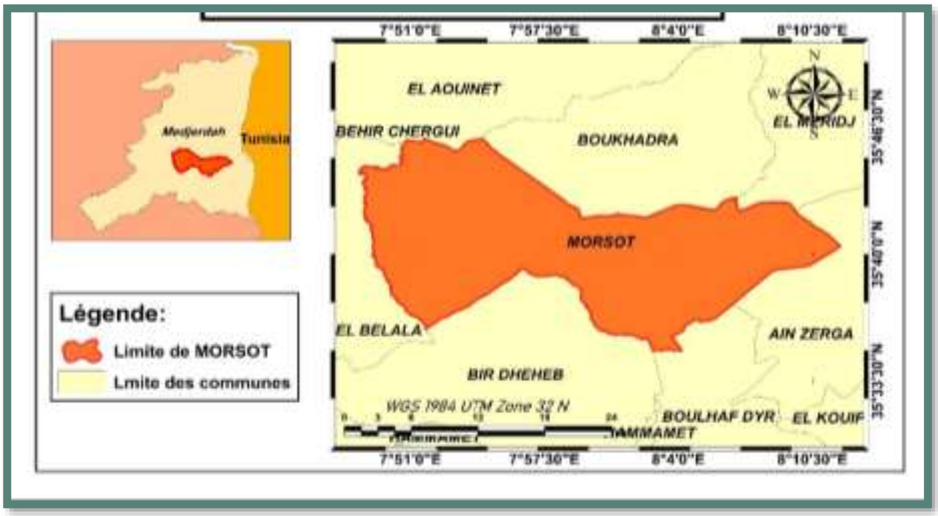

Figure 1. Geographical position of study Area

We carried out the collection of water samples (figure 2) during the month of March. The qualitative study of groundwater is based on the analysis of physicochemical parameters: pH, T °C, electrical conductivities, TDS, Chloride, Nitrate, Sulfate, Sodium, Potassium, Calcium and Magnesium.

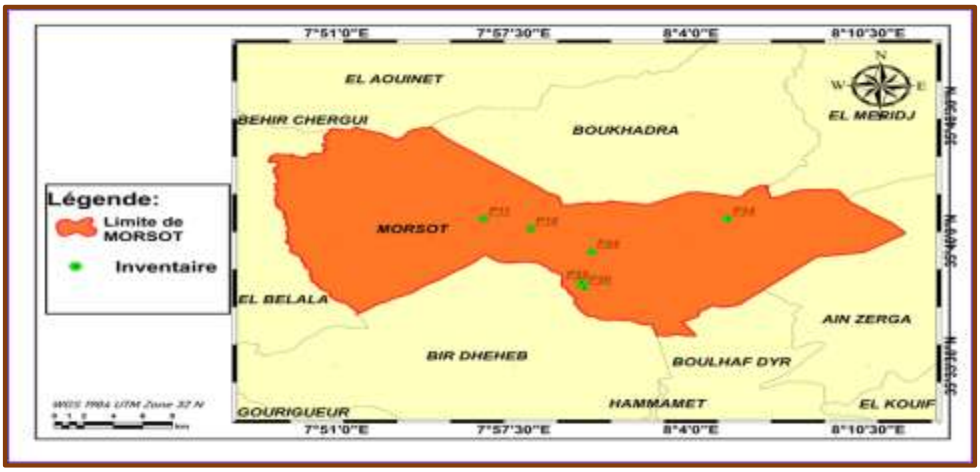

Figure 2. inventory map of sampling

RESULTS AND DISCUSSION

Climate analysis

The observation of the graph (Fig.3) shows an almost cyclical variation of deficit episodes and surplus episodes. The average annual water blade is equal to 362.23 mm. The period from (2000-2001 to 2011-2012), is characterized by a surplus. On the other hand, the driest years are 1993, 2000, 2013 -2014 to 2015-2016

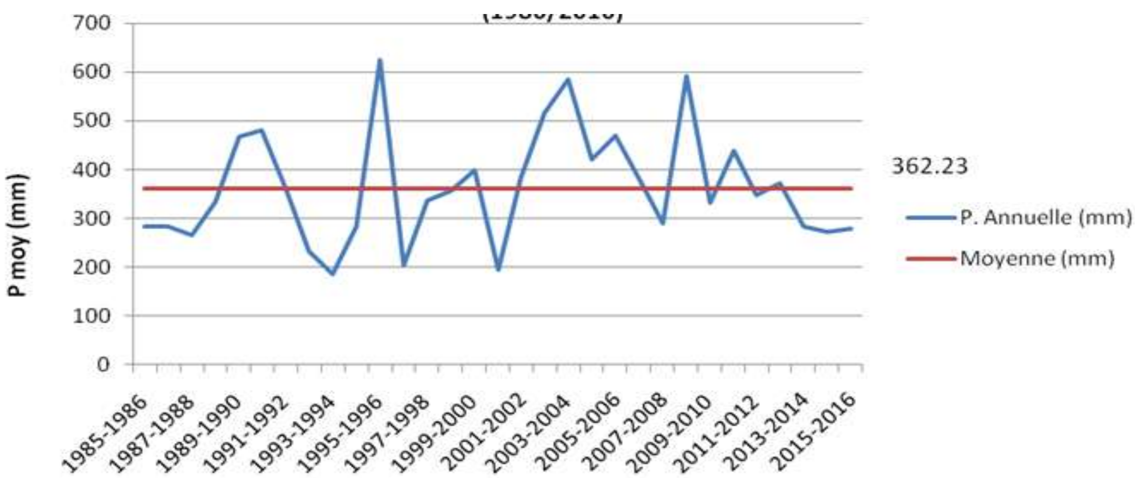

Figure 3 variation of precipitation in study area

The annual mean temperatures vary between 13.5 °C (2008-2009) in the coldest year and 19.08 °C (2000-2001) in the warmest year. The rest varies between 14.5 and 17.3 °C, the mean is 16.75 °C and a standard deviation is 2.79. (Fig.4)

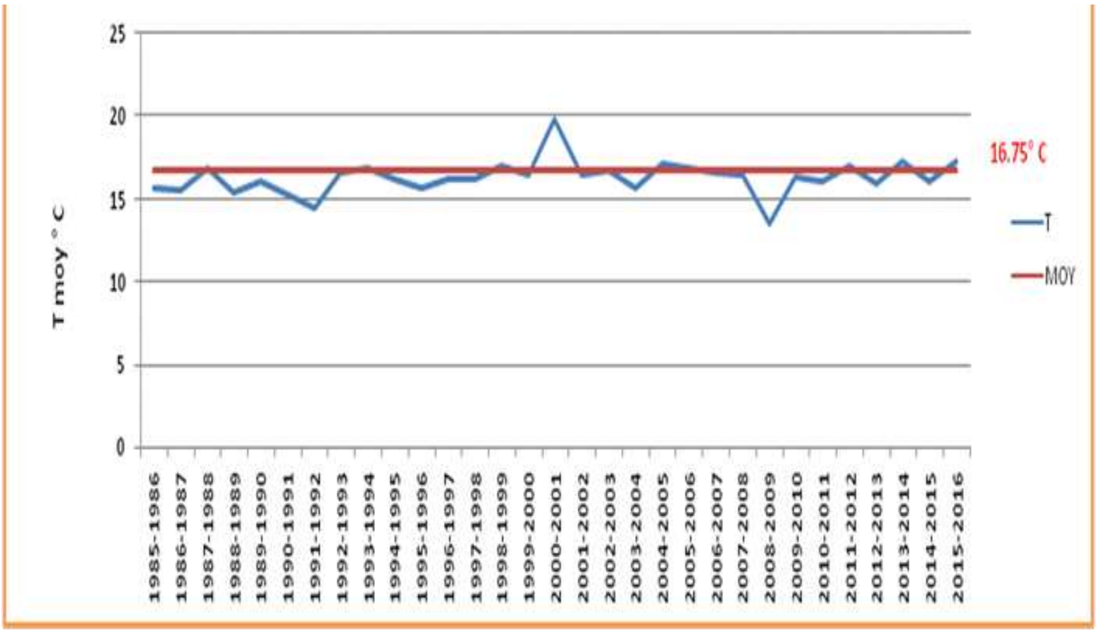

Figure 4 Average annual temperatures of the Tébessa

Physicochemical parameters

Water samples are characterized by a basic pH that varies between 7.80 and 9. The water temperature varies between 15.22 °C and 20.46 °C TDS (total dissolved salts): Very high values vary between 1200 mg/l and 1.728 x104 mg/l An increase in the values of Electrical conductivity varies between 1700 µS/cm and 3000 µS/cm (Fig. 5)

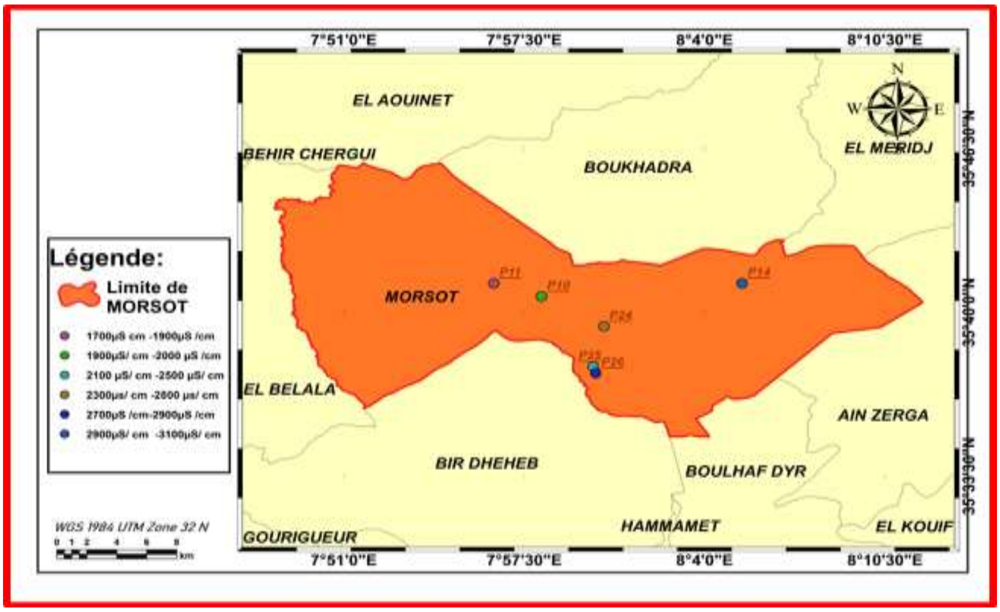

Figure.5.Distribution of electrical conductivity values of samples

Variation of anion and cation contents

HCO3- values ranged between [50mg/l - 80 mg/l]

$SO4^{-2}$ contents ranged between [60 mg/l – 120 mg/l]
Cl^{-} values ranged between [60 mg/l - 160mg/l]
Ca^{+2} values ranged between [02 mg/l - 30 mg/l]
Mg^{+2} contents ranged between [2 mg/l - 160 mg/l]
Na^{+} values ranged between [2 mg/l - 30 mg/l]
K^{+} values ranged between [1.5mg/l - 161 mg/l]

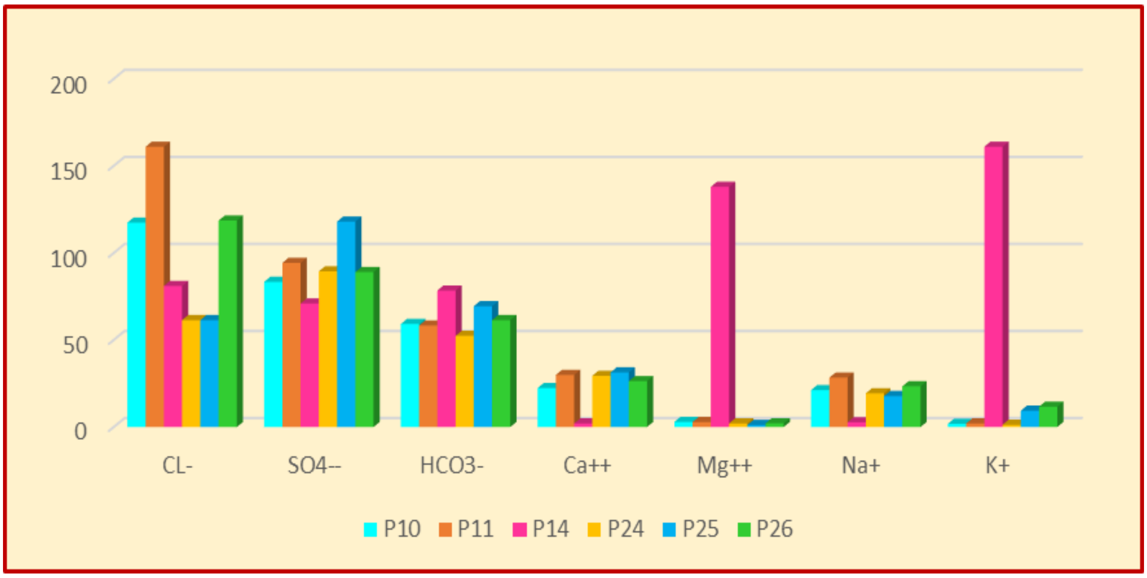

Figure.6. Variation of the contents (Ca+2, Mg+2, Na+, K+) and (Hco3-, Cl-, So4-2) of groundwater

Chemical facies of waters

The samples are distributed between three facies: calcium chloride and calcium sulfate and magnesium chloride Fig.7,

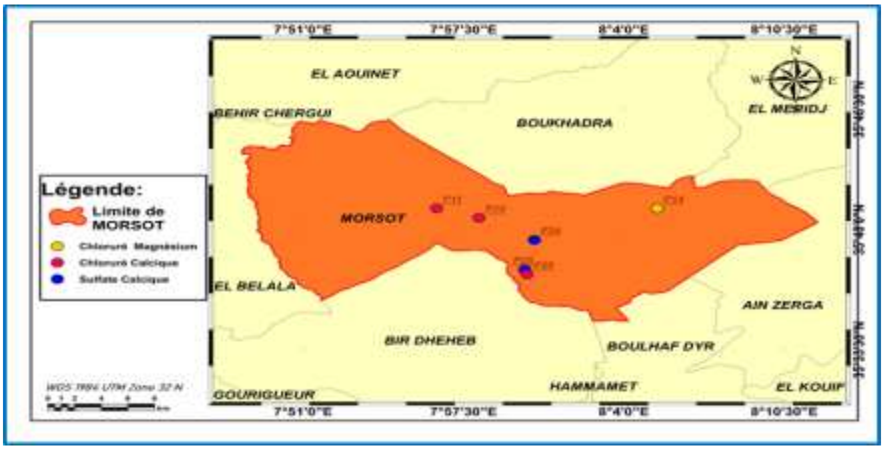

Figure.7. Distribution of chemical facies of the samples

After having plotted all the water points on the RICHARDS diagram (Fig.8) we obtain the following classes: Class C3S1: designates the waters admissible for the irrigation of salt-tolerant crops, on well-drained soils or with good permeability whose salinity must be controlled. Class C4S1: indicates the mediocre waters highly mineralized, likely to be suitable for the irrigation of certain species well tolerant to salts and on well-drained and leached soils.

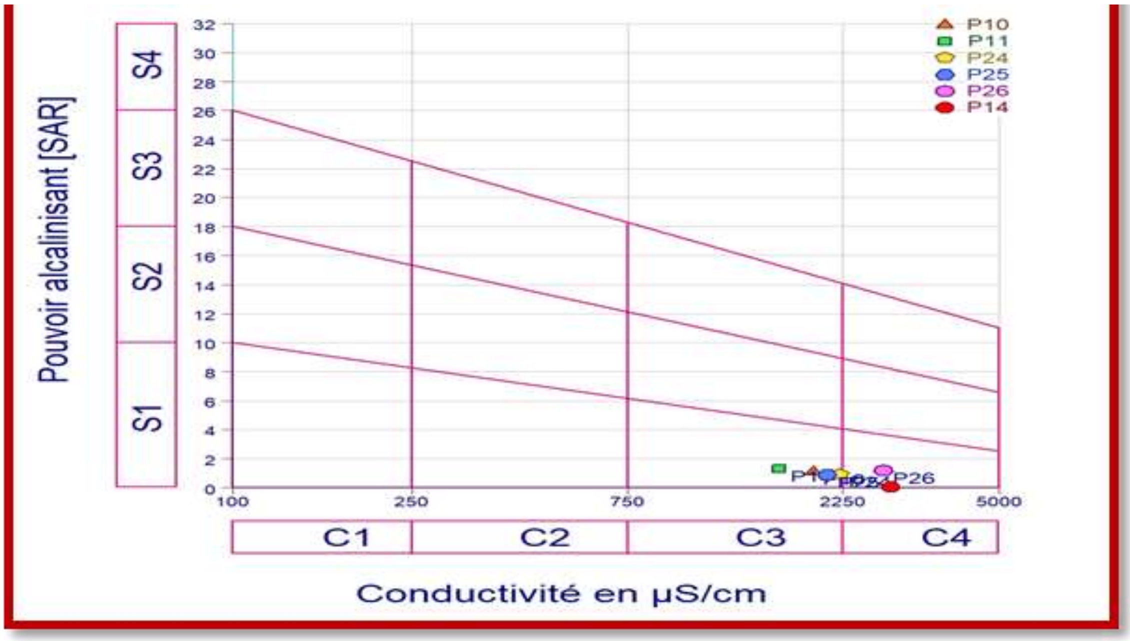

Figure 8. Representation on the RICHARDS diagram) of the waters “March 2021”.

The richness in elements Na^+, Cl^-, Ca^{2+} and SO_4^{--} is linked to the dissolution of minerals likely to form by evaporation of waters loaded with salts and by dissolution of evaporite formations. On the other hand, the elements Ca^{2+}, Mg^{2+} and HCO_3^- are linked to the dissolution of carbonates

CONCLUSIONS

The results obtained showed that the waters are characterized by very high values of total dissolved salts varying between 1200 mg / l and 1.728 x104 mg / l. The values of the electrical conductivity are generally high, varying between 1630 µS / cm and 3100 µS / cm, the pH of the samples is basic which oscillates between 7.80 and 9. The water temperature vary between 15.22 ° C and 20.46 ° C. The samples are distributed between three facies: calcium chloride and calcium sulphate and magnesium chloride. The groundwater in the region is moderately to highly mineralized, which poses a risk of soil damage. This mineralization would come from the dissolution-precipitation -of the aquiferous rock, in particular gypsiferous marls and evaporites.

AN APPLICATION OF HEAVY METAL POLLUTION INDEX AND HEAVY METAL EVALUATION INDEX TO EVALUATE THE WATER QUALITY OF ATIKHISAR DAM LAKE (ÇANAKKALE, TÜRKIYE)

Cem Tokatlı

Trakya University, Evrenos Gazi Campus, İpsala Vocational School, Department of Laboratory Technology, Edirne / Türkiye
**Corresponding Author: cemtokatli@trakya.edu.tr*

ABSTRACT

Environmental pollution is a significant global problem today and the concentrations of potentially toxic elements (PTEs) in especially freshwater habitats are rising day by day. Dam Lakes are artificial stagnant water bodies built for various purposes such as irrigation and drinking water supply and flood protection. However, over the years, they can become unusable as a result of various factors such as pollution and sedimentation. The Atikhisar Dam Lake that is located in the south-west part of the Marmara Region has a great importance for the local people and for the region. In this research, concentrations of 9 PTEs including chromium (Cr), nickel (Ni), copper (Cu), zinc (Zn), arsenic (As), cadmium (Cd), lead (Pb), manganese (Mn) and boron (B) were investigated in water of Atikhisar Dam Lake. Heavy Metal Pollution Index (HPI) and Heavy Metal Evaluation Index (HEI) were used to evaluate the water qualities of investigated locations in terms of PTEs contamination. According to the applied heavy metal risk assessment indices, water of Atikhisar Dam Lake was recorded as "Low heavy metal contamination (HPI < 100)" in terms of applied HPI and "Low contamination (HEI < 10)" in terms of HEI.

Keywords: Atikhisar Dam Lake, Heavy Metal Pollution Index, Heavy Metal Evaluation Index

INTRODUCTION

Atikhisar Dam Lake is located in the Çanakkale Province of Türkiye and it meets the drinking water needs of the region. Therefore, the reservoir has a very critical impact on the health of many people living in the Çanakkale Province (Anonymous, 2020). The reservoir has a capacity of approximately 53 million m³ and it was built on the Çanakkale Stream in 1975 by State Hydraulic Works (DSİ). The body volume of the reservoir is 1.990.000 m³ and its height from the riverbed is 43 meters. The volume of the reservoir is about 40 hm³ and the reservoir area is about 3.30 km² at the normal water level (Anonymous, 2020; http://suyonetimiormansu.gov.tr).

Toxic metal risk assessment indices are used to evaluate the risk of toxic metal contamination in water and many risk assessment indices are developed to evaluate the synergistic effects of toxic metals. Heavy Metal Pollution Index (HPI) and Heavy Metal Evaluation Index (HEI) are 2 of the most significant water quality risk assessment indices used commonly all over the world (Tokatlı et al., 2021; Varol and Tokatlı, 2022; Haque et al., 2022; Jannat et al., 2022; Mutlu et al., 2023; Mia et al., 2023; Tokatlı et al., 2023; 2024; Yüksel et al., 2024). The aim of this research was to evaluate the water quality of Atikhisar Dam Lake in terms of potentially toxic elements (PTEs) by using Heavy Metal Pollution Index (HPI) and Heavy Metal Evaluation Index (HEI).

MATERIAL AND METHOD

Study Area and Collection of Samples

In the present study, levels of PTEs in water of Atikhisar Dam Lake were determined and the data were evaluated by using HPI and HEI. Surface water samples were collected from 3 stations (AH 1 – AH3; input of dam, mid of dam and output of dam) selected on the Atikhisar Dam Lake in rainy (winter) season of 2022 (Figure 1).

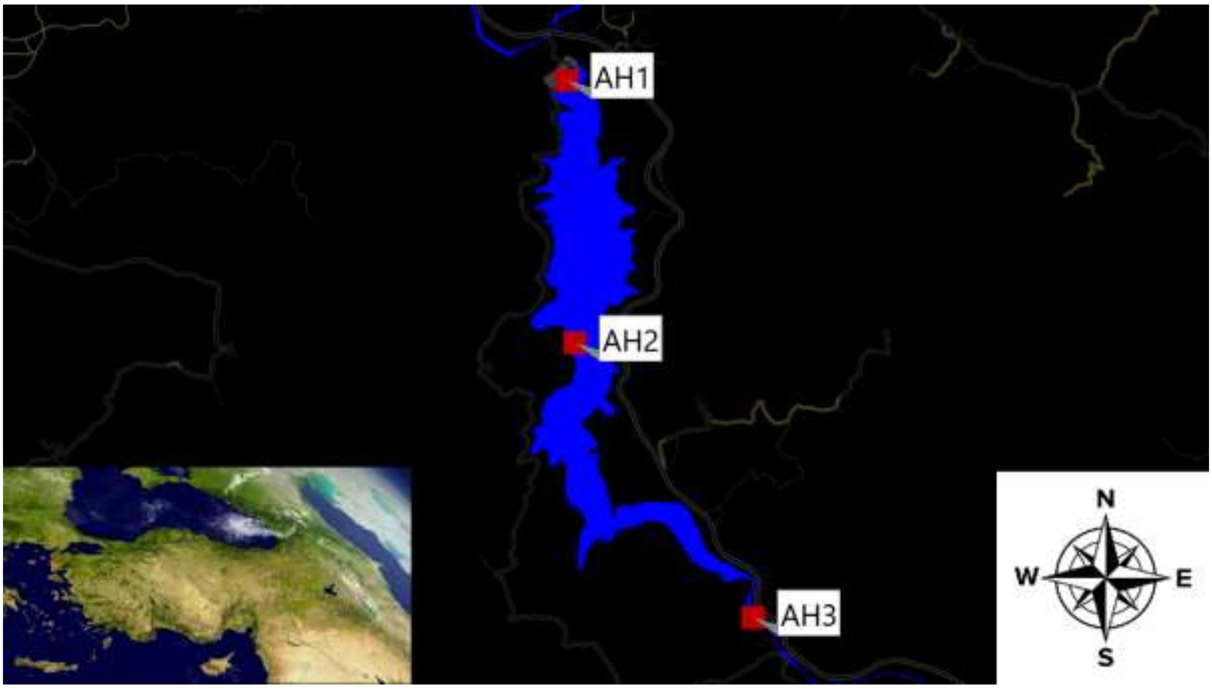

Figure 1. Study area and selected stations

Chemical Analysis

For determination of chromium (Cr), nickel (Ni), copper (Cu), zinc (Zn), arsenic (As), cadmium (Cd), lead (Pb), manganese (Mn) and boron (B) concentrations in water of Atikhisar Dam Lake, samples of one liter were adjusted to pH 2 by adding 2 ml of HNO_3 into each. Afterwards, all the samples were filtered (cellulose nitrate, 0.45 µm) in such a way as to make their volumes to 50 ml with ultra-pure water. The element levels in water samples were determined by using the "Agilent 7700 xx" branded Inductively Coupled Plasma – Mass Spectrometer (ICP-MS) device in Trakya University Technology Research and Development Application and Research Center (TÜTAGEM). The center has an international accreditation certificate within the scope of TS EN / ISO IEC 17025 issued by TÜRKAK (representative of the World Accreditation Authority in Turkey). The element analyses were recorded as means triplicate measurements (APHA, 1992; EPA, 2001).

Calculation of Risk Assessment Indices

Heavy Metal Pollution Index (HPI) (formulas 1 and 2) (Mohan et al., 1996) and Heavy Metal Evaluation Index (HEI) (formula 3) (Edet and Offiong, 2002) are being calculated according to the following formulas:

$$HPI = \frac{\sum_{i=1}^{n} W_i Q_i}{\sum_{i=1}^{n} W_i} \qquad (1)$$

$$Q_i = \sum_{i=1}^{n} \frac{M_i}{S_i} \times 100 \qquad (2)$$

$$HEI = \sum_{i=1}^{n} \frac{H_C}{H_{MAC}} \qquad (3)$$

“Qi” is the sub – index of the toxic element, “Wi” is the unit weight of the ith parameter, “Mi” is the monitored values of toxic metals, “Si” is the standard values of the parameter and n is the number of parameters considered (WHO, 2011). Water quality ratings for applied HPI are given in Table 1.

"Hc" is value observed for each parameter and "Hmac" indicates the value of maximum admissible concentration (MAC) for each parameter (WHO, 2011). Water quality ratings for applied HEI are given in Table 1.

Table 1. Water quality ratings for indices

Value	Rating of Water Quality	Usage Possibilities
Heavy metal pollution index (HPI)		
< 100	Low heavy metal contamination	Suitable
> 100	High heavy metal contamination	Not suitable
Heavy Metal Evaluation Index (HEI)		
< 10	Low contamination	Suitable
10 – 20	Medium contamination	Not suitable
> 20	High contamination	Not suitable

RESULTS AND DISCUSSION

According to the of applied heavy metal risk assessment indices, water of Atikhisar Dam Lake was recorded as "Low heavy metal contamination (HPI < 100)" in terms of applied HPI and "Low contamination (HEI < 10)" in terms of HEI (Figure 2). The monomial risk ranking of toxic metals were found as in terms of HPI: As > Pb > Mn > Cd > Ni > Cr > Cu > Zn > B; while the risks in terms of HPI were as follows: As > Mn > Pb > Ni > Cd > Cr > Cu > Zn > B (Figure 3). It was also determined that although the water quality of Atikhisar Dam Lake increases from input stations to output station, water of the whole reservoir found as "Suitable for consumption and use", in general.

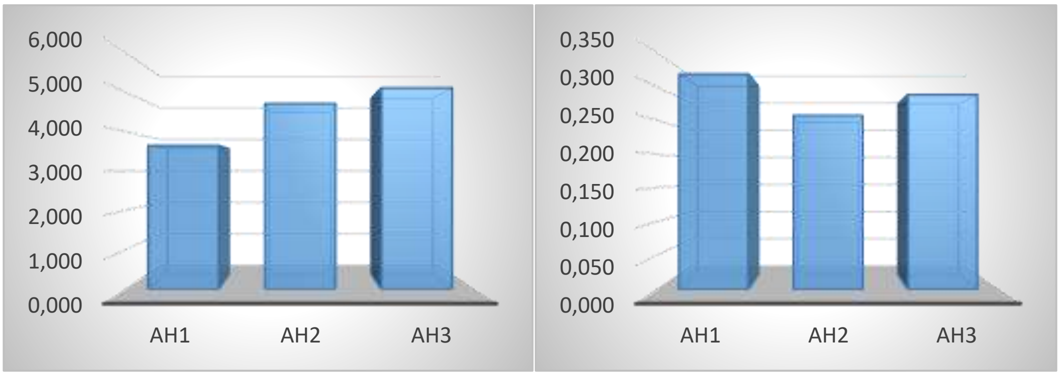

Figure 2. Results of applied HPI (left) and HEI (right)

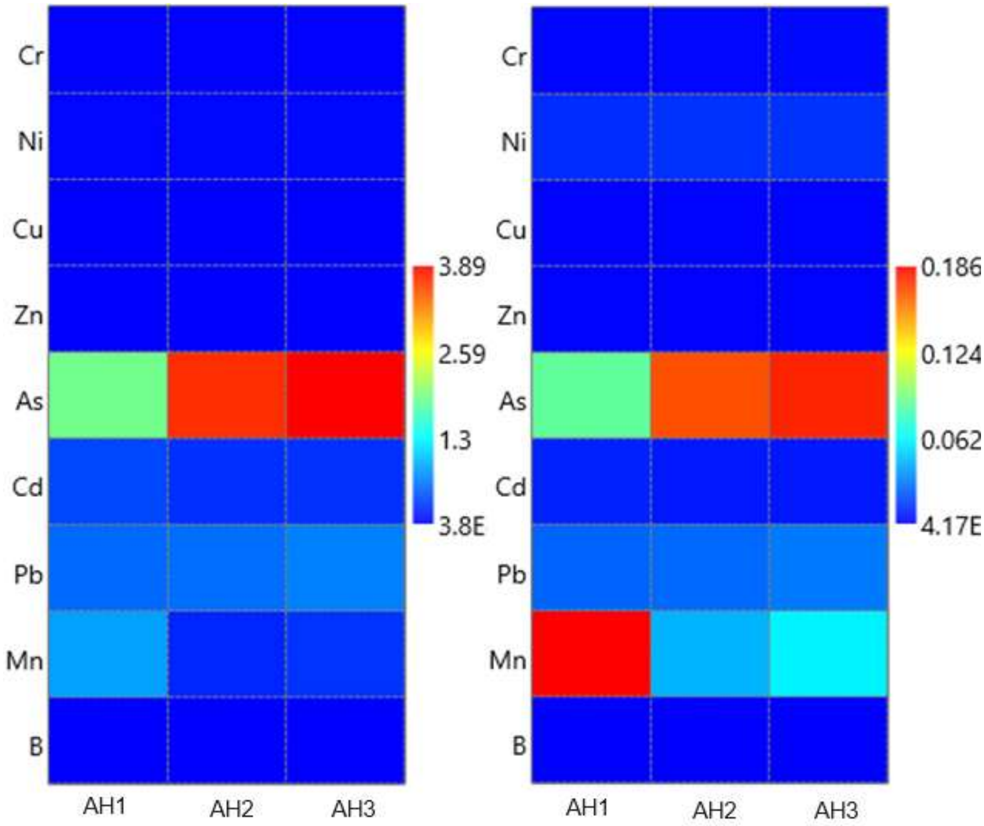

Figure 3. Monomial results of applied HPI (left) and HEI (right)

CONCLUSIONS

In this research, water quality of Atikhisar Dam Lake located in the Çanakkale Province of Türkiye was evaluated in terms of PTEs contamination by using HPI and HEI. According to the results of applied toxic metal risk assessment indices, Atikhisar Dam Lake was found as "Low heavy metal contamination" in terms of applied HPI and "Low contamination" in terms of HEI. The data of the present research also reflects the importance, applicability and necessity of the use of different toxic metal risk assessment indices together on evaluation of surface water ecosystems.

ABSTRACT

Brassicaceae is a large, and economically important plant family with a broad distribution. Some weedy species of the Brassicaceae family have critical impact on the global agriculture. In particular, those occupy cultivated areas can cause serious yield losses depending on the species and its density in the corresponding area. Identification of the weedy species and their phylogenetic relationships can help with sustainable controlling methods and therefore improve the agricultural production. Here, we attempted to identify, and also understand genetic relationships of the common Brassicaceae species occur in the wheat fields investigated from several provinces of Turkey, based on the nuclear ribosomal DNA (rDNA) sequence data. The study material was obtained from the seeds of weedy Brassicaceae species collected from their wild populations and subsequently germinated in greenhouse. Our results displayed presence of *Sinapis arvensis*, *S. alba*, *Chorispora purpurascens*, *Sisymbrium altissimum*, *Diplotaxis tenuifolia*, *Brassica elongate*, *Lepidium draba* and *Capsella bursa-pastoris* as the common Brassicaceae members found in the studied areas. Several of these species (e.g., *S. arvensis*, *S. alba*, *C. bursa*) were observed with considerable genetic divergence.

Keywords: agriculture, brassicaceae, rDNA, weed, wheat

INTRODUCTION

Brassicaceae is a large plant family exist across a wide range of habitats in the world.
The family includes 4000 species that are mainly adapted to the temperate and tropical regions of the world. While some of these species are economically important plants like cabbage, oilseed rape, mustard, and broccoli cultivated for food and industrial purposes etc., some others are invasive plants such as wild mustard, garlic mustard etc. (Appel and Al–Shehbaz 2003; Warwick et al. 2009).

Weedy Brassicaceae species can be detrimental to agricultural production. Previous studies (Ateş and Üremiş 2022) have reported the losses of the complete yield resulted from the weedy species took advantages of the rainy seasons. Besides hosting diseases and pests, since they compete for the nutrients, water, and light, weeds can considerably reduce the amount and the quality of the grown crops (Plaza et al. 2022). Weed invasions, also have a large negative impact on the wheat production, the cereal of a great importance to the global agriculture. For instance, weed seeds commix with the raw grains at harvest can significantly lower the quality of the composition, colour, flavour, and smell of the durum wheat (Ateş and Üremiş 2018). Moreover, such seeds can be toxic for the consumers including livestock (Keywanloo et al. 2021).

Controlling of the weedy species is usually performed by using herbicides function differently, a process known with limited success despite the economic and environmental costs. Improper applications of the herbicides, one of the common reasons of (Sevim et al. 2023) the poor success, frequently resulted from the incorrect identification of the weeds. Unfortunately, many weedy Brassicaceae species are confused by non–specialists due to their morphological aspects such as yellow flowers, and therefore treated with chemicals of no use. Furthermore, several different weedy species may co-exist in the cultivation land, a case requires more careful actions as each species needs to be evaluated separately. Briefly, the effective weed controlling can be achieved primarily by accurate characterization of the weeds, and that includes understanding of the weed species and their origins, how they adapt to a particular environment, and the genetic basis of their adaptations, and also the level of the preserved genetic variations (Sakai et al. 2001). This knowledge can help in finding more efficient ways of coping with the weeds.

The work presented here is a preliminary study focuses on the identification of the most common weedy Brassicaceae species occupy wheat growing fields in various regions of Turkey. By using sequence data of nuclear ribosomal DNA (rDNA) ITS locus, one of the most widely used markers in phylogenetic studies of the family Brassicaceae (German et al. 2009, Warwick et al. 2009), we have attempted to firstly identify the collected weeds, and then understand their genetic relationships which may provide insights into their controlling methods.

MATERIALS AND METHODS

Plant material was collected during 2020–2021 from wheat growing fields distributed to 10 provinces in the east, south–eastern, northern and western Turkey regions. In each province, three separate fields were visited, and approximatley15 Brassicaceae samples had reached to seed maturity were collected from each location. Collected samples were initially morphologically evaluated based on the literature (e.g., Kloos 1927; Ibérica 1993; González 2014) as well as the virtual herbaria, and grouped accordingly. To get the fresh material of the sampled plants, seeds from selected individuals were treated with 50% NaOH solution for 10 minutes in priori and germinated in an incubator at 20°C (Ateş et al. 2017). Germinated seeds were moved to the pots containing a mixture of peat, soil, and sand (1:1:1). The samples were kept in greenhouse (24 ºC ± 2 and 40% humidity) until they sufficiently grown. DNA isolation was made from the fresh leaves processed with liquid nitrogen (LN2) using the DNeasy Plant Mini Kit (Qiagen, Germany). Amplification of the rDNA ITS locus was performed via Vivantis–DNA–amplification kit (Vivantis, Lithunia) under the manufacturer's instructions. PCR and sequencing reactions were carried out with the universal primers of

ITS4 and ITS5. All amplified products were checked on an agarose gel, and the samples with proper bands were sent to BM Labosis (Ankara, Turkey) for sequencing.
Chromatograms were visualized and edited via UGENE–38.1. under the default settings. The final sequences were blasted (Johnson et al. 2008) against standard databases using "blastn" algorithm provided by National Center for Biotechnology Information (NCBI). The sequences hit to the queries with 95% or above similarity are considered for the determination of the collected samples in addition to the morphological evidence. Identified sequences were subjected to multiple sequence alignment using MAFFT as implemented in Geneious Prime 2022.1.1 (Biomatters, USA), and afterwards, manually adjusted regarding the improper positions. Genetic relationships of aligned sequences were estimated via PhyML, a Maximum Likelihood (ML) phylogenetic approach, available in https://ngphylogeny.fr (Dereeper et al. 2008, Lemoine et al. 2019). The estimated ML tree of the ITS sequences was illustrated with FigTree v1.4.4 (Rambaut 2018).

RESULTS AND DISCUSSION

The morphological examination and data from GenBank supported for the presence of a minimum10 distinct Brassicaceae species (excluding those we were not able to identify). Our results showed the occurrence of *Sinapis arvensis* L., Sinapis. *alba* L., *Chorispora purpurascens* (Banks & Sol.) Eig, *Sisymbrium altissimum* L., *Diplotaxis tenuifolia* (L.) DC, *Lepidium draba* L., Capsella bursa-pastoris (L.) Medik, and *Brassica elongata* Ehrh. as the common Brassicaceae members found in the studied wheat fields. Despite the effort, several *Sisymbrium* samples could not be determined at species level since their similarity to sequences listed by standard databases stayed below the thresholds value (%95) applied to the blast–search, neither the morphological features provided a clear sign. In order to be resolved precisely, such samples are required either a more detailed morphological characterization or sequencing of other loci except than ITS. In total, molecular data matrix was constructed with 15 sequences representing all studied samples. The alignment length of these 15 sequences is observed as 796 nucleotide characters long. Phylogenetic relationships of the identified samples are displayed in Figure. 1. Based on the phylogenetic analysis, the studied areas are occupied by fairly divergent weeds.

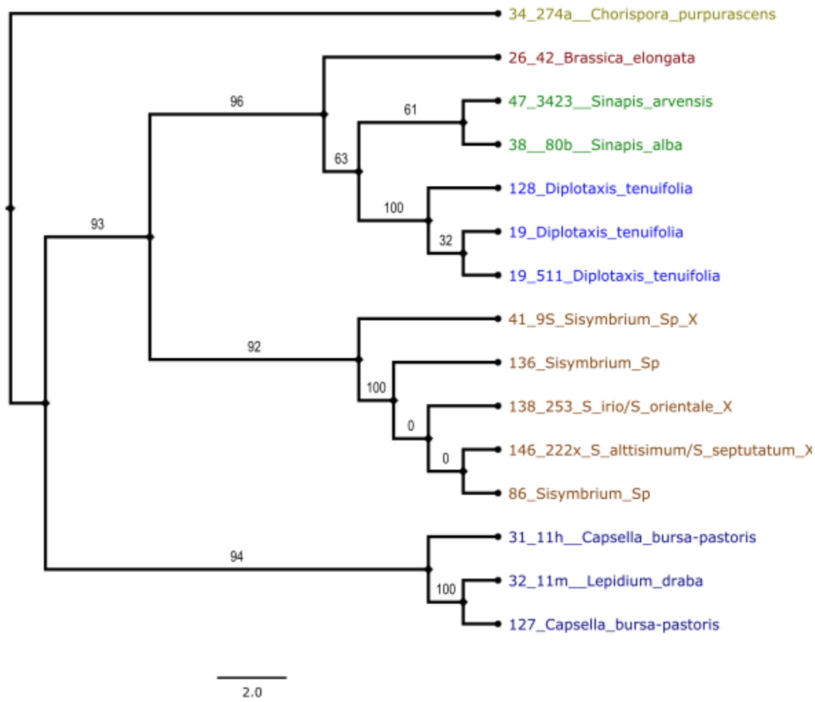

FIGURE 1. Phylogenetic relationships of the Brassicaceae samples based on ITS locus, inferred via Maximum Likelihood method. Bootstrap values (Bs) are placed above the corresponding branch. "X" appears at the end of the tip's name denotes the uncertainty associated with the diagnosis of the sample. Scale bar reflects the number of substitutions per site. The tree is rooted from midpoint for visualization, and branches are shown as proportional.

ML gene tree placed the studied samples in to four well resolved major clades that correspond to the defined genera. Genera *Brassica*, *Sinapis*, *Diplotaxis* and *Sisymbrium* are positioned as closer compared to the genera *Capsella*, and *Lepidium*. The relationships among the studied genera are largely congruent with the results generated by earlier studies (e. g., Zhao et al., 2010). In agreement with the recent studies (e.g., Inaba and Nishio 2002), *S. alba* and *S. arvensis* are demonstrated as sister species however, without support (Bs: 61). *C. purpurascens* is observed as the species most distantly related to the rest of the samples, as expected from examined morphological aspects.

CONCLUSIONS

Identification of the weed species and their genetic relationships can potentially be important for developing sustainable and effective controlling methods. Our study verifies the common weedy Brassicaceae species occur in the wheat growing fields in Turkey. We showed that, all 10 of the identified weed species have a wide range of morphological and genetic differentiation, co-exist in a single cultivation area. These results may specifically be beneficial for the herbicide selection that should be based on the full weed diversity of the area in question.

ABSTRACT

Being one of the top most-produced cereal wheat is a crop of great importance to the global agriculture. Turkey is one of the countries with highest wheat cultivation. The quality and amount of the wheat can be drastically reduced by the weedy species coexist in the growing area. Such species not only compete for nutrients, water, and light of the crop, but also host diseases and pests, which all jointly lower the production. The knowledge of weedy species in priori can prevent mixing of them with harvest if proper strategies of weed control are applied. It may also help with the optimization of harvesting machines, and related post-harvest processes. Advances in these procedures can improve the crop production and lower the labour, and other environmental costs. This study focuses on the determination of weed seeds contaminants of the wheat produced in Bingöl, Turkey. The plant material was obtained from the wheat grains cultivated in 2022. Following the harvest, samples were collected from the wheat stacks representing each wheat growing field. Using a mechanical separation method, the seed material was sorted and categorized based on the morphological observations. The results showed presence of 33 weedy species contaminate the studied wheat stacks. The mixing incidence of all the determined weedy species was found to be 5.8 %, which indicate the poor controlling of the weeds in the wheat cultivated areas in Bingöl.

Keywords: Turkey, Bingöl, harvest, weeds, wheat

INTRODUCTION

Wheat (*Triticum* spp.) is an important crop cultivated across the globe. It has been used as the main energy supply in the alimentation of different cultures throughout history. According to FAO (2024) data, approximately 761 million tons of wheat are produced worldwide. In Turkey, in an area of about 86 million hectares, 20.5 million tons of wheat are produced per year (FAO, 2024). The amount of produced wheat can be limited by a number of biotic and abiotic factors. Among the biotic factors, weeds can lower the yield at a rate of 15-52% (Ateş, 2022). In fact, in rainy seasons, weeds can destroy all the yield by invading the entire wheat field. Besides the problems seen during the active growing period, weeds cause a series of troubles at harvest, and even at post harvesting stages like storage and processing.

Depending on ecological conditions, weed behaviours deviate from those of cultivar's (Buhler, 2003). For instance, some weedy species emerge following the end of chemical controlling period. In this case, such species are picked at the harvest (Karlsson and Milberg, 2007; Ateş and Üremiş, 2018), and their seeds commix to the wheat grains. They can also, disrupt the regulation and efficiency of the harvesting machines (Zimdahl, 2018). Moreover, they may lead to rotting of the stored yield due to their wet content introduced to the dried crop (Oerke, 2006). Further, these undesired contaminants lower the market value of the product (Tursun et al., 2006). Post-harvest refining of the weed seeds, on the other hand, higher the costs and labour. As summarized above, controlling of the weedy species in wheat fields is essential to increase the amount and quality of the product. This can be done either with the cultivation methods, which are related to the planting strategies, and-or via chemical controlling. Chemical controlling is based on the herbicides that are applied in various time schemes such as pre-planting, pre/post-emergence, depending on the mechanisms of the action (HRACGLOBAL, 2024). Thus, at each stage of the production, determination of the type and density of the weeds commix to the product is crucial for improving agricultural production. This study aims to determine the weed seeds and their densities in the wheat sampled from the wheat stacks harvested from Bingöl province in 2022.

MATERIAL AND METHODS

Plant material of the study is composed of wheat seeds and their contaminants harvested in Bingöl province at the end of the growing season of 2022. The material was obtained from the wheat stacks sampled from randomly selected villages. Each visited stack was sampled by drilling 1 kg of wheat from 4 different points (Gökalp and Üremiş, 2015). In total, 4 kg of wheat were taken from each of the wheat stack. The collected material was sifted using mechanical and physical techniques, and grouped accordingly. The categorized weed seeds were then examined under a microscope, and diagnosed based on the related literature. The seeds could not be determined were grouped as others. Each group of weed seeds were counted and weighed. The "occurrence frequency" of the species was calculated according to Baş (2011). The "mixing ratios" was determined as the "ratio of the amount of detected weed seeds" to the "full amount of the sample" (Tursun et al., 2006). The prevalence of the weed seeds was defined regarding the scale given in Pamukoğlu (2011), expressed as following: Very Common (CR): >50.0%, Common (CR): 25.0-49.9%, Significant (CR): 10.0-24.9%, Rare (NR): 9.9%>.

RESULTS AND DISCUSSION

The details of the weed seeds were detected in the wheat harvested from Bingöl province are presented in Table 1. A total of 4810 seed grains were counted from 1 kg of wheat sample. Their total weight was measured as 58.5 g, and the mixing ratio was estimated to be 5.8%. We detected 33 weedy species belonging to the 10 plant families cover 29 genera. Distribution of these species to the families follows as: Apiaceae (3), Asteraceae (3), Brassicaceae (5), Convolvulaceae (2), Dipsacaceae (1), Fabaceae (5), Papaveraceae (1), Poaceae (9), Ranunculaceae (2) and Rubiaceae (2). While 9 of these species are assigned to the "narrow-leaved", 24 of them are placed in the "broad-leaved" weed groups.

Table 1. Details of the contaminants of the wheat harvested from Bingöl province in 2022. The estimates are based on 1 kg of wheat.

R. arvensis was observed with the highest frequency (0.625%) among the species having a "prevalence ratio" of higher than %25. *H. spontaneum* (0.529%), *G. tricornutum* (0.252%), *C. arvensis* (0.103%), *S. arvensis* (0.062%), and *Vicia sp*. (0.043%) were the ones following *R. arvensis*, respectively.

In their survey conducted in the wheat fields of Bingöl province, Esim and Çoruh (2021) reported presence of 109 weed species which encompass the 33 ones that are recorded in our work. Our findings also overlap with the prevalence, and density estimates reported by Esim and Çoruh (2021).

The contaminants of the wheat produced in Bingöl province are similar to the weed seeds contaminants of the wheat grown in Mardin (Gökalp and Üremiş, 2015); Diyarbakır (Pala et al., 2018), and Kahramanmaraş (Tursun and Kantarcı, 2006) provinces, in the mean of diversity. However, the density estimates of the species reported from the later regions are incompatible. This result indicates the differences among the ecological conditions, size of the irrigated land, farming practices, and performance of the harvesting machines of the mentioned regions.

CONCLUSIONS

This study shows the weed seeds contaminants of the wheat produced in Bingöl province in 2022. 1 kg of wheat grown in this region is found to be comprised 58.5 g (5.8%) of weed seeds. Based on the prevalence frequencies of the observed seeds, *R. arvensis L, H. spontaneum, G. tricornutum, C. arvensis, S. arvensis* and *Vicia sp*., relatively, are the species with highest impact. Our results, display the need for more efficient weed controlling strategies in which biological characteristics of the weeds, and ecological conditions of the growing area are fully accounted.

ABSTRACT

The study area located in the lower valley of the Kebir East watershed is included in a rich environment in natural resources forming part of the El Kala National Park (P.N.E.K) with various RAMSAR classification. A number of water quality indices are being used for assessing irrigation water including: sodium adsorption ratio (SAR), sodium percentage (Na %), potential salinity (PS), Kelly ratio (KR), permeability index (PI), potential salinity (PS), permeability index (PI), Magnesium hazard (MH), Synthetic Harmful Coefficient (K) and Irrigation Coefficient (Ka). All of the strategies used in this investigation yielded similar and complementary results. The lower valley of the Kebir East wadi waters are highly mineralized, as evidenced by total dissolved solids and electrical conductivity. Based on the Doneen categorization, the permeability index indicates that higher values correspond to higher quantities of HCO3 and Na+. Because of high potential salt level (over 50%) and magnesium hazards (above 5 meq/l), the waters in the study region are considered unsuitable for agricultural use.

Key words: Kebir east watershed, wetland, irrigation purposes, mineralization, SAR, salinization.

INTRODUCTION

Because to weathering of rocks and organic matter from chemical fertilizers, the Kebir East (Mafragh) watershed's use for agriculture has resulted in a decline in water quality (Zaidi FK, et al.2015, Bhat NA, et al.,2016). Optimizing the safe use of this wadi water for agricultural uses is the objective of this research and improving the effectiveness of how land resources are used. This research is based on a number of classical. This model's parameters are EC, Na+, Cl−, SAR, and HCO_3 (Meireles et al. 2010). This research can contribute to improving the ecosystem's condition by making a balance between the need for environmental flows and the use of water for consumptive applications (drinking water, industry, and irrigated agriculture) (Matthess, G.1982, EPA. 2005).

MATERIALS AND METHODS

Study area

According to the watershed agency (2000) the Kebir East wadi includes many tributaries, along with Bougous, Guerguour, Boulatane, and Bounamoussa (Hedjal S., Zouini D., Benamara A. 2018). With 750 mm of interannual rainfall, the wadi contributes around 28 Hm^3 over a period of a year. The terrain is mountainous, with 1,041 meters as the highest point, and is covered with oak, cork, and maquis woods (El Tarf forests protection agency, 2019) (Figure.1).

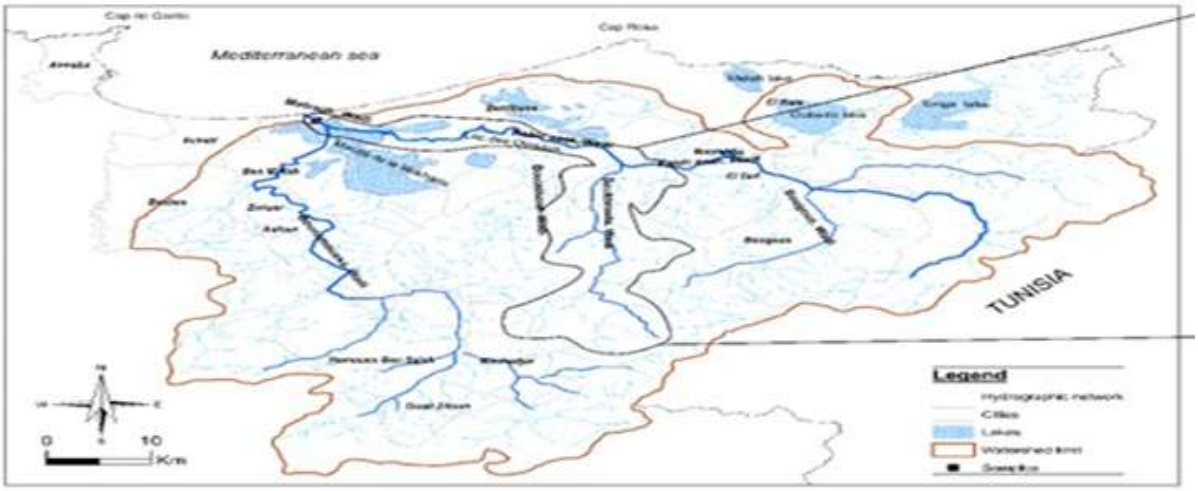

Figure. 1. Map of the study area location

The database that is currently accessible in the Boutheldja meteorological station (longitude Est 8° 12' 22" latitude Nord 36° 47' altitude 20m, code:03-17-01). spans 20 years, from 2000 to 2020. The subhumid Mediterranean climate of the study region is marked by an average annual precipitation of 756 mm. This climate is characterized by an effective infiltration rate of around 13% and evapotranspiration of roughly 63%, the predicted yearly runoff is 186 mm (24%). December had the lowest recorded temperature (-0.6°C), July and August have the highest temperature (46°C). December and January have the highest monthly air humidity levels. An estimate of the yearly average wind speed is 27 m/s.

The geological investigation was completed by Marre. A and Vila J.M (Vila J.M., 1980. Marre A., 1992). These formations belong to the Tell-Algerian region of northeastern Algeria, which extends from the Constantinian area to the Algerian-Tunisian border. The alternation of sandstone, clay-gravelly, and sandstone colluvium forms older geologic formations (Marre A., 1992). The tectonic position is indicated by four faults that are subparallel to the Kebir East wadi.

Used data

The surface water samples from the 2023 campaign are listed on the table below (Table.1). They were taken upstream along the Kebir east wadi (El Mafragh) at eight (08) different points, spaced a few hundred meters apart. pH, EC, DO, NH4, PO4, NO2, NO3, TA, TH, TDS, Ca2+, Mg2+, K+, Na+, Cl-, and SO4 are the parameters that were studied in this research. To guarantee a sufficiently good quality, the charge balance error (CBE) was computed and a 5% margin of error was considered appropriate for CBE values. Mg, Ca, Na, and K rank highest among the cations, whereas HCO3, SO4, Cl, and NO3 rank lowest among the anions. Ca-Mg-HC03 facies or water type is detected. Statistical description (range, mean and standard error) of physicochemical parameters was determined and shown in (Table.1).

Table.1 Statistics on the parameters analyzed in the Kebir East wadi water (El Magragh).

	Ca^{2+}	Mg^{2+}	Na^{+}	K^{+}	HCO_3^-	SO_4	Cl^-	NO_3	PO_4	NO_2	NH_4	EC	TDS	Turb
Max	180	212	180	8.3	672,23	376,8	286.41	65.09	0,52	1,33	2.1	1972	1183.2	29
Min	100	129.65	54	0,55	167.95	139.55	156.41	18	0,01	0,06	0,45	559	335.4	18,57
average	149.31	163.85	78.16	2.38	444.09	236.82	194,57	35.03	0.11	0.61	1.17	965	604.65	22,47
SD	26.54	29.51	39.03	2.51	185.85	76,81	15,68	8,05	0,17	0,43	0.61	414.8	247.77	3,51

The results show that all parameters (except Mg, SO_4, NH_4, NO_3 and NO_2) do not exceed the standards allowed for surface water, including the maximum values of Ca^{2+}, Na^{+}, K^{+}, HCO_3, TDS, Cl^-, NO_3, and CE. The concentration ranges for magnesium and sulphate ions are respectively 212 mg/l to 129.65 mg/l and 376,8 to 139.55 mg/l, carbonate dissolution is suggested as the cause of the high magnesium content. The potential sources of SO_4 ions in the study area may be derived from agricultural activities (fertilizer inputs) and/or domestic sewage. Furthermore, the application of chemical fertilizers to agricultural land in the research region is the source of organic matter ions, represented by NO3, NH4, PO4 and NO2, which range from 65.09 to 18 mg/l, from 2.1 to 0.45 mg/l, from 0.52 to 0.01 mg/l and from 1.33 to 0.06 mg/l respectively (Sani, A., et al, 2020). Kebir East wadi water is classified as slightly troubled water (5>NTU<30) based on its turbidity, which indicates the presence of suspended particles in the water and fluctuates from 26 to 18.57 NTU.

Irrigation water assessment methods

Agriculture is the main economic activity in this region. Most of the water required for this purpose comes from surface water, notably from the Kebir East wadi (El Mafragh). In this case, various parameters, including the kind of salt and the overall concentration in the water, were created to assess the water's suitability for irrigation (Wilcox, L.V. 1955). The sodium percent (Na%) is a commonly employed measure to assess water suitability for irrigation (Hendry MJ, Wassenaar LI. 2000). Water containing more than 60% salt can lead to sodium buildup, which will deteriorate the physical characteristics of the soil (Adams S.S., et al 2001, Datta PS, Tyagi SK.1996). Additionally, an overabundance of sodium mixed with carbonate results in the production of alkali soils. The Na% is calculated with the formula below:

$$\boldsymbol{Na}\,\% = \frac{\boldsymbol{Na}}{\mathbf{Mg + Ca + K + Na}}\ \mathbf{100}\%$$

The salinity of water is often measured in terms of electrical conductivity (EC) or total dissolved solids (TDS). The quantity of dissolved ions in water is determined by the salinity hazard (Singh, A.K.; et al. 2008). Because harmful substances dissolved in water can damage plants, total dissolved solids (TDS) should be taken into consideration, particularly when it comes to irrigation water (Olivier Montreuil. 2008). Intense agricultural practices that result in the buildup of salts are the primary source of the high TDS value in the water.

A further essential variable in assessing whether irrigation water is desirable is the sodium adsorption ratio (SAR). Irrigation water with a high SAR value has a detrimental impact on crop productivity and soil fertility. As a result, Na ions replace the Ca and Mg ions in the soil, which is unfavorable for agricultural purposes (Richards, L.A. 1954). The SAR is proposed by Richards (1954) and defined as:

$$\boldsymbol{SAR} = \frac{\mathbf{Na}}{\sqrt{(\mathbf{Ca + Mg})/\mathbf{2}}}$$

The parameter-based Permeability Index (PI) measures the permeability of soil, or the ability of water to pass through it. In terms of soil porosity, the concentration of Na+, Ca2+, Mg2+, and HCO3 in water defines the soil profile (Doneen., 1962). Additionally, prolonged usage of rich water on Ca2+, Mg2+, Na+, and HCO3 decreases soil aeration. Irrigation water was categorized in 1962 by Doneen using the permeability index (PI), which took into account the soil's Na^{+}, Ca^{2+}, Mg^{2+}, and HCO_3 levels. It was defined as:

$$\boldsymbol{PI} = \frac{\boldsymbol{Na} + \sqrt{\mathbf{HCO3}}}{\mathbf{Ca + Mg + Na}}\ \mathbf{100}\%$$

According to the PI, water may be divided into three classes: class I (100% maximum permeability), which is appropriate for irrigation; class II (75% maximum permeability), which is somewhat appropriate; and class III (25% maximum permeability), which is not appropriate for irrigation.

The amount of soil structure damage caused on by magnesium in irrigation water is indicated by the magnesium hazard (MH) or magnesium adsorption ratio (MAR) (Bauder, T.A.,2011).

Alkalinity of the soil is caused by a high concentration of Mg2+ ions in groundwater. The infiltration capacity of the soil is also decreased due to a significant quantity of water adsorbed between the magnesium and clay particles, which is bad for crops. Whereas groundwater with a value of MH < 50 is appropriate for irrigation, groundwater with a value of MH > 50 is hazardous. The following formula is used to determine the MH:

$$\boldsymbol{MH} = \frac{\mathbf{Mg}}{\boldsymbol{Ca} + \boldsymbol{Mg}}\ \mathbf{100}\%$$

An essential measure for assessing irrigation water quality based on Na^{+} concentration in comparison to Ca^{2+} and Mg^{2+} concentrations was introduced by KELLY (1963) named the Kelly ratio (KR). Water is not appropriate for irrigation if Kelly's index (KR > 1) is more than 1, indicating an overabundance of sodium in the water (Kelley, W.P., 1940, 1963). Consequently, water that has a KR of less than one (KI <1) is more appropriate for irrigation. The value of this measure is expressed in terms of the ratio of Na^{+} concentrations (meq/L), the sum of Ca^{2+} and the Mg^{2+} (meq/L). The following formula is used to compute this ratio :

$$\boldsymbol{KR} = \frac{\mathbf{Na}}{\mathbf{Ca} + \mathbf{Mg}}$$

The concentration of bicarbonates and carbonate ions in water is the objective of residual sodium bicarbonate (RSBC). Water with a high RSBC therefore has a high pH, which makes the soil it irrigates unusable and causes sodium carbonate to build on the soil. To calculate the RSBC the formula below is used:

$$\boldsymbol{RSBC} = \boldsymbol{HCO}\mathbf{3} - \boldsymbol{Ca}$$

The concept of residual alkalinity is typically employed to forecast how water's chemical composition will change over time. Bicarbonate, carbonate, calcium, and magnesium ions are involved in residual sodium carbonate (RSC) or residual alkalinity (RA), which is described using the formula below:

$$\boldsymbol{RSC} = (\boldsymbol{HCO}\mathbf{3} + \boldsymbol{CO}\mathbf{3}) - (\boldsymbol{Ca} + \boldsymbol{Mg})$$

In the case that the RSC is positive, precipitation occurs in an alkaline manner, conversely, if the RSC is less than zero, precipitation occur in a neutral saline way (Szabolcs, I.; Darab, 1964).
– Following the addition of sulphates associated with the gypsum precipitation, the residual alkalinity becomes positive; this is the neutral saline manner with sulfate dominances.
– Even with the addition of sulphates, the residual alkalinity becomes negative; in this case, the process is known as the neutral saline process with a chloride dominance.

Another metric that's frequently used to describe the quality of water for irrigation is potential salinity, which is represented by ions such as sulfates and chlorides (Marlet, S., et J.O. Job, 2006). There are three established classes: PS <3 indicates exceptional quality, 3 to 5 denotes fair quality, and 5 and higher denotes unsuitable for use. The formula below is used to compute the PS:

$$\mathbf{PS} = \boldsymbol{Cl} + \frac{\mathbf{1}}{\mathbf{2}}\boldsymbol{SO4}$$

We also used the Irrigation Coefficient (Ka) and Synthetic Harmful Coefficient (K) approaches to assess the water quality of the Boukhroufa wadi for irrigation. These coefficients represent the water's alkali and salt hazards. TDS and SAR are added to produce K, which is defined as follows (M is the total dissolved solids in g/l).

$$\boldsymbol{K} = \mathbf{12,4}\boldsymbol{M} + \boldsymbol{SAR}$$

The irrigation coefficient Ka, which was first created in Soviet Russia, is a common method for determining whether water is suitable for irrigation. It is produced through investigating the relative damage of sodium salt and the utmost damage of alkaline solutions. Since the conditions for sodium ion concentrations in our study are lower than those for chlorides, the following formula is employed to get the irrigation coefficient (Ka):

$$\boldsymbol{Ka} = \frac{\mathbf{288}}{\mathbf{5Cl}}$$

RESEARCH RESULTS AND INTERPRETATION

Results of classical indexing methods

The terms "salts, salinity, **electrical conductivity**, or total dissolved solids" are favored in most publications when referring to salinity risk (Marlet, S., et J.O. Job, 2006) One of the most important indicators of irrigation water quality is electrical conductivity, which shows how much of all ion concentrations are dissolved in the water. Water having an EC value above 2250 µs/cm is considered "Fair" or inappropriate and has the potential to significantly impact crop yield or productivity. ‘‘Excellent’’ refers to waters with EC values less than 250 µs/cm (EPA, 2005).

The measured Electrical Conductivity values of the Kebir East (El Mafragh) wadi water range from 1972 to 559 µS/cm for an average of 1007.93 µS/cm. They are classified in two classes, 83% of samples are ranged in class 3 making them doubtful for irrigation purposes, the remaining 17 % of samples fill in class 2 which categorized as good for irrigation use.

The average of **total dissolved solids (TDS)** in the water of Kebir East (El Mafragh) wadi is 604.64 mg/l, with a range of 1183.2 to 335.4 mg/l. Since 66.67% of samples fall into class 2 and have TDS levels that do not exceed 1000 mg/l, irrigation is deemed permissible. Of these, 25% fall into class 1, which is desirable for irrigation usage. Class 3, where water is deemed acceptable, covers the remaining 8.33%.

An overview of water suitability for irrigation is provided by Wilcox's 1955 categorization of water based on the **Sodium percentage (Na%)** (Wilcox LV.1948, 1955). In the water under examination the Na% varies from 29, 36% to 10% for an average of 15.29 %. The Kebir East wadi water samples are classified as excellent for irrigation when 83.33% of them fall into class C1. and as good quality when the remaining 16.66% fall into class C2, this means that depending on the sodium percentage (Na%), the water in the research region is appropriate for irrigation (Figure.2).

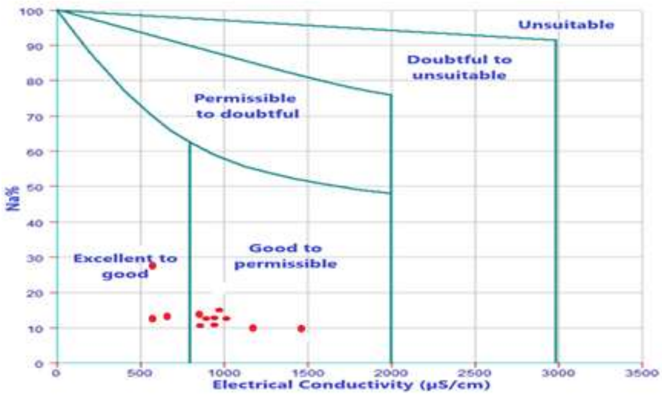

Figure.2 Classification of irrigation water quality based on EC and % Na (Wilcox 1955)

The infiltration and permeability hazard (IPH) or permeability index (PI) defined by Donen in 1962 is calculated for Boukhroufa water samples (Doneen., 1962). The range of PI values is 35.81 to 18.03 meq/l. Doneen's classification results in 58.33% of water samples being classified as class III (PI<25%), meaning that the water is not appropriate for irrigation. This is because the content of Na, Ca, Mg, and HCO3 in irrigation water has a significant impact on soil permeability (Figure.3).

The remaining 41.66% belong to Class II (75%), which makes irrigation with them slightly suitable. Elevated PI values are associated with elevated Na^{+} and HCO_3 levels, may be caused by cation exchange and carbonate dissolution.

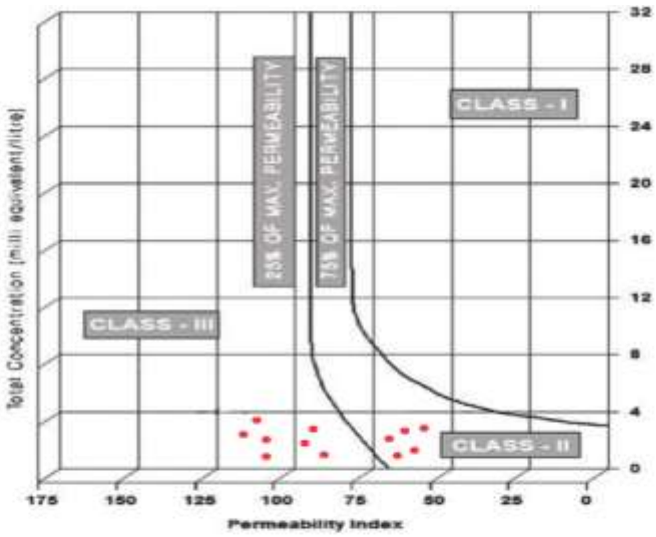

Figure.3 Classification of irrigation water quality based on Doneen diagram (Doneen 1962)

Based on the **salt adsorption ratio (SAR),** water samples taken from the research region are excellent for irrigation. The graphical representation of the sodium absorption ratio (SAR) and the electrical conductivity makes it possible to deduce that all the samples belong to the class (C3) of medium to poor quality in terms of the EC, and in class (S1) of excellent quality in terms of the SAR (Richards, L.A. 1954). Consequently, on well-drained soils, irrigation with Kebir East (El Mafragh) wadi water is appropriate for crops that can tolerate salts, although salinity has to be managed. (Figure.4).

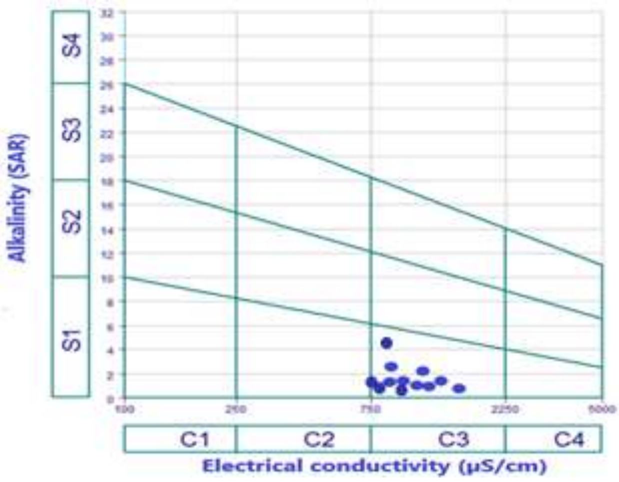

Figure.4 Classification of irrigation water quality based on EC and SAR (Richards 1954)

Also, the classification of water for irrigation purposes can be determined graphically by plotting SAR and EC values on **US Salinity Laboratory diagram (USSL).** The representation (Figure.5) demonstrates that 75% of the samples are grouped in C3S1and 25% in C2S2. This indicates that all of the samples were categorized as low salinity categories based on SAR. In addition, based on EC 25% of samples in medium salinity categories and 75 % in high salinity categories. With these findings, soils with adequate drainage may be irrigated using water from the study area. The USSL diagram indicates that the risk of salinization was not expected in the tested irrigation water samples, and all of the samples could be considered as good medium category of irrigation water.

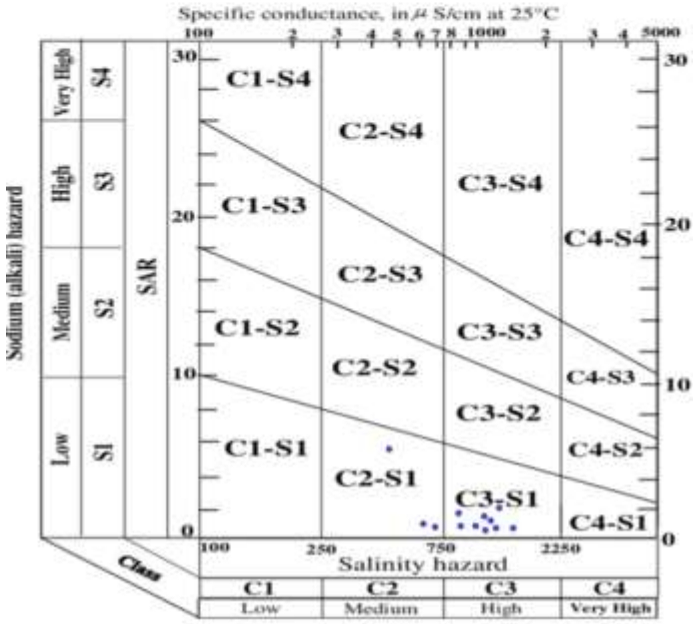

Figure.5 Representation of Kebir East wadi water samples on USSL diagram

The water samples' **Residual Sodium Bicarbonate (RSBC)** values vary from 6.03 mg/L to -6.06 mg/L. A limited amount of CO3 was present in the samples, however the range of HCO3 ions is 672.23 mg/l to 167.95 mg/l. Since more than 50% of the samples have positive RSBC values, the amount of carbonate and bicarbonate in the sample is greater than the amount of dissolved magnesium and calcium ions. Of the water samples, 91.67% are deemed suitable for irrigation, while 8.33 are considered marginal for use in agriculture. Due to their high bicarbonate content and to precipitate insoluble magnesium and calcium, they increase the SAR value and the percentage of sodium (Szabolcs, I.; Darab, C. 1964).

Residual alkalinity, or residual sodium carbonate (RSC), was taken into consideration as an alternate method in the evaluation of irrigation water quality in order to assess the sodization and alkalinization risk of these waters (Szabolcs, I.; Darab, C. 1964). The neutral saline process is operating in the Boukhroufa wadi water, as shown by the negative estimated RSC findings with chloride predominating. This water falls into class 1(RSC<1.25) where water is considered good for irrigation use with a low risk of soil degradation.

With an average of 64.42%, the **magnesium hazard (MH)** of the samples varied from 77.75 to 55.14 percent. In 58.33% of Boukhroufa wadi water samples in the research region had an MH more than 50 making it doubtful for irrigation, the remaining 41.66 % of samples are classed in C3 (>65) where water is unsuitable for irrigation.

The average **Kelly's Ratio (KR)** in water samples was found to be between 0.42 and 0.11 for an average of 0.19. Since all KR values were determined to be below the allowed limit of 1.0, the water in the research region is categorized in C1 class, meaning that it is appropriate for irrigation. Kelley, W.P., 1963).

Table.5 Used approaches for irrigation water

Parameters	Units	Samples (%)	Water quality	Effects on soil and crops
CE	µs/cm	83	*Doubtful*	*Mineralisation excess, the rate of water uptake by plants decreases*
		17	*Good*	
TDS	mg/l	66.67	Permissible	
		25	Desirable	
		8.33	Acceptable	
SAR	/	100	Excellent	Nothing dangerous or damaging to report
Na%	%	83.33	Excellent	
		16.66	Good	
PI	%	58.33	*Unsuitable*	*high levels of Na and HCO3, affect soil porosity,*
		41.66	*Slightly suitable*	
MH/MAR	%	58.33	*Doubtful*	*Soil structure damage, reduice infiltration capacity, adverse effects on crops*
		41.66	*Unsuitable*	
KR	/	100	Suitable	Nothing dangerous or damaging to report
RSBC	meq/l	91.67	Satisfying	*Causes infertile soils, deposition of sodium carbonate*
		8.33	*Marginal*	
RSC	meq/l	100	Good	Nothing dangerous or damaging to report
PS	meq/l	100	*Injurious to unsatisfactory*	*Hight level of chlorides and sulfates ions*
K	/	100	Excellent	Nothing dangerous or damaging to report
Ka	/	100	Excellent	*Relative damage of sodium salt on soil and crops*

Three classes are used to categorize the water quality for irrigation based on **potential salinity (PS)**, PS below three, water is good to excellent, below five water is good to harmful and beyond five water is harmful to unsatisfactory. With a mean of 7.49 meq/l the PS values in the

Kebir East wadi water samples ranged from 10.44 to 5.88 meq/l. 100% of the samples fall into class 3, where they are considered injurious to unsatisfactory for irrigation due to their potential salinity (more than 5).

For Kebir East water samples the synthetic harmful coefficient (K) has a mean of 9.51 and a range of 15.7 to 6.31. Since all of the samples are greater than 25 (Class 1) they are all deemed excellent for irrigation use.
Four classifications constitute the **irrigation coefficient (Ka)** categorization method for water. Water quality with a Ka value of more than 18 is excellent for irrigation, whereas water quality with a Ka value of less than 1.2 is inappropriate for irrigation purposes. The Ka values for Kebir East water vary from 13.03 to 7.12 meaning that all water samples (100%) are listed in class 1, which are excellent for use in agriculture.
The table below includes a list of every method used in this investigation (Table.5) where the findings are consistent and complementary.

CONCLUSION

The appropriateness of 08 irrigation water samples in the research region was evaluated based on hydrochemical results and categorization using a variety of methods. These approaches have been used to examine the Kebir East (El Mafragh) wadi's water quality for irrigation purposes. This wadi's waters are often highly mineralized. According to the data, 83% of samples are doubtful for irrigation due to increased EC values. Based on the permeability index, more than half of the water samples are not appropriate for irrigation, where soil porosity is affected by elevated Na^+ and HCO_3 values. Additionally, because of the increased risk of magnesium hazards (MH) 58.33% and 41.66% of total samples are doubtful and unsuitable respectively for agricultural use. As a result, higher concentrations of sulfates and chlorides can have a negative impact on crops and alter the structure of soils (reducing infiltration capacity). The water used for irrigation facilitates the deposition of sodium carbonate and results in soil infertility, as demonstrated by the analysis of the water quality index of residual sodium bicarbonate (RSBC), which shows that 91.66% and 8.33% of the total samples of our study area fall under satisfying and marginal category respectively. For the potential salinity (PS), 100% of samples are injurious to unsatisfactory for irrigation purposes.
The average Kelly's Ratio (KR) indicates that all samples tested were determined to be below the permissible limit of 1.0, indicating that the water in the research region has an equilibrium of sodium, calcium, and magnesium ions. The sodium adsorption ratio (SAR) and sodium % data show that there is no sodium risk in the study region water and no hazard of alkalization when using this few sodium content in the water for irrigation.
Based on the wadi's sample locations, upstream is considered to have higher levels of mineralisation, permeability index (PI), sodium percent (Na%) and potential salinity (PS) than downstream. This indicates that the primary process governing the chemistry of the groundwater in this region is the weathering of minerals. The contact between water and rock, which specifically results in cation exchange, is most likely the cause of the unusually high concentration of Na+ ions in wadi water. Furthermore, upstream agricultural practices including the use of agrochemicals might raise the salt concentration. Therefore, from the

perspective of irrigation, water samples obtained downstream are preferred to those collected upstream due to the dilution phenomena that occurred, as demonstrated by the findings of all the used parameters. In terms of viewpoint, both field monitoring and experimental research to follow and anticipate the geochemical and physical development of soils irrigated by various types of water in the region are required.

ABSTRACT

Certainly, environmental pollution and its impact on freshwater habitats are critical issues that require attention. Large dams are constructed worldwide for various purposes, including flood control, water supply, hydroelectric power generation and recreation and reservoirs may alter the aquatic ecology and river hydrology both upstream and downstream, affecting water quality and quantity. The Sazlıdere Dam Lake is located in the north part of Marmara Region and meets the drinking water needs of İstanbul Province of Türkiye. Therefore, it has an important effect on the health of many people. In this research, concentrations of 9 PTEs including chromium (Cr), nickel (Ni), copper (Cu), zinc (Zn), arsenic (As), cadmium (Cd), lead (Pb), manganese (Mn) and boron (B) were investigated in water of Sazlıdere Dam Lake. Heavy Metal Pollution Index (HPI) and Heavy Metal Evaluation Index (HEI) were used to evaluate the water qualities of investigated locations in terms of PTEs contamination. According to the applied heavy metal risk assessment indices, water of Sazlıdere Dam Lake was recorded as "Low heavy metal contamination (HPI < 100)" in terms of applied HPI and "Low contamination (HEI < 10)" in terms of HEI.

Keywords: Sazlıdere Dam Lake, İstanbul Province, Risk Assessment Indices

INTRODUCTION

Sazlıdere Dam Lake is located in the İstanbul Province of Türkiye and it meets the drinking water needs of the region. Therefore, the reservoir has a very important effect on the health of many people living in the İstanbul Province (Anonymous, 2020). The reservoir, which has a capacity of approximately 92 million m³, was built on the Sazlıdere Stream in 1996 by State Hydraulic Works (DSİ). The body volume of the Sazlıdere Dam Lake, which is a rock body fill type, is 1.880.000 m³ and its height from the riverbed is 48 meters. The reservoir volume is about 92 hm³ and the reservoir area is about 11.81 km² at the normal water level (Anonymous, 2020; http://suyonetimiormansu.gov.tr).

Heavy metal risk assessment indices are useful tools to evaluate the water quality in terms of human health and Heavy Metal Pollution Index (HPI) and Heavy Metal Evaluation Index (HEI) are among the most commonly used risk assessment indices (Tokatlı et al., 2021; Varol and Tokatlı, 2022; Haque et al., 2022; Jannat et al., 2022; Mutlu et al., 2023; Mia et al., 2023;

Tokatlı et al., 2023; 2024; Yüksel et al., 2024). The aim of this research was to evaluate the water quality of Sazlıdere Dam Lake in terms of potentially toxic elements (PTEs) by using Heavy Metal Pollution Index (HPI) and Heavy Metal Evaluation Index (HEI).

MATERIAL AND METHOD

Study Area and Collection of Samples

In the present study, levels of PTEs in water of Sazlıdere Dam Lake were determined and the data were evaluated by using HPI and HEI. Surface water samples were collected from 3 stations (input of dam 1 – SD1, input of dam 2 – SD 2 and output of dam – SD3) selected on the Sazlıdere Dam Lake in rainy (winter) season of 2022 (Figure 1).

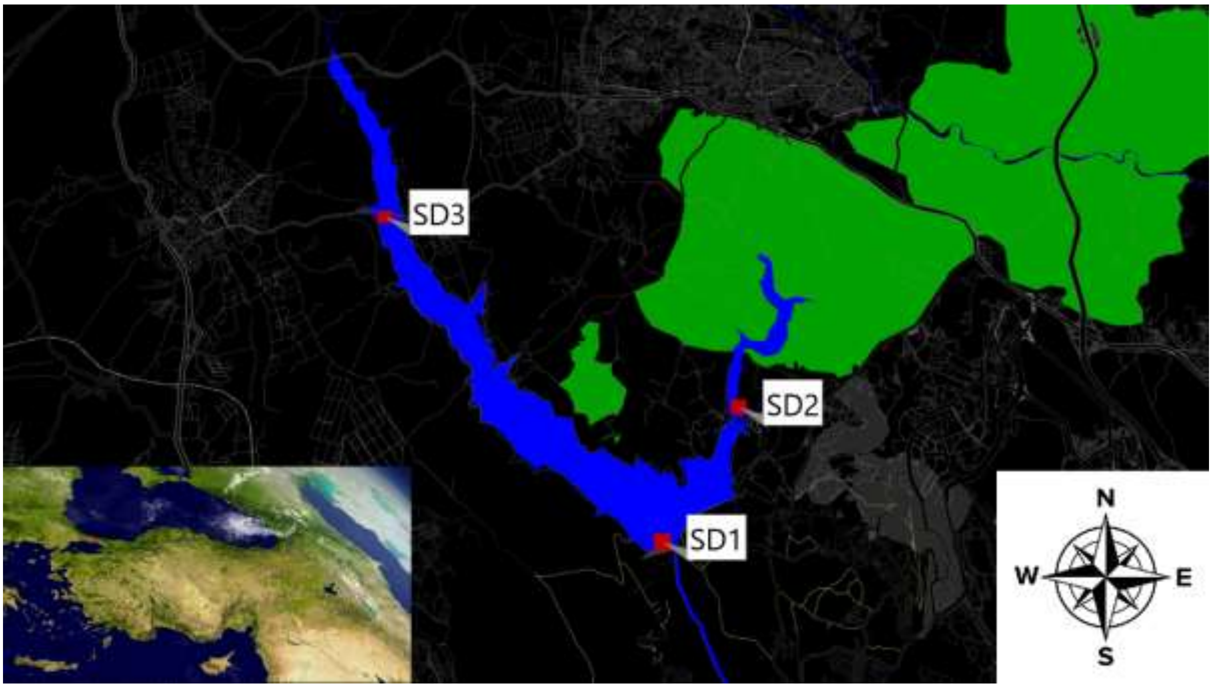

Figure 1. Study area and selected stations

Chemical Analysis

For determination of chromium (Cr), nickel (Ni), copper (Cu), zinc (Zn), arsenic (As), cadmium (Cd), lead (Pb), manganese (Mn) and boron (B) concentrations in water of Sazlıdere Dam Lake, samples of one liter were adjusted to pH 2 by adding 2 ml of HNO_3 into each. Afterwards, all the samples were filtered (cellulose nitrate, 0.45 µm) in such a way as to make their volumes to 50 ml with ultra-pure water. The element levels in water samples were determined by using the "Agilent 7700 xx" branded Inductively Coupled Plasma – Mass Spectrometer (ICP-MS) device in Trakya University Technology Research and Development Application and Research Center (TÜTAGEM). The center has an international accreditation certificate within the scope of TS EN / ISO IEC 17025 issued by TÜRKAK (representative of the World Accreditation Authority in Turkey). The element analyses were recorded as means triplicate measurements (APHA, 1992; EPA, 2001).

Calculation of Risk Assessment Indices

Heavy Metal Pollution Index (HPI) (formulas 1 and 2) (Mohan et al., 1996) and Heavy Metal Evaluation Index (HEI) (formula 3) (Edet and Offiong, 2002) are being calculated according to the following formulas:

$$HPI = \frac{\sum_{i=1}^{n} W_i Q_i}{\sum_{i=1}^{n} W_i} \quad (1)$$

$$Q_i = \sum_{i=1}^{n} \frac{M_i}{S_i} \times 100 \quad (2)$$

$$HEI = \sum_{i=1}^{n} \frac{H_C}{H_{MAC}} \quad (3)$$

“Qi” is the sub – index of the toxic element, “Wi” is the unit weight of the ith parameter, “Mi” is the monitored values of toxic metals, “Si” is the standard values of the parameter and n is the number of parameters considered (WHO, 2011). Water quality ratings for applied HPI are given in Table 1.

"Hc" is value observed for each parameter and "Hmac" indicates the value of maximum admissible concentration (MAC) for each parameter (WHO, 2011). Water quality ratings for applied HEI are given in Table 1.

Table 1. Water quality ratings for indices

Value	Rating of Water Quality	Usage Possibilities
Heavy metal pollution index (HPI)		
< 100	Low heavy metal contamination	Suitable
> 100	High heavy metal contamination	Not suitable
Heavy Metal Evaluation Index (HEI)		
< 10	Low contamination	Suitable
10 – 20	Medium contamination	Not suitable
> 20	High contamination	Not suitable

RESULTS AND DISCUSSION

As a result of applied toxicological risk assessment indices, water of Sazlıdere Dam Lake was found as "Low heavy metal contamination (HPI < 100)" in terms of applied HPI and "Low contamination (HEI < 10)" in terms of HEI and it was recorded as "Suitable for consumption and use" (Figure 2). The monomial risk ranking of elements were found as in terms of HPI:

As > Cd > Cr > Ni > Pb > Mn > B > Cu > Zn; while the risks in terms of HPI were as follows: Cr > B > Ni > As > Cd > Mn > Pb > Cu > Zn (Figure 3). It was also determined that the spatial pollution degrees of the investigated locations on the Sazlıdere Dam Lake were as follows: SD1 > SD2 > SD3, in general.

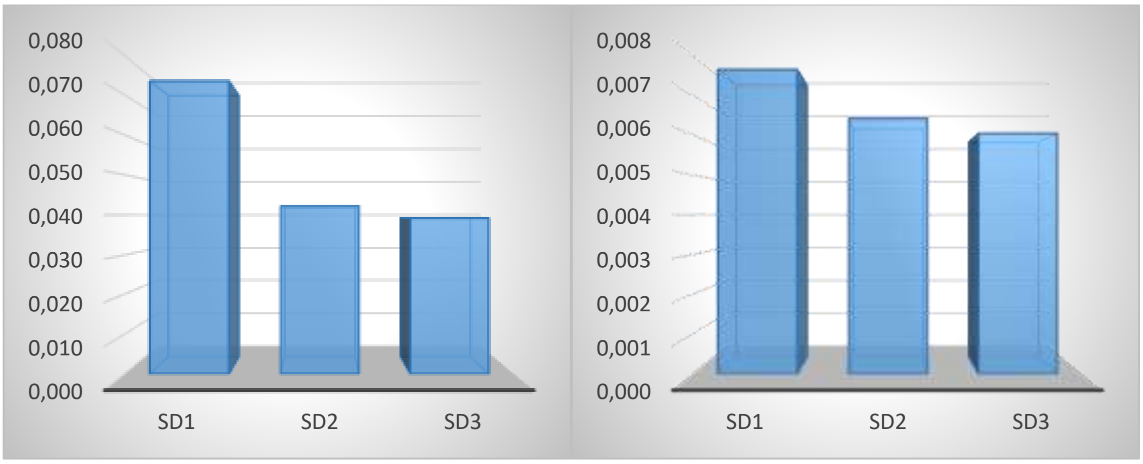

Figure 2. Results of applied HPI (left) and HEI (right)

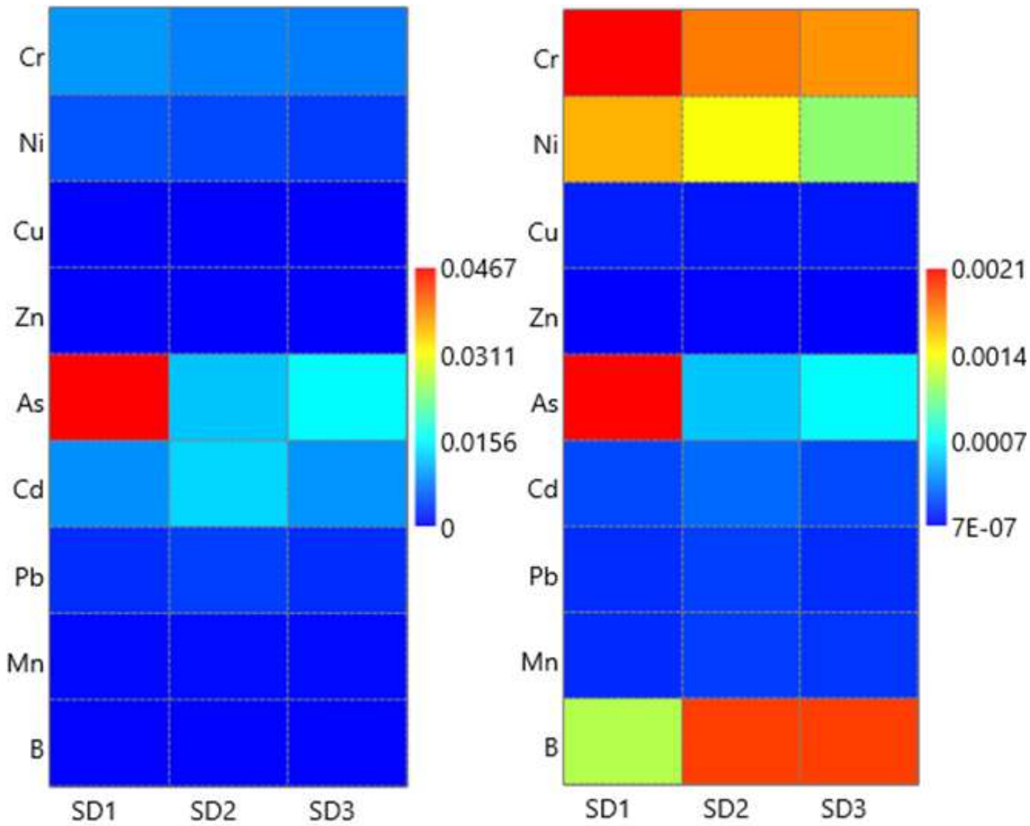

Figure 3. Monomial results of applied HPI (left) and HEI (right)

CONCLUSIONS

In this research, water quality of Sazlıdere Dam Lake located in the İstanbul Province of Türkiye was evaluated in terms of PTEs contamination by using HPI and HEI. According to the results of applied toxic metal risk assessment indices, Sazlıdere Dam Lake was found as "Low heavy metal contamination" in terms of applied HPI and "Low contamination" in terms of HEI. The data of the present research also reflects the importance, applicability and necessity of the use of different toxic metal risk assessment indices together on evaluation of surface water ecosystems.

ACKNOWLEDGEMENTS

THE ONGOING FOURTH INDUSTRIAL REVOLUTION AND THE CIRCULAR ECONOMY

Nicoleta SEICARU BUCATA, Liviu MARCUTA

ABSTRACT

We are already facing the consequences of using the linear economy model. Many alarm signals have been raised that this model involves the excessive exploitation of the environment with the aim of increasing consumption and implicitly profit. This cannot go on indefinitely. However, we see a hope given by the Circular Economy model supported by the fourth industrial revolution. This refers to new technologies from artificial intelligence, digitization, renewable energies, sustainability. Many researchers see a singularity point soon, a point where the changes brought to society by developments in technology will occur at an unimaginable pace. This paper argues (based on some concrete examples) that the solution to sustainable development is the Circular Economy based on the innovations of the fourth industrial revolution. In the era of IND 4.0 the Circular Economy will be digital, automated and augmented or it will not exist at all.

Key Words: History of Economics, IND 4.0, Circular Economy, singularity, Succes Stories for Circular Economy

INTRODUCTION

One must understand the past before making assumptions about the future. The history of our species had not always a linear development, but rather a winding evolution, thriving civilizations, followed by devastating wars, weakened ecosystems, then new developments of the world and above all a steep dynamic. It is also a story of technological advances with close relationship between societal structures and access to material and energy resources.
From time to time, the discovery of an innovative tool changes everything and leads to a new stage of civilization. Some consider the first technological revolution to be the Upper Paleolithic Revolution, about 50,000 years ago. The invention of tools, the ability to control and use fire led to the emergence of behavioral modernity. These events formed the basis for the first waves of migration, when people left Africa and began to settle on other continents.
There are many examples of similar pulses in history: the agricultural techniques developed the first civilizations to rise from the river plains of the Near East and Asia 13,000 years ago; the invention of modern weapons; the print technology (Guttenberg); the mechanical inventions of the Renaissance period (Leonardo da Vinci); the commercial revolution of the 16th century when Europeans developed through colonialism and the scientific revolution of the 17th century with a systematic distribution of knowledge. These all represent radical transformations that have altered the course of civilization in part due to technological booms. However, we must note that these transformations have not always been 100% positive.

Important innovations drive technological revolutions, and this leads to a series of subsequent changes. Different discoveries influence each other and cause the transition from a type of society to another. These changes can sometimes have dramatic effects. In just a few decades, production systems, education systems, political regimes and dominant business models can be radically transformed.
The First Industrial Revolution (end of the 18th century - beginning of the 19th century) was characterized by the transition from manual to mechanized production. Inventions such as the steam engine, textile mills, and ironworking technology led to increased productivity and the development of industry.
The Second Industrial Revolution (late 19th century - early 20th century) brought major technological innovations such as electricity, the telegraph, the telephone, the internal combustion engine, and mass production. This Revolution led to a significant increase in industrial production and the expansion of transportation networks.
The Third Industrial Revolution (20th century - early 21st century), also known as the Digital Revolution, was marked by the development of information and communication technologies such as personal computers, the Internet, mobile technology and Industrial automation. It has had a significant impact on the way people work, communicate and live.
The Fourth Industrial Revolution (present - near future) is based on the convergence of digital, physical and biological technologies such as artificial intelligence, advanced robots, 3D printing, biotechnology and renewable energies. This has the potential to fundamentally change the way society works, including in areas such as health, transport, manufacturing and the environment.

The Ongoing Fourth Industrial Revolution (IND 4.0)

The first three Industrial Revolutions were characterized by major innovations in areas such as manufacturing, energy, communications, and automation. The Fourth Industrial Revolution focuses on the convergence of digital, physical, and biological technologies. The fourth Industrial Revolution (IND 4.0) is based on technologies such as artificial intelligence, the Internet of Things (IoT), big data analysis (big data), blockchain, advanced robotics, virtual and augmented reality, 3D printing, biotechnology, renewable energies, etc. These technologies combine to transform economic and social sectors.
A central feature of the Fourth Industrial Revolution is digitization, which involves the transformation of processes and activities into digital forms, and connectivity, which enables communication between devices, people and systems. This can lead to efficiency optimization, personalized choice, better resource management, etc.
Robots and intelligent systems are becoming increasingly capable of performing complex tasks and making decisions based on data and context. This can lead to increased productivity in the industry, but it can also have significant implications for the workforce human work.
The fourth Industrial Revolution can bring significant transformations in the labor market. Certain jobs will disappear or transform, while new opportunities will emerge in technology, design, data management, and more. Thus, adapting and re-educating the workforce becomes essential.
With the increasing adoption of advanced technologies, industries such as healthcare, manufacturing, transportation, agriculture, renewable energies and many others are likely to undergo significant transformations. IND 4.0 can also contribute to solving major challenges such as climate change and global health.
It is important to note that discussions of the Fourth Industrial Revolution are developing, and its ultimate impact on society and the economy will continue to evolve as technologies advance and are widely adopted.

Linear Economy vs. Circular Economy

Linear economy is a system in which people buy a product, use it, and then throw it away. The term linear refers to the straight progression that a product can follow, with a beginning, a middle and an end. There is no thought along the line regarding recycling or reuse. This model is characterized by a high volume of new manufacturing. The linear economy is a polluting system that can hurt nature and the climate. It causes loss of biodiversity.

Linear economic thinking has been around for most of the 20th century. It is based on the desire to make products and offer services for the lowest price. Raw materials are extracted from nature at the lowest cost, turned into products with the least amount of labor, and sold at the highest price.

This linear “take-make-use-dispose” economy is not working. We are extracting virgin raw materials at a pace so fast that they cannot be replenished. We are already having problems extracting some critical raw materials that are in constant demand. At the same time, the amount of waste keeps growing. Global waste generation is expected to increase by 70% by 2050.

What is a Circular Economy?

The ideal type of economy is a circular one that tries to minimize waste and use resources again and again. A Circular Economy is based on three principles: reduce, reuse, and recycle. In a Circular Economy, waste is minimized, natural resources are conserved, and pollution is reduced. The first step is to eliminate the over-extraction of raw materials by using secondary raw materials salvaged from existing products.

Secondary raw materials are products that have already been used in the manufacturing process. These are products designed so that at the end of their lives, they can be upgraded, repaired or go through a new manufacturing process. They also are more durable and resilient.

How the fourth industrial revolution will help Circular Economy

Although there are many discussions and policy initiatives regarding the Circular Economy, it is usually ignored that IND4.0 provides the technological, economic and social framework in which the Circular Economy will flourish or fail. For example, it is estimated that the implementation of the Circular Economy in the European Union will create up to 1.2-3 million new jobs by 2030. However, the report seems to ignore the fact that the activities necessary in preparing for reuse, debugging and disassembly would have to be automated and robotic or otherwise could not be economically viable. In the era of IND4.0 the Circular Economy will be digital, automated and augmented or it will not exist at all.

On the other hand, discussions of IND4.0 usually focus on the resource and labor productivity advantages, the radical changes in business models and the social challenges involved. It is rarely discussed (except when avoiding the linear "business as usual" approach) that IND4.0 will simultaneously stimulate and accelerate resource depletion and pollution in an era where Earth is rapidly approaching or has even exceeded its characteristic limits. IND4.0 will coexist with the Circular Economy or accelerate environmental degradation and the potential collapse of ecosystems and human societies.

The question that arises is whether IND4.0 and the Circular Economy will converge, thus providing not only more efficient resource management but also a sustainable future for all? Or will IND4.0 evolve along the linear "business as usual" model, leaving the Circular Economy a passing fad, leading to faster depletion of resources, accelerating environmental degradation and deepening inequalities? A realistic response must involve the transformation of the waste management sector.

Artificial Intelligence for Waste Reuse

Artificial intelligence (AI) is revolutionizing the way we manage waste, transforming it from a problem into a valuable resource. Some examples of how AI is being used for waste reuse are: Waste Sorting and Recycling (AI-powered Sorting, Fill Level Monitoring), Waste Management Optimization (Route optimization, Predictive maintenance, Capacity planning), Waste-to-Energy, Circular Economy (Material recovery, Product design optimization), Waste tracking, Waste prevention.
Some examples for Waste Reuse AI-driven are:

- ZenRobotics from Finland which uses AI-powered robotic arms to sort and separate waste materials. These robots are equipped with advanced sensors and AI algorithms to identify and pick out valuable materials like metals, wood, and plastics from mixed waste streams.
- AMP Robotics from United States which employs AI and computer vision to automate the sorting of recyclables. Their systems can identify and separate various types of materials, including plastics, metals, and paper, from a conveyor belt in recycling facilities.
- Tomra Sorting Solutions from Norway uses AI-enhanced optical sorting systems for waste management. These systems utilize machine learning algorithms to improve the identification and separation of different types of waste, such as plastics, glass, and metals.
- Bin-e from Poland. The bins are equipped with sensors and machine learning algorithms to identify and segregate waste accurately.
- Waste2Wear from Netherlands that uses AI to facilitate the transformation of plastic waste into sustainable textiles. Their AI-driven platform matches plastic waste sources with manufacturers that can recycle the waste into fabric.
- Lasso Loop from United States that uses AI in its home recycling appliance that cleans, sorts, and processes recyclable materials. The AI system identifies the type of waste and ensures it is properly cleaned and prepared for recycling. By streamlining the recycling process at the source (homes), Lasso Loop increases recycling rates and improves the quality of materials sent to recycling facilities.
- Everledger from United Kingdom that employs AI and blockchain technology to track and verify the provenance of recycled materials, such as plastics and metals. This ensures the transparency and authenticity of recycled products.

By leveraging AI, we can significantly improve waste management practices, conserve resources, and create a more sustainable future.

CONCLUSION

The Circular Economy has a key role in the Fourth Industrial Revolution (IND4.0), with numerous correlations. How they interact could decide the future of society. With all the discussions about the Circular Economy and the fourth Industrial revolution, it is rarely recognized that they are deeply interconnected, and in real life they cannot be separated.

Circular Economy is not just a fad, but a necessity. Our planet faces several environmental challenges, and the Circular Economy offers a viable solution for a more sustainable future. Moving to a Circular Economy will require a change in mindset at all levels of society, but the benefits are clear and worth the effort.

ABSTRACT

The aim of this study is to determine some heavy metal contents and contamination status of soils under different land use types around the Sultan Marshes ecosystem. For this purpose, 36 topsoil (0-20 cm) samples were taken from some of the different land use types in the wetland ecosystem (rangeland. agriculture, marsh and dry lake) and Cr, Pb, Fe, Zn, Cu, Co, Mn, Cd, Mo, As, Ni) were determined by ICP MS and ICP OES devices. Relationships between heavy metals were found by Pearson correlation analysis. Pollution status of the soils according to land use patterns was evaluated according to the contamination factor (C_f) the degree of contamination (C_d). Soils taken from the Southern Marshes had higher values than other land use types in terms of average Cr, Fe, Zn, Co, Cu and Ni concentrations. According to C_f, dry lake soils were exposed to extreme pollution in terms of As and moderate pollution in terms of Cd. Soils under other land use types have been exposed to low-moderate pollution in terms of various heavy metals according to this factor. According to the C_d factor, rangeland and agricultural areas were exposed to significant levels of pollution in terms of Cd, and the dry lake area was exposed to a very high level of pollution in terms of As. Monitoring and taking measures to control heavy metal pollution in soils under all land use types is necessary for ecosystem sustainability.

Keywords: Sultan marshes, land use types, heavy metal, pollution

INTRODUCTION

Wetlands are valuable areas with important ecosystem services. To meet various human needs, wetland areas can be drained and converted into agricultural land, or used for purposes such as settlement, livestock farming, reed cutting, etc. These and similar changes in land use are among the most significant environmental changes affecting ecosystem functions and biodiversity (Ferreira et al., 2016). Land use changes resulting from intense human activities and urbanization have a significant impact on soil quality (Xia et al., 2011). Human activities that involve changing land use can also alter the elemental composition of soils (Wang and Xu, 2014).

Land use changes occur in wetlands for various purposes. One of the issues that degrade soil quality in wetland ecosystems and pose risks to living organisms is heavy metal contamination. Therefore, it is extremely important and necessary to determine the characteristics of heavy metal distribution in wetland soils, assess pollution risks and sources, and identify measures to protect the health of wetland ecosystems (Wang et al., 2019). In a study by Nuralykyzy et al. (2021) on metal levels in different land uses, they found that concentrations of Cu, Cr, Ni, and As were higher in agricultural areas compared to orchards, pastures, and industrial areas. However, Bai et al. (2010) also noted that soils under cultivation along a typical plateau lake in China showed relatively lower heavy metal concentrations compared to abandoned cultivated wetland soils.

Many wetlands in Turkey have undergone significant changes due to various pollution factors, such as heavy metals (Türker and Vymazal, 2021). For the health of wetland ecosystems, it is necessary to properly establish land use policies. The Sultan Marshes wetland ecosystem is one of the areas in Turkey that has been subjected to the effects of human pressure on wetlands. In a study conducted in the Sultan Marshes, Demirezen and Aksoy (2004) reported heavy metal pollution (Cd, Pb, Ni, Cr, Cu, and Zn) in sediments, water, and some reed plants. Aksoy et al. (2005) revealed that Cr concentrations were particularly high in plants and sediment. Furthermore, Demirezen and Aksoy (2006) discussed biological indicators for Fe and Mn pollution and detected heavy metal contamination in *Phragmites australis*, *Ranunculus sphaerosphermus* plants, and sediment. In another study conducted in the Sultan Marshes, researchers investigated the sources of heavy metal pollution in and around the Sultan Marshes, noting that various heavy metal concentrations were derived from geological, mining, industrial, residential, traffic, and agricultural sources (Yalçın et al., 2007)."

This wetland has been subjected to land use changes since the 1940s, with some sections being drained and converted into agricultural land (DSI 1970; Gürer 2004; Gürer and Yıldız 2008; Yaşar Korkanç et al., 2022). Yaşar Korkanç et al. (2022) also noted that changes in land use in the Sultan Marshes ecosystem have affected the carbon stock and various soil properties. Existing research on heavy metal pollution in different wetland ecosystems has shown that the degree of heavy metal contamination varies among wetland types and that the potential ecological risk of heavy metals in inland wetlands is increasing (Sandilyan and Kathiresan, 2014; Liu et al., 2015). A review of past studies reveals a need for data on whether the differences in land use within the research area have impacted heavy metal concentrations. Identifying changes in selected heavy metals based on land use types, assessing the status of different land use types in terms of heavy metal pollution, determining the ecological risk, identifying measures that can be taken based on the level of contamination, and establishing land management plans will provide a crucial foundation.

The aim of this study is to determine the heavy metal content and pollution status of soils under different land use types in the Sultan Marshes.

MATERIAL AND METHOD

Site Description

The Sultan Marshes wetland is located in the Kayseri-Develi Closed Basin, between the latitudes of 38°12'14"-38°25'49" North and longitudes of 35°09'20"-35°22'20" East. The surface area varies seasonally between 8,000 and 13,000 hectares. The study area is situated on alluvium in the center of the Develi Closed Basin, with an elevation ranging from 1,070 to 1,150 meters above sea level. The average slope is 2% (DSI, 1995; Gürer, 2004). The annual average precipitation is 363 mm, and the annual average temperature is 11°C (Özesmi and Gürer, 2003). The climate type is semi-arid subtropical Mediterranean continental (Aksoy, 2004; Karadeniz, 1995). Generally defined as the Develi Closed Basin, the region features basalt, andesite, and tuffs resulting from the volcanic activities of Mount Erciyes in the north and northwest. In the central part of the basin, as one approaches the wetland, finer-grained alluvium is found, while in the south, thick, massive layers of gray limestone are present. The sedimentary rock units in the Develi Closed Basin extend in an east-west direction, while the magmatic rocks stretch in a narrow strip in a north-south direction (DSI, 1995). The Sultan Marshes National Park and Ramsar Site encompass various habitats, including freshwater and saltwater ecosystems, reed/marsh areas, and surrounding meadow, pasture, and steppe areas (Aksoy, 2004). The land in Sultan Marshes is used for agriculture, grazing, settlement, mining, and other human activities (Yaşar Korkanç et al., 2022).

Methods

The research was designed according to a completely randomized block design. Based on field conditions, the land use types in the wetland ecosystem where soil sampling was conducted were identified as follows: 1. Rangeland areas, 2. Southern Marshlands (Örtülüakar Marshes), 3. Former wetlands that were converted to agricultural land (orchards and farmland) at different times due to DSI projects, and 4. The Dry lake area (around Yay Lake) that became exposed after water receded. Three sampling plots (20x30 m) were selected for each land use type, and disturbed soil samples were taken from the topsoil layer (0-20 cm) at three points within each sampling plot.

In the laboratory, the soil samples, which were air-dried at room temperature, were prepared for analysis by passing them through a 0.2 mm nylon sieve. The soil samples were sent to the laboratories of the General Directorate of Mineral Research and Exploration (MTA), where they were prepared according to the TS ISO14869-1 Standard method (URL 1). The concentrations of Cr, Pb, Fe, Zn, Fe, Mn, Cu, Co, Mo, As, and Ni in the soil samples were determined using Inductively Coupled Plasma Mass Spectrometry (ICP-MS) and Inductively Coupled Plasma Optical Emission Spectrometry (ICP-OES). The relationships between heavy metal concentrations in the soils were determined using Pearson correlation analysis with the IBM SPSS 24.0 statistical software package (Zar, 1996). The pollution status of the soils in the study area was assessed using the contamination factor (C_f) ($C_f \leq 1$: low contamination; $1 \leq C_f < 3$: moderate contamination; $3 \leq C_f < 6$: considerable contamination; $C_f \geq 6$: very high contamination) and the degree of contamination (C_d) ($C_d < 11$: low contamination; $11 \leq C_d <$

22: moderate contamination; 22 ≤ C_d < 44: considerable contamination; 44 ≤ C_d < 44: high contamination; C_d ≥ 44: very high contamination) (Hakanson, 1980).

C_f, the contamination factor, was calculated by dividing the heavy metal concentration in the studied soil by the average concentration of that metal in the soil, using the following formula (Hakanson, 1980):

$$C_f = C_{metal}/C_0 \tag{1}$$

In the formula, C_{metal} represents the concentration of the metal in the soil sample, and C_0 is the average background concentration of the metal in soil, according to Turekian and Wedepohl (1961). For the heavy metals in our research, the background reference values according to Turekian and Wedepohl (1961) are Cr=90, Pb=20, Fe=47200, Mn=850, Zn=95, As=13, Cd=0,3 , Co=19, Cu=45, Mo=2,6 ve Ni=68.

Contamination Degree (C_d) were calculated by summing of all pollution factors of a particular basin (Hakanson, 1980). Hakanson's (1980) thresholds for contamination have been modified for your study since it includes 11 heavy metals. The "low contamination" threshold, initially set at 8, has been adjusted to 11, with other threshold ranges revised accordingly.

RESULTS AND DISCUSSION

The Distribution of Heavy Metal Concentrations in Soils According to Different Land Uses

In the Southern Marsland, the concentrations of heavy metals varied as follows: Cr: 91.90-158.60 mg/kg, Pb: 17.10-34.80 mg/kg, Fe: 17,624-32,869 mg/kg, Mn: 443-559 mg/kg, Zn: 58-282 mg/kg, As: 4.5-24.50 mg/kg, Cd: 0.09-1.20 mg/kg, Co: 7.50-13.30 mg/kg, Cu: 21.20-152.20 mg/kg, Mo: 1.90-10.10 mg/kg, Ni: 89.20-204.40 mg/kg. Based on the average values, the heavy metal concentrations in the Southern Marsland were ranked from highest to lowest as follows: Fe > Mn > Ni > Zn > Cr > Cu > Pb > As > Co > Mo > Cd (Figure 1). It was found that in the Southern Marsland, Cr exceeded the background reference values by 39.58%, Pb by 25.72%, Zn by 41.05%, Cd by 80.74%, Mo by 105.56%, and Ni by 101.13%. Cu was at the threshold level, and As was close to the reference value.

In the rangeland soils, the concentrations of heavy metals varied as follows: Cr: 30.80-141 mg/kg, Pb: 17.0-42.90 mg/kg, Fe: 6,631-25,964 mg/kg, Mn: 165-587 mg/kg, Zn: 40-96 mg/kg, As: 6.90-110.40 mg/kg, Cd: 0.09-1.60 mg/kg, Co: 2-11.20 mg/kg, Cu: 13.60-29.60 mg/kg, Mo: 1.30-7 mg/kg, Ni: 23-144.20 mg/kg. The average heavy metal concentrations in the rangeland soils were ranked from highest to lowest as follows: Fe > Mn > Zn > Cr > Ni > As > Pb > Cu > Co > Mo > Cd (Figure 1). It was found that in the pasture soils, the average concentrations of Pb exceeded the background reference values by 23.50%, As by 110.09%, Cd by 158.89%, and Mo by 60.26%.

In the dry lake area soils, the concentrations of heavy metals varied as follows: Cr: 23.80-25.60 mg/kg, Pb: 7.80-17.80 mg/kg, Fe: 6,904-7,374 mg/kg, Mn: 180-198 mg/kg, Zn: 20-32 mg/kg, As: 70.2-120 mg/kg, Cd: 0.30-1.20 mg/kg, Co: 1.50-2.60 mg/kg, Cu: 7.70-10.80 mg/kg, Mo: 0.60-2.10 mg/kg, Ni: 14.20-19.0 mg/kg. The average heavy metal concentrations in the dry lake area soils were ranked from highest to lowest as follows: Fe > Mn > As > Zn > Cr > Ni > Pb > Cu > Co > Mo > Cd (Figure 1). It was found that the average concentrations of Cd in the soils exceeded the background reference values by 114.81%, and As concentrations exceeded by 574.44%

In the agricultural soils, the concentrations of heavy metals varied as follows: Cr: 27.90-169.70 mg/kg, Pb: 8.50-75.20 mg/kg, Fe: 5,626-35,229 mg/kg, Mn: 87-678 mg/kg, Zn: 19-116 mg/kg, As: 0.10-29 mg/kg, Cd: 0.09-1.40 mg/kg, Co: 1.60-15.20 mg/kg, Cu: 10-104.40 mg/kg Mo: 1.60-9.50 mg/kg, Ni: 11.80-198.60 mg/kg. The average heavy metal concentrations in the agricultural soils were ranked from highest to lowest as follows: Fe > Mn > Zn > Cr > Ni > Cu > Pb > As > Co > Mo > Cd (Figure 1). It was found that in the agricultural soils, the average concentrations of Pb exceeded the background reference values by 62.92%, As by 29.55%, Cd by 124.72%, and Mo by 28.21%.

Variation in Correlations Between Heavy Metals According to Land Use Types

In the Southern Marsland, the statistically significant relationships between heavy metal concentrations in the soil were as follows: Cr showed a positive correlation with Fe, Co, and Ni. Fe exhibited a positive correlation with Cr, Mn, Co, and Ni. Mn had a positive correlation with Fe, Co, and Ni. Co was positively correlated with Cr, Fe, Mn, and Ni. Ni showed a positive correlation with Cr, Fe, Mn, and Co (Table 1).

The statistically significant correlations between heavy metal concentrations in the soil of the rangeland area were as follows: Cr showed a positive correlation with Fe, Mn, Co, Cu, Mo, and Ni, while Pb showed a positive correlation only with Zn. Fe exhibited a positive correlation with Cr, Mn, and Co, whereas Mn showed a positive correlation with Cr, Fe, Co, and Ni. Zn showed a positive correlation with Pb, and Co had a positive correlation with Cr, Fe, Mn, Cu, and Ni. Cu showed a positive correlation with Cr, Co, and Ni. Mo exhibited a positive correlation with Cr and Ni, while Ni showed a positive correlation with Cr, Mn, Co, Cu, and Mo (Table 1).

When examining the correlations between heavy metal concentrations in the soils taken from the Dry lake area, it was found that only Zn and As have a significant negative correlation (Table 1).

*Significant correlations at 0.05 level (2-tailed),

**Significant correlations at 0.01 level (2-tailed)

The statistically significant correlations between heavy metal concentrations in the soils from the agricultural area were as follows: Cr shown a positive correlation with Fe, Mn, Co, Mo, and Ni. Pb shown a positive correlation with Fe, Mn, Zn, Co, and Cu, while Fe exhibited a positive correlation with Cr, Pb, Mn, Zn, Cd, Co, Mo, and Ni. Mn had a positive correlation with Cr, Pb, Fe, Zn, Co, Cu, and Ni, whereas Zn shown a positive correlation with Pb, Fe, Mn, Co, and Cu. Cd shown a positive correlation only with Fe. Co shown a positive correlation with Cr, Pb, Fe, Mn, Zn, Mo, and Ni, while Cu exhibited a positive correlation with Pb, Mn, and Zn. Mo shown a positive correlation with Cr, Fe, Co, and Ni, and Ni exhibited a positive correlation with Cr, Fe, Mn, Co, and Mo (Table 1).

When heavy metal sources are similar or identical, there is typically a significant correlation between their concentrations. The strength of the relationship between heavy metal elements can therefore reflect their source environments (Luo et al., 2018; Zeng et al., 2018). The correlations in this study also suggest that the heavy metals may have originated from a common or similar source. Similarly, Nuralykyzy et al. (2021) found strong correlations between Zn–Cd ($p < 0.01$), Cr–Ni ($p < 0.05$), and Ni–Pb ($p < 0.05$). Additionally, Jiang et al. (2017) reported that Co, Cr, Cu, Pb, and Zn have significant positive correlations with each other, indicating they may have originated from the same sources.

Evaluation of Pollution

Based on the average C_f values, the heavy metals measured in the soil of the Southern Marsland area could be ranked as follows: Mo (2.06) > Ni (2.01) > Cd (1.81) > Zn (1.41) > Cr (1.40) > Pb (1.26) > Cu (1.0) > As (0.86) > Mn (0.60) > Co (0.52) > Fe (0.51). According to the C_f values, 88% of the soil samples from the Southern Marshland area were moderately contaminated with Ni, 100% with Cr, 77% with Mo and Pb, 44% with Zn and Cd, 33% with As, and 11% with Cu. Significant contamination was observed in 22% of samples for Cd and 11% for Cu. Low contamination was found for As, Mn, Co, and Fe.

In the rangelands, the heavy metals ranked by average C_f values were as follows: Cd (2.59) > As (2.10) > Mo (1.60) > Pb (1.24) > Ni (0.75) > Cr = Zn (0.68) > Mn (0.47) > Cu (0.44) > Fe (0.36) > Co (0.30). In this area, 67% of soil samples were moderately contaminated with As, Cr, and Mo; 33% with Cd; 22% with Cr and Ni; 33% of samples were significantly contaminated with Cd; and 11% were highly contaminated with As. Low contamination was observed for Ni, Cr, Zn, Mn, Cu, Fe, and Co.

For the Dry lake area, the heavy metals ranked by average Cf values were as follows: As (6.74) > Cd (2.15) > Pb (0.61) > Mo (0.58) > Cr = Zn (0.27) > Ni (0.24) > Mn (0.22) > Cu (0.20) > Fe (0.15) > Co (0.11). In this area, 78% of soil samples were highly contaminated with As, 22% were significantly contaminated with As, 89% were moderately contaminated with Cd, and 11% were significantly contaminated with Cd. Low contamination was observed for Pb, Mo, Cr, Zn, Ni, Mn, Cu, Fe, and Co.

In the agricultural area, the heavy metals ranked by average C_f values were as follows: Cd (2.25) > Pb (1.63) > As (1.30) > Mo (1.28) > Zn (0.78) > Cu (0.76) > Cr (0.67) > Ni (0.61) > Fe (0.41) > Mn (0.39) > Co (0.31). In this area, 58% of soil samples were moderately contaminated with Pb, 42% with Zn, 67% with As, 50% with Cd, and 33% with Mo. Significant contamination was observed in 25% of samples for Cd, 8% for Pb, and 8% for Mo. Low contamination was observed for Zn, Cu, Cr, Ni, Fe, Mn, and Co.

When the soil samples taken from the Southern Marshland area were evaluated in terms of C_d, it was observed that C_d values range between 4.6 and 18.49, indicating low to moderate contamination. The percentage contribution of each element to the total C_d in the Southern Marshland soils could be ranked from highest to lowest as follows: Mo (15.29%) > Ni (14.96%) > Cd (13.45%) > Zn (10.50%) > Cr (10.38%) > Pb (9.37%) > Cu (7.42%) > As (6.44%) > Mn (4.48%) > Co (3.89%) > Fe (3.80%). Based on C_d values, the soils from Southern Marshland were moderately contaminated with Mo, Ni, Cd, Zn, Cr, and Pb, and were slightly (low) contaminated with other heavy metals.

In the rangeland area, the C_d values of the soil samples ranged from 2.68 to 23.30, indicating low to significant contamination. The percentage contribution of each element to the total C_d in the rangeland soils was as follows: Cd (23.08%) > As (18.72%) > Mo (14.28%) > Pb (11.03%) > Ni (6.71%) > Zn (6.08%) > Cr (6.07%) > Mn (4.23%) > Cu (3.89%) > Fe (3.25%) > Co (2.65%). Based on C_d values, the soils from the rangeland area were significantly contaminated with Cd, moderately contaminated with As, Pb, and Mo, and slightly (low) contaminated with other heavy metals.

For the Dry lake area, the C_d values of the soil samples ranged from 1.36 to 19.33, indicating low to moderate contamination. The percentage contribution of each element to the total C_d in the Dry lake soils was as follows: As (58.41%) > Cd (18.60%) > Pb (5.29%) > Mo (5.0%) > Cr (2.38%) > Zn (2.32%) > Ni (2.10%) > Mn (1.90%) > Cu (1.70%) > Fe (1.31%) > Co (0.99%). Based on C_d values, the soils from the Dry lake area were highly contaminated with As, moderately contaminated with Cd, and slightly (low) contaminated with other heavy metals.

In the agricultural area, the C_d values of the soil samples ranged from 3.74 to 26.96, indicating low to significant contamination. The percentage contribution of each element to the total C_d in the agricultural soils was as follows: Cd (21.63%) > Pb (15.71%) > As (12.48%) > Mo (12.35%) > Zn (7.49%) > Cu (7.32%) > Ni (7.36%) > Cr (6.46%) > Fe (3.95%) > Mn (3.71%) > Co (3.0%). Based on C_d values, the soils from the agricultural area were significantly contaminated with Cd, moderately contaminated with As, Mo, and Pb, and slightly (low) contaminated with other heavy metals.

CONCLUSION

-This study was conducted to evaluate the heavy metal concentrations and contamination levels in various land uses within the Sultan Marshes ecosystem.

-The average concentrations of Cr, Fe, Zn, Co, Cu, and Ni in the soils from the Southern Marshland area; Cd concentrations in the rangeland soils; Pb concentrations in the soils from agricultural areas; and As concentrations in the soils from the Dry lake area were higher than those in other land use types. Some heavy metal concentrations have exceeded historical reference values depending on the different land uses.

-According to C_f values, the soils from the Southern Marshland area showed moderate contamination for Mo, Ni, Cd, Zn, Cr, Pb, and Cu, with low contamination for other heavy metals. In the rangeland area, there was moderate contamination for Cd, As, Mo, and Pb, and low contamination for other heavy metals. In the Dry lake area, there was extreme contamination for As, moderate contamination for Cd, and low contamination for other heavy metals. In the agricultural area, there was moderate contamination for Cd, Pb, As, and Mo, and low contamination for other heavy metals.

-Based on C_d values, soils from the Southern Marshland area exhibited moderate contamination for Mo, Ni, Cd, Zn, Cr, and Pb, with low contamination for other heavy metals. Soils from the rangeland area showed significant contamination for Cd, moderate contamination for As, Pb, and Mo, and low contamination for other heavy metals. Soils from the Dry lake area were extremely contaminated with As, moderately contaminated with Cd, and have low contamination for other heavy metals. Soils from the agricultural area were significantly contaminated with Cd, moderately contaminated with As, Mo, and Pb, and had low contamination for other heavy metals.

-It was generally believed that the heavy metals in the Sultan Marshes ecosystem might originate from natural sources as well as various human activities.

-Measures should be taken to reduce or prevent heavy metal input from human activities in soils under different land uses. Agricultural fertilization and pesticide use, as well as livestock activities, should be controlled, and good agricultural practices should be adopted. Mining activities and mining-based industrial activities in the vicinity must be strictly regulated. Uncontrolled waste and wastewater discharges into the system should be prevented. Specifically, heavy metal pollution sources in Southern Marshland, rangeland, and agricultural areas should be controlled, as there is a higher risk of heavy metals entering the food chain in these areas.

ABSTRACT

Soil and water are among the natural resources that provide crucial services to humans. Water erosion is one of the most significant global problems threatening the sustainable use of these two essential natural resources. To reduce or prevent water erosion, various soil conservation practices are implemented worldwide. Mulching is one such practice used to protect both soil and water. The aim of this study is to determine the effects of different mulch types and application rates on some hydrological (surface runoff, runoff coefficient, time to runoff initiation, percolated and retained water) and erosional (soil loss, sediment concentration) behaviors of soils developed on metamorphic parent material under artificial rainfall conditions in the laboratory. For this purpose, three different mulch types (wheat straw, dry weed, and peanut hay straw) were applied at three different rates (2, 4, 6 tons/ha) to experimental plots created under laboratory conditions. Artificial rainfall was applied at a rate of 97 mm/h for one hour. During the application, the time to runoff initiation was measured, and surface runoff and percolation water were collected to measure the mentioned parameters. The results of the study showed that peanut hay mulch was the most effective application in reducing surface runoff and runoff coefficient. All three mulch types reduced soil loss, with straw mulch being the most effective. The most effective mulch application rate in reducing erosion was found to be 6 tons/ha.

Keywords: Mulching, runoff, rainfall simulation, erosion

INTRODUCTION

Soil is a crucial natural resource due to the services it provides, such as ecosystem functions, its importance in the global biogeochemical cycle, its role in mitigating climate change, and more (Du et al., 2022). Soil erosion is a very serious problem that reduces soil productivity in many parts of the world, especially in semi-arid and semi-humid regions. Soil erosion, driven by excessive surface runoff, leads to the loss of fertile topsoil, resulting in the degradation of soil functions (Biddoccu et al., 2016). The severity and frequency of water erosion are largely dependent on physical conditions. However, the timing and causes of erosion are also strongly influenced by human factors, such as improper land management and changes in land use (Lal, 1984; Cerda, 1994; Montgomery, 2007; Martínez-Casasnovas et al., 2016).

To reduce or prevent erosion and surface runoff, a wide range of methods can be employed in soil and water conservation efforts. Traditional methods primarily include engineering approaches, biological approaches, and agricultural measures (Li et al., 2021). Among agricultural measures, mulching is a method that has been widely used in soil and water conservation worldwide due to its low cost and rapid effectiveness (Fan et al., 2023; Li et al., 2020). Gupta and Gupta (1986) noted that mulching reduces evaporation and increases infiltration, thereby preserving/increasing the soil's moisture content. Mulching can improve the soil's organic matter, nutrient content, and microbiological properties (Jiménez et al., 2016; Srilakshmi et al., 2012). Various studies have reported that mulching reduces runoff, nutrient loss, soil loss, and sediment content (Vega et al., 2012; Lee et al., 2018; Yaşar Korkanç and Şahin, 2021; Yaşar Korkanç and Şahin, 2024; Bogunovic et al., 2023). Organic and inorganic materials can be used as mulch. Organic materials include living cover, straw, plant residues, tree bark, etc. (Li et al., 2021). However, the type of mulch, the amount to be applied, and its cost-effectiveness may vary depending on local conditions. Indeed, Pan et al. (2022) reported a negative relationship between mulch application and soil loss and surface runoff. Therefore, applying different methods under various conditions is deemed necessary to achieve the most effective and feasible conservation.

In this context, the aim of this study is to determine the effects of organic mulch applications, using different types and doses of mulch, on certain hydrological (surface runoff, runoff coefficient, time to runoff initiation, percolation water, and water remaining in the soil) and erosional (soil loss, sediment concentration) behaviors of the soil.

MATERIAL AND METHOD

In this study, the topsoil (0-20 cm) developed on sedimentary bedrock within the boundaries of Gümüşler Town in Niğde province was used to establish the experimental plots. The land from which the soil samples were taken is flat to nearly flat with a slight undulation. The current land use is pasture (but previous land use was farmland). The soil samples have a sandy loam texture, with 90.38% sand, 3.55% clay, 6.07% silt, a pH of 7.02, electrical conductivity of 125.15 μS/cm, loss on ignition of 5.35%, and aggregate stability of 4.95%. The study utilized an artificial rainfall simulator as detailed in Yaşar Korkanç (2018). The artificial rainfall was applied at a rate of 97 mm/hour for 1 hour using a Lechler 460.646-type nozzle under a pressure of 0.5 bar. The plots where the soil samples were placed measured 30x50x15 cm and were made of metal. The erosion plots had drainage holes at the bottom, where gauze was first laid, followed by a 7 cm layer of sand, which was leveled. Another layer of gauze was placed on top of the sand, and then the plot was filled with 5 cm of soil, which had been passed through an 8 mm sieve, up to the surface runoff pipe exit, and the surface was carefully leveled (Akalan, 1967; Taysun, 1986). The experimental plots were treated with three different mulch materials (mixed grass, wheat straw, and peanut plant residues) applied at three different doses (Dose 1: 2 tons/ha, Dose 2: 4 tons/ha, and Dose 3: 6 tons/ha) (Figure 1). The materials used as mulch were dried at 65°C before application. Immediately after the mulch application, the experimental plot was placed on a stand with a 9% slope, and artificial rainfall was applied (Yaşar Korkanç and Şahin, 2021). The study was conducted using a two-factor (mulch type and mulch dose) completely randomized block design. During the artificial rainfall application, the time of runoff initiation was measured, and the surface runoff and percolation water were collected for calculating parameters such as surface runoff, runoff coefficient, soil loss, sediment concentration, percolation water, and water remaining in the soil(retained water). Statistical evaluations were conducted using the SPSS 24.0 software package. The effects of different types and doses of mulch on the mentioned parameters were assessed using variance analysis (ANOVA) (P=0.05), and if differences were found, the differences between the means were determined using the Duncan test (Zar, 1996).

Figure 1. A view of the experimental plots used in the study

RESULTS AND DISCUSSION

The statistical evaluation results showed that different types and doses of mulch applications significantly affected the parameters of surface runoff, runoff coefficient, time to runoff initiation, percolation water, retained water, soil loss, and sediment concentration (P<0.05) (Figures 2-8)

Surface Runoff

The change in surface runoff observed after the application of different mulch types was presented in Figure 2. Compared to the control plot, peanut hay mulch was found to be more effective in reducing surface runoff than the other mulch types. In contrast, an increase in surface runoff was observed in the plots where the other two types of mulch were applied (Figure 2)

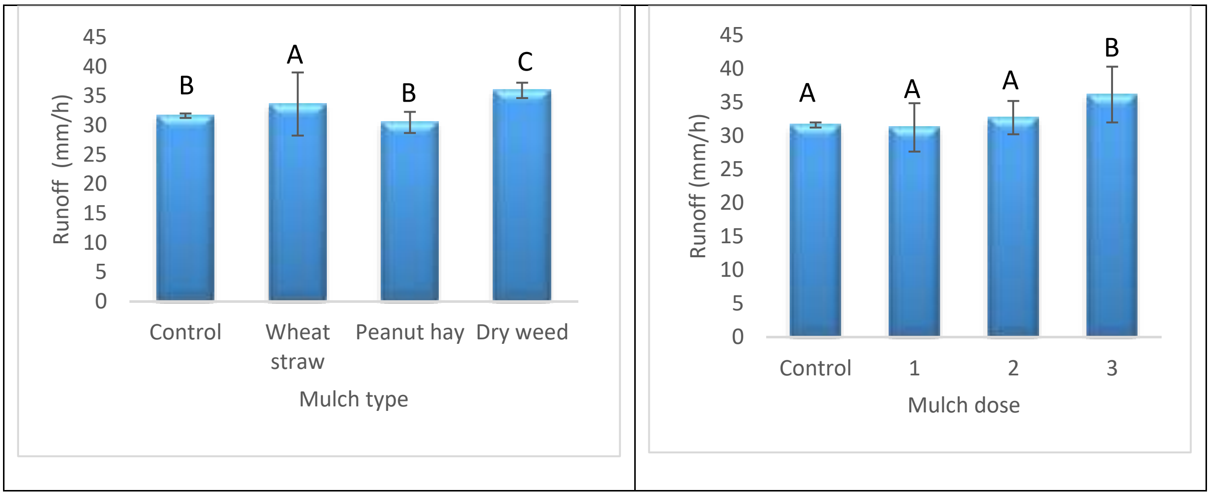

Figure 2. Changes in surface runoff according to different types and doses of mulch applications

The changes in surface runoff according to different mulch doses were shown in Figure 2. The surface runoff from the plots where the 1st dose was applied close to those of the control plot. As the dose application amount increased, a general increase in surface runoff was observed. The highest increase compared to the control plot was noted in the plots where the 3rd dose was applied (Figure 2).

Runoff Cofficient

Figure 3 shown the change in runoff coefficient according to different mulch types. The runoff coefficient was most reduced in the plots where peanut hay mulch was applied compared to the control plot. In contrast, straw and dry weed mulch were found to increase the runoff coefficient (Figure 3).

The change in runoff coefficient in plots with different dose applications was presented in Figure 3. The values closest to the runoff coefficient of the control plot were found in the plots where the first dose was applied. Overall, an increase in mulch dose resulted in a higher runoff coefficient (except 1^{st} dose) (Figure 3).

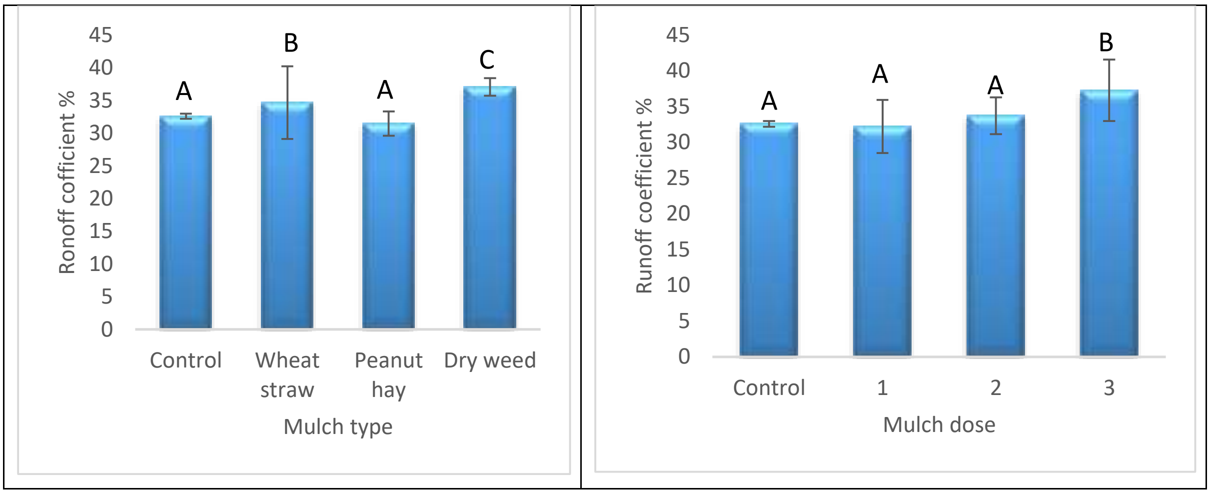

Figure 3. Changes in runoff coefficient according to different types and doses of mulch applications

Time to Runoff Initiation

The change in time to runoff initiation according to different mulch types was shown in Figure 4. All three mulch types led to a decrease in time to runoff initiation compared to the control plot (Figure 4).

The change in time to runoff initiation with different mulch doses was presented in Figure 4. All three doses reduced the time to runoff initiation compared to the control. However, as the dose amount increased, a tendency for time to runoff initiation to increase was observed (Figure 4).

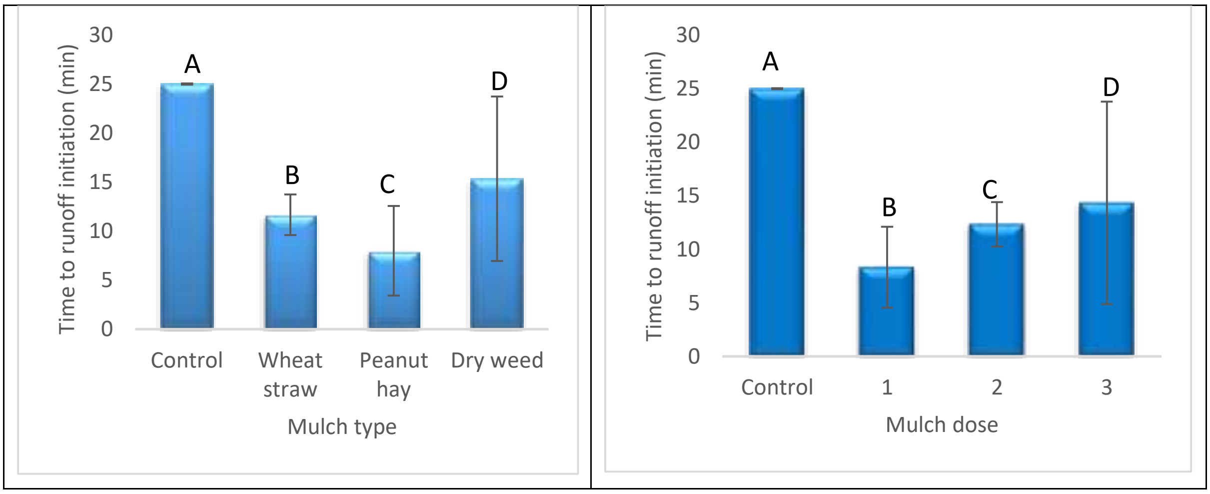

Figure 4. Changes in time to runoff initiation according to different types and doses of mulch applications

Percolated (Drained) Water

The change in the amount of percolation water according to different mulch types was presented in Figure 5. All three mulch types caused a decrease in the amount of water percolated from the soil. The mulch type with the highest decrease was in the plots where straw mulch was applied, followed by dry weed mulch. The values closest to the percolation water in the control plots were found in the peanut hay mulch applications (Figure 5).

The changes in percolation water according to different mulch doses were presented in Figure 5. All three mulch dose applications caused a decrease in percolation water. In general, it was observed that percolation water tended to increase as the mulch dose increased (Figure 5).

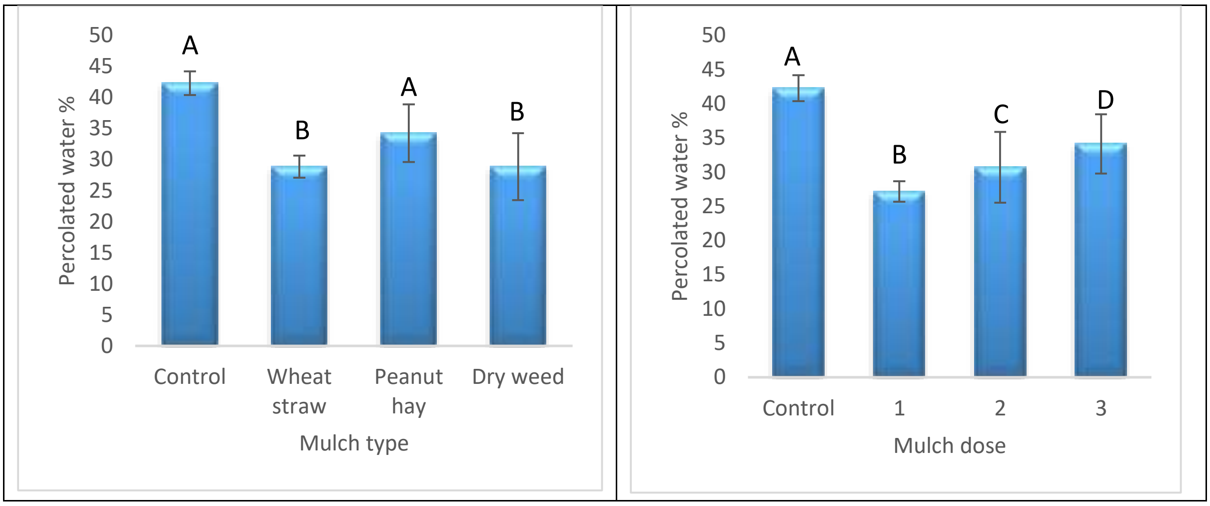

Figure 5. Changes in percolated water according to different types and doses of mulch applications

Retained Water

The changes in retained water in the soil according to different mulch types were presented in Figure 6. It was found that all three mulch types increased the water retention in the soil. The most effective mulch type in increasing the retained water in the soil was straw mulch. The least effective mulch type was determined to be dry weed mulch (Figure 6).

The variation in retained water in the soil according to different dose applications was as shown in Figure 6. All three mulch doses had a positive effect on water retention in the soil. The most effective mulch dose is the 1st dose, while the least effective mulch dose is the 3rd dose application (Figure 6).

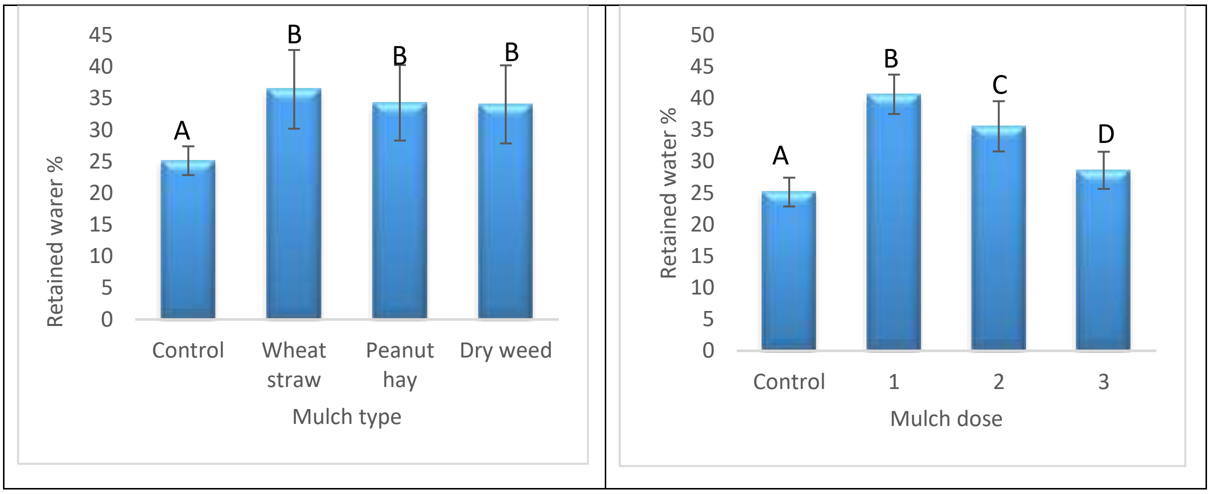

Figure 6. Changes in retained water according to different types and doses of mulch applications

Soil Loss (Erosion)

The changes in soil loss due to different types of mulch applications was presented in Figure 7. It was found that all three types of mulch were effective in reducing soil loss. The most effective mulch type for preventing soil loss was wheat straw mulch, followed by peanut hay mulch and dry weed mulch (Figure 7).

The variation in soil loss according to different mulch doses was shown in Figure 7. All mulch doses reduced soil loss compared to the control values. The most effective mulch dose for preventing soil loss was the 3rd dose application, followed by the 1st and 2nd dose applications (Figure 7).

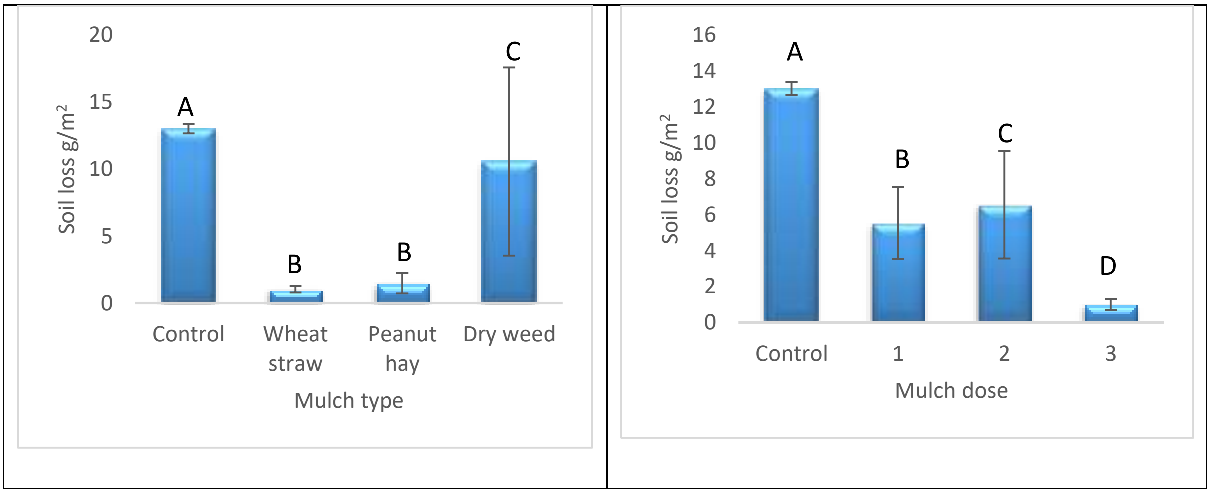

Figure 7. Changes in soil loss according to different types and doses of mulch applications

Sediment Concentration

The variation in sediment concentration according to different types of mulch was shown in Figure 8. Sediment concentration decreased in plots with wheat straw mulch and peanut hay mulch compared to the control, while it did not decrease in plots with dry weed mulch. The most effective mulch type for reducing sediment concentration was wheat straw mulch (Figure 8).

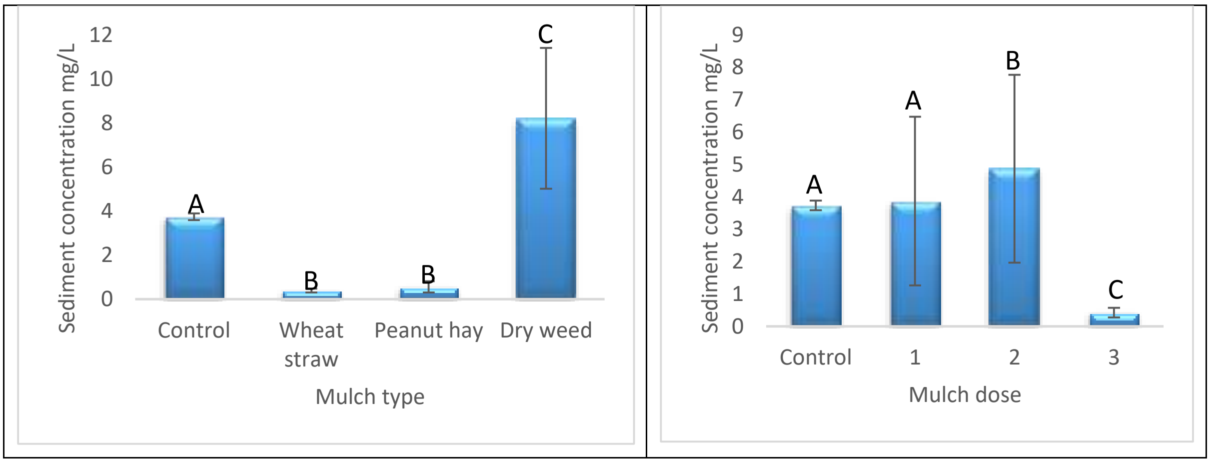

Figure 8. Changes in sediment concentration according to different types and doses of mulch applications

CONCLUSIONS

This study was conducted to investigate the effects of different types and amounts of organic mulch on various hydrological and erosional behaviors of soils. The most effective mulch type and dose for reducing runoff and runoff coefficient wasthe 1st dose of wheat straw mulch. All three types and doses of mulch caused a reduction in the time to runoff. As the mulch dose increased, the time to runoff initiation also increased. All three types and doses of mulch resulted in a decrease in percolation water. Each type and dose of mulch was effective in increasing the amount of water retained in the soil, with straw mulch being the most effective type and the 1st dose application being the most effective dose. All three mulch types were effective in reducing soil loss, with wheat straw mulch being the most effective type and the 3rd dose application being the most effective dose. Based on the results obtained under these conditions, mulching can be recommended as a nature-based practice for reducing soil loss and conserving soil moisture. However, to determine the most economically suitable type and dose of mulch, the number of studies in different conditions should be increased with regional trials.

ACKNOWLEDGEMENT

The authors would like to thank Prof. Dr. Mustafa KORKANÇ from Department of Geological Engineering, for his laboratory support during the plot trials of this study.

ABSTRACT

Management and sustainable use of fish stocks is considered to be a challenging task due to the continuous interaction of internal and external drivers. These forces can move the stocks out of their equilibrium state, which can result in abrupt shifts. Identifying possible causes of such changes in natural systems remains difficult, as they can arise under various circumstances. Threats are often not recognized until the species have suffered large population declines. Abrupt changes may hinder the success of management measures and have severe ecological, economic and social consequences. In this study we used a systematic approach that classifies a time series to a trajectory type (no-change, linear, quadratic and abrupt change) along with statistical changepoint analyses to identify past abrupt changes in the biomass of the most important commercial fish species in the Adriatic Sea. This classification approach allowed us to identify the best-fitted trajectory and also investigate additional change points in the biomass. Our analysis shows that an abrupt trajectory better explains the dynamics of five out of the seven species we investigated, compared to the other trajectories considered. This study represents the first step towards the identification of non-linear dynamics in the biomass of Adriatic Sea fish species and evaluating their potential drivers. Considering the magnitude and rapid change of many drivers during the Anthropocene, diagnosing abrupt changes and their underlying causes becomes particularly important, due to the profound and increasing consequences for the sustainability of fish stocks.

Keywords: abrupt change, fish stocks, biomass, non-linear dynamics

INTRODUCTION

Over the last decades, despite the efforts of fisheries management to improve the status of many fish stocks by rebuilding their populations to sustainable levels, nearly 50 % of the stocks still remain below biomass targets (Britten et al., 2021). Despite recovery efforts, the sustainable use of fish stocks can be hindered or inhibited by the continuous interactions of multiple external drivers such as fishing and climate change (Brander, 2007; Lotze et al., 2011b;

Conversi et al., 2015). Although it is generally assumed that natural populations respond in a predictable and gradual manner to these external disturbances, such observations are rarely encountered (Clark and Luis, 2020). Instead, several studies have shown sudden and unexpected abrupt shifts of populations (Folke et al., 2004; Ratajczak et al., 2018; Turner et al., 2020). Abrupt changes are difficult to predict and can occur under various circumstances, including both gradual and sudden changes in drivers, as well as interactions among multiple drivers (Bestelmeyer et al., 2011; Ratajczak et al., 2018).

Abrupt changes differ widely in scale, some are mild and can be reversed by restoring the driver variables to previous levels, whereas in other cases they can persist long after the drivers returned to their initial conditions (Bestelmeyer et al., 2011; Ratajczak et al., 2018). Often, they are considered indicators of transitions between alternative states. Abrupt shifts represent a critical transition whose likelihood increases as the system approaches a so-called tipping point, where even a small disturbance can initiate a self-propagating shift to a new state (Scheffer, 2009).

Depending on their characteristics, some ecosystems may be able to absorb stronger disturbances than others, an ability recognized as resilience. However, marine ecosystems are generally recognized to be particularly vulnerable to drastic and unexpected changes (deYoung et al., 2008). The likelihood of these abrupt changes is expected to increase in both strength and frequency in the future following the intensification of anthropogenic disturbances and climate change (Möllmann et al., 2015; Turner et al., 2020; Clark and Luis, 2020). These changes can have important socio-ecological consequences, particularly under the increasing pressure from climate driven disturbances (O'Leary et al., 2017; Turner et al., 2020). Even though numerous examples of non-linear dynamics in various marine systems world-wide led to severe ecological, economic and social consequences, current management strategies still rely largely on continuous dynamics (Levin and Möllmann, 2015; Sguotti and Cormon, 2018).

The Adriatic Sea is considered as one of the most impacted areas in the Mediterranean due to anthropogenic activities, with fishing and land-based pollution identified as the major contributors (Coll et al., 2012; Micheli et al., 2013). The basin is considered as the most productive area across the Mediterranean and a hotspot for biodiversity, hosting more than 7000 species (Furlan et al., 2019). It has a long history of exploitation which has caused significant changes in the species composition with dramatic declines of top predators, demersal and pelagic species (Lotze et al., 2011a; Piroddi et al., 2017; Sguotti et al., 2022). High fishing pressure over the years has caused significant reductions in the biomass of the most important fish stocks and management has failed to reduce fishing pressure to the required target levels (Piroddi et al., 2017). In addition, recent climate change projections have identified the Adriatic as one of the most vulnerable areas of the world ocean (Coll et al., 2012). Climate change is expected to affect its fisheries as well as biodiversity and ecosystem functioning in general (Marbà et al., 2015; Piroddi et al., 2017; Hidalgo et al., 2019b). Recent studies have identified fisheries and climate change as the main drivers of past regime shifts in fish community composition, with previously dominant large-bodied species being replaced by smaller, lower trophic level organisms (Sguotti et al., 2022).

Our analysis revealed that an abrupt trajectory better explains the dynamics of five out of seven species we studied. This study marks the first step toward identifying non-linear dynamics in the biomass of Adriatic Sea fish species. Considering the magnitude and rapid change of many drivers during the Anthropocene (Rockström et al., 2009), diagnosing abrupt changes and their underlying causes becomes particularly important due to the profound and increasing ecological, social and economic losses and to ensure an effective management of fish stocks.

MATERIALS AND METHODS

Data

Our analyses of trajectory selection and change point identification were based on stock assessment data for seven commercially important fish species from the Adriatic Sea: European hake (*Merluccius merluccius*), red mullet (*Mullus barbatus*), common sole (*Solea solea*), Norway lobster (*Nephrops norvegicus*), deep water rose shrimp (*Parapenaeus longirostris*), sardine (*Sardina pilchardus*) and anchovy (*Engraulis encrasicolus*). Data for European hake, red mullet, common sole and deep water rose shrimp were obtained from the Joint Research Center (JRC) publications repository (JRC, 2023). Data for Norway lobster, sardine and anchovy were obtained from the General Fisheries Commission for Mediterranean (GFCM) database of stock assessment results (https://www.fao.org/gfcm/data/star/en/). The longest time series corresponded to common sole, spanning 62 years (1962-2020), while the shortest time series were for sardine and anchovy, covering 2000 to 2023. Data for hake included the years 1998 – 2022, for red mullet 1973-2021, for Norway lobster 1972-2021 and deep water rose shrimp 1996-2022. The data included information on recruitment (R), spawning stock biomass (SSB), landings and fishing mortality (F). The only exception was the deep water rose shrimp, for which SSB data were unavailable because the stock assessment model used a production model (SPICT) and not a fully analytical one (JRC, 2023), as a consequence total biomass (B) data was used instead.

Statistical analyses

In order to determine the presence of abrupt shifts in spawning stock biomass of the most important commercial species of the Adriatic Sea, we followed a two-step process combining trajectory classification and changepoint analysis. By following the approach by Pélissié et al. (2024) we employed a trajectory classification methodology to evaluate the presence of abrupt shifts in our time series. This approach integrates several existing methods in a three-step classification process, including model selection, validation and reliability confirmation, in order to classify any time series to one of the following trajectory types, i.e. linear, non-linear (quadratic) or abrupt change, and confirms the occurrence of potential abrupt shifts. The most parsimonious model was selected by comparing Akaike Information Criteria values corrected for small sample size (AICc). The reliability of the classification was assessed using three different indices: weighted AIC (wAIC), Leave One Out (LOO) and Normalized Root Mean Square Error (NRMSE). Considering that the classification is more reliable for timeseries of at least 25 timepoints and in order to minimize the risk of missing abrupt shifts, the breakpoint validation step was skipped for the shorter time series corresponding to hake, deep water rose shrimp, anchovy and sardine (see Pélissié et al., 2024). This step served as a primary filter to identify abrupt trajectories in the spawning stock biomass (biomass in the case of deep water rose shrimp) of the analysed species. The species, whose trajectory was not classified as abrupt were not considered for further analyses.

In addition, after identifying the trajectory type, abrupt changes in the time series of SSB for each species selected in the first step were detected using two different statistical change point methods (Möllmann et al., 2021; Blöcker et al., 2023), each employing a different algorithm, provided by the R packages *changepoin*t (Killick and Eckley, 2014) and *bcp* (Erdman and Emerson, 2008). These methods identify the points where changes are observed in the statistical properties of a time series. Within the *cpt.mean* function of the *changepoint* package we used the *BinSeg* algorithm and set a minimum segment length of at least 5 years between change points to ensure a reasonable length for quasi-stable periods. In contrast, the Bayesian change point approach, applied through the package *bcp*, calculates the posterior probabilities of change at any given point in time series.

Table 1. Trajectory classification and abrupt changes in Adriatic Sea fish stocks

Species	**Trajectory Classification**		**1st change point**		**2nd change point**	
	Trajectory	Break date	BinSeg	BCP	BinSeg	BCP
European hake	Abrupt	2009	2009	2010	2017	2019
Red mullet	Abrupt	1992	1992	1992	2011	2012
Common sole	Abrupt	2003	2003	2003	2014	2014
Deep water rose shrimp	Abrupt	2015	2015	2015	-	-
Anchovy	Abrupt	2010	2010	2010	-	-
Sardine	Quadratic	-	-	-	-	-
Norway lobster	Linear	-	-	-	-	-

RESULTS AND DISCUSSION

In our analyses, we combined a systematic approach for trajectory classification introduced by Pélissié et al., (2024) with changepoint analyses to investigate abrupt shifts in biological data-series from the Adriatic Sea. The systematic approach allowed us to classify the time series to a trajectory type: no change, linear, quadratic and abrupt change. Meanwhile, the statistical changepoint analysis, employing two different methods, identified the location of additional past abrupt changes in the biomass (SSB and B) of the most important commercial fish species in the Adriatic Sea; European hake, red mullet, common sole, Norway lobster, deep water rose shrimp, sardine and anchovy. The classification process identified abrupt trajectories for five out of 7 analysed species: European hake, red mullet, common sole, deep water rose shrimp and anchovy (Table 1). For the remaining species, a linear trajectory for Norway lobster and a quadratic trajectory for sardine were identified. Hence, these two species were excluded from further identification of abrupt changes location through changepoint analyses. Due to the method's sensitivity to the length of the time series and to minimize the risk of missing abrupt shifts (Pélissié et al., 2024), only the first step was applied to the data for European hake (25 timepoints), deep water rose shrimp (27 timepoints), sardine (24 timepoints) and anchovy (24 timepoints). This adjustment resulted in an abrupt trajectory classification for European hake and anchovy, which were previously classified as quadratic and linear, respectively. However, it did not identify a different trajectory for deep water rose shrimp and sardine.

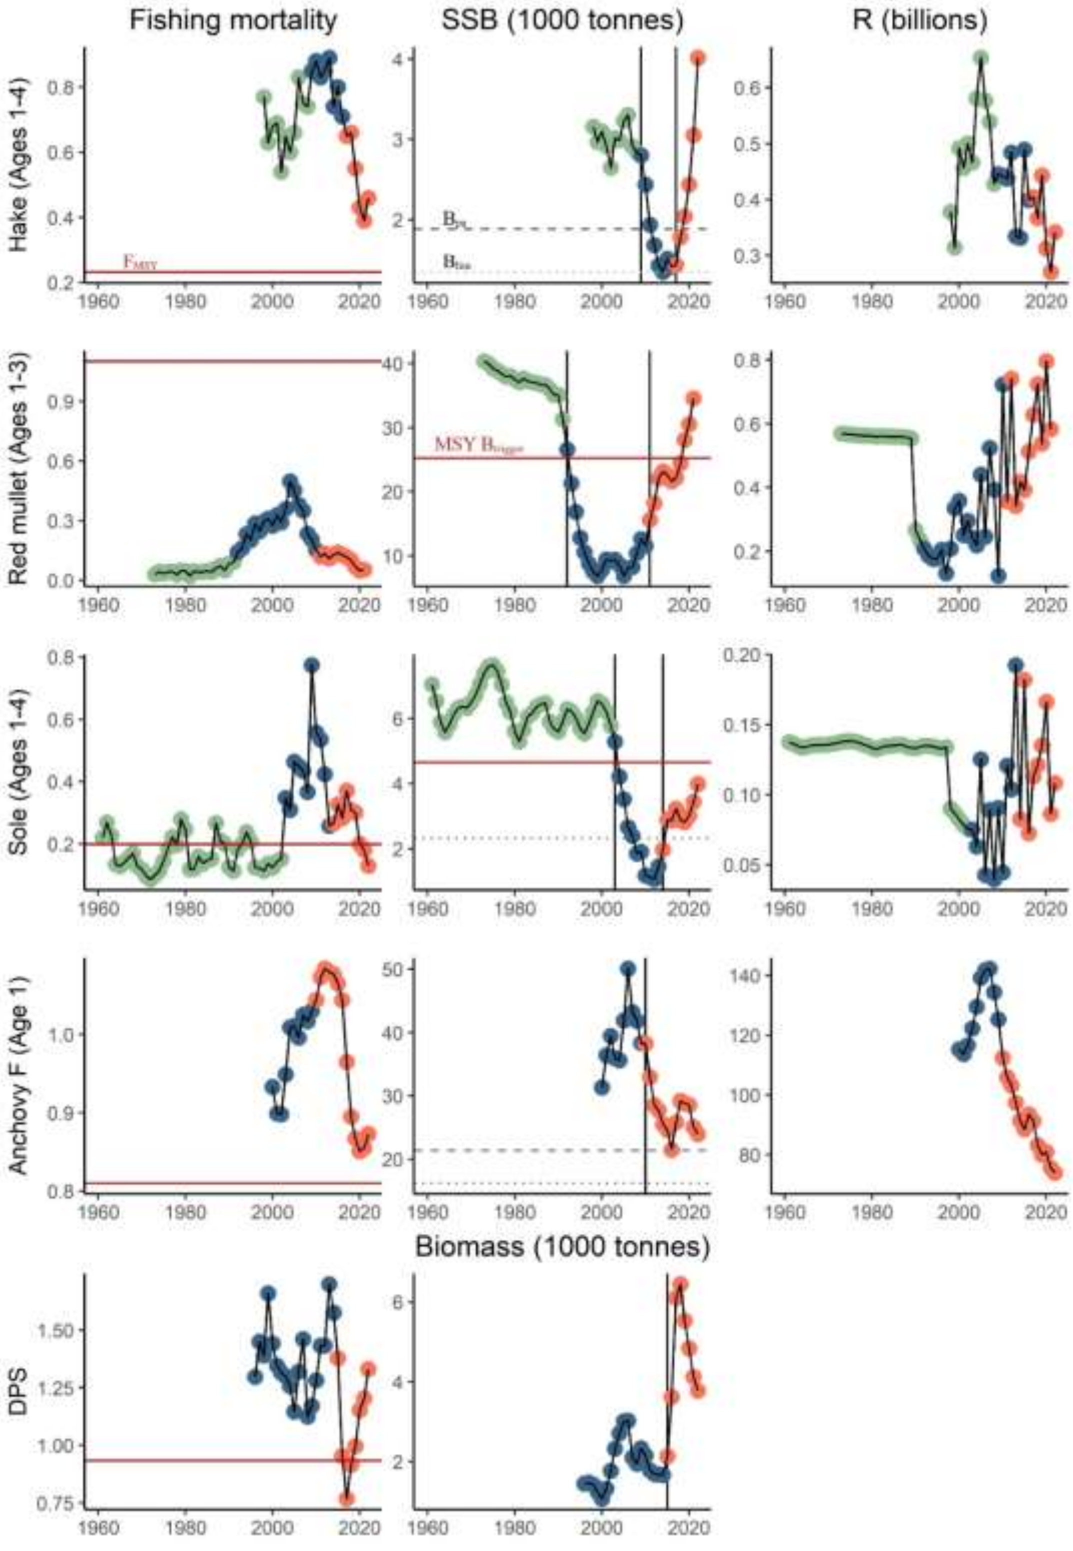

Figure 1. Abrupt changes in the spawning stock biomass (SSB) and total biomass (B) of Adriatic Sea fish stocks. Color ranges indicate the identified periods for SSB or B. The figure includes time series of fishing mortality (F), SSB or B, and recruitment (R). Horizontal lines indicate the management reference points: in the first column, the F level that leads to the Maximum Sustainable Yield (F_{MSY}); in the second column, the SSB level triggering

management actions (MSY $B_{trigger}$) as well as the precautionary level (B_{pa}) and limit reference point of SSB (B_{lim}); DPS: deep water rose shrimp (*Parapenaeus longirostris*).

The analysis of the time series of fishing mortality (F), spawning stock biomass (SSB) and recruitment revealed important insights in the development of the targeted fish stocks. Fisheries management succeeded to reduce F in the mid-2010s decade, interrupting its previous increasing trend (JRC, 2023). For three out of five analysed stocks (European hake, anchovy and deep water rose shrimp) F was above the present F_{MSY} target (Figure 1 – left column).
Management measures adopted in the Mediterranean fishery rely on controlling fishing effort and in the implementation of technical measures, such as mesh size regulation, minimum landing size and the closure of areas and seasons for fishing (Colloca et al., 2013; Vasilakopoulos et al., 2014; Cardinale et al., 2017). However, the management approach limited mainly on input control, has been found to be ineffective due to a lack of adherence to scientific evidence and the absence of strong institutional frameworks (Cardinale et al., 2017). Regardless of the species, the 2000s decade marks an important increase of F which however decreased during the last decade. Still, the target F_{MSY} is not reached for all the stocks. Here we showed that, with the exception of red mullet, where fishing mortality has constantly remained below $F_{MSY,}$ and common sole, where management efforts successfully reduced F below target values only during the last two years, the exploitation rate for the remaining species (hake, deep water rose shrimp and anchovy) is significantly higher than the current estimated F_{MSY}. Moreover, the realized effort reductions have always been much smaller than advised and have not always been followed by a corresponding reduction in fishing mortality (Colloca et al., 2013; Cardinale et al., 2017).

Effort control had varying effects on the dynamics of different Adriatic stocks. All stocks experienced a drastic decrease in SSB to levels far below sustainable thresholds following an increase in F. While the reduction of F resulted in a significant increase in the SSB of hake, red mullet, common sole and the total biomass of deep water rose shrimp, the opposite was observed for anchovy, where SSB and R continued their negative trend (Figure 1- middle and right column). Although the drastic decrease in anchovy SSB is at least partially related to heavy commercial exploitation (Santojanni et al., 2006), with F reaching values up to 30% higher than the target F_{MSY} (JRC, 2023), the lack of recovery of SSB, even after reducing F, suggests that stock dynamics are also influenced by additional factors. Furthermore, the trend in R may also reflect stock status, as R tends to follow SSB patterns in overexploited stocks (Szuwalski et al., 2015), such as in the case of anchovy (GFCM, 2024).
Previous studies have shown that anchovy recruitment is highly sensitive to environmental conditions such as sea surface temperature, chlorophyll-a, wind mixing and river runoff. These drivers influence directly and indirectly the physiology, growth and behaviour of the species, as well as ecosystem productivity (Martín et al., 2012; Santojanni et al., 2006). The Adriatic Sea has experienced a continuous increase in sea surface temperatures (Bonacci and Vrsalović, 2022) in recent years, which may be contributing to the ongoing decline in anchovy stock (Martín et al., 2012). Although anchovy is generally expected to positively correlate with rising temperatures (Tzanatos et al., 2014), findings in the Western Mediterranean indicate that their

productivity is negatively affected by higher-than-average temperatures due to these combined influences (Santojanni et al., 2006; Martín et al., 2012).
While recruitment levels of red mullet and common sole showed an increasing trend, a decline in R is also observed in the European hake stock, regardless of SSB development (Figure 1-right column). This decline can be attributed to several factors, including fishing and environmental variability (Colloca et al., 2013; Vasilakopoulos et al., 2014; Hidalgo et al., 2019a). Throughout the Mediterranean, hake fisheries are characterized by low selectivity and the overexploitation of recruits and juveniles, as larger individuals are less susceptible to the trawling due to offshore occurrence of the spawners (Colloca et al., 2013; Vasilakopoulos et al., 2014). Additionally, the survival of hake juveniles is strongly influenced by environmental factors, particularly by primary production. In the Adriatic, hake survival is negatively correlated with primary production and food availability, likely due to the increased inter-specific competition within the nektobenthic community, which may limit food availability for hake and reduce juvenile survival (Hidalgo et al., 2019a). Even though these exploitation patterns are associated with reducing the risks of stock depletion and collapse, their effects on yield, population structure and economic consequences remain poorly investigated (Colloca et al., 2013).
A similar discussion applies to the common sole stock. Although management measures have successfully reduced F over the last decade, leading to an increasing trend in SSB and R, SSB remains below the target B_{MSY} values and R has exhibited considerable fluctuations during this period (Figure 1). The species displays distinct spatial distribution patterns, with juveniles found closer to the shore and mature individuals inhabiting offshore areas where trawl operations are challenging. Additionally, the distribution of fishing effort shows a high overlap with juvenile distribution areas, indicating significant juvenile mortality that determine spawning stock biomass trend and recruitment rates (Scarcella et al., 2014).

Furthermore, statistical changepoint analyses revealed several abrupt changes in the SSB and B. For hake, red mullet and common sole, two abrupt changes were detected, indicating three distinct periods (Table 1). In all cases, the first abrupt change was detected from the *chngpt* algorithm incorporated in the trajectory identification process, as well as the *BinSeg* and *bcp* algorithms. The second abrupt change was detected only by the *BinSeg* and *bcp* algorithms.
The low SSB phases of these species, defined by the two abrupt changes, persisted across different decades. The earliest abrupt change was observed in the red mullet SSB at the beginning of the 1990's (1992). This low phase lasted approximately 20 years before a second abrupt change occurred in 2011. In addition, common sole and hake experienced similar changes in the subsequent decades. Common sole experienced its first abrupt change at the beginning of the 2000's (2003), with SSB remaining at low levels until the second abrupt change in 2014. Hake experienced these changes later, with a low SSB period persisting during the 2010s (2009-2017). Meanwhile, only one changepoint was identified for the remaining species: anchovy in 2010 and deep water rose shrimp in 2015.
Abrupt changes can be considered as an initial indicator of regime shifts (Blöcker et al., 2023), however they do not necessarily indicate a transition to an alternative state, as these changes may also represent a reversable response to gradual or rapid changes in external drivers (Ratajczak et al., 2018). Current analyses have confirmed the abrupt changes in the biomass of

the most important stocks of the Adriatic Sea and further investigations will provide important insights regarding the persistence and the underlying causes of these changes, which are crucial components in the detection of state changes (Bestelmeyer et al., 2011).

CONCLUSIONS

In this study, we applied a combination of methods in order to investigate the occurrence of abrupt changes in the biomass of the most important fish stocks in the Adriatic. The combination of different methods allowed us, first to identify the trajectory type that explains better the biological data-series and also detect the location of the past changepoints. Our analysis shows that an abrupt trajectory better explains the dynamics of five out of seven species we investigated, compared to the other trajectories considered. This study marks the first attempt to study the presence of abrupt dynamics in the biomass of the most important commercial stocks in the Adriatic. Further analyses are needed in order to evaluate the persistence of the changes, to identify the drivers, and the ability of management measures to restore the stocks to the previous conditions.

ABSTRACT

Dangke is a traditional Indonesian cheese originating from Enrekang in South Sulawesi that has gained significant recognition in the dairy sector due to its distinctive qualities and possible advantages for health. Lactic acid bacteria (LAB) are important for creation and maturation of Dangke cheese because they contribute to its unique taste and texture. These LABs generate exopolysaccharide (EPS), a noteworthy influence on the physicochemical and microbiological characteristics of Dangke cheese. LAB-produced EPS in Dangke cheese not only improves the cheese's functional characteristics but also provides significant health benefits. This review provides a comprehensive analysis of the EPS classification and its possible physiological advantages. In addition, EPS has advantages for human health, particularly in relation to the use of functional food. It acts as an antibacterial, antioxidant, cholesterol-lowering, and anticancer agent. The review findings indicate that EPS derived from lactic acid bacteria in Dangke cheese may enhance general well-being and facilitate the creation of functional dairy products with additional health benefits.

Keywords: Dangke, exopolysaccharide, health benefits, lactic acid bacteria.

INTRODUCTION

Dangke is a typical Indonesian cheese that is classified as a variety of fresh, soft cheese originating from Enrekang, South Sulawesi. The production of Dangke cheese involves curdling fresh cow or buffalo milk with papaya enzyme [1, 2]. The addition of papain, which comes from papaya gum, causes a cohesive structure to form in dangke by separating the water and protein. The amount of papain added and the cooking method affect the qualities of Dangke, including its physical, chemical, and organoleptic aspects [3]. Dangke cheese has gained increasing recognition in the dairy sector due to its unique characteristics and potential health benefits. The research conducted by Syah et al. [4] confirmed the presence of lactic acid bacteria in dangke. A study conducted by Mukhlisah et al. [5] successfully identified 30 LAB isolates in dangke. After sequencing the 16S rRNA gene, five of these isolates were identified.

The fermented food sector extensively employs LAB. Lately, there has been an increasing curiosity with the microbial metabolic characteristics of lactic acid bacteria, owing to their significant contribution to the food sector and the advantageous impacts of probiotics [6, 7]. Lactic acid bacteria possess the capacity to decompose complex structures in food, such as indigestible polysaccharides, and transform unpleasant flavor chemicals. In addition, throughout their metabolic processes, they have the ability to generate various compounds such as short-chain fatty acids, bacteriocins, vitamins, amines, and exopolysaccharides [8, 9].

Bacterial exopolysaccharides (EPS) have garnered recent attention for their distinct structure, characteristics, and potential applications in many domains such as science, industry, medicine, and technology [10]. Bacterial exopolysaccharides encompass various categories of polysaccharides. Several of polysaccharides have similarities to plant polysaccharides such cellulose, amylose, amylopectin, and algin. Additional polysaccharides that exhibit resemblances to animal-derived polysaccharides are glycogen and hyaluronic acid [11, 12].

EPS offers numerous practical advantages. Firstly, commercial scale production of EPS is possible. In addition, EPS is harmless and can improve the quality of food, especially when present in little amounts. In addition, EPS does not contribute to environmental contamination because it easily degrades. Moreover, EPS has potential uses in the treatment of several disease and the pharmaceutical sector [13,14]. Scientists in the field of food microbiology are motivated to explore the possible benefits of bacteria in manufacturing EPS due to the rapid progress of human civilization and the limiting supply of arable land. Fermented milk starters can produce exopolysaccharides, which provide advantages over those produced by other microorganisms [11].

The EPS in Dangke cheese comes from lactic acid bacteria and has many benefits, such as being able to stop blood clots, boost the immune system, fight cancer, and introduce new cells into the body. This is believed to be attributed to the production of EPS [15]. The EPS also carries a minor danger of toxin exposure and offers superior quality. EPS generated by LAB functions as a food stabilizer, gelling agent, and immunostimulant, contributing to its role as a nutritious food [16]. This paper will examine the process of producing EPS from LAB derived from Dangke cheese and explore its potential applications in promoting health as a functional food product.

The History of Dangke and Its Manufacturing Process

Indonesia has many kinds of traditional soft cheeses that are typical of the region, and one of them is Dangke, which hails from the Enrekang Regency in South Sulawesi and holds great potential as a traditional culinary additive. Dangke, renowned in Enrekang's culinary scene, is a highly acclaimed product known for its cheese-like flavor and tofu-like soft texture [17, 18].

Figure 1. Dangke [18].

The practice of Dangke processing has been in existence since 1905, transmitted over generations, and continues to endure to this day. The product has expanded its presence in the Enrekang Regency, becoming a prominent food industry at the household level across several places [19]. The word "dangke" originates from the Dutch expression "*dank u well*", which the Dutch employed during the colonial period to convey appreciation when the Enrekang people offered them food [20]. Regrettably, the Enrekang community abbreviated this term to "Dangke" due to its inherent complexity. The word's meaning is "thank you," and it also serves as a designation for a unique variety of soft cheese [21].

Dangke, a classic cheese product, is characterized by its oval shape, dense and chewy texture, powerful milk aroma, and savory taste. Dangke is produced by combining fresh cow or buffalo milk with coagulating enzymes [22]. The traditional method of producing dangke involves heating fresh milk and adding papaya sap as a coagulating enzyme. This results in the formation of two distinct phases, curd (solids) and whey (liquid) [23]. The sap of the papaya tree is extracted by incising the petiole, allowing the sap to flow out. Subsequently, the sap is gathered and stored in a receptacle. The entire quantity of cow's milk is subjected to gentle heating at a temperature of approximately 75–80 °C for a duration of 5 minutes. Subsequently, a solution containing 0.75% (v/v) papaya leaf sap is introduced into the milk while continuously stirring, resulting in the formation of milk tofu. Subsequently, the milk curd is subjected to filtration and compression in order to inhibit the drainage of whey, 1 liter of milk yielded 250 grams of milk curd [24, 25, 26].

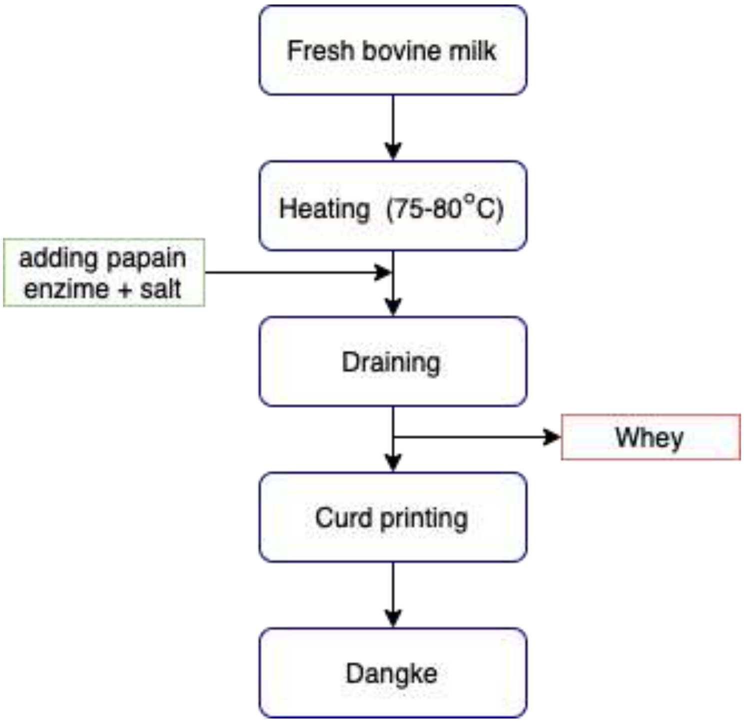

Figure 2. Dangke making processing.

Dangke, a dairy product, has a commendable nutritional composition. Dangke has a macronutrient composition of 14.02% protein, 13.32% fat, 9.72% crude fiber, 4.70% carbs, and 47.94% water [27]. Currently, a wide range of technologies have been implemented to enhance the quality and extend the durability of Dangke products. The utilization of LAB will enhance coagulation and result in dangke with a denser and tender texture. Chemicals that enhance the aroma and flavour of dangke are synthesised during the fermentation process by LAB. LAB is responsible for the synthesis of lactic acid, which results in an increase in the acidity of dangke cheese. The presence of lactic acid in dangke serves as an acidifier, which lowers the pH and inhibits the proliferation of harmful bacteria that might cause spoilage or disease [1, 28, 29]. The incorporation of LAB in the manufacturing process of dangke exhibits significant promise in enhancing product quality, nutritional content, and health advantages. Despite being in the developmental phase, this innovation has the potential to be a significant advancement in modernizing and enhancing the competitiveness of dangke in the food market [30, 31].

Table 1. LABs isolated from Dangke-cheese.

Genus	Strain	Reference
Lactobacillus	*Lactobacillus fermentum*	[4, 32, 33]
	Lactobacillus plantarum	[33, 34]
	Lactobacillus acidhophilus	[34]
	Lactobacillus casei	[35]
	Lactobacillus brevis	[35]
Enterococcus	*Enterococcus faecium*	[36]
Weisella	*Weisella confusa*	[32]

Characterization and Biosynthesis of EPS from LAB

Lactic acid bacteria (LAB) are known for their capacity to produce a wide variety of heteropolysaccharides, commonly known as exopolysaccharides (EPS). These EPS have attracted considerable attention in the food and pharmaceutical industries due to their diverse functional characteristics [37, 38]. The EPS display a diverse array of structural complexity, encompassing differences in monosaccharide content, glycosidic linkages, and branching patterns. Comprehending the process of how these microbial exopolysaccharides are produced, purified, and studied is crucial for their efficient application [39].

The word EPS, established by Sutherland in 1972, encompasses all forms of bacterial polysaccharides found external to the cell wall [40]. EPS production is observed in multiple species of Gram-positive bacteria and Gram-negative LAB, and it has been thoroughly investigated in various study domains. Microorganisms synthesize extracellular polymeric substances (EPS) to create a protective barrier that is impervious to drought, amoebic assault, bacteriophages, and leukocytes [41, 42, 43]. EPS can be categorized into two primary classes according to their content and synthesis mechanism: homopolysaccharides and heteropolysaccharides [31].

EPS are LAB secondary metabolites that are secreted under specific conditions. EPS have the capacity to attach to and colonise the intestinal mucosa, hence inhibiting the growth of harmful bacteria [44]. EPS can be categorised as either heteropolysaccharides or, depending on the structure and composition of monosaccharides [45]. Heteropolysaccharides consist of many monosaccharides that are synthesised intracellularly, whereas homopolysaccharides consist of a singular kind of monosaccharide and are created extracellularly [46]. The main components of EPS are primarily monosaccharides, accompanied by non-carbohydrate molecules such as succinate, phosphate, acetate, and pyruvate [47].

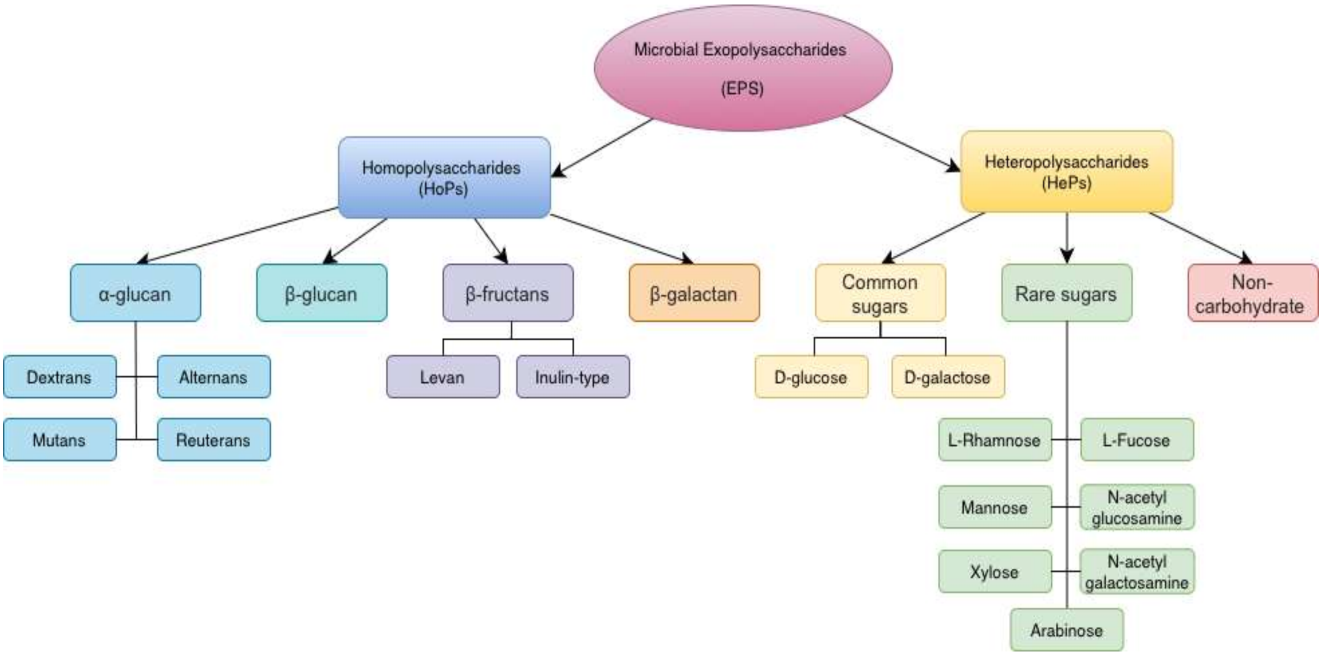

Figure 3. Microbial exopolysaccharides classification.

Homopolysaccharides, such as glucose or fructose, are polymers made up of only one type of monosaccharide. Heteropolysaccharides usually comprise a combination of two to four different monosaccharides. Both categories of polymers can have either a linear or branching structure, and may incorporate acyl or other substituents [48]. Macromolecules that are composed of a singular monosaccharide, such as glucose or fructose, are referred as homopolysaccharides. Additionally, the chains of this particular EPS polymer can be found in either a linear or a branched configuration[11, 49]. Dextran, levans, and curdlan are specific instances of homopolysaccharide EPS. Heteropolysaccharides are polysaccharides composed of a mixture of two to four different monosaccharides, including glucose, galactose, mannose, fucose, and rhamnose [38, 50]. Pullulan is a heteropolysaccharide that belongs to the EPS category. Ongoing research is being conducted on the composition, production, and other elements of early microorganism EPS cultures [40].

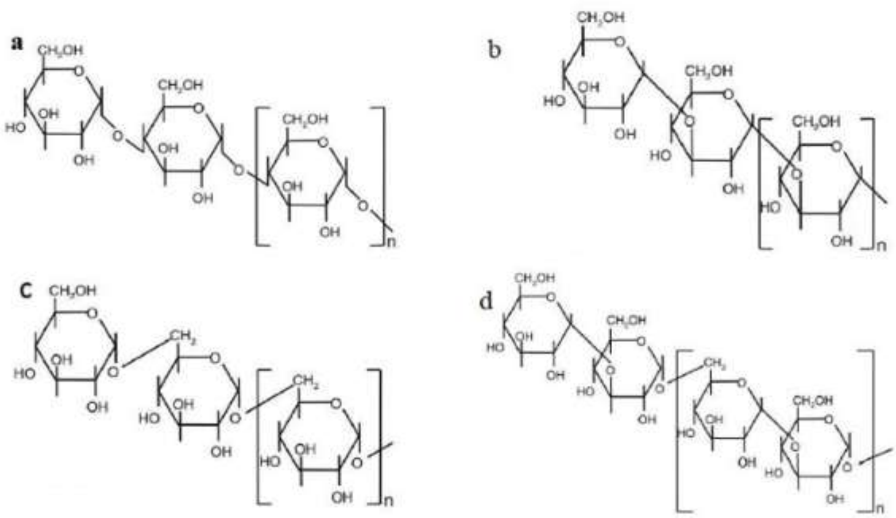

Figure 4. Homopolysaccharides glucan structure a) reutran; b) mutan; c) dextran; and d) alternan [51].

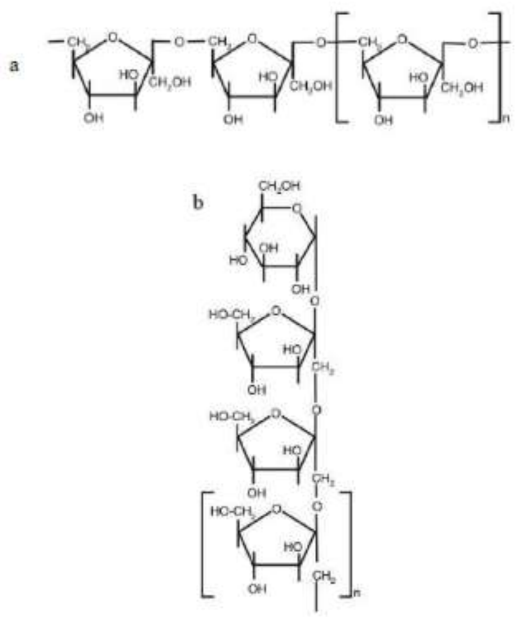

Figure 5. Homopolysaccharides fructan structure a) levan; and b) inulin-type [51].

Some examples of bacteria that can produce homopolysaccharides are *Weissella*, *Leuconostoc*, *Lactobacillus*, and *Pediococcus*. Extracellular enzymes, specifically glucan-sucrase or fructan-sucrase, aid in the synthesis of homopolysaccharides in these bacteria [48]. Both enzymes catalyze the transfer of monosaccharides from specific substrates, resulting in the formation of polysaccharide chains through the hydrolysis of monosaccharides. These monosaccharides are subsequently connected to the glycan acceptor chain. The activity of glucansucrase is regulated by the glycosyltransferase gene (gtf), whereas the activity of fructansucrase is regulated by the fructosyltransferase gene (ftf) [52, 53]. Glucansucrase is a component of the amylase enzyme that functions as a hydrolyzer of glycoside linkages, contributing to the formation of glucan and fructan [46].

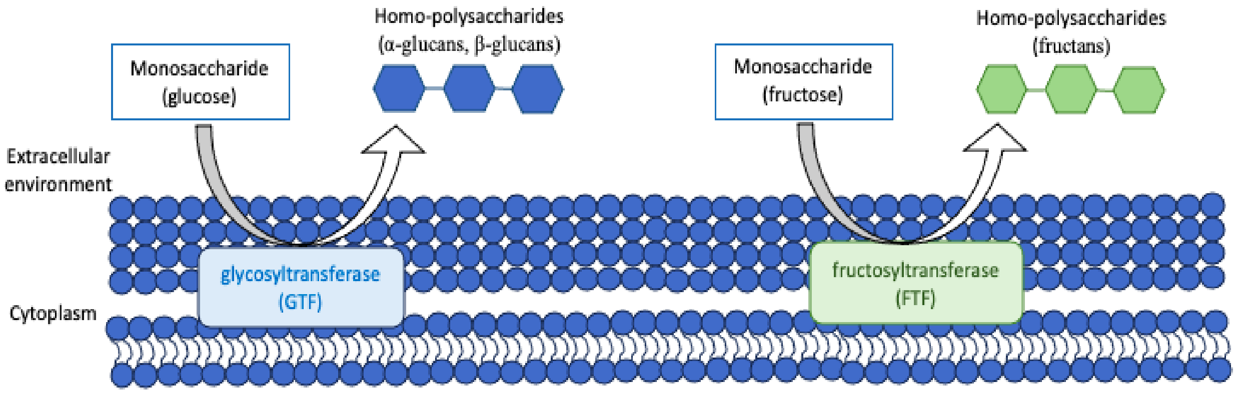

Figure 6. Biosynthesis of homopolysaccharides.

Different types of homopolysaccharides produced by LAB include glucans, fructans, and galactans, which are composed of D-glucose, D-fructose, and D-galactose, respectively [38]. Glucans are created through the arrangement of glucose molecules in a primary structure, featuring different levels of branching and binding sites that differ among different bacterial strains [54]. It is possible to divide glucans into two separate groups, α-glucans and β-glucans. Many different species of *Lactobacillus*, *Leuconostoc*, *Streptococcus*, and *Weissella* produce them [55].

There are four discrete categories of alpha-glucans such as dextrans are water-soluble polysaccharides. Mutans, however, are typically unable to dissolve in water. Reuteran are polysaccharides that are soluble in water. On the other hand, alternans have alternating bonds, resulting in decreased solubility and viscosity in water [38]. Beta-glucan is a type of homopolysaccharide that is synthesized by *Pediococcus* and *Streptococcus spp.* Fructose-based polymers created fructans that are soluble in water. They are made by some strains of bacteria, including *Leuconostoc mesenteroides*, *Streptococcus salivarius*, *Lactobacillus reuteri*, *Lactobacillus johnsonii*, and *Lactobacillus sanfranciscensis* [38, 56, 57]. Water-soluble galactans are not very common and include galactose units bound together in an α-(1→6) configuration. They are created by specific types of LAB, such as *Lactococcus lactis subsp. lactis*, *Lactobacillus delbrueckii subsp. bulgaricus* and *Weissella confusa* [58].

Heteropolysaccharides exhibit a higher level of structural complexity in comparison to homopolysaccharides. This is due to their composition of multiple repeating sugar units, such as N-acetylated monosaccharides (N-acetyl-glucosamine and N-acetyl-galactosamine), hexoses (D-glucose, D-galactose, D-mannose), pentoses (D-ribose, D-arabinose, D-xylose), or uronic acids (D-glucuronic acid, D-galacturonic acid). Heteropolysaccharides can also have branching or be unbranched [51, 59, 60]. Bacteria belonging to the genera *Lactobacillus*, *Lactococcus*, and *Streptococcus* are the ones responsible for the creation of these bacteria. LAB create heteropolysaccharides in limited quantities, although these compounds exhibit significant thickening capabilities even at low concentrations [38, 61].

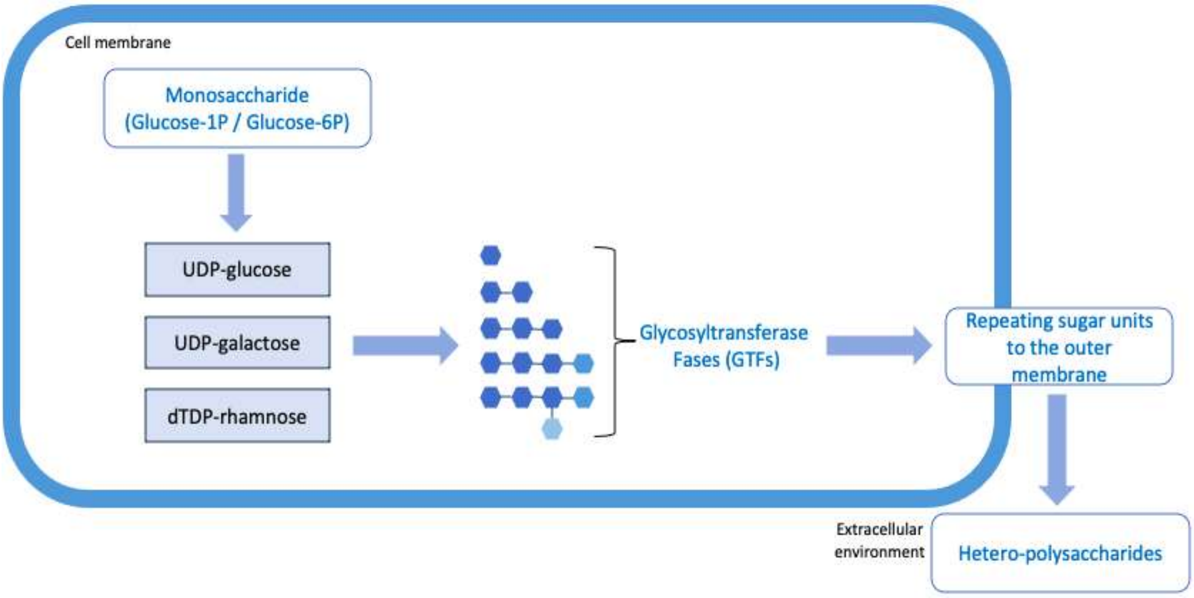

Figure 7. Biosynthesis of heteropolysaccharides.

Heteropolysaccharide synthesis entails a series of several steps: 1. Sugars are carried into the cytoplasm of bacterial cells and undergo phosphorylation to become either glucose-1-phosphate or glucose-6-phosphate; 2. Within the cell, uridine-diphosphate-glucose (UDP-glucose), UDP-galactose, and deoxythymidine-diphospho-mammnose (dTDP-rhamnose) nucleotides are produced; 3. The cell membrane contains undecaprenol diphosphate (UDA) anchors to which individual repeat units are linked. These repeat units are generated using numerous GTFs; 4. The repeat sugar units are then transported to the outer membrane; 5. In the end, the sugar molecules are joined together to create intricate carbohydrates called heteropolysaccharides. These are subsequently released into the extracellular environment as EPS. EPS molecules attach to the cell wall either as a capsule or as a sticky polymer. The genes responsible for the production of heteropolysaccharides in thermophilic Lactobacillus are acquired by chromosomal replication, but in mesophilic *Lactobacillus*, these genes are gained from plasmid replication. The same genes have a regulatory function in the production of heteropolysaccharides [53, 62, 63].

Potential Health Benefits of EPS

Lactic acid bacteria (LAB) are a heterogeneous group of microorganisms that have gained recognition for their versatility and importance in various industries, including food production, biotechnology, and medicine [64, 65]. These bacteria have the ability to produce exopolysaccharides (EPS), complex carbohydrate polymers that have attracted significant attention due to their potential physiological benefits [66, 67].

The therapeutic uses of EPS generated by LAB include anticancer activity, immune-boosting action, and the ability to lower blood cholesterol levels [38, 68]. These biologically active compounds have also been studied as possible biothickeners in the food and dairy sectors, offering powerful emulsifying capabilities that are crucial in numerous food formulations [64, 68].

Gaining insight into the mechanisms that drive the biosynthesis of these exopolysaccharides is crucial for enhancing production and fully exploring their capabilities [69]. Scientists have examined the intricate genetic and metabolic processes involved in the production of these external polysaccharides. This research has opened up the possibility of making genetic changes that could lead to higher production levels and enhanced performance [65].

EPS derived from LAB exhibit exceptional versatility and feature health-enhancing properties, rendering them highly sought-after natural constituents in the culinary, pharmaceutical, and medical sectors [70]. The on-site generation of EPS by food-grade cultures is a promising substitute for conventional additives, as it fulfils the increasing consumer need for natural and clean-label products. This approach offers similar rheological and sensory properties while also providing additional health benefits [64, 71].

Antimicrobial agents

EPS synthesized by LAB have demonstrated antibacterial properties against a range of diseases. These characteristics provide them appealing options for natural preservatives and prospective substitutes for synthetic antimicrobials [72]. EPS has the ability to disrupt the process of biofilm development in harmful bacteria. They have the ability to vie for attachment sites or disrupt intercellular communication (quorum sensing) that is necessary for the production of biofilms [73].

Certain EPS demonstrate direct bacteriostatic or bactericidal properties against microorganisms. This could be attributed to the chemical composition or distinct functional groups present in the EPS. EPS can augment the efficacy of other antimicrobial compounds generated by LAB, such as bacteriocins or organic acids [37, 73, 74]. EPS has the ability to activate the immune system of the host, so indirectly aiding in the management of pathogens. This encompasses the stimulation of macrophages and heightened synthesis of antimicrobial peptides[68, 75]

EPS has the ability to create a protective barrier on surfaces, which hinders the attachment and growth of harmful microorganisms. Certain EPS (extracellular polymeric substances) can cause acidity of the surrounding environment, which creates adverse conditions for numerous infections. EPS has the ability to attach to vital nutrients, rendering them inaccessible to harmful microorganisms and impeding their proliferation. Specific EPS have demonstrated the ability to damage the cell membrane of pathogens, resulting in either cell death or growth inhibition. Certain EPS demonstrate antiviral capabilities, which can potentially impede the attachment or penetration of viruses into host cells [76].

EPS derived from certain LAB strains have demonstrated potent antifungal properties, particularly against fungi that cause food deterioration. The antibacterial efficacy of extracellular polymeric substances (EPS) can exhibit substantial variation among various strains of LAB. Notable LAB strains that produce EPS with significant antibacterial properties include *Lactobacillus plantarum, Lactobacillus rhamnosus, Streptococcus thermophilus, Lactobacillus bulgaricus*, and *Weissella confusa*. The EPS from LAB has demonstrated antimicrobial efficacy against a range of pathogens, such as *Escherichia coli, Salmonella spp, Listeria monocytogenes, Staphylococcus aureus*, and *Candida albicans* [71, 77, 78]. The in vitro test shown that the EPS produced by *L. plantarum* C70, which was isolated from camel milk, resulted in a significant reduction of 2-3 logs in the viability of *E.coli* and *S. aureus* when exposed to these bacterial pathogens [79]. The EPS derived from *L. rhamnosus,* which was obtained from human breast milk, exhibits potent antibacterial effects against *E. coli* (12–14.3 mm) and *S. typhimurium* (10–13 mm). Additionally, it demonstrates remarkable prevention of S. typhimurium biofilm formation (58–71%) under laboratory conditions [80].

Possible uses of the antimicrobial properties of EPS from LAB include natural food preservatives, food preservatives, and bioactive packaging materials. Topical antimicrobial agents are substances used in cosmetics or medical applications to kill or inhibit the growth of microorganisms on the skin's surface [81]. Possible substitute or addition to traditional antibiotics The antibacterial efficacy of EPS can be modified by several factors, including the particular structure and chemical composition of EPS, ambient circumstances such as pH and temperature, the microorganisms being targeted, and the concentration of EPS [40]. While numerous research have demonstrated the antibacterial capabilities of EPS derived from LAB, the majority of these investigations were conducted in controlled laboratory environments or within food systems. Additional investigation is required to comprehensively comprehend their efficacy within a living organism and their prospective utilization in therapeutic environments.

Antioxidant

EPS derived from LAB exhibits antioxidant properties and holds potential as a significant attribute with health-related applications [82]. EPS has the ability to directly counteract different types of free radicals, including superoxide anion, hydroxyl radical, and DPPH (2,2-diphenyl-1-picrylhydrazyl) [83]. This capability aids in safeguarding cells against oxidative harm induced by reactive oxygen species. Several EPS have the ability to attach to metal ions, such as iron and copper. EPS inhibits the involvement of these metals in free radical-generating processes, such as the Fenton reaction, by chelating them [84, 85, 86].

EPS frequently demonstrate the ability to decrease the oxidation state of other compounds, enabling them to transfer electrons to reactive substances. The measurement of this feature is typically conducted using assays such as the iron-reducing antioxidant power test (FRAP). EPS has the ability to safeguard crucial cellular constituents, such as lipids, proteins, and DNA, against oxidative harm. This protective effect aids in preserving the structural and functional integrity of cells [87, 88]. Several studies indicate that EPS may enhance the synthesis or function of the body's antioxidant enzymes. The enzymes that are included in this group are superoxide dismutase (SOD), catalase, and glutathione peroxidase. The chemical structure of EPS is frequently credited for its antioxidant action [89]. Antioxidant capacity can be influenced by factors such as molecular weight, monosaccharide content, and the presence of functional groups, such as hydroxyl groups. EPS has potential to enhance the effects of other antioxidants in both cellular and dietary settings, and this could enhance the overall antioxidant capacity [76, 90].

Several EPS derived from LAB maintain their antioxidant properties under different temperature and pH conditions. Their stability renders them potentially valuable in different applications, such as food processing [91]. The antioxidant capacity of EPS may vary considerably across various LAB strains, even within the same species. Some LAB strains that are known for producing EPS with significant antioxidant activity include *Lactobacillus plantarum, Lactobacillus helveticus, Streptococcus thermophilus,* and *Lactobacillus casei*. *Weissella cibaria* is a species of bacteria identified [83, 89]. The EPS produced by L. *fermentum, L. plantarum*, and *L. paracasei*, which were isolated from commercial yogurt, had significant antioxidant properties in terms of their ability to scavenge DPPH free radicals, reduce ferric ions, and contain high levels of total phenolic compounds [92].

Possible uses of the antioxidant properties of EPS derived from LAB encompass Food preservation: utilizing natural antioxidants to prolong the duration of freshness. Functional foods and nutraceuticals aim to offer advantageous effects on health. Cosmetics are used in goods that aim to combat the effects of aging and protect the skin. Possible medical applications include the management of disorders related to oxidative stress [93, 94, 95]. It is crucial to acknowledge that while numerous in vitro studies have shown the antioxidant capabilities of EPS from LAB, additional study is required to comprehensively comprehend its efficacy in vivo and its potential uses in human health. The antioxidant properties of EPS may differ depending on the structure, concentration, and oxidative stress model employed in the study.

Immunomodulatory

EPS are complex carbohydrates with a large molecular size that are released by microbes into their external surroundings. Their immunomodulatory activities have garnered considerable attention, as they can impact the immune system in diverse manners [96]. The immunological response is a vital component of the body's defense mechanism against foreign particles, encompassing both acquired immunity and innate immunity [97]. The immune system is composed of various components, such as humoral immunity which involves antibodies, physical barriers, and cellular immunity which involves leukocytes that can communicate with each other using cytokines [98].

Recently, there has been a surge in scientific investigation into the biological properties of microbial exopolysaccharides, emphasizing their potential for use in the field of biomedicine [39, 90, 99]. Polysaccharides, obtained from microbial sources, have demonstrated the ability to regulate the immune system by stimulating or enhancing the activity of T-cells and macrophages, hence raising the activity of interleukins. This has the potential to result in elevated quantities of antibodies and improved modulation of immune function [100].

EPS derived from LAB has the ability to activate macrophages, dendritic cells, and natural killer cells. This stimulation results in an augmentation of phagocytosis and the generation of cytokines and chemokines. EPS can disrupt the equilibrium between proinflammatory and anti-inflammatory cytokines, leading to an upregulation of anti-inflammatory cytokines such IL-10 and TGF-β [100, 101, 102]. EPS can function as adjuvants, hence enhancing the efficacy of vaccines. They have the ability to enhance the growth and reproduction of B-cells and the generation of antibodies.

Certain EPS demonstrate antioxidant properties, which help to decrease oxidative stress on immune cells. It has the potential to enhance the functionality and lifespan of immune cells. EPS has the ability to attach to Toll-like receptors (TLRs) and other receptors that recognize specific patterns. These contacts can initiate signaling cascades that regulate immune responses [39, 89]. Furthermore, EPS has the ability to regulate adaptive and acquired immune responses, safeguard against gastrointestinal disorders, and modify the activity of the immune system by regulating cytokines [103].

The immunomodulatory effects of EPS can vary based on their origin, composition, and molecular weight. It should be emphasized that various EPS can have varying or even contradictory impacts on the immune system. The immunomodulatory qualities of EPS make it a highly intriguing option for a range of applications, such as the treatment of inflammatory and autoimmune illnesses, as well as the use of prebiotics in functional foods.

Antitumor activity

EPS have the ability to directly trigger apoptosis or programmed cell death in cancer cells. They have the ability to disturb the structure of cell membranes or hinder the metabolic processes within tumor cells [104]. EPS have the ability to augment the function of natural killer (NK) cells and cytotoxic T-lymphocytes, which play a crucial role in monitoring and eradicating tumors. They have the ability to enhance the production of cytokines that decrease tumor growth, such as IFN-γ and TNF-α ([96, 104]. Specific exopolysaccharides have the ability to hinder the development of fresh blood vessels (angiogenesis) that are necessary for the growth and spread of malignancies. One way to accomplish this is by inhibiting pro-angiogenic factors like VEGF [105].

EPS possess the capacity to enhance the effectiveness of traditional chemotherapy medications while minimizing their adverse effects. They have the potential to combat medication resistance in certain types of malignancies. EPS has the potential to disrupt important signaling pathways that play a role in the advancement of cancer, such as NF-κB, MAPK, and PI3K/AKT pathways [106, 107].

Certain EPS (extracellular polysaccharides) have the ability to stimulate macrophages, enhancing their ability to destroy tumors and improving their ability to display tumor antigens. Specific EPS have demonstrated the ability to trigger cell cycle arrest in cancer cells, hence inhibiting their proliferation. EPS with demonstrated anticancer properties encompass EPS derived from lactic acid bacteria, specifically species like *Lactobacillus* and *Bifidobacterium* [38, 108]. Several studies indicate that EPS has the capacity to impact epigenetic pathways, which could potentially reverse abnormal epigenetic alterations in cancer cells. The anticancer activity of EPS can significantly differ based on their origin, composition, and molecular weight.

CONCLUSION

The identification of lactic acid bacteria (LAB) in Dangke, as determined by many investigations, is essential for its production and characteristics. The LAB have the ability to generate exopolysaccharides (EPS), which have attracted interest due to their wide range of uses in the fields of research, industry, medicine, and technology.

The EPS generated by LAB in Dangke cheese provides multiple benefits. At low concentrations, it has the ability to improve the quality of food, and its biodegradability makes it environmentally friendly. Additionally, it shows promise in disease treatment and has prospective uses in the pharmaceutical industry. The EPS derived from Dangke cheese offers several health benefits, such as antibacterial, antioxidant, cholesterol-lowering, and anticancer properties.

In addition, the synthesis of EPS by LAB in fermented milk starters, such those found in Dangke, offers benefits compared to EPS produced by other microbes. Dangke shows great potential as a candidate for the production of functional food. EPS can be utilized as a food stabilizer, gelling agent, and immunostimulant. The increasing fascination in the microbial metabolic characteristics of LAB, together with the potential of EPS in Dangke cheese, creates new opportunities for study and advancement in the food and health sectors. Further research aimed at maximizing EPS synthesis from LAB produced from Dangke cheese and investigating its potential uses in functional food products has the potential to drive groundbreaking advancements in nutrition and health promotion.

ACKNOWLEDGMENT

The author would like to thank for PMDSU scholarship support by Ministry of Education, Culture, Research and Technology. Author would like to express gratitude also to Directorate of Research, Technology and Community Service (DRTPM) Ministry of Education, Culture, Research and Technology for funded this study under contract number: 02035/UN4.22.2/PT.01.03/2024.

ABSTRACT

The fig (*Ficus carica* L.) is a deciduous fruit tree in temperate climates. The cultivation of figs dates back to ancient Anatolia, coinciding with human history. Historical records indicate that figs were first cultivated in the Arabian Peninsula and Middle East. In the Mediterranean diet, figs are consumed as a symbol of healthy and long life, and in recent years, they have gained considerable attention as an exotic fruit in Western and Northern countries. This interest is primarily due to the high nutritional content of figs, their richness in fiber, minerals, and polyphenols, and the fact that they contain no fat or cholesterol, thereby increasing their commercial value.

Fig seeds aid digestion due to their high fiber content, helping to lower cholesterol levels and protect against cardiovascular diseases. Additionally, fig seeds have a protective effect on metabolism due to their content of vitamins E and D. Studies have shown that fig seeds are rich in omega-3, omega-6, and omega-9 fatty acids. Fig seed oil is richer in unsaturated fatty acids than saturated ones, suggesting its potential use as a dietary supplement. Furthermore, fig seeds are found to have a lactogenic effect, provide energy, and be beneficial for diabetics and those with weight issues.

Fig seeds, with their high-fat content, carbohydrates, calcium, potassium, phosphorus, and unsaturated fatty acids, enhance the nutritional value and stability of food products. When used in biscuit formulations, Fig seed powder increases fiber content, total phenolic content, and antioxidant activity, and also improves the nutritional value and stability of bakery products, dairy products, and beverages.

This study aims to determine the phytochemical properties of fig seed oil and its usability in terms of food and human health. The potential health benefits, commercial value, and applications of fig seed oil in food products have been examined in this context.

Keywords: Fig, *Ficus carica L.*, Human health, Food Industry, Fig Seed Oil

INTRODUCTION

Figs (*Ficus carica* L.) have long been revered not only for their delicious fruit but also for the myriad health benefits they offer. In recent years, research has increasingly focused on the seeds of figs, revealing their significant potential in the food industry due to their rich phytochemical composition and associated health benefits. Fig seeds, once considered a byproduct of fig processing, are now recognized as a valuable source of nutrients, including essential fatty acids, antioxidants, and other bioactive compounds (Güven et al., 2019; Özyurt, 2019).

The oil extracted from fig seeds is particularly notable for its high content of polyunsaturated fatty acids (PUFAs), including alpha-linolenic acid (omega-3) and linoleic acid (omega-6), which are essential for human health and cannot be synthesized by the body. these fatty acids play crucial roles in reducing inflammation, supporting cardiovascular health, and maintaining proper cellular functions (Güven et al., 2019). Moreover, fig seed oil is rich in tocopherols, particularly gamma-tocopherol, a potent antioxidant that helps protect the body against oxidative stress, which is linked to chronic diseases such as cancer and cardiovascular disorders (Güven et al., 2019; Özyurt, 2019).

Beyond the nutritional value, fig seeds exhibit strong antioxidant activity, which can enhance the shelf-life and stability of food products. The phenolic compounds in fig seeds contribute to their high antioxidant capacity, making them a promising ingredient for the development of functional foods designed to promote health and well-being. (Güven et al., 2019; Özyurt, 2019). Additionally, the extraction of fig seed oil through cold pressing preserves these bioactive compounds, ensuring that the oil retains its health-promoting properties (Özyurt, 2019).

The growing interest in natural and health-promoting ingredients within the food industry highlights the commercial potential of fig seeds. As consumers increasingly seek products that not only satisfy their nutritional needs but also support their overall health, fig seeds offer a unique opportunity for innovation in food products that cater to this demand. Their integration into the food industry could not only reduce waste from fig processing but also provide a new source of revenue, particularly in regions where figs are abundantly grown (Güven et al., 2019). By harnessing the phytochemical properties of fig seeds, the food industry can develop products that align with the trends toward natural, functional, and health-oriented foods. This shift not only benefits consumers but also contributes to more sustainable and economically viable food production systems.

Recent research has increasingly focused on the essential fatty acids and natural antioxidants found in fruit seeds (Chougui et al., 2013). Consequently, various fruit seeds have been explored for their potential applications in the food and industrial sectors as new Sources of bioactive compounds. Among these, seeds from fruits like Oputina ficus-indica, papaya, honeydew, mangosteen, rambutan, durian, and date palm have shown promise as novel Sources of industrial oils (Raihana et al., 2015). Additionally, fruits commonly included in the Mediterranean diet, known for their rich phytochemical and antioxidant content, have garnered significant attention (Hssaini et al., 2019).

BIOCHEMICAL AND PHYTOCHEMICAL CONSTITUENTS OF FIG SEEDS

There are a limited number of studies on fig seeds in the literature. Hssaini et al. (2020) reported that fig seed oil is generally pale yellow and the yield can vary significantly depending on the genotype, with some genotypes providing up to 30% oil content. However, the majority of studies in the literature focus on fig leaves, aerial roots, and bark (Aljane and Ferchichi, 2007; Aljane and Ferchichi, 2009; Khan, 2011; Sadia et al., 2014; Lo Turco et al., 2020). Given their high oil content, fig seeds hold significant potential for industrial applications, similar to other types of fruit seeds.

Nakilcioğlu and Hışıl (2013) have determined that the main phenolic compound in figs is epicatechin. An average of 1090-1100 mg of polyphenol is found in 100 g of fig-dried fruit (Duman and Yazici, 2018). Dried fig seeds oil contains 18.99% oleic, 33.72% linoleic, 32.95% linolenic, 5.23% palmitic, 8% stearic, 1.05% arachidonic fatty acids (Joseph and Raj, 2011). A study conducted by Ergun and Bozkurt (2020) stated that the highest fatty acid in fig seed oil was α-Linolenic acid at 26.31%, followed by linoleic acid at 24.27% and oleic acid at 19.65%. Nazan Güven et al. (2019) stated that fig seed oil obtained from Turkey contains high amounts of alpha-linolenic acid (ALA) and that it can be used in the treatment of cardiovascular disorders, gastrointestinal disorders, and diabetes. They also emphasized that this oil can be used externally for skin moisturizing purposes (Güven et al., 2019). A study by Lahcen Hssaini et al. (2020) examined the fatty acid composition in fig kernel oil obtained from four different fig cultivars. This study showed that the predominant unsaturated fatty acids in the oil were linolenic and linoleic acids, while the predominant saturated fatty acids were palmitic and stearic acids (Hssaini et al., 2020). In a study conducted by Yıldırım Vardin et al. (2023), it was found that the most dominant fatty acid in fig seed oil was linolenic acid at 40%.

The quality of seed oils and whether they are beneficial to human health is determined by the abundance and quantity of proteins, fats, fibers, minerals, phenolic compounds, flavonoids, and antioxidants they contain. Intake of unsaturated fatty acids has been associated with various health benefits. Numerous studies have explored the connection between dietary unsaturated fats and the risk of developing coronary heart disease. Wolfram (2003) highlights in his research that unsaturated fatty acids, especially Omega-3 fatty acids, significantly protect against coronary heart disease compared to saturated fatty acids, which contribute to the early development of CHD (Wolfram, 2003). Some researchers suggested that replacing energy from saturated fatty acids with polyunsaturated fatty acids rather than monounsaturated fatty acids or carbohydrates can help prevent coronary heart disease (Jakobsen et al., 2009; Hu et al., 2001).

In a study involving the analysis of volatile compounds in the fruit peels and pulp of five different *Ficus carica* (fig) cultivars native to Portugal, various volatile compounds have been identified in the pulps and peels of five different Portuguese varieties of *Ficus carica* fruits. These include aldehydes such as 3-methyl-butanal, 2- mthyl butanal, (E)-2-pentanal, hexanal, heptanal, octanal, and nonanal; alcohols like 1-penten-3-ol, 3-methyl butanol, benzyl alcohol, (E)-2-nonenol, and phenyl ethyl alcohol; a ketone, specifically 6-methyl-5-hepten-2-one; esters including methyl hexanoate, methyl salicylate, and ethyl salicylate; monoterpenes such as limonene, menthol, α-pinen β-pinene, linalool, and eucalyptol; sesquiterpenes including α-cubenene, copaene, β-caryophyllene, τ-muurolene, τ-cadinene, and germacrene D; a nor isoprenoid, β-cyclo citral; and other compounds such as eugenol (Oliveira et al., 2010). However, there is no research in the literature that studies only the volatile components in fig seed oil.

Irchad et al. (2023), reported the protein content of fig seeds between 6.08 ± 0.04%- 24.11 ± 2.32%., Ustun-Argon et al. (2021) found 14.65%, and Nakilcioğlu-Tas (2019) found between 14.74- 5.07%. Protein content in fig seeds offers various health benefits, including muscle repair, immune support, metabolic functions, dietary supplementation, and potential antioxidant effects. while fig seeds provide valuable plant-based protein, they should be part of a balanced diet that includes diverse protein Sources to ensure a complete amino acid profile (Shahidi & Zhong, 2008; Gilani et al., 2012; Mert et al., 2021)

Fig seeds are rich in micro-elements such as iron, zinc, manganese, and copper, which play critical roles in enzymatic functions and overall health. Irchad et al. (2023), reported the iron content ranged from 38.98 mg/kg in the "INRA 2105" genotype to 332.58 mg/kg in the "Aicha Moussa" genotype, the zinc content ranged from 4.55 mg/kg to 37.53 mg/kg across different genotypes, the manganese content ranged from 6.03 mg/kg to 20.08 mg/kg, the copper content ranged from 19.33 mg/kg to 34.73 mg/kg. Scientific evidence suggests that a diet rich in minerals can play an important role in the prevention and treatment of various diseases such as diabetes, heart disease, stroke, and cancer (Tolonen, 1990; Branco et al., 2016). Macroelements such as calcium, phosphorus, sodium, magnesium, and potassium participate in vital cellular transmission and signaling processes, while microelements such as copper, iron, manganese, selenium, and zinc serve as structural components of many enzymes (Gharibzahedi and Jafari, 2017).

In their research, Hssaini et al. (2020) found the total phenolic amount to be between 69.83 ± 13 mg GAE/100 g of oil in the 'Bourjassotte Noir' cultivar and 100.99 ± 12.78 mg GAE/100 g of oil in the 'White Adriatic' cultivar. For instance, one study reports a TPC of 79.5 mg GAE/100 g in fig seed oil, indicating a moderate level of phenolic compounds (Ustun-Argon et al., 2021).

In a study, the antioxidant activity of fig seed oil was investigated in detail. According to the DPPH free radical scavenging test results, the antioxidant activity varied between 226.46 ± 10.95 mg Trolox equivalent/g oil in the C7A14 variety and 294.36 ± 9.78 mg Trolox equivalent/g oil in the White Adriatic variety. In addition, similar results were obtained in the ABTS radical scavenging test, with the White Adriatic variety having the highest inhibition rate (136.65 ± 91.00 mg Trolox equivalent/g oil). These findings reveal that fig seed oil has a strong antioxidant capacity (Hssaini et al., 2020).

Fig seeds and fig kernel oil have remarkable health potential with their biochemical and phytochemical components. Fig kernel oil can be evaluated as a functional ingredient in the food industry thanks to its rich fatty acid profile, high phenolic component content, and strong antioxidant capacity. In addition, fig seeds, rich in microelements and proteins, are important not only as a nutritional additive but also with their health-supporting properties. Current research shows that fig kernel oil can be used in both preventive and therapeutic health applications, and future studies in this field will allow this valuable component to find a wider area of use. Further research is needed to better understand the positive effects of fig seeds on nutrition and health and to expand the industrial applications of these components.

HEALTH BENEFITS

There are various studies on fig seed oil. Fig seed oil showed significant protective and restorative effects on 5-fluorouracil (5-FU)-induced intestinal mucositis in rats; this effect was proven by its positive effect on inflammation markers and histological improvements (Alan et al., 2024). Fig seed oil application showed positive effects on kidney tissue and serum GSH levels in a myoglobinuric acute kidney injury model in rats. The study showed recovery of morphological damage and increased antioxidative capacity (Isler et al., 2022). Fig seed oil was found to have positive effects on blood glucose levels in diabetic rats and has potential as a protective agent on pancreatic tissues. This study emphasizes the antioxidant activity of the oil (Mert et al., 2024). Fig seed oil has shown strong antimicrobial activity against Escherichia coli, but weaker effects were observed against *Pseudomonas aeruginosa* and *Klebsiella pneumoniae*. This study examines the potential antimicrobial properties of fig seed oil (Duman et al., 2018). Fig seed oil has been identified as a source of omega-3 and gamma-tocopherol, containing high levels of linolenic acid, linoleic acid, and oleic acid. Therefore, it is considered a valuable oil in terms of nutrition (Tarlacı, 2021a).

Fig seed oil has significant potential in protecting and improving health with its rich nutritional components and biological activities. Its antioxidant, anti-inflammatory, and antimicrobial effects make this oil a versatile natural ingredient, and it provides positive results, especially in critical health areas such as intestinal health, kidney function, and blood sugar regulation. In addition, fig seed oil, which is rich in essential fatty acids such as omega-3 and gamma-tocopherol, can have an important place in diets due to its high nutritional value. All these findings reveal the potential of fig seed oil for use in both therapeutic and preventive health applications and are promising for future research.

APPLICATIONS OF FIG SEEDS IN THE FOOD INDUSTRY

Fig seeds are increasingly popular in the food industry and have various applications. Fig seeds, which have high nutritional value, are used especially as a source of vegetable oil. Tarlacı (2021) emphasizes that fig seeds are rich in omega-3 fatty acids and gamma-tocopherol and that these seeds can be an important component in the formulation of health-supporting foods. Thanks to these properties, fig seed oil is used as a nutritional additive in functional foods. In addition, fig seeds are valuable in terms of protein, fiber, and mineral content. Nakilcioğlu-Tas (2019) suggested that fig seeds are rich in these components and can be used in functional food products, such as snack bars and bread varieties, with these properties. Such foods are preferred by consumers as products with high nutritional value and health benefits. In addition, the antioxidant properties of fig seeds are also important in the food industry. Ustun-Argon et al. (2021) state that the oil obtained from fig seeds has high antioxidant activity and can be used to extend the shelf life of food products thanks to this feature. Antioxidants protect the quality of products and preserve their freshness for a long time by preventing oxidative deterioration in foods. These scientific findings show that fig seeds have various applications in the food industry and can be used as a valuable ingredient in the production of healthy, functional foods. Fig seeds contain biologically active compounds, which makes them suitable for use as natural preservatives. A study by Gaaliche et al. (2011) revealed that fig seeds have antifungal and antibacterial properties and can therefore be used as an ingredient to increase food safety. This feature provides a great advantage, especially in organic and natural food products where the use of preservative additives is limited or eliminated.

Bölek (2020) used fig seed powder as an innovative ingredient in biscuit formulation. The study revealed that fig seed powder, when used as a replacement for wheat flour up to 10%, significantly increased the total phenolic substance content and antioxidant activity, while also improving sensory properties such as smell, taste, and overall impression.

Baykara et al. (2021) investigated the antimicrobial properties of fig seed oil as an additive in chitosan-based films and the usability of these films in food products. This study showed that fig seed oil can be used to extend the shelf life and increase microbial safety in foods.

Erdoğan and Gökçe (2021) evaluated the protective effects of nanostructured lipid carriers loaded with fig seed oil against oxidation in bakery products. This study shows that fig seed oil has a potential application area in extending the shelf life of products and improving quality.

Ozturk-Kerimoglu et al. (2019) evaluated fig seed oil in gel emulsion systems that can be used instead of beef fat in fermented sausages. This study revealed that fig seed oil can potentially improve chemical and sensory quality.

As a result, fig seeds have significant potential in developing innovative and functional products in the food industry. With their high nutritional value, antioxidant properties, and biologically active components, fig seeds are a valuable ingredient for producers who want to produce healthy foods. Rich contents such as omega-3 fatty acids, protein, fiber, and minerals make fig seeds an integral part of functional foods, while their natural protective properties offer innovative solutions to increase food safety. As scientific studies have shown, fig seeds may find wider use in the food industry in the future with both their nutritional and protective properties and may contribute to the development of products that support consumer health.

CONCLUSION

As a result, fig seeds have great potential for both human health and the food industry thanks to their rich biochemical and phytochemical components. Their high protein, fat, fiber, and mineral content, as well as health-supporting components such as phenolic compounds, flavonoids, and antioxidants, make these seeds an indispensable component of functional foods and nutritional supplements. The oil obtained from fig seeds is rich in nutrients such as unsaturated fatty acids, omega-3, and gamma-tocopherol, and offers significant health benefits in areas such as cardiovascular health, reducing inflammation, and antioxidant protection.

In the food industry, fig seeds can be used in a wide range of products from bakery products to beverages, offering innovative solutions that increase the nutritional value of products and address consumer demands. In addition, the natural protective properties of fig seeds provide a great advantage in increasing food safety, especially in the organic and natural product market. Current scientific research indicates that the use of fig seeds in functional foods and health-oriented products will become widespread. Future research and innovation will enable this valuable ingredient to find wider use and enable the development of products that both support consumer health and contribute to sustainable production processes.

THE COMPARISON OF FUNCTIONAL BEVERAGES BASED ON THEIR NUTRITIONAL VALUES

Dilara Kızılkaya , Hilal Soyocak & Nebahat Şule Üstün

Ondokuz Mayıs University / Department of Food Engineering

ABSTRACT

Functional foods are similar to conventional foods (beverage, food matrix) and have essential nutritional functions. They are biologically active foods that can reduce the risk of chronic diseases and be consumed as part of daily nutrition. Functional drinks in this group are generally rich in vitamins, minerals, amino acids, plant extracts, or other bioactive ingredients. They are formulated to meet various needs, such as increasing energy, providing vitality, increasing concentration, and supporting immunity. Examples of functional drinks: Energy drinks, sports drinks, vitamin waters, probiotic drinks and antioxidant drinks can be given. Unlike everyday beverages, these drinks are usually enriched with special ingredients and are generally low in calories. The popularity of functional beverages is increasing among consumers who want to adapt to the intense pace brought by the modern lifestyle. As a result, functional drinks are generally formulated for various purposes and are preferred by consumers to improve their health and performance.

Keywords: Functional food, Probiotic, Drinks.

INTRODUCTION

With the increase in living standards in the last century, it has been observed that consumers have become more consicious and are turning towards healthy foods. Todays, foods are not only consumed to suppress hunger and meet Daily nutrient requirements. In this regard, functional foods have an important role. The increase in helath and care costs and the rise in expectations regarding quality of life have been effective in increasing the demand for functional foods (Demirbag et al., 2023)

Functional foods are not foods that are clearly defined within a single definition or whose characteristics are clearly delineated. In fact, many foods can be considered functional foods. This concept includes components, with or without nutrients, that affect health and/or reduce the risk of disease. Functional foods are defined as foods or food components that, beyond meeting the body’s basic nutritional needs, provede additional benefits on human physiology and metabolism and are effective in preventing diseases and leading a healthier life. Many terms are used around the World to describe such foods, many of which are quite unique. These terms include nutraceuticals, regulatory foods, pharmaceutical foods and medical foods (Karaduman, 2011).

The basic principle of functional food production is the partial or complete removal of components with negative physiological effects from food and the addition of components with benefical physiological effects instead of these components. The concept of functional food as defined by the authorities is "foods that have a similar appearance to traditional foods consumed Daily and are developed to be beneficial for health as well as basic nutrition" (Bayram et al., 2013).

The idea of developing functional foods first emerged in Japan in the 1980s following rising health care costs. Japan's Ministry of Health introduced a regulatory system to approve certain foods with documented health benefits. Its main aim was to improve the health of the country's aging population (Henry, 2010). Subsequently, following the studies initiated in 1984, the "functional food forum" was established and this process continued. The Japanese Ministry of Health defined the term "Special Food for Health" as FOSHU (Food for Special Health Use) (Farr, 1997). The term "Functional Food" first appeared in Nature journals in 1993 under the title "Japan explores the boundary between food and medicine" (Swinbanks & O'Brien, 1993).

Looking at the global consumption of functional foods, Japan, China and the United States are followed by European contries (France, Germany, and Italy) (Bogue et al., 2017). Milk and dariy products are among the most preferred funcitonal foods in Turkiye. Especially, yogurt and cheese are foods with probiotic and prebiotic properties. Such foods have a large share in the functional food sector (Dölekoğlu, 2012).

Functional Food Ingredients

Probiotics

The word probiotic, composed of terms "pro" and "biota", means "for life" and is the opposite of the term antibiotic. Probiotics are defined as foods containing live bacteria that are beneficial for helth. The positive effect of microorganism with probiotic proporties on human health were first brought to the agenda in 1908 by the Nobel Prize-winning Russian scientist Elie Metchnikoff. Metchnokoff had observed years ago that Bulgarian peasants lived longer lives and when he examined the yogurt, he encountered live bacteria. He named these bacteria *Lactobacillus bulgaricus*. Today, the most widely used probiotics ar Lactobacilli. Lactobacilli are include as probiotics in infacr formulas, probiotic-added milk and various pharmaceutical products (Taşdemir, 2017).

The majority of probiotic microorganism are among the Lactobacillus and Bifidobacterium species labeled as "generally recognized as safe (GRAS)" by the Food and Drug Administration (FDA) (Çakır & Çakmakçı, 2004). These microorganisms prevent the proliferation of pathogenic bacteria by lowering the pH level of the intestinal biota and contribute to the protection of intestinal health. In addition, probiotics have important effects such as prevention of allergic reactions, reduction of symptoms and signs related to lactose intolerance, prevention of viral-induced and antibiotic-associated diarrhea such as rotavirus, reduction of risk related to carcinogenicity and mutagenicity, and prevention of inflammatory bowel diseases (Kara & Çoskun, 2014). Fermented dairy products are among the most widely consumed probiotic sources in the Daily diet (Biçer et al., 2022).

Prebiotics

Prebiotics were defined by Gibson and Roberfroid in 1995 as “a non-digestible food additive that benefits the host by promoting the activity and/or growth of a specific or limited number of bacteria in the colon, thereby improving the health of the host” (Huebner et al., 2007; Huebner et al., 2008). This defination was later improved by other researchers and nowadays prebiotics are defined as “a fermentable component that allows specific changes in the activity and/or composition of the gastrointestinal flora taht contribute to the health and well-being of he host”. Based on these definitions, new prebiotics are identified in accordance with the specified criteria. Recently, there has been a great interest in the use of prebiotics as functional foods to regulate the composition of the gastrointestinal microbiota in order to contribute to the health of the host (Saad et al., 2013).

Prebiotics are very important nutrients in many aspects such as gastroenteritis treatment, reduction of cancer risk, regulation of lipid metabolism and calcium-magnesium absorption (Demirbağ et al., 2023). Prebiotics are found in some vegetables and fruits such an onion, garlic, leek, wheat, banana, pea, chicry and yam (İnanç et al., 2005).

Synbiotics

Synbiotics, named after the synergistic effects of prebiotics and probiotics, are defined as foods or additives that contain probiotic and prebiotic components together. The most widely known synbiotics are combinations of Bifidobacterşa with FOS, Lactobacillus with lactylol and Bifidobacterium with GOS. Consuming a synbiotic food allows to benefit from the positive effects of both probiotics and prebiotics on health ant hese products have attracted considerable attention in recent years (Sezen, 2013; Çınar & Dayısoylu, 2005). Studies have shown that the gut microbiota improves in infants with atopic dermatitis (Markowiak & Śliżewska, 2017).

Dietary Fibers

Dietary fiber refers to the edible parts of plants thar are not digestible in the human small intestine but are fully or partially fermented in the large intestine. Various complex substances found in plants that cannot be digested like other nutrients because they are not affected by digestive enzymes are called fiber. Fibers refer to the indigestible and relatively solid parts of vegatables and fruits, such as peels, membrabes, stems and seeds. Interest in this subject dates back to ancient times, eceb to Hippocrates in the 5th century BC. The indigestible components that make up the plant cell Wall first named “dietary fiber” by Hispley in 1953. Especially in the last quarter century, interst in dietary fibers has increased significantly. The main reason fort his is te emergence of some heath problems caused by diaary fiber deficiency in foods in developed countries, which Burkitt and Towell defined as “diseases of civilization” (constipation, hemorrhoids, colon cancer, obesity) (Düler and Gahan, 2011).

Essential Fatty Acids

There are certain components that are vital fort he healthy performance of various metabolic processes in the body. One of these components is essential fatty acids, which cannot be synthesized naturally in the body and must be obtain from external sources. Dietary essential fatty acids are absorbed from the small intestine and then enter the bloodstream and reach the target tissues. Linoliec acid (w-6) and linolenic acid (w-3) are among these essential fatty acids. While w-3 fatty acids are found in high amounts in fish such as salmon, tuna, mackerel and sardines, as well as in soybean and canola oil; w-6 fatty acids are present in soybean, sunflower, corn and safflower oil. Studies have shown that these fatty acids reduce the risk of coronary artery disease and serum triglyceride levels. In addition, these fatty acids are necessary fort he formation of new tissue, including nerve tissue, and brain development during pregnancy (Demirbağ et al., 2023).

Conjugated Linoleic Acid

CLA is a generic term for a mixture of various conjugated positional and geometric isomers of linoleic acid containing 18 carbon atoms and two double bonds. Conjugated linoleic acid, a functional component of animal orgin, is found in high amounts in dairy products and meat of ruminants. It has anticarcinohenic and antiatherogenic properties. It regulates eicosanoid synthesis and shows positive effects on immune respone (Gürsoy & Kınık, 2011).

Carotenoids

The comjugated double bond in their molecular structure shows antioxidant properties, preventing the occurrence of free radical reactions or protecting tissues against oxidative and photo-oxidative damage by suppressing free radicals and reactive oxygen compounds. There are many studies demonstrating the benefits of vitamin C for cancer prevention. Vitamin C functions as a water-soluble antioxidant both intracellularly and extracellularly, inhibiting lipid oxidation by various cellular mechanisms. Vitamin C is considered as a substance that eliminates free radicals and it is thought that consuming high amounts of vitamin C-rich foods may be effective in reducing the incidence of gastric cancer (Özkarabulut & Öztürk, 2021).

Phenolic acid and Flavonoids

Flavonoids are divided into six main categories accroding to the changes in the carbon ring they contain (flavones, flavanols, flavanones, catechins, anthocyanidins and isoflavones). Quercetin, which belongs to the flavonol group, is found in hidh amounts in onions. Similarly, tea is a food rich in quercetin and kaempferol. Phenolic compounds are found in vegetables and fruits. Walnuts, coffee, pomegranates, grapes, blackberries, peanuts, tea, olive oil and flaxseed are among the foods with the highest concentration of polyphenols. In addition to the cholesterol-lowering effect of phenolic acid, there is information that it is also effective againts some types of cancer (breast and colon). In addition, flavonoids have been observed to have protective properties againts free radicals, viruses, ulcers, liver toxins, platelet aggregation and inflammation (Demirbağ et al., 2023).

Phytoestrogenes

Phytoestrogenes are polyphenolic nonsteroidal compounds of plant origin. Thay can also be found structurally or functionally in mammals and can Show estrogen-like effects. Research suggests that 350 different plant species have estrogenic activity. The entry of phytoestrogen into the human body can be achieved through the consumption of plants with phytoestrogen propeties or products obtained from animals fed with these plants (Antmen & Ögenler, 2018).

Phytosterol and Phytostanols

Plant sterols are similar to cholesterol but differ in the presence of methyl, ethyl groups or double bonds. The most widely known sterols iclude sitosterol, campesterol and stigmastreol. Plant-derived sterols are less absorbed from the intestines than animal-derived cholesterol. Plant sterol or stanols have the abilty to lower cancer, total cholesterol and LDL cholesterol levels bu reducing cholesterol absorption in the body furthermore, plant sterols have an antiatherosclerosis effect by inhibiting the excessive proliferation of vascular smooth muscle cells, which are involved in the development of atherosclerosis. In addition, plant sterols have antioxidant, antiulcer and antifungal properties (Demirbağ et al., 2023).

Vitamins and Minerals

Vitamins, a sub-branch of the micronutrient category, are organic compounds that have vital roles in growth and development, maintenance of the normal functioning of the nervous and digestive systems, efficient utilization of nutrients in the body, support for immune system functions and maintenance of normal cel functions, as well as important fucntions in metabolism. The production of vitamins in the body is very limited or does not ocur at all. For this reason, they need to be supplied from outside through food (Çınar & Okay, 2013).

Minerals are inorganic components necessary for healthy growth and reproduction of animals. The need for minerals increases with the increase in body weight during pregnancy, lactation and growth and development. Although mineral substance deficiencies may have negative effects on fertility, such deficiencies can be eliminated by supplementing the necessary mineral subctances to the ration in the feding program under field conditions (Yeşil & Sarıözkan, 2017).

FUNCTIONAL DRINKS

Functional beverages are an important segment of functional food products (Table 1) as it allows them to contain the desired nutrients and bioactive compounds to maintain human hydration and have anti-aging, energizing, rekaxing or beauty-enhancing effects (Ghoshal & Kansal, 2019). Functional beverages may contain various bioactive components such as soluble dietary fiber, minerals, vitamins, fatty acids, phytochemicals (such as phytoestrogens, phenolic compounds, flavonoids and carotenoids) and probiotics. Due to the presence of these substances, beverages can be important in disease prevention methods, especially in the early stages of diseases. Consumption of functional beverages is increasing worldwide due to their nutritional value, convenient packaging, attravtive desing, easy transportation and storage, and long shelf-life (Gebre et al., 2024).

Table 1. Functional Drinks and Ingredients

Functional Beverage	**Components**
Energy Drinks	Taurine, caffeine, and plant extracts asuch as ginseng, guarana, yerba mate and green tea extracts
Drink and relax	Amino acids (GABA or 1-theanine) and lemongrass
Protein drinks	Protein-enriched drinks beyond weight training. The most popular drinks containing whey protein isolates, collagen proteins, MCT, etc.
Drinks without additives	Coconut water. The perfect sports drink that provides all the minerals and vitamins you need after your workout.
Vitamin blends	İt is very popular to use vitamin mixtures that contain not only vitamins but also functional ingredients such as lutein, omega 3, goji extract, ginseng.
Fortified water	Vitamins, minerals, antioxidant, amino acids and in some cases fatty aicd components found in water.
Fiber drink	Soluble dietary fibers (peçtin, inulin, gums and mucilages) Insoluble dietar fibers (cellulose, hemicelluloses, lignin-non-carbohydrate compounds)
Fruit juice concentrates	Goji juice concentrate, acerola, pomegranate
Sweetened beverages	Reduced sugar or naturally sweetened products (stevia, monk fruit extract or Lo-han, grape juice concentrate, xylitol or agave)
Herbal extracts	The most trendy are those of Brazallian origin. Acai, maça, macu camu or yerba mate and artichoke extract

Energy Drinks

Energy drinks are the main segment in functioal beverages, follewed by sports drinks and nutraceutical drinks. They are a group of beverages used to provide an extra boost of energy, cognitive enhancement, reverse the eddects of fatigue, maintain alertness and endurance, especially by young people who mix energy drinks with alcohol. In general, energy drinks contain caffeine, taurine, glucuronolactone, sugar, vitamins B and herbal extract (ginseng, guarana, yerba mate and green tea extracts), so regular consumption can increase the risk of caffeine overdose in non-caffeine users; the risk of caffeine overdose in those who regularly consume caffeine from coffee; and alcohol, nicotine and other drug dependence (Abdulrahman, 2015).

Sports Drinks

Sports drinks are flavored beverages formulated to help people rehydrate during or after exercise. They are designed to prevent dehydration and depletion of the body’s carbohydrate stores. They promote voluntary fluid intake, gastric emptying and rapid absorpton into the intestines. Sports drinks are developed using essential minerals such as sodium, potassium chloride, calcium, phosphate and magnesium, which are lost through sweatin during exercise; amino acids can slow fatigue and improve muscle function; Vitamins B are used to boost metabolism and produce energy; simple carbohydrates can provide a quick burst of energy and complex carbohydrates are used to replenish energy reserves during and after exercise (Ghoshal & Kansal, 2019).
There are three main types of sports drinks according to their osmolality (Table 2);

1. ***Isotonic drink***

Isotonic drinks provide carbohydrate support by replacing fluids lost through rapid sweating. These types of drinks are preferred by many athletes, such as middle and long distance runners and team athletes. Prolonged exercise and sweating lead to two important conditions; depletion of carbohydrate stores in the body and dehydration. Especially in summer, when temperatures are high, both amateur and Professional athletes are at risk of sweating profusely. Carbohydrate intake before, during and after training helps the body to maintain glycogen reserves while preventing excessive drops in blood glucose levels. Since most athletes cannot consume food before or during sports, the consumption of beverages with carbohydrate-rich formulas in benefical (Hayoğlu & Toğrul, 2020).

2. ***Hypertonic drinks***

They contain a higher concentration of salt and sugar compared the huan body. Their high carbohydrate content has the effect of increasing the rate of water flow in the intestines. They are usually consumed after training to supplement Daily carbohydrate intake and muscle glycogen stores. They are preferred in high energy demanding sports as long distance running. However, in such cases, they are recommended to be used with isotonic drinks to prevent fluid loss (Anlı & Müniroğlu, 2022).

3. Hypotonic drinks

They are less concentrated in salt and sugar than the human body. They help to quickly replace fluids lost through sweating. They are ideal for sports that do not require carbohydrate sepplementation. For example, sports drinks preferred by gymnasts are usually moderately isotonic. On average, they contain 4-5 g of sugar per 100 mL. They appear to be more effective than hypertonic or isotonic drinks in increasing central hydration during exercise (Anlı & Müniroğlu, 2022).

Table 2. Ingredients of different sports drinks

Isotonic drinks	Electrolytes + 6-8% carbohydrates
Hypotonic drinks	Electrolytes + low levels of carbohydrates
Hypertonic drinks	high levels of carbohydrates

Probiotic Drinks

Consumption of beverages and foods containing probiotic microorganism is an increasing trend worldwide. According to the World Health Organization, probiotics are defined as “live microorganism that, when administered in adequate amounts, can provide many health benefits to the host” (Tiwari et al., 2011). Probiotic consumption prevents the formation and spread of harmful substances such as toxins and carcinogens in our body. It has been proven by scientific research that it helps many diseases such as diarrhea and constipation, bloating, gas and indigestion, infections and problems in organs such as stomach and intestines, cholesterol and blood sugar imbalances, acceleration of the healing process, fungal infections and allergic reactions, urnary tract infections, bladder cancer, eczema. Today, among the probiotic foods we obtain from various food sources, there are also some drinks that we are familiar with. Ayran, kefir, pickle juice, goat’s milk, kombucha, turnip and boza are examples of probiotic drinks. Probiotic foods are of great importance for a healthy digestive system (Anonymous, 2017).

Dairy beverages (fresh milk, fermented milk and yoghurt drinks) are the most common products used as carriers for probiotics, prebiotics, minerals, herbs, vitaminsi amino acids, antioxidant, plants, raw fruits and vegetables. However, non-dairy probiotic drinks prepared from cereals, millets, legumes, fruits and vegatebles have also been developed as carriers of functional compounds to satisfy the consumer’s palate and alleviate health risks associated with milk-based probiotic foods, such as lactose intolerance, high cholesterol content and allergy to milk proteins (Ghoshal & Kansal, 2019).

The faster digestion of liquid foods allows probiotics to be less affected by the harsh conditions of stomach acid. This has led to increases interet in fruit and vegatable-based probiotic drinks. A variety of raw materials such as applesi orangesi pineapplesi blueberries, mangoes, grapes, carrots, tomatoes, cabbage and beets are often used to develop such beverages. Table 3 shows the diffrent probiotic drinks produced commercially (Şengül & Yahşi, 2021).

Table 3. Various commercially produced fruit and vegetable based probiotic drinks

Product content	Probiotic strain	
Orange	*L. reuteri*	Sweden
Orange and mango	*L. rhamnosus* GG	Norway
Peach and banana	*B. lactis*	Sweden/Finland
Pineapple, carrot, β-carotene and calcium	*L. rhammosus* GG	United Kingdom
Raspberries, black currants and grapes	*L. plantarum* 299v	Sweden
Orange, peach, prebiotics and vitamin C	*L. rhamnous* GG	Finland/Sweden
Carrot, ginger and cane sugar	*L. plantarum* 299v	USA
Ginger, curranti blueberry and 19 different aromatic plant extraxts	*L. acidophilus, L. rhamnosus, L. casei, L. lactis, L. salivarus, B. lactis, B. longum*	Denmark
Strawberry, blackcurrant, mango, banana and oligosaccharide	*B. lactis*	USA
Plums, grapes and orange	*L. paracasei*	Thailand

Health Trend Functional Drinks

- Blcak tea (*C. sinensis*)

Polyphenols found in black tea (thealavins, theflavin 3-o-gallate, theaflavin 30-o-gallate, theaflavin 3,30-o-gallate, epigallocatechin gallate, epicatechin gallate, catechins, 2-quetcetin glycosides, quinic acid, gallic acid and caffeine) may prevent obesity. They restrict pancreatic lipase by inhibiting fat absorptio from the intestine. Pancreatic lipase in an important enxyme for lipid absorption (Ghoshal & Kansal, 2019).

- Green tea

Green tea polyphenols and caffeine interact synergistically by prolonging noradrenaline release and Brown adipose tissue thermogenesis. Catechin polyphenols reduce catechol-o-methyl-tranferase, an enzyme that can inhibit noradrenaline and caffein release, and cleave transcellular phosphodiesterase enzymes that can inhibit the tissue regulator. Moreover, green tea produces anti-obesity, antioxidant, hypolipidemic and hepatoprotective effects by increasing the lipolytic pathway. Tea and tea polyphenols repress the fatty acid synthase gene by down-regulating the human protein transcription factor EGFR/PI3K/Akt/Sp-1 (Ghoshal & Kansal, 2019).

- White tea

White tea decreases blood triacylglycerols by increasing blind gut lipids and oxidative stress in liver and adipose tissue. Herbal teas may have phenolic and antioxidant levels similar to or superior to those of black tea, and many of them suppress the activity of enzymes involved in metabolic syndromei namely alpha-amlyla, alpha-glucosidase, pancreatic lipase and angiotensisn I-converting enzyme (ACE) (Ghoshal & Kansal, 2019).

- Mate tea

Mate tea contains caffeine and antioxidants that can produce vasodilation and reduce weight, lipid and LDL-cholesterol levels. Moreover, they have a synergistic effects with statins, inhibiting pancreatic lipase and activating adenosine-monophosphate-activated protein kinase (Ghoshal & Kansal, 2019).

- Coffee

Coffee intake alleviates glucose intolerance. Chlorogenic acid lowers hepatic triglyceride levels, Di-caffeoyl quinic acids and feruloyl guinic acids inhibit maltase, sucrose and pancreatic lipase, reducing postprandial hyperglycemia, hyperinsulinemia, obesity and cardiovascular disease. Mono- or di-caffeoyl quinic acids improve energy metabolism, inhibit abdominal ad liver fat accumulation, reduce infiltration of macrophages into adipose tissue and decrease fat synthesis in the liver. While caffeine suppresses fat absorption, mixtures of neocholorogenic acid and feruloyl guinic acid increase hepatic carnitine palmitoyltransferase and suppress visceral fat accumulation and body weight gain (Ghoshal & Kansal, 2019).

CONCLUSION

In recent years, with the rise of healthy living trends, the market for functional bevereges has grown tremendously. These drinks aim to not only qurnch your thirst, but also offer specific health benefits. Containing nutrients such as vitamins, minerals, antioxidant and herbal extract, these drinks can have positive effects on both physical and mental health. Functional beverages have grown in popularity as consumers have become more health. Functional beverages include enrgy boosting drinks, digestion-supporting drinks, immune-boosting drinks and stress-reducing drinks. Especially athletes and individuals with a busy work schedule prefer these drinks to improve their performance and support their overall health. However, in order to fully appreciate the benefits of functional everages, some important points need to be considered. First, the quality and effectiveness of the nutrients used in these beverages play a critical role. It should also be kept in mind that functional beverages are nor a subrtitute for a balanced diet and excessive consumption can lead to health problems. In conclusion, functional beverages can be effective tools support wellness and performance goals. However, the conscious and balanced consumption of these beverages should be considered as part of an overall health strategy. Sticking to the basic principles of a healthy lifestyle, such as a balanced diet and regular physical activity, should always be prioritized.

ABSTRACT

Nettle (*Urtica dioica*) is a plant with serrated leaves and tough fibrous stems belonging to the Urticaceae family. Its flowers are generally greenish in color. It is widespread worldwide, especially in temperate climates and moist soils. Nettle has been used by humans for both nutritional and medicinal purposes for thousands of years. Its young leaves are usually consumed and have a spinach-like flavor when cooked. Dried leaves can also be consumed as tea. Nettle seeds can also be ground into flour or used as grains, providing a gluten-free alternative, especially for celiac patients. Its nutritional content is rich in iron, calcium, magnesium, and vitamins A and C. Its iron content is an essential source for those with iron deficiency anemia. Also rich in antioxidants, nettle supports the immune system, can reduce inflammation, and improve skin health. It has been frequently used in traditional medicine as a diuretic, blood purifier, and against skin diseases. Additionally, studies have shown that nettle has anti-inflammatory properties. This feature can be used to treat joint inflammations and skin problems such as acne and eczema. Nettle also has blood sugar-lowering effects and can be considered supportive in diabetes. Additionally, nettle can support hair and nail health and reduce hair loss.

Keywords: nettle, health, food, antioxidant

INTRODUCTION

Nettle (*Urtica dioica* L.) is a plant that grows in temperate and tropical wastelands worldwide. This plant has been one of the important plants in the European Pharmacopoeia since ancient times (Asgarpanah & Mohajerani, 2012). The genus *Urtica* L. belongs to the main group of angiosperms (Angiospermae) in the family Urticaceae and consists of 46 species of flowering plants (Table 1). The best-known members of this genus are *U. dioica* L. and *U. urens* L., native to Asia, Europe, Africa, and North America. Urtica plants are perennial and annual herbaceous plants. The toothed leaves are attached to the stem in pairs. The leaves and the rest of the plant are covered with hairs, some of which cause pain. Toothed, hairy leaves and needles are generally considered characteristic of this plant (Yiğen, 2023).

Table 1. Some Urtica species distributed worldwide and their distribution areas (Woodland, 1982).

Species	Country
Urtica angustifolia	China, Japan, Korea
Urtica ardens	China
Urtica atrichocaulis	Himalayas, Southwestern China
Urtica atrovirens	Western Mediterranean
Urtica cannabina	Western Asia
Urtica dioica	Europe, Asia, North America
Urtica dubia (Broadleaf nettle)	Canada
Urtica ferox (Tree nettle)	New Zealand
Urtica fissa	Japan, China
Urtica galeopsifolia	Central and Eastern Europe
Urtica hyperborea	Himalayas
Urtica incisa (Bush nettle)	Australia
Urtica laetivirens	Japan, Manchuria
Urtica morifolia	Canary Islands
Urtica parviflora	Himalayas
Urtica pilulifera (Romanian nettle)	Europe
Urtica platyphylla	China, Japan
Urtica pubescens	Southwestern Russia
Urtica rupestris	Sicily
Urtica sondenii	Southeastern Europe, Northern Asia
Urtica taiwaniana	Taiwan
Urtica thunbergiana	Japan
Urtica urens (Dwarf nettle, annual)	Europe, North America

Plants of the *Urtica* genus are unisexual or bisexual. Young plants can be green, mature plants can be red-purple. Formic acid and histamine in the hairs of the nettle plant are irritating, burning and stinging. The ideal soil type for the plant is moist, alkaline, humus-rich soil. Heavy metals can be found in the soil where the plant is located and can accumulate in the leaves, so attention should be paid to the soil in which it grows before consuming it as food (Aydın, 2022; Kavalalı, 2011; Yalçın, 2011). The nettle plant usually blooms between May and August and can reach 30-300 cm in length, has oval leaves with petioles and toothed edges. The leaves are arranged in opposite directions on the stem and measure 4-11 x 3-10 cm. Female and male flowers are together (Bhusal et al., 2022; Ayan et al., 2020). The flowers bloom in September, are small and green in color (Otles & Yalçın, 2012). While the ovaries of female flowers are in the carpel structure where 4-5 petals come together, male flowers have 5 stamens, higher than female flowers and in a prominent position. The fruit of the nettle plant is dark brown-black and has a nut-like round structure. The plant has many lateral roots and thus can spread to large areas (Öztürk & Özdemir, 2024).

Chemical Substance Content of *Urtica dioica* L. Plant

There are nearly 20 different chemical substances in the structure of nettle. These substances include fatty acids, lectins, sterols, amines, acids and polysaccharides. These chemicals are found separately above and below the soil of the plant (Table 2 & Table 3) (Karakaş, 2003).

Table 2. Chemical substances found in leaves and above-ground parts

Fatty acids	palmitic	oleic	linoleic	linolenic					
Acids	formic	silisic	citrc	fumaric	malic	oxalic	phosphoric	succinic	threonic
Flavonoids	kaempferol	isorhamnetin	quercetin	glycosides					
Other substances	ß-sitosterol	scopoletin	phenylpropane derivatives						

Table 3. Chemical substances found in underground parts

Fatty acids	palmitic	linoleic		
Lectins	*Urtica dioica* agglutinin (UDA)			
Polysaccharides	glycans	galactoglucans		
Other Substances	triterpenes	ß-sitosterol	scopoletin	phenylpropane derivatives

Apart from these chemicals, roots contain starch, albumin, lignin, chlorophyll, histamine and resins, while leaves contain gums, waxes, chlorophyll and some alkaloids (Karakaş, 2003). Easily digestible and highly nutritious, nettle species are rich in essential amino acids, ascorbic acid, essential fatty acids, as well as vitamins A, B, C, E, K and minerals such as iron, magnesium and calcium (Ayan et al., 2006; Öztürk & Özdemir, 2024).

USE OF NETTLE AS A FOOD SOURCE

Nettle is collected in spring months from certain periods until the beginning of flowering and is evaluated in different ways in various cultures. Nettle species are highly nutritious and easily digestible. The above-ground parts of the plant, especially the leaves, are rich in iron, vitamins C and A, essential amino acids, ascorbic acid, various mineral elements and essential fixed fatty acids (Ayan et al., 2020).

The nutritional aspect of *U. dioica* is mainly due to two parts of the plant: green leaves and seeds. Young leaves and shoots are used as food because they are a rich source of polysaccharides, vitamins ß-carotene), iron, potassium, manganese, calcium protein, silicon, phosphate and vitamin C for the absorption of iron. However, its leaves, which are low in saturated fat, contain essential fatty acids such as α-linolenic acid and linoleic acid, essential amino acids and carbohydrates, carotenoids including Ω-6 fatty acids, lutein, ß-carotene in abundance. Due to its high nutritional value, its leaves are used for human consumption, to strengthen the body, in the preparation of soups and as a natural food flavoring source. Nettle can be an important source of dietary fiber due to its high pectin content. The chlorophyll content in *U. dioica* leaves was found to be between 1 and 5, of which 75% was α-chlorophyll and 25% was ß-chlorophyll (Jan et al., 2017).

Nettle is consumed as a leafy vegetable in many parts of the world. It is a highly valued plant due to its medicinal properties and can be beneficial for diabetics, heart patients and people with high blood pressure. It is also considered one of the healthiest foods on the planet. When nettle greens are harvested, only the most tender, tallest shoots and uppermost green leaves are selected or plucked. The tender young leaves and shoots of nettle are cooked like other leafy vegetables. It is used as soup, vegetable, tea, juice and medicine (Bhusal et al., 2022).

MEDICAL USE OF NETTLE

Urtica dioica L., commonly known as Nettle, is widely distributed in temperate and tropical regions worldwide. Since ancient times, people have used this sting to stimulate circulation and bring warmth to joints and extremities by swaying arthritic or paralyzed limbs with the fresh plant, a treatment known as urticaria (Joshi et al., 2014).

Studies conducted throughout Turkey show that nettle is used in folk medicine for various treatments such as cancer, kidney disease, respiratory tract disease and cough treatment, prevention of hair loss, shortness of breath, paralysis, blood pressure, stomach ache, rheumatism, fungal infections, osteoporosis, eczema and pain caused by eczema, treatment of hemorrhoids, gynecological diseases, passing kidney stones and facilitating digestion (Şimşek et al., 2004; Gürhan & Ezer 2004).

Nettle contains different types of organic compounds of medicinal importance including phytosterols, saponins, flavonoids, tannins, sterols, fatty acids, carotenoids, chlorophylls, proteins, amino acids and vitamins. The plant has been reported to possess various pharmacological activities such as antioxidant, anti-inflammatory, antiulcer, anti-colitis, antiviral, anticancer, antibacterial, antimicrobial, antifungal, antiandrogenic, insecticide, immunomodulatory, hypocholesterolemic, hypoglycemic, cardiovascular effects, analgesic, natriuretic, hypotensive, hepatoprotective and rheumatoid arthritis (Joshi et al., 2014).

Antioxidants are emerging as prophylactic and therapeutic agents that scavenge free radicals or reactive oxygen species and prevent their harmful effects. Free radicals have been associated with the pathogenesis of disorders such as cancer, diabetes, cardiovascular diseases, autoimmune diseases, neurodegenerative disorders and aging. In the study conducted by Joshi et al. (2014), hydro-alcoholic extract of *Urtica dioica* plant showed significant results in terms of antioxidant activity with a half inhibitory concentration (IC50) value of 88.33 ± 2.88 µg/ml.

Some studies have found that nettle plant delays the development of breast and prostate cancer, which are hormone-dependent cancer types (Tello et al., 2008).

Many studies on nettle have found that nettle has antihistamine effects when taken orally. One study showed that nettle leaf extract inhibited both lipoxygenase and cyclooxygenase activity. Lipoxygenase and cyclooxygenase are responsible for the conversion of arachidonic acid to rostaglandins and leukotrienes. This is probably due to the negative feedback effect of histamine taken orally from nettle leaves, thus reducing allergic reactions (Altınterim, 2012).

Asgarpanah & Mohajerani (2012) reported on the antiviral activity of nettle. Several plant-derived mannose-binding proteins inhibit human immunodeficiency virus (HIV) replication and selectively target viruses that exhibit reduced N-glycosylation sites on the GP120 envelope. The N-acetylglucosylation protein from *U. dioica* (UDA) inhibits HIV expression. In contrast to mannose-binding proteins that have 50- to 100-fold reduced anti-HIV activity against mutant strains exposed to UDA, UDA reduced anti-HIV activity to a very limited extent against mutant strains lacking at least 9 of the 22 glycosylation sites on their GP120 envelopes.

The list of drugs with medicinal origin obtained from different parts of the nettle tree, either pure or with valuable extracts, and produced in Europe are given in Table 4. According to Table 4, it is understood that Germany uses nettle extensively in the production of medicinal drugs (Ayan et al., 2020).

Table 4. Health products containing Nettle species

Product Name	Content	Main Producer Company and Country	Treatment Purpose
Arthrodynat	Nettle Herba and Other Plants	Ziethen, Germany	Arthritis
Bazoton	Nettle Root	Canolt, Germany	Prostatic disorders
Befelka	Nettle herb tincture	Befelka, Germany	Skin disorders Metabolic disorders Circulatory disorders
Cholaflux	Nettle leaf and other herbs	Nattermann Tee Arznei, Germany	Herbal tea
Colchicum-Strath	Nettle leaf and other plants	Strath-Labor, Germany	General disorders
Combudoron	Nettle leaf and other plants	Weleda, Germany	Skin disorders
Combudoron	Nettle (urens) and other plants	Weleda, England	Homeopathic ingredients
Crinocedin	Nettle (dioica) and other plants	Wolfer, Germany	Hair tonic
‘Vital Tonicum’	Nettle Leaf	Grandel-Synpharma, Germany	Tonic
Fragador	Nettle (dioica) leaf and other plants	Weleda, UK	Stress
Heparchofid S	Nettle herb, seed and other plants	Fides, Germany	Digestive disorders Liver and bile disorders

Kleer	Nettle (dioica) and other herbs	Modern Health Products, England	Skin disorders
Liruptin	Nettle herb and other plants	Fides, Germany	Reproductive system
Nephropur	Nettle herb and other plants	Repha, Germany	Reproductive system disorders
Nosenil	Nettle and other plants	Farbo, Italy	Kidney stones
Prostaforton N	Nettle (dioica) roots	Plantorgan, Germany	Prostatic disorders
Prostagalen N	Nettle (dioica) roots and other plants	Galenika, Germany	Prostatic disorders
Prostaherb cum 'Belladonna N'	Nettle roots and other herbs	Redel, Germany	Prostatic disorders
Prostatin N	Nettle roots and other plants	Kanoldt, Germany	Reproductive system
Prostatin N-Liquidum	Nettle roots and other plants	Kanoldt, Germany	Reproductive system
Rheuma	Nettle herb and other herbal tea	Stada, Germany	Rheumatic disorders
Rheumex	Nettle herb and other plants	Labopharma, Germany	Rheumatic disorders
Salus Kurbis–Tonicum	Nettle Herba-root and other herbs	Salushaus, Germany	Prostatic disorders
Salus Rheuma u. Stuffwechsel Funktionstee Nr.12	Nettle leaves and other plants	Salushaus, Germany	Rheumatic disorders
Salus Rheuma-Tee Krautertee Nr.12	Nettle herb-root and other plants	Salushaus, Germany	Rheumatic disorders
Secerna	Nettle herb-seeds and other plants	Fides, Germany	Tonic
Simic	Nettle roots	Zyma, Swiss	Prostatic hypertrophy
Stoffwechsel Dragees	Nettle herb and other plants	Molitor, Germany	Digestive system
Tisane antirhumatismale 'H'	Nettle herb and other plants	Hanseler, Switzerland	Musculoskeletal and general disorders
Tisane d'allaitement 'H'	Nettle herb and other plants	Hanseler, Switzerland	Loss of appetite

Uvirgan	Nettle root and other plants	Konolt, Germany	Urinary system disorders
Vollmers präparierter grüner	Nettle herb and other plants	Salush-aus, Germany	Urinary system disorders
Urtica plus	Nettle (dried leaves of *U. dioica*)	Euro pharm, Austria	Urinary system disorders
Urtica plus N	Nettle (dried leaves of *U. dioica*)	Hayer, Germany	Bening prostatic
Urtica prostate Uno	Nettle (dried leaves of *U.* dioica)	Azupharma, Germany	Bening prostatic
Urticaria	Nettle (dried leaves of *U. dioica*)	Biocur, Germany	Benign prostatic hyperplasia
Urtipret	Nettle (dried leaves of *U. dioica*)	Bionorica, Germany	Prostatic adenoma

CONCLUSION

Nettle has a long history of offering a variety of health benefits in traditional medicine. Its anti-inflammatory, decongestant, blood sugar regulating and nutritional support properties make it a valuable resource in the health field. However, due to its potential side effects and drug interactions, caution should be exercised in the medical use of nettle and expert advice should be sought. Nettle is generally used as a food in soup, salad, tea or bread. Vetamen (especially A, C and K vetamen), minerals and liver enzymes, and thanks to its properties that support syndere. In addition, it can be included in various supplements due to its potential benefits for certain health conditions. More research and clinical studies can help us understand more about the beneficial effects of nettle and help us optimize these potential health benefits.

ABSTRACT

Legumes are a very healthy and important part of millions of people's diets around the world. All over the world, the production of legumes has grown. The most common types of legumes eaten are beans, lentils, peas, chickpeas, and broad beans. This is because they are low in lipids and high in complex carbohydrates, vitamins, and minerals. Often, their high protein content necessitates their addition to other protein sources. Most of the proteins in legumes are storage proteins. The other proteins are enzymes, as well as two types of macromolecules called antinutrients (lectins and protease inhibitors). Many people germinate legume seeds to make sprouts that you can eat. This simple bioprocess allows legume seeds to have more health benefits. Germination generally enhances the bioavailability of minerals, improves the digestibility of proteins and essential amino acids, and increases the availability of vitamins. It also makes starch, lipids, and antinutritional factors less present in legumes. This process also alters the physicochemical properties of flours derived from germinated legumes, thereby influencing the functional properties of the resulting foods. This study examined the physicochemical, chemical, and nutritional values of legumes following their germination.

Keywords: Legumes, Germination, Bioactive Compounds, Physicochemical Properties, Nutritional Profile

1. INTRODUCTION

Legumes are the third in the classification of chicotyledonous flowering plants, with 750 genera and 16,000-19,000 species. It is part of the *Fabaceas* or *Leguminosae* family (Borges et al., 2013; Sharif et al., 2018). Soybeans, beans, peas, lentils, chickpeas, broad bean, lupine, and peanut are the most well-known legumes in the world (Clemente & Olias, 2017).

Legumes are the second most important food source consumed worldwide after grains due to their nutritional properties and healthiness. Legumes are a high source of protein (20-45%) and are rich in the essential amino acid lysine (Phillips, 1993). It has approximately twice the protein content of grains (Kouris-Blazos & Belski, 2016) and most plant foods in addition to these features, they are also rich in complex carbohydrates (30-60%) and dietary fiber (5-37%) (Kouris-Blazos & Belski, 2016; Phillips, 1993). There are various processes for its consumption, such as soaking, cooking, or germination. Germination is a traditional technique for food processing and is well suited to increase the nutritional value of legumes (Herrera, J., Alizaga, R., Guevara, E., 2006). During germination, seeds (e.g. chickpeas, green lentils) change from a dormant state to a metabolically active state. (Hedley, 2000) This process is affected by biochemical changes that occur depending on germination conditions such as temperature, moisture, time, light, and soaking. During legume germination, bioactive compounds such as essential amino acids, riboflavin, thiamine, biotin, pantothenic acid, niacin, vitamin C, tocopherols, and phenolic compounds increase; It also increases protein digestibility and amino acid availability (Donkor et al., 2012; Khatoon & Prakash, 2006). Germination enhancement also increases reducing sugars, soluble fibers, peptides, and amino acids as well as insoluble phenolic compounds (Hung et al., 2012; Koehler et al., 2007). On the other hand, germination also helps reduce the concentration of antinutritional factors such as alkaloids, trypsin inhibitors, lectins, tannins, and saponins (El-Adawy, 2002). With all these features, the germination process is the most effective and simpler method for improving the nutritional value of legumes due to its ease of use.

1.1. Legumes: A General and Nutritional View

Legumes belong to the *Fabaceae* or *Leguminosae* family, which is the third biggest family among dicotyledonous flowering plants. This family comprises 750 genera and 16,000-19,000 species (Borges et al., 2013; Sharif et al., 2018). They are distributed worldwide due to their ability to adapt to various biotic regions on the planet, such as savannas, humid and dry forests, Mediterranean areas, and temperate regions. This adaptability has led to a wide range of physical characteristics and a diverse array of intrinsic traits (such as nitrogen fixation and reproductive diversity) and extrinsic systems that have played a crucial role in their successful evolution (Koenen et al., 2013). The legumes that are currently the most widely recognized and extensively consumed worldwide are soybeans (*Glycine max*), beans (*Phaseolus vulgaris*), pea (*Pisum sativum*), lentils (*Lens culinaris*), chickpea (*Cicer arietinum*), broad bean (*Vicia faba*), lupine (*Lupinus angustifolius*), and peanut (*Arachis hypogaea*) (Clemente & Olias, 2017).

Legumes have a distinctively low fat content and are abundant in protein and complex carbohydrates, which include dietary fibers. They also have a low glycemic index, as indicated by studies (Duranti, 2006; Gueguen & Cerletti, 1994). Legumes are a valuable source of high quality protein, often containing 20-45% protein content, and are particularly abundant in the important amino acid lysine (Phillips, 1993). Legumes include a greater amount of protein compared to most other plant-based diets, with almost twice the protein content of cereals (Kouris-Blazos & Belski, 2016). Protein legumes and cereals complement each other because grains have significant levels of sulphur amino acids, which are lacking in legumes, while legumes are rich in lysine, which is scarce in cereals (Staniak et al., 2014). Consuming legumes in combination with cereals greatly enhances the protein quality of legumes (Phillips, 1993).

Carbohydrates, which compose 30-60% of legumes, are the second most significant component in terms of nutrition and chemistry. The digestion of starch from legumes is slower compared to starches from tubers and grains. Legumes possess a low glycaemic index (GI) rating, making them appropriate for individuals at a heightened risk of developing diabetes and those who already have the condition (Elhardallou et al., 2013; Phillips, 1993). Legumes are a rich source of dietary fibre, with a content ranging from 5-37%. They include substantial levels of both soluble and insoluble dietary fibre (Kouris-Blazos & Belski, 2016; Phillips, 1993).

In addition, they contain significant quantities of vitamin E, as well as water-soluble vitamins from the B group, including thiamine, niacin, pyridoxine, pantothenic acid, and notably, folate. Furthermore, legumes contain substantial quantities of minerals like calcium, phosphorus, copper, magnesium, iron, zinc, selenium, and potassium, with potassium being the most prevalent among them (Caballero et al., 2015). Essential minerals have crucial physiological functions, including promoting bone health (Ca, P), regulating enzyme activity and iron metabolism (Cu), supporting carbohydrate and lipid metabolism (Cr, Zn), facilitating haemoglobin formation (Fe), and contributing to antioxidative activity, protein synthesis, and plasma membrane stabilization (Zn) (O et al., 2015). Several investigations have shown that the majority of the biologically active substances found in legumes have antioxidant capabilities. These substances are important in preventing chronic degenerative diseases such as hypertension, diabetes, heart disorders, osteoporosis, malignancies, and others (Ndidi et al., 2014).

Legumes include many antinutritional chemicals derived from proteins, such as enzyme inhibitors and lectins, as well as nonprotein components such tannins, phenolics, alkaloids, and phytates (Becerra-Tomás et al., 2018).They disrupt the capacity of certain minerals to be absorbed by the body and hinder the digestion of proteins, leading to negative physiological effects (Aguayo-Rojas et al., 2012) .

Additionally, legumes are considered to be functional foods due to the fact that they are nutrient-dense and offer components that contribute to the enhancement of health. This is because legumes are sources of complex carbohydrates, protein, dietary fiber, and folate, and they also include considerable quantities of vitamins and minerals (Cappa et al., 2018). Nevertheless, legumes are conventionally ingested via a series of procedures including soaking, boiling, and germination. Food processing can alter the nutritional composition of foods, leading to enhancements in their nutritional characteristics (López-Martínez et al., 2017).

1.2. Strategies for the Process of Germination

Germination is a widely used and effective method for enhancing the nutritional properties of seeds. The germination period and presence or absence of light are extrinsic elements that affect this process. These factors either accelerate or hinder the biochemical processes of seed reserve materials (Herrera, J., Alizaga, R., Guevara, E., 2006). In order for germination to occur, several favourable environmental conditions must be present: a moist substrate, sufficient oxygen for aerobic respiration, and an appropriate temperature for metabolic processes and seedling development (López-Amorós et al., 2006).

Germination initiates when the desiccated seed starts to absorb water, triggering a sequence of physiological processes involving cell membranes and metabolic activities in stage I. In stage II, germination concludes as the radicle emerges through the endosperm and the protective coat that enveloped it (Montemurro et al., 2019; Weitbrecht et al., 2011). Various seeds are germinated for human consumption, and the specific germination methods employed depend on the type of seed. These methods typically involve steps such as sterilizing, soaking, and sprouting.

1.2.1. Sterilization

Sterilization is conducted prior to seed soaking to prevent microbial proliferation; however, it is not mandatory for seed germination. The utilization of it will mostly rely on the state of the seeds and the objective of germination. The most frequently utilized sterilization agent for seed germination is a solution containing 0.07% NaClO (María Landete et al., 2015; Pająk et al., 2014). Additionally, ethanol or 70% ethanol has been reported to effectively sterilize seeds within a maximum sterilization period of 3 min (Embaby, 2010; Hooda & Jood, 2003). However, the majority of studies do not perform the sterilization process prior to soaking the seeds. This is likely due to concerns about the possible harmful effects of sterilizing chemicals on the seeds, as well as the potential dangers to food safety for consumers (Gan et al., 2017).

1.2.2. Soaking

Soak seeds in water to make them more water-soluble before they grow. Seeds should be soaked at different times and temperatures, and the weight ratio of the seeds should be followed. Between 24 and 30ºC, seeds can be soaked for 30 minutes to 24 hours at a time, with a water-to-seed ratio of 1:1 to 1:20 (w/v) (Gan et al., 2017; Ghanem et al., 2017; María Landete et al., 2015; Wang et al., 2005). Different conditions for soaking seeds should be linked to things about the seeds, like how thick their coats are, how big they are, and how much water they can hold.

1.2.3. Sprouting

In order to complete this stage of the process, it is essential to place the seeds in incubators or specialized germinators, taking into account parameters such as light, temperature, irrigation, humidity, and time (López-Martínez et al., 2017; Tuan et al., 2019). During the process of sprouting, numerous chemical transformations take place to convert stored carbs and proteins into the developing sprout. This results in the formation of simple carbohydrates, free amino acids, and necessary nutrients that are easily utilized by the body (Duenas et al., 2016). Hence, the process of sprouting greatly enhances the nutritional value of seed sprouts and reduces the presence of antinutrients like α-galactosidases, trypsin inhibitors, and phytic acid (Çavuşoğlu & Kabar, 2010) in the seeds. This makes legume sprouts easier to digest, less likely to cause flatulence, and improves their overall nutritional quality.

1.3. The Impact of The Germination Process on The Physicochemical Characteristics of Legumes.

Germination is an inexpensive method that is highly beneficial for enhancing the nutritional content of leguminous seeds. It improves the digestibility of proteins and carbohydrates, and also increases the concentration of certain vitamins such as riboflavin, niacin, and ascorbic acid. Additionally, germination helps eliminate or reduce the presence of non-nutritional substances found in the seed's reserve compounds (Vidal-Valverde et al., 2002).

Effective methods have been employed to enhance the nutritional and nutraceutical properties of legumes. This involves breaking down and breaking apart the primary nutrients, namely carbohydrates, proteins, and fatty acids. As a result, simple sugars, free amino acids, and organic acids are produced, while the digestibility of starch is increased. Additionally, the hydrolysis of oligosaccharides (raffinose and stachyose) takes place, and the presence of antinutritional and indigestible factors, such as protease inhibitors and lectins, is reduced (Caballero et al., 2015; Monteros et al., 2011; González-Montoya et al., 2018; Saleh et al., 2019). During germination, the levels of reducing sugars, soluble fibre, peptides, amino acids, and non-soluble phenolic compounds increase. However, the specific biochemical changes that occur during germination are influenced by factors such as temperature, humidity, time, light, and soaking (Hung et al., 2012; Koehler et al., 2007). In the process of germination, there is an increase in the quantity of phytase, an enzyme that is responsible for the decomposition of phytic acid (Reddy et al., 1982).

Additionally, germination aids in the reduction of non-nutritional substances such as trypsin inhibitors, lectins, tannins, and saponins. However, it is particularly effective in lowering chemicals like phytic acid, stachyose, and raffinose (El-Adawy, 2002). Germination enhanced the protein characteristics, resulting in a reduction in the surface tension at the air-water interface, facilitating the formation of foam (Kaur et al., 2015). The amphiphilic quality of the protein affects how the flour forms emulsions and how stable it is. The biomolecules around the oil drops changed the type of emulsion that was made. How stable an emulsion is depends on how well the proteins and lipids connect with each other. The stronger the interaction, the more stable the emulsion will be. The better quality of protein and fat in germinated legumes is what makes their emulsification traits better (Sibian et al., 2017). In addition, the process of germination enhances the ability to digest proteins, resulting in changes to the sequence of amino acids. This can result in the creation of peptides that have increased functionality and/or different biological activities compared to those found in ungerminated seeds (Souza Rocha et al., 2015; Saleh et al., 2019).

Sangronis & Machado (2007) found that germinated black beans (*Phaseolus vulgaris L.*), white beans (*Phaseolus vulgaris L.*), and pigeon beans (*Cajanus cajan L. Millsp*) showed a significant reduction in TIA, phytic acid, and tannins, as well as an increase in thiamine, protein digestibility, and ascorbic acid, when compared to their ungerminated seeds. In addition, it was discovered that the process of germination led to a considerable increase in the concentration of ascorbic acid by 300%, 208.4%, and 33.2% in white beans, pigeon beans, and black beans, respectively.

Ghumman, Kuar and Singh (2016) found that the process of germination improved the amount of protein, the ability to foam, the ability to absorb water, and the breakdown viscosity of lentil (Lens culinary) seeds. On the other hand, their stability in foaming, emulsifying, and gravity viscosities decreased. The found rise in protein content might be connected with the production of proteolytic enzymes, which break down proteins into amino acids, break down several compounds, and break down large molecules into simple peptides (Khalil et al., 1995; Uwaegbute et al., 2000).

Alonso et al. (2000), the process of germination enhanced the in vitro protein digestibility (IVPD) of common bean by 10.3%. The researchers determined that this increase could be related to the partial or complete elimination of antinutrients.

Uppal & Bains (2012) showed that germination led to an elevation in vitro protein digestibility in mung bean, chickpea, and cowpea. The rise ranged from 15% to 25% in mung bean and from 6% to 17% in both chickpea and cowpea, as compared to the seeds that were not germinated. In addition, they discovered that the in vitro starch digestibility had a considerable rise ($p<0.05$) following germination. The documented percentage rise ranged from 8 to 12% in mung bean, 9 to 11% in chickpea, and 10 to 13% in cowpea, in comparison to their respective unfermented seeds.

Sangronis & Machado (2007) found that the digestibility of black and white bean proteins rose by 3% following a 5 day germination period of the seeds.

Mubarak (2005) found that the levels of phytic acid and tannins in mung bean (Phaseolus aureus) seeds were dramatically decreased by the processes of germination and cooking, with a statistical significance of $p<0.05$. Both methods also greatly enhanced the in vitro protein digestibility of mung bean seeds. The enhanced digestibility can be related to the denaturation of protein, deactivation of trypsin inhibitors, and reduction of tannins and phytic acid levels resulting from the processes of germination and cooking.

Gaafar et al. (2017) found that extrusion heating of germinated chickpea seeds (*Cicer arietinum L.*) resulted in a notable reduction (p<0.05%) in the levels of protein and fat in the extrudes. However, the levels of fibre, ash, and carbs were not impacted. Additionally, they observed a substantial reduction in the levels of phytic and tannic acid, ranging from 40.64% to 46.07% and 40.46% to 44.88%, respectively.

Dikshit & Ghadle (2003)reported that the process of germination led to a significant enhancement in the digestibility of soy proteins, with an increase of up to 39%. Alonso et al. (2000)observed a rise in protein digestibility. Previous research has demonstrated that the presence of bean trypsin inhibitors decreases by 27% and 84% after a period of 2-3 days of germination, as shown in related studies (Alonso et al., 1998; Bishnoi & Khetarpaul, 1994; Hobday et al., 1973). Conversely, the red bean experiences a decrease in antitrypsin levels ranging from 17% to 63% following intervals of 1 to 10 days (Alonso et al., 2000; El-Hag et al., 1978; Sathe et al., 1983). Studies have shown that germination of lentils can lead to reductions in the range of 21 to 54% after 4 and 6 days, respectively (El-Mahdy et al., 1985). According to the studies conducted by Vidal-Valverde et al. (2002) and Frias et al. (1997), inhibitors are utilized as a source of energy for the growth and development of seedlings. In contrast, the reduction percentages in chickpea germinated for 3-6 days range from 24% to 83% (Bansal et al., 1988). According to Wilson (1980)the decrease in legumes may be caused by the enzymatic mobilization and breakdown of proteins, such as trypsin inhibitors, during the germination of the seeds. Nevertheless, Ryan (1983)'s research indicate that this decrease is not associated with any specific biochemical mechanism during seed germination.

Rusydi et al. (2012) conducted an analysis on the phytic acid content in germinated soybeans (at a temperature of 28°C for 48 hours) and non-germinated soybeans. They observed a reduction in phytic acid concentration from 63.35 to 49.58 mg/100g following germination. The decrease in phytate content could be attributed to the activation of the naturally occurring phytase enzyme during the germination process.

Crans et al. (1995) discovered that after 6 days of germination, beans and peas saw a 60% reduction in phytic acid. The varying reduction percentages observed in common bean and other legumes are likely attributed to the distinct methods by which phytic acid is broken down in each species, namely the differential activity of endogenous phytases. The reduction of phytic acid through hydrolysis increases the nutritional value of the seed. This process releases phosphorus that can be absorbed during digestion. Additionally, it enhances the bioavailability of minerals that are naturally linked to this compound as salts.

Jiang et al. (2013) observed a 50% rise in the overall phenolic content and a decrease of 27.5% and 35% in the levels of phytic acid and trypsin inhibitory activity, respectively, following a 50 hour germination period. A study has been conducted to examine the impact of germination on the composition and distribution of isoflavones in soymilk.

CONCLUSIONS

With the growing understanding of the importance of legumes around the world, their importance in human nutrition has increased. There are various methods of consuming legumes. One of these is the germination of legumes. Studies show that germinated legumes make minerals more accessible, proteins and important amino acids more digestible, and vitamins more available. It also makes starch, lipids, and antinutritional factors less present in legumes. Many studies show that the amount of phytic acid, an anti-nutritional factor, decreases with the germination of legumes. As a result, the germination of legumes is a cheap method and has many nutritional benefits.

ABSTRACT

Plants that are legumes are in the family *Leguminosae*. Chickpeas, lentils, beans and peas are the varieties of legumes that are consumed the most commonly in the worldwide. They have a high nutritional content and are an excellent source of proteins, dietary fiber, vitamins and minerals. The germination of legumes is a simple and inexpensive process. Recent research has shown that the process of germination can further enhance the medical and nutritional properties of legumes. In addition, germination has the potential to enhance human nutrition and health by preventing malnutrition and chronic diseases. This is because it can augment the levels of certain nutrients, bioactive compounds, and biological activities in edible seeds. Germination can accumulate various bioactive compounds in germinated legumes, such as g-aminobutyric acid (GABA), polyphenols and vitamins. Several biological activities, including as anti-inflammatory, antidiabetic, anticancer, antioxidant, antibacterial, antihypertensive and immunomodulatory capabilities, have been discovered for bioactive compounds as a result of their investigation. Overall, germinated legumes rich in bioactive compounds and nutrients can be considered for the prevention of some chronic diseases and malnutrition as functional foods. In this study, the effect of germination on bioactive components in legumes and their benefits for human health were examined.

Keywords: Bioactive compounds, Legumes, Germination of legumes, Human health

1. INTRODUCTION

Numerous bioactive compounds found in legumes may provide defense against metabolic illnesses (Raju & Mehta, 2008). Because they have so many bioactive ingredients, they are an essential cereal alternative, especially for those watching what they eat. They are therefore a great choice for people who are disease (Maphosa & Jideani, 2017). A popular conventional method that increases nutrient digestibility and boosts bioactive and anti-nutritional components while reducing some of the latter is germination (Rizvi et al., 2022). Depending on the seed type and the circumstances around germination, some changes may take place inside the seed during the soaking and germination process. The most effective method for lowering pulses' anti-nutritional chemicals is reported to be germination (Sangronis & Machado, 2007). Bioactive compounds like pantothenic acid, riboflavin, thiamine, biotin, biotin, essential amino acids, vitamin C, tocopherols, and phenolic compounds increase during

legume germination. It also increases the the accessibility of amino acids and the digestibility of protein (Donkor et al., 2012; Khatoon & Prakash, 2006). Along with insoluble phenolic chemicals, germination improvement also results in an increase in reducing amino acids, peptides, soluble fibers, and sugars (Hung et al., 2012; Koehler et al., 2007). Conversely, germination also aids in lowering the concentration of antinutritional elements such saponins, tannins, lectins, trypsin inhibitors, and alkaloids (El-Adawy, 2002).
Furthermore, because they are rich in nutrients and provide elements that support improved health, legumes are regarded as functional foods. This is due to the fact that legumes contain significant amounts of vitamins and minerals along with complex carbs, protein, dietary fiber, and folate (Cappa et al., 2018).

2. Impact of legume germination on bioactive compounds

Legumes are considered to be a viable economic and nutritionally significant part of the human diet. The variety of their nutritious components, which include complex carbohydrates (60%), dietary fiber (3-57%), and proteins (20-45%), shows to their quality. Furthermore, the fat content of legumes is generally low (~5%), with the exception of chickpeas (15%), and much higher (45-50%) in the case of peanuts and soybeans. Legumes also include a variety of bioactive substances that may offer protection against metabolic diseases (Raju & Mehta, 2008). Owing to their low glycemic index and a lot of bioactive components, they represent a vital substitute for cereals, particularly for individuals who are careful of their nutritional intake. As such, they are an excellent option for individuals with celiac disease and diabetes (Maphosa & Jideani, 2017).

The biological process of germination is one that results in the transformation of the embryo into a plant by enzyme activation in legumes, cereals, and pseudo-cereals. Three different phases can be recognized in germination (Aguilar et al., 2019; Cho & Lim, 2016). The dry grain rapidly absorbs water in the first phase (phase I), which causes hydration and activates intercellular enzymes. This starts the metabolic processes that have been inactive to resume, and then there is a period of restricted water absorption. Important irreversible metabolic processes occur during Phase II, such as the mobilization of resultant small molecules (low molecular weight proteins and peptides, fatty acids, sugars), to various seed parts and the breakdown of reserve molecules by enzymes (high molecular weight proteins, triglycerides and starch). Phase III sees a modest rise in water content, particularly in the radicle cells that are increasing due to mitotic divisions and cell development in the seedlings. Some big seeds that have a significant molecular reserve may continue to absorb water after the radicles emerge. Genetic variations and compositional changes account for the variation in the pattern of water absorption, enzymatic reactions, and size among plant species (Choque-Quispe et al., 2021). According to research (Urbano et al., 1995; Vidal-Valverde et al., 2002, 2003), legumes that have undergone germination tend to have higher levels of dietary fiber, accessible carbohydrates, free amino acids, and other nutrients while having fewer antinutritive chemicals present. It also increases the levels of bioactive compounds like phenolics and flavonoids, which increases nutrient absorption (Miyahira et al., 2021).

Antinutrient content is decreased during the germination phase, whereas antioxidant component content and release-such as those of vitamins, polyphenols and minerals are greatly increased. This could be as a result of germination increasing content by release (e.g., cotyledon cell structure disintegration activates hydrolytic enzymes) or biosynthesis (e.g., de novo production of vitamins or polyphenols) (Alkaltham et al., 2020). Starch digestibility rises as a result of the breakdown of fats and carbohydrates, which are frequently consumed in abundance in western diets (Jyothi & PR, 1981; Subbulakshmi et al., 1976; Vidal-Valverde & Frias, 1992) Both dietary fiber and phytotic acid have an impact on the digestive tract's ability to absorb micronutrients, and they undergo distinct changes throughout the germination process (Pawar et al., 1986; Vidal-Valverde & Frias, 1992). Moreover, a recent study shown that the germination of lentils and fava beans enhances the release of bioactive peptides and amino acids during digestion. The length of time that seeds take to germinate, grow sprouts, and speed up the process of proteolysis are all significantly influenced by their permeability. Antinutrient degradation and seed microstructure disintegration affect protein digestibility and the release of bioactive peptides during digestion (Bautista-Expósito et al., 2021). During germination, the digestibility of protein in chickpea was twice as high as in raw chickpea (Milán-Noris et al., 2018) the amount of flavonoids and polyphenols also increased significantly (Gupta et al., 2017). During germination, the amount of oligosaccharides, α-galactosides that cause flatulence, and chymotrypsin and trypsin inhibitors that influence protein digestion can all be decreased (Frias et al., 1995; Urbano et al., 1995; Vidal-Valverde et al., 1994; Vidal-Valverde & Frias, 1992).

3. Benefits to human health of germinated legumes

3.1. Vitamins and Minerals

Prodanov et al. (1997) reported that the quantity of riboflavin, total accessible niacin and thiamine in faba beans and lentils changed depending on the frequency of washing, the availability of light, and the germination time when seeds were processed in a separating funnel at 20ºC. Vidal-Valverde et al. (2002) observed the germination of beans, peas, and lentils on different days, as well as the levels of total inositol phosphate, total soluble sugar, B1 and B2. As a result of the prolonged germination durations for all three species, the total vitamin B2 and sugar increased while the total inositol phosphate content and vitamin B1 dropped. Abdullah et al. (1984) observed a increase of ascorbic acid, riboflavin, thiamin and niacin after the germination of mung bean and soybean for 3 days. After peas germinated for six days in the dark, vitamin B1 declined by 83% while vitamin B2 became by two times, according to Sierra et al. (1999). The plant species, maturity, environment, harvesting and storage practices, and vitamin content all affect how long a seed takes to germinate and how much of it takes (Masood et al., 2014).

Urbano et al. (2006) observed that in their experiments where Mg and Zn sprouted at different periods in peas, their bioavailability was higher on the second and fourth days.

3.2. Antioxidant activity

Through the elimination of free radicals from cells, antioxidants play a vital part in preventing the deterioration of degenerative diseases and food. To protect cell membrane lipids from polyunsaturated fatty acid (PUFA) peroxidation, fat-soluble antioxidants like carotenoids and tocopherols work against in the aqueous phase, reactive oxygen species (ROS). Hydrophilic antioxidants, on the other hand, counteract ROS in the water phase. Both hydrophobic and hydrophilic phases of phenolic compounds, such as flavonoids, demonstrate antioxidant potential (Munteanu et al., 2021).

Antioxidant component content and availability may increase during germination; this can be attributed to the release of antioxidant chemicals from of the disintegration of cell walls or to the production of bioactive compounds by means of secondary metabolic pathways being activated. Loss of these compounds can sometimes be linked to low molecular weight polyphenolic compound polymerization, complex formation with proteins, or leaching during soaking (Bhinder et al., 2021).

Past research confirms that an increase in germination time correlates with an increase in antioxidant activity; López-Amorós et al. (2006a) also noted this pattern. In a similar vein, studies conducted by Saleh et al. (2019) provided evidence that an increase in germination time was connected to an elevation in antioxidant activity. The active macro and micro components that are already present in the seed are what are responsible for this increase in antioxidant capability.

The defenses that phenolic compounds provide against oxidative stress are crucial.(Gopi et al., 2007; Pedranzani et al., 2007). The content of phenolic compounds in germinated beans was positively connected to an intensify in antioxidant capability. After five days of germination, the phenolic compound content of ungerminated seeds significantly increased in soybeans, beans and peanuts.(Tan Khang et al., 2016).

The TPC (Total Phenolic Compound) of pulses (red lentil, chickpea and kidney bean) varied for non-germinated grains, ranging from 0.6 to 1.1 g/kg, per (Mamilla & Mishra, 2017). Due of the thicker seed coat and enhanced polyphenol oxidase activity, which decreased water absorption, germination changed the TPC of red lentil and chickpea but not kidney beans (Boesewinkel & Bouman, 2018).

Depending on the pulse, the TPC increased during germination at 30ºC and 40ºC, respectively, between 0.8 and 1.82 g/kg and 0.75 to 1.1 g/kg. Lin & Lai (2006) made similar observations. At 40ºC, the antioxidant activity (AA) was at its greatest. With germination, the total flavonoid content (TFC) of the following increased: 0.19 to 0.32 g/kg for kidney beans, 0.17 to 0.25 g/kg for red lentils, and 0.22 to 0.42 g/kg for chickpeas. At 30ºC for chickpea germination, and 40ºC for red lentil and kidney bean germination, TFC rose. These variations might result from variations in how the germination rates depend on temperature.

Legume species belonging to Homogalgena (lentil and chickpea) often have a lower germination temperature (30ºC) than phaseoloid-clad legumes (kidney bean) (Mierziak et al., 2014). The antioxidant activity and phenolic content of lentils that have germinated have been investigated by Gharachorloo et al. (2013) . The total phenolic content of sprouted lentils was found to be higher (78 mg/kg) than that of raw lentil seeds (53 mg/kg) after 5 days of germination.

Cevallos-Casals&Cisneros-Zevallos (2010) measured the concentrations of phenolic compounds in faba seeds at various stages of germination. 7 days sprouts>dormant seeds>ingested seeds was the general trend distribution of accumulated phenolics and total antioxidant capacity. Seeds are an excellent source of phenolic antioxidants for food because the phenols released during germination may lead to greater phenol concentrations and antioxidant activity.

The investigation conducted by López-Amorós et al. (2006b) looked at how germination affected the phenolic profile. The results of the study demonstrated that the process of germination altered the phenolic profile of the legumes, affecting both the flour's functional qualities and antioxidant capacity. According to Sokrab et al. (2012), germination causes the phenolic content of germinated seeds to become soluble, which causes its content to increase. Furthermore, as evidenced by the browning of the germinated seeds, Sokrab et al. (2012) and Duenas et al. (2009) found that germination causes condensed tannins to become soluble and phenolic compounds to move to the outer layer. Consequently, the germinated seeds exhibit an increase in their overall phenolic content. Additionally, during seed germination, the enzyme systems are activated and mobilized, which decreases the concentration of the hydrophilic component of the seed and, therefore, the amounts of tannin, anthocyanin, and total phenolics. (Sokrab et al., 2012).

Chauhan et al. (2022) studied how black soybean nutrients, anti-nutrients, and bioactive components were affected by soaking, germination, fermentation, and roasting. The phenolic contents increased dramatically (p<0.05) throughout germination, roasting and fermentation according to the results. During germination and fermentation, treated grains exhibited a considerable (p<0.05) increase in antioxidant activity. Phytic acid and tannin levels, two anti-nutritional chemicals, dramatically dropped following processing. The primary causes of the surge in sprout intake are convenience and complex physiological modifications that enhance the nutritional profile and reduce absorption-hindering antinutrients.

CONCLUSIONS

The germination process means sprouting legumes (such as chickpeas, lentils, beans) and this process can lead to various positive changes in their nutritional values. The germination process increases the proteins' bioavailability and digestibility, increases the levels of some vitamins and minerals such as vitamin C, vitamin B, folate and antioxidants, and reduces antinutritional factors in legumes. The bioactives that come from legumes undergo major modifications as a result of the germination process.

The health benefits of these bioactives have been demonstrated in various studies. However, the health effects of germination and legume-based products need further in vitro and in vivo research.

ABSTRACT

In this study, it was aimed to determine some physicochemical properties of fruits and seeds of Viburnum L. species collected in two different years and grown naturally in different provinces of Turkey (Kayseri/Melikgazi, Ankara/Yenimahalle, Amasya/Taşova, Balıkesir/Erdek) and to determine the oil yield and mineral substance contents of the seeds and to compare between species. According to the results of the study, when the averages of the two-year data of the fruits of Viburnum species were evaluated, the averages of moisture content, ash content, dietary fiber content and protein content varied between 7,10-8,83 %, 2,44-5,64 %, 35,92- 65,03 g/100g, 2,35-3,88 %, respectively. On the other hand, when the averages of the two-year data of the seeds of Viburnum species were evaluated, seed length, seed width, thousand grain weight, fruit flesh/seed weight, moisture content, ash content, dietary fiber content, protein and fat content, respectively; 5,19- 7,52 mm, 3,89- 7,06 mm, 25,73- 35,21 g, 1,74- 6,56, 6,40- 7,54 %, 1,49- 2,88 %, 58,07- 71,62 g/100g, 7,84-10,79 %, 7,92-18,83 %, respectively. In addition, the mineral matter concentrations of the seeds of Viburnum L. species were analyzed by Inductively Coupled Plasma Mass Spectrometry (ICP-MS). It was determined that each of the species was rich in Ca, K, Mg, P minerals and also had a significant content of Al, Fe, Zn minerals.

Keywords: *Viburnum* L., Fruit, Seed, Physicochemical, Food

INTRODUCTION

The genus *Viburnum* L., belonging to the family *Adoxaceae*, comprises approximately 200 species of small trees and shrubs. These species are distributed in temperate and subtropical regions ranging from South America to Southeast Asia (Ran et al., 2020; Xiang et al., 2020). In Turkey, the genus *Viburnum* L. is represented by four species: *Viburnum opulus* L., *Viburnum lantana L.*, *Viburnum orientale Pallas*, and Viburnum tinus L. (Altun et al., 2010; Davis, 1970). The most extensively studied species include *Viburnum opulus* L., *Viburnum tinus* L., *Viburnum lantana* L., and *Viburnum orientale Pallas* (Konarska and Domaciuk, 2018; Wang et al., 2010).

The edible dark red fruits of *V. opulus* are used to produce a traditional beverage called "gilaburu" in Central Anatolia (Baytop, 1999). The fruit yield per tree is approximately 8,4 kg, and the juice yield is about 43,5% (Alizadeh et al., 2007; Davis, 1970). Gilaburu is harvested in October and November in Turkey and is used to make dried fruit, pickles, and jam (Alizadeh et al., 2007; Kalyoncu et al., 2013). Gilaburu (*Viburnum opulus* L.), primarily grown in Kayseri and its surroundings, is a fruit with high levels of vitamin C and phenolic compounds, and due to its valeric acid content, it has a strong, distinctive taste (Dinç et al., 2012). In a study conducted with genotypes of *V. opulus* in Gümüşhane province of Turkey, it was reported that the most abundant organic acids in gilaburu fruits were tartaric acid (98-114 mg/100g) and malic acid (85-130 mg/100g), while fumaric acid (7-15 mg/100g) and succinic acid (3-9 mg/100g) were found in small amounts (Ozrenk et al., 2020). Another study reported that the dry content of gilaburu fruit contained 7,81% water-soluble dry matter, 5,83% reducing sugar, 6,71% crude protein, 9,86% dietary fiber, 560 mg/kg ascorbic acid, and 402,62 mg/kg sodium (Herrera, 1987).

V. lantana is notably rich in protein, saponins, and volatile oils (Konarska and Domaciuk, 2018). In a study examining the scavenging effects of plant extracts on superoxide anion at three different concentrations (2,5, 5, and 10 mg/ml), it was found that although *V. lantana* fruit extract did not show any scavenging activity on superoxide anion at the tested concentrations, the branch extract of *V. lantana* exhibited a strong superoxide radical scavenging effect (IC50 3,1 mg/ml) (Levent Altun et al., 2008). When the essential oil compositions of *V. opulus* and *V. lantana* were examined, the main components of *V. opulus* were identified as phytol (7,8%), trans-β-damascenone (4,9%), α-cadinol (4,8%), γ-cadinene (4,7%), Δ-cadinene (4,5%), and methyl pentanoate (4,1%). In contrast, the main components of *V. lantana* were occidenol (6,3%), α-cadinol (5,6%), γ-cadinene (4,6%), 2E,4E-decadienal (4,5%), n-heptanal (3,9%), and Δ-cadinene (3,4%) (Yılmaz et al., 2008). Essential oils obtained from the dried leaves of *V. orientale* were determined to have linalool (58,50%), α-terpineol (12,63%), and geraniol (12,53%) as the main components (Yürüker et al., 1995). In a study investigating the chlorogenic acid content of *V. orientale* and *V. tinus*, it was found that the highest chlorogenic acid content (0,5069%) was in *V. orientale* fruit samples, while the lowest chlorogenic acid content (0,0141%) was in *V. tinus* branches. Chlorogenic acid has strong antioxidative and free radical scavenging activities, enhances the resistance of LDL to lipid peroxidation, and prevents DNA damage. Therefore, it has been suggested that *V. orientale* fruits can be considered a good source of chlorogenic acid (Özbilgin et al., 2015). In a study investigating the antimicrobial activities of essential oils obtained from *V. opulus*, *V. lantana*, and *V. orientale* against *E. coli*, *K. pneumoniae*, *P. aeruginosa*, *E. faecalis*, *S. aureus*, and *B. cereus* bacteria and fungi, it was observed that the essential oils of *V. opulus* and *V. lantana* showed no antimicrobial activity against all tested microorganisms, while the essential oil of *V. orientale* exhibited weak antibacterial activity against Gram-positive bacteria *E. faecalis*, *S. aureus*, and *B. cereus* (Yılmaz et al., 2008).

Although information is available in the literature regarding the species *V. opulus*, comprehensive data on the physicochemical properties of fruits and seeds of other *Viburnum*

L. species are lacking. Accordingly, this study aimed to determine the moisture content, ash content, protein content, and dietary fiber content of fruit and seed samples of four different *Viburnum* L. species grown in Turkey, as well as some basic physical properties, crude oil content, and mineral content in seed samples. The differences between the species were identified through the analyses mentioned in the material and methods section.

MATERIAL AND METHODS

Materials

Fruit samples of four different *Viburnum* L. species used in the study were obtained over two consecutive years from four different provinces in Turkey (*V. opulus* L.-Kayseri, *V. lantana* L.-Ankara, *V. orientale Pallas*-Amasya, *V. tinus* L.-Balıkesir).

Preparation of Samples

The fruit samples of *Viburnum* L. species were weighed in the laboratory, and the seeds and fruits were separated from each other. The fruit pulp parts of the fruits from which the seeds were removed were dried. The seeds were washed with pure water, then drained and dried. All samples, once dried, were stored in cloth bags at +4 °C.

Methods

Analyses Performed on Fruits and Seeds

Ratio of Fruit Weight to Seed Weight

For each species brought to the laboratory, selected fresh fruit samples were weighed on a balance with 0,01 g accuracy, the seeds were removed, and the seed weights were determined. Then, for each sample, the ratio of fruit weight to seed weight was calculated.

Moisture Content

Dried and ground samples of 10 g of fruit and seeds were previously dried in an oven at 105 °C and weighed in desiccators until a constant weight was achieved. The moisture content of the fruit and seed samples was calculated as a percentage of weight loss. Analysis calculations were performed based on dry weight (Cemeroğlu, 2010). Other analyses were also based on dry weight according to the obtained moisture results.

$$\%\ Nem = \frac{(m_2 - m_3)}{(m_2 - m_1)} x100$$

m_1: Weight of dried empty drying container (g)

m_2: Weight of analysis sample and drying vessel (g)

m_3: Weight of the drying container with the analysis sample after drying (g)

Ash Content

Dried and ground samples of 3 g each of fruit and seeds were weighed in crucibles that had been dried and cooled, then placed in a muffle furnace at 750 °C until completely combusted. Subsequently, the ash content was calculated as a percentage (Cemeroğlu, 2007).

$$\% \, Kül = \frac{(m_2 - m_1)}{\mathrm{m}} x100$$

m_1= Weight of crucible brought to fixed weighing (g)
m_2= Crucible and ash weight after incineration (g)
m = Weight of sample taken (g)

Protein Content

Protein content in dried and ground fruit and seeds was determined using the Kjeldahl method. The amount of nitrogen (N) determined by the Kjeldahl method was multiplied by a factor of 6.25 to calculate the protein content (Kacar, 1994).

Dietary Fiber Content

Total dietary fiber content of dried and ground fruit and seeds was measured using the AOAC method (AOAC, 1985).

Analyses Performed on Seeds

Seed Size

The length and width measurements of homogeneously obtained seed samples were performed using a caliper.

Seed Weight per Thousand Seeds

Homogeneous samples of 1000 seeds were weighed on a balance with 0,01 g accuracy to determine the weight per thousand seeds (Aksoy, 1991).

Crude Fat Content

From dried and ground seed samples, 10 g were weighed into Soxhlet thimbles and placed in an extractor. 150 ml of n-hexane was added as a solvent, and the extraction was carried out for 6 hours at the solvent's boiling temperature. After the extraction process was completed, the solvent was removed, and the crude fat content was calculated based on dry weight (Ferrentino et al., 2020).

Mineral Content

From dried and ground seed samples, approximately 0,5 g samples were placed in a burning vessel, and 9 ml of pure HNO_3 and 1 ml of H_2O were added. The sample was digested in a Milestone Ethos UP microwave device at 210 °C and diluted to the desired volume with water. The concentrations were determined using ICP-AES (Agilent Technologies 7800 ICP-MS) (Skujins, 1998).

Statistical Analysis

All analyses were repeated at least twice. Comparison of the measured properties was carried out using one-way ANOVA and Tukey tests. Statistical analyses were performed using the Minitab 21 package program (Minitab, 2021).

RESEARCH FINDINGS AND DISCUSSION

In the context of this research, the physicochemical properties of the fruits of *Viburnum* L. species are given in Table 1.

Table 1. Physicochemical properties of fruits of *Viburnum* L. species

Tür	Hasat	Nem miktarı (%)	Kül miktarı (%)	Protein miktarı (%)	Diyet lif miktarı (g/100g)
Viburnum opulus L.	1. Yıl	9,47±0,39^{A}	2,80±0,24^{B}	2,22±0,08^{D}	37,05±1,63^{C}

±: Standard deviation; A-D: Statistical comparison of species within themselves in the 1st harvest year (at the $p<0.05$ level); a-d: Statistical comparison of species within themselves in the 2nd harvest year (at the $p<0.05$ level); **A-B**: Statistical comparison of harvest year averages of species within themselves (at the $p<0.05$ level).

Table 1. presents the moisture content, ash content, protein content, and dietary fiber content of the fruits of different *Viburnum* L. species. The two-year average moisture content of the fruits of all species was found to be 8,35% for *V. opulus*, 7,57% for *V. lantana*, 7,10% for *V. orientale*, and 8,83% for *V. tinus*. The analysis results showed a significant difference in moisture levels among the *Viburnum* L. species in the first harvest year. Specifically, the moisture content of *V. opulus* and *V. tinus* was found to be higher than that of *V. lantana* and

V. orientale. Similarly, a significant difference in moisture levels was also observed among the *Viburnum* species in the second harvest year. It was determined that the moisture content of *V. tinus* was higher than that of *V. opulus, V. lantana*, and *V. orientale* species. Previous studies in the literature have reported the moisture content of fresh *V. opulus* fruits. The moisture values presented in Table 1. reflect the results of moisture analysis conducted on dried fruits. According to the literature, Akbulut et al. (2008) reported the moisture content of fresh *V. opulus* fruits as 88,2%, while Cam et al. (2007) reported it as 89,16%. Therefore, the results obtained in our study cannot be directly compared with those in the literature because our analysis was conducted on dried fruits of *Viburnum* L. species.

The two-year average ash content of the fruits of all species was determined to be 2,44% for *V. opulus*, 3,23% for *V. lantana*, 5,64% for *V. orientale*, and 2,81% for *V. tinus*. In the first harvest year, a significant difference was observed in the ash content among the *Viburnum* L. species. Specifically, *V. orientale* had a higher ash content compared to the other species. Similarly, in the second harvest year, a significant difference in ash content was also observed among the *Viburnum* L. species. The highest ash content was found in *V. orientale*, while the lowest was in *V. opulus*. Previous studies in the literature have reported the ash content of the fruits of *V. opulus* species. According to these studies, the ash content of *V. opulus* fruits was reported as 0,38% by Cam et al. (2007), 0,11% by Kalyoncu et al. (2013), and 1,28% by Akbulut et al. (2008). Compared to these reported results, the ash content of *V. opulus* fruits was found to be higher in our study.

The two-year average protein content of the fruits of all species was determined to be 2,47% for *V. opulus*, 3,51% for *V. lantana*, 3,88% for *V. orientale*, and 2,35% for *V. tinus*. In the first harvest year, a significant difference was observed in the protein content among the *Viburnum* L. species. Specifically, the highest protein content was found in *V. orientale*, while the lowest was in *V. opulus*. Similarly, in the second harvest year, a significant difference in protein content was also observed among the *Viburnum* L. species. It was determined that *V. tinus* had a lower protein content compared to the other species. Previous studies in the literature have only reported the protein content of *V. opulus* fruits. Ozrenk et al. (2020) reported that the protein content of the *V. opulus* genotypes they studied ranged between 5,67% and 6,71%. Akbulut et al. (2008) reported the protein content of *V. opulus* fruits as 6,48%. In our study, a lower protein content was found compared to these two studies. However, compared to another study conducted by Kalyoncu et al. (2013), which reported the protein content of *V. opulus* fruits in Turkey as 0,2%, a higher protein content was found in our study.

The two-year average dietary fiber content of the fruits of all species was determined to be 39,92 g/100g for *V. opulus*, 39,27 g/100g for *V. lantana*, 35,92 g/100g for *V. orientale*, and 65,03 g/100g for *V. tinus*. In the first harvest year, a significant difference was observed in the dietary fiber content among the *Viburnum* L. species. Specifically, the highest dietary fiber content was found in *V. tinus*, while the lowest was in *V. orientale*. Similarly, in the second harvest year, a significant difference in dietary fiber content was also observed among the *Viburnum* L. species. The highest dietary fiber content was found in *V. tinus*, while the lowest dietary fiber contents were found in *V. lantana* and *V. orientale*. Akbulut et al. (2008) reported the crude cellulose content of *V. opulus* fruits as 18,07%, and Kalyoncu et al. (2013) reported the crude fiber content as 6,56%. In a comprehensive morphological and biochemical characterization study of 14 *V. opulus* L. genotypes collected from Gümüşhane province in Turkey, the crude cellulose content of all *V. opulus* genotypes was reported to range between 16,6% and 18,7% (Ozrenk et al., 2020). According to the literature, the dietary fiber content of the *V. opulus* species was found to be higher.

Table 2.1. and Table 2.2. show the physicochemical properties of the seeds of *Viburnum* L. species.

Table 2.1. Physicochemical properties of seeds of *Viburnum* L. species

Tür	Hasat	Çekirdek boyu (mm)	Çekirdek eni (mm)	Bindane ağırlığı (g)	Meyve ağırlığı/ Çekirdek ağırlığı	Nem miktarı (%)

±: Standard deviation; A-D: Statistical comparison of species within themselves in the 1st harvest year (at the $p<0.05$ level); a-d: Statistical comparison of species within themselves in the 2nd harvest year (at the $p<0.05$ level); **A-D**: Statistical comparison of harvest year averages of species within themselves (at the $p<0.05$ level).

Table 2.1. presents the seed length, seed width, thousand seed weight, fruit weight/seed weight ratio, and moisture content of *Viburnum* L. species. The two-year averages of seed lengths for all species were determined as follows: *V. opulus* 7,52 mm, *V. lantana* 6,62 mm, *V. orientale* 7,44 mm, and *V. tinus* 5,19 mm. A significant difference was observed among *Viburnum* L. species in terms of seed length during the first harvest year. When examining this significant difference, it was found that the seed lengths of *V. opulus* and *V. orientale* were larger than those of *V. lantana* and *V. tinus*. A significant difference was also observed in the second harvest year in terms of seed length. In this significant difference, the species with the highest seed length was *V. orientale*, and the species with the lowest seed length was *V. tinus*. The two-year averages of seed widths for all species were determined as follows: *V. opulus* 7,06 mm, *V. lantana* 4,88 mm, *V. orientale* 5,77 mm, and *V. tinus* 3,89 mm. A significant difference was observed among *Viburnum* L. species in terms of seed width during both the

first and second harvest years. When examining this significant difference, it was found that the species with the highest seed width in both harvest years was *V. opulus*, and the species with the lowest seed width was *V. tinus*. In terms of shape, *V. tinus* has a spherical structure, while the other species have a flattened and oval structure. In the literature, Kalyoncu et al. (2013) reported the average seed length and width of *V. opulus* as 7,76 mm and 7,67 mm, respectively. These values are consistent with our study. Kaliniewicz and Choszcz (2021), in their study on different *Viburnum* L. species, reported the seed length and width of *V. lantana* as 9,89 mm and 6,90 mm, respectively. According to these reported values, the seed length and width in our study were found to be lower.

The two-year averages of the thousand-seed weights for all species were determined as follows: *V. opul*us 35,21 g, *V. lantana* 25,73 g, *V. orientale* 35,19 g, and *V. tinus* 32,09 g. A significant difference was observed among *Viburnum* L. species in terms of thousand-seed weight during the first harvest year. When examining this significant difference, it was found that the species with the highest thousand-seed weight was *V. orientale*, and the species with the lowest thousand-seed weight was *V. lantana*. A significant difference was also observed in the second harvest year in terms of thousand-seed weight. In this significant difference, the species with the highest thousand-seed weight was *V. opulus*, and the species with the lowest thousand-seed weight was *V. lantana*. In the literature, Alizadeh et al. (2007) reported the thousand-seed weight of *V. opulus* as 76,57 g in terms of wet weight. Keskin and Kaya (2011) stated that the weight of a single seed of *V. opulus* ranges between 0,104-0,112 g in terms of wet weight. Kaliniewicz and Choszcz (2021) reported that the weight of a single seed of *V. lantana* ranges between 32-37 mg in terms of dry weight, while the weight of a single seed of *V. opulus* ranges between 27-32 mg. These values are consistent with the values determined in our study.

The two-year averages of the ratios of fruit weights to seed weights for all species were determined as follows: *V. opulus* 6,56, *V. lantana* 3,44, *V. orientale* 3,08, and *V. tinus* 1,74. A significant difference was observed among *Viburnum* L. species in terms of the ratio of fruit weight to seed weight during both the first and second harvest years. When examining this significant difference, it was found that the species with the highest ratio of fruit weight to seed weight in both harvest years was *V. opulus*, and the species with the lowest ratio was *V. tinus*. Upon reviewing the literature, no studies were found that reported the ratio of fruit weight to seed weight for *Viburnum* L. species, but values for the wet weight of a single seed and a single fruit of *V. opulus* were encountered. Apart from the ratio of fruit weight to seed weight mentioned in Table 2.1., the fresh fruit and seed weights in terms of wet weight for all *Viburnum* L. species were also determined. In this context, the two-year averages of the fresh single fruit weights of *Viburnum* L. species were determined as follows: *V. opulus* 0,60 g, *V. lantana* 0,19 g, *V. orientale* 0.,32 g, and *V. tinus* 0,15 g The two-year averages of the fresh single seed weights of *Viburnum* L. species were determined as follows: *V. opulus* 0,09 g, *V. lantana* 0,05 g, *V. orientale* 0,11 g, and *V. tinus* 0,08 g. Ozrenk et al. (2020) reported that the fresh fruit weights of *V. opulus* range between 0,53-0,86 g, while Keskin and Kaya (2011) indicated that they range between 0,765-0,768 g Kalyoncu et al. (2013) reported the fresh single fruit weight of *V. opulus* as 0,87 g, and Akbulut et al. (2008) reported it as 0,65 g Kalyoncu et al. (2013) also reported the single seed weight of *V. opulus* as 0,08 g in terms of wet weight. These reported values are consistent with the values determined in our study.

The two-year averages of the moisture content of seeds for all species were determined as follows: *V. opulus* 6,40%, *V. lantana* 7,47%, *V. orientale* 6,82%, and *V. tinus* 7,54%. A significant difference was found among *Viburnum* L. species in terms of seed moisture content during the first harvest year. When examining this significant difference, it was found that the moisture content of *V. tinus* was higher than that of the other species. In the second harvest year, no significant difference was found in terms of seed moisture content. In the literature, Cam et al. (2007) reported the moisture content of seeds in fresh *V. opulus* fruits as 9,31%. Yunusova et al. (2004) examined some changes in *V. opulus* seeds during storage under natural conditions and reported that the seed moisture content ranged between 5,3% and 9,3%. These reported values are consistent with the values determined in our study.

Table 2.2. Physicochemical properties of seeds of *Viburnum* L. species (continuation of Table 2.1.)

Tür	Hasat	Kül miktarı (%)	Protein miktarı (%)	Ham yağ miktarı (%)	Diyet lif miktarı (g/100g)

	2.Yıl	2,72±0,03^{a}	10,37±0,06^{ab}	8,08±0,21^{c}	60,18±1,28^{b}
	Ortalama	2,88±0,22$^{\mathbf{A}}$	10,79±0,59$^{\mathbf{A}}$	7,92±0,23$^{\mathbf{C}}$	58,07±2,99$^{\mathbf{A}}$

±: Standard deviation; A-D: Statistical comparison of species within themselves in the 1st harvest year (at the $p<0.05$ level); a-d: Statistical comparison of species within themselves in the 2nd harvest year (at the $p<0.05$ level); **A-C**: Statistical comparison of harvest year averages of species within themselves (at the $p<0.05$ level).

Table 2.2. presents the ash content, protein content, crude fat content, and dietary fiber content of the seeds of *Viburnum* L. species. The two-year averages of the ash content of seeds for all species were determined as follows: *V. opulus* 1,81%, *V. lantana* 1,49%, *V. orientale* 2,25%, and *V. tinus* 2,88%. A significant difference was found among *Viburnum* L. species in terms of ash content during both the first and second harvest years. When examining this difference, it was found that the species with the highest ash content in both years was *V. tinus*, while the species with the lowest ash content was *V. lantana*. In the literature, Elagamey et al. (2013) reported that the ash content of grape seeds in certain varieties ranges between 2,52-2,68%. Polka et al. (2019) studied *V. opulus* in terms of its fruit, flower, and bark, and found

the ash content to be 2,96 g/100g, 4,07 g/100g, and 9,32 g/100g in dry weight, respectively. In the literature, the ash content of *V. opulus* seeds was reported only by Cam et al. (2007), who stated that the ash content of *V. opulus* seeds was 1,68%. The values obtained in our study are consistent with those reported in the literature.

The two-year averages of the protein content of the seeds for all species were determined as follows: *V. opulus* 10,76%, *V. lantana* 7,84%, *V. orientale* 9,68%, and *V. tinus* 10,79%. A significant difference was found among *Viburnum* L. species in terms of protein content during the first harvest year. When examining this difference, it was found that the protein content of *V. lantana* was lower compared to the other species. A significant difference was also found among *Viburnum* L. species in terms of protein content during the second harvest year. Again, the protein content of *V. lantana* was found to be lower compared to the other species, while the highest protein content was observed in *V. opulus*. In the literature, Yunusova et al. (2004) examined some changes in the seeds of *V. opulus* during storage under natural conditions and reported that the protein content in the seeds ranged between 4,9% and 6,0%. Elagamey et al. (2013) reported that the protein content of grape seeds in certain varieties ranged between 6,51% and 7,71%. Yan et al. (2020) reported that the seeds of *Cinnamomum camphora* contained 19,34% protein. In the literature, only the protein content of *V. opulus* among the species studied in our research was reported, and when compared with our findings, the values obtained in our study were found to be slightly higher.

The two-year averages of the crude fat content of the seeds for all species were determined as follows: *V. opulus* 13,12%, *V. lantana* 13,89%, *V. orientale* 18,83%, and *V. tinus* 7,92%. Significant differences were found among *Viburnum* L. species in terms of crude fat content during the first harvest year. When examining these differences, the species with the highest crude fat content was *V. orientale*, and the species with the lowest fat content was *V. tinus*. Significant differences were also found among *Viburnum* L. species in terms of crude fat content during the second harvest year. When examining these differences, it was found that the crude fat content of *V. opulus* and *V. lantana* was lower than that of *V. orientale* but higher than that of *V. tinus*. In the literature, Yunusova et al. (2004) examined the fat content in the dry weight of *V. opulus* seeds during eleven months of storage under natural conditions and reported fat content ranging from 12,1% to 15,1%. Cam et al. (2007) reported the fat content of *V. opulus* seeds as 13,88%. In a study on the seed oil of a different fruit, the Zivzik pomegranate, an average fat content of 19,48% was obtained through Soxhlet extraction (Yeniçeri et al., 2020). The crude fat content obtained in our study for the *V. opulus* species is consistent with the results of studies reported in the literature.

The two-year averages of the dietary fiber content of the seeds for all species were determined as follows: *V. opulus* 63,61 g/100g, *V. lantana* 71,62 g/100g, *V. orientale* 59,04 g/100g, and *V. tinus* 58,07 g/100g. Significant differences were found among *Viburnum* L. species in terms of dietary fiber content during the first harvest year. When examining these differences, it was found that the dietary fiber content of *V. lantana* was higher compared to all other species. Significant differences were also found among *Viburnum* L. species in terms of dietary fiber content during the second harvest year. When examining these differences, it was found that the dietary fiber content of *V. opulus* and *V. lantana* was higher compared to the dietary fiber content of *V. orientale* and *V. tinus*. In the literature, Kalyoncu et al. (2013) reported 6,56% crude fiber in the seeds of *V. opulus*. Kamel et al. (1985) reported the dietary fiber content of watermelon (*Citrullus vulgaris*) and grape (*Vitis vinifera*) seeds as 47,7% and 38,6%, respectively. The results obtained in our study were found to be higher than those reported in the literature.

Tables 3.1. and 3.2. show the mineral content of *Viburnum* L. species seeds and the average harvest years of mineral content of *Viburnum* L. species seeds.

±: Standard deviation; A-D: Statistical comparison of species within themselves in the 1st harvest year (at the $p<0.05$ level); a-d: Statistical comparison of species within themselves in the 2nd harvest year (at the $p<0.05$ level); A-C: Statistical comparison of harvest year averages of species within themselves (at the $p<0.05$ level); -: Could not be determined.

When examining Table 3.1., the two-year averages of the macro minerals found in the seeds of *Viburnum opulus* L., *Viburnum lantana* L., *Viburnum orientale Pallas*, and *Viburnum tinus* L. species were determined as follows: Sodium (Na) mineral, 294685,73 ppb, 264084,66 ppb, 449832,51 ppb, 331361,55 ppb, respectively; Potassium (K) mineral, 7507134,88 ppb, 5703430,77 ppb, 10978999,20 ppb, 14310484,83 ppb, respectively; Calcium (Ca) mineral, 1,097535,43 ppb, 885633,21 ppb, 1073943,12 ppb, 1569977,49 ppb, respectively; Magnesium (Mg) mineral, 2876076,10 ppb, 1917113,06 ppb, 2645858,14 ppb, 2914929,58 ppb, respectively; and Phosphorus (P) mineral, 3083021,91 ppb, 2069287,35 ppb, 3662347,54 ppb, 2641958,80 ppb, respectively. In addition to these macro minerals, Boron (B), Aluminum (Al), Manganese (Mn), Iron (Fe), Copper (Cu), Zinc (Zn), Rubidium (Rb), Strontium (Sr), Tin (Sn), and Barium (Ba) minerals were also detected at certain levels in the seeds of all species. Among the macro minerals in the seeds, *Viburnum orientale Pallas* was determined to be the richest species in terms of Na and P, while *Viburnum tinus* was found to be the richest species in terms of Mg, K, and Ca. The ash content of the seeds was also found to be consistent with the mineral content, with *Viburnum tinus* L. and *Viburnum orientale Pallas* being the species with the highest ash content.

When examining the mineral content of *Viburnum* species, it was found that there are no mineral analyses of seeds in the literature, but analyses have been conducted on fruits. Kalyoncu et al. (2013) showed that the fruits of *Viburnum opulus* are rich in K, P, Ca, and Mg (10764,764 ppm, 1304,169 ppm, 1228,711 ppm, 1289,088 ppm, respectively). Akbulut et al. (2008) reported that the two highest minerals among 18 minerals were K and Ca (8420,00 ppm, 2441,00 ppm, respectively). Taşkin et al. (2019) showed that except for the copper mineral, the amounts of other minerals in the leaves of *Viburnum opulus* were higher than in its fruits and stems.

CONCLUSION

Based on these results, it has been determined that the identified physicochemical properties of *Viburnum* species can vary depending on the species and the harvest years. The fruits of *Viburnum* L. species are particularly rich in dietary fiber, and although the seeds of *Viburnum* L. species have low fat content, they are quite rich in protein, dietary fiber, and minerals, indicating that they possess functional properties. The results obtained from this study contribute to the literature on the species of the *Viburnum* genus growing in Turkey, benefiting many different scientific disciplines (biology, chemistry, food science, pharmacology, etc.).

Explanation

This full text has been prepared by the authors from a part of the ongoing doctoral thesis study of Benan DİNÇ GİRGİN.

ACKNOWLEDGMENT

The identification of the species of four different *Viburnum* L. samples used in this study in Turkey was carried out by Associate Professor Dr. Aslı KOCA from Hacettepe University, Faculty of Science, Department of Biology, Botany Division. I would like to express my gratitude to Associate Professor Dr. Aslı KOCA for her contributions to the study.

EDIBLE INSECTS AS ALTERNATIVE PROTEIN SOURCES

İsa EKİN[1], Nilgün ERTAŞ[1]

ABSTRACT

With the increase in the world's population, possible deficiencies in protein sources have come to the fore. Inadequacies in protein sources will also bring nutritional deficiencies. With the limited natural resources, the fact that accessible, affordable, nutritious, healthy, reliable and sustainable food production will become even more important in the future emerges. For this purpose, insects, seaweed, genetically modified organisms and artificial meat are thought to be used as food or food components needed as a protein source in the future. Although reasons such as not being accepted by the society and ethical concerns are among the factors preventing the commercialization of artificial meat, it is thought that artificial meat produced in a controlled manner can be presented as a healthier and safer production by reducing the risk of disease originating from raw materials. Algae, which are rich in protein, essential amino acids and vitamins, are also considered to be among the alternative food sources with their biomass and rich biodiversity. In addition, edible insects provide the opportunity for high-volume production in smaller areas with lower feeding costs and less waste compared to traditional meat production. In this context, the nutritional properties of edible insects, which are seen as alternative food or food ingredients and contain high amounts of bioactive substances as well as high protein content, are examined in this compilation study, focusing on their production and use as food and their effects on the environment and human health.

Keywords: Nutritional deficiencies, protein sources, edible insects, alternative foods.

INTRODUCTION

One of the concerns that has emerged today is the sustainable nutrition of people, which is becoming more important with the increase in the world's population. In order to feed the world population, which will reach approximately 9.1 billion people in the near future, the amount of food produced needs to be doubled on average (FAO, 2022). Considering that even today, 1.3 billion people do not have access to food; more than 2 billion people are affected by micronutrient deficiencies and cannot be nourished adequately, it is predicted that serious difficulties will be experienced in meeting the food requirement at an adequate level in the future and that production will need to be increased or new alternative sources will need to be found to feed the growing population (FAO, 2019; WHO, 2021). It has become necessary to develop new policies to prevent food scarcity caused by factors such as increasing environmental pollution, changing climates, increased migration from rural to urban areas, decreases in agriculture and animal husbandry, and food waste (Özertan, 2020). However, considering the limited resources, the carbon and water footprint of overproduction, and the limitations that global warming will bring, it becomes clear that new policies should be addressed from a different perspective (Andaç and Yılmaz Tuncel, 2023). In this respect, insect, microalgae and bacterial proteins that have high nutritional properties and environmentally friendly breeding conditions can be shown as alternatives to traditional protein sources (Van der Spiegel et al., 2013). Due to their high nutritional values and environmentally friendly breeding conditions, the consumption of edible insects as an alternative food source is recommended by the Food and Agriculture Organization of the United Nations (FAO, 2013; Aksoy and El, 2021). The ease of accessibility, high fertility rates, fast growth, being an economic source and being environmentally friendly play an important role in the acceptance of edible insects as sustainable food (Halloran et al., 2018). When the production of 1 unit of protein produced from beef, pork or chicken meat is compared with the production of the same amount of insect protein; It has been determined that with more cultivation area, more water and feed resource usage, greenhouse gas production is also quite high (Gahukar, 2016).

Although the concept of "entomophagy", which is not a new phenomenon for humans and means consuming insects as food, has a very old history, it has attracted considerable attention in recent years (Evans et al., 2015; Selçuk and Gencal, 2023). Archaeological findings prove that insects have a deep-rooted history throughout the evolutionary history of humans (Peniche, 2021). Although there are consumers who have a negative attitude towards edible insects, when the nutritional and culinary cultures of countries are examined, it is revealed that they can change over the years and that many products that are not consumed as food can become traditional foods. For example, frog meat consumption, which was previously only in the diet of the French, has become popular worldwide; lobster, which was considered worthless, was added to the diets of servants and prisoners as a punishment, but today it has begun to be defined as a food with high social value (Bukkens, 2005; Tao and Li, 2018). In addition, 'sushi', which was unknown in European countries until recently, has started to be consumed in many countries, including our country. These examples are an indication that cultures, habits and negative attitudes towards new foods may change in the future (Baş Aksoy and El, 2021).

With over one million known species, insects are the group with the most species diversity among animals. Interest in edible insects and the number of scientific publications on this subject have been increasing every year, especially since the 2010s (Del Mastro, 2021). Although the diversity of edible insects varies by region, the most frequently consumed insects are reported to be crickets, ants, mealworms, locusts, butterflies, moths, cockroaches and flies (FAO, 2013). The species and numbers of edible insects recorded in the world are given in Table 1.

Table 1. Edible Insect Species and Numbers

Class	Common Names	Number of species
Thysanura	Silverfish	1
Anoplura	Lice	3
Ephemeroptera	Mayflies	19
Odonata	Dragonfly	29
Orthoptera	Grasshopper, Cockroach, Cricket	267
Isoptera	Termites	61
Hemiptera	Half Wings	102
Homoptera	Cicadas, Dwarf Cicadas, Cotton Lice	78
Neuroptera	Nerve Wings	5
Lepidoptera	Butterflies, Moths, Silkworms, Caterpillars	253
Trichoptera	Crownflies	10
Diptera	Flies, Mosquitoes	34
Coleoptera	Beetles	468
Hymenoptera	Ants, Bees, Wasps	351
	Total	1.681

Ramos and Elorduy, (2005)

Although insects are common food in many parts of the world, they are viewed with suspicion by many Western consumers. However, it is believed that in the near future they will think otherwise. The main reason for turning edible insects into a normal food ingredient today is that they are delicious, nutritious, sustainable and healthy (Del Mastro, 2021).

Nutritional Properties of Edible Insects

Since the number of edible insect species exceeds 2000, the types and amounts of nutrients differ among species (Rumpold and Schlüter, 2013). Insects are rich in proteins, fats and dietary fibers and provide approximately 400-500 kcal of energy per 100 g depending on the species (Rumold and Schlüter, 2015). Insects have a protein content of 38% to 77% of their total dry weight. Many insect species have been reported to have higher protein content per 100 g dry weight (e.g. crickets 68.7%) than red meat (27.4%) or cod (28.5%) (Gahukar, 2011). A comparison of some edible insects in terms of nutritional values is given in Table 2.

Table 2. Comparison of some edible insects in terms of nutritional values

Nutrients	Cricket	Butterfly	Mealworm	Cockroach	Grasshopper	Fly	Ant
Moisture (%)	69.2	73.9	63.7	71.2	62.7	3.8	74
Ash (%)	3.6	3.7	3.3	4.3	3.2	8.6	6.5
Protein (%)	66.6	45.6	65.3	78.8	71.8	47	63.5
Oil (%)	22.1	35	14.9	20	10.2	32.6	13.5
Dietary fiber (%)	10.2	6.5	20.4	-	6.4	6.7	6.9

Baş Aksoy and El, 2021;USDA National Nutrient Database, 2015; Bukkens, 1997; Finke, 2007, 2013; Ramos-Elorduy and ark., 1997. Cırcır böceği (Acheta domesticus),Kelebek (Anaphe panda, larva), Un kurdu (Tenebrio molitor, yetişkin), Hamam böceği (Blatella germanica), Çekirge (Zonocerus sp.), Sinek (Hermetiaillucens, larva), Karınca (OIecophylla smaragdina).

Since insect proteins are highly digestible, consumption of insects can significantly increase the nutritional quality of human nutrition by contributing to total protein intake (Bukkens, 1997; Belluco et al., 2013). Almost all edible insect species meet the essential amino acid content (e.g. phenylalanine, tyrosine, tryptophan, threonine and lysine) recommended by the World Health Organization (2007) (WHO, 2007). The total fat content of insects varies between 2% and 62% (Williams et al., 2016). In terrestrial trials, edible insects have been reported to contain higher amounts of long-chain polyunsaturated fatty acids, especially omega-6 fatty acids, than aquatic insects (Fontaneto et al., 2011). The mineral content of edible insects also varies greatly among species. Insects are generally low in calcium and potassium. Crickets and grasshoppers are rich in magnesium; cricket powder has been found to contain high levels of magnesium, copper and zinc (Rumpold and Schlüter, 2013; Montowska et al., 2019). Although information on the vitamin content of edible insects is limited, it has been reported that some species contain relatively high levels of B complex vitamins (riboflavin, pantothenic acid and biotin) and have a low vitamin C content (Rumpold and Schlüter, 2013; Finke and Oonincx, 2014; Klaus and Yukiko, 2021). The exoskeleton of insects, which contains a significant amount of fiber, consists of chitin, a long-chain N-acetyl-glucosamine polymer that constitutes approximately 10% of the dry weight (Belluco et al., 2013; Van Huis et al., 2013).

It has been reported that the addition of edible insects to diets may have positive effects on health by increasing the gastrointestinal system and human immunity as well as reducing the risk of bacterial infections (Nowakawski, Miller, Xiao, & Wu, 2021). Chitosan, a form of chitin in particular, is considered as a functional food ingredient that provides potentially beneficial effects on wound healing, colonic and cardiovascular health, cholesterol reduction, and innate and adaptive immune responses (Prosky, 2000; Shahidi & Abuzaytoun, 2005; Lee et al., 2008; Tripathi & Singh, 2018; Klaus & Yukiko, 2021).

Production, Consumption and Environmental Impact of Edible Insects

Today, 92% of the insects consumed are traditionally collected from nature, while the rest are obtained as a result of industrial production (Demirci and Yetim, 2021). Different types of insects are collected from nature in regions with high temperatures. However, this sometimes causes the ecological balance to be disrupted. It has been reported that with the increase in edible insect consumption in the future, cultivation conditions should be provided under the name of mini-animal husbandry (Ramos Elorduy, 2006; Akpalu et al., 2009; Van Huis, 2015; Selçuk and Gencal, 2023). With the recommendation of the Food and Agriculture Organization of the United Nations (FAO) for the consumption of edible insects, many companies have established insect farms and started to raise insects under hygienic conditions (FAO, 2013). In addition, insects are ground into powder and put on the market under names such as insect powder or insect flour, and many companies producing insect-based foods have started to produce this product, which is in the form of flour, by adding it to foods (Van Huis, 2013). Since insects do not require advanced technology for production, they are thought to be a potential food production source for poor and technologically underdeveloped countries (Kibar, 2017).

In Thailand, where there are twenty thousand farms, it has been reported that 7,500 tons of insects are produced annually (Hanboonsong et al., 2013). Although in the West, they are mostly grown for pet food, some companies in the Netherlands also grow for human consumption (Van Huis, 2015). In Turkey, the only insect production farm in our country, established in Antalya for the sole purpose of producing animal feed, sometimes also meets the demands for human consumption (Selçuk and Gencal, 2023).

The market size of edible insects is estimated to be approximately 8 billion dollars by 2030 (Van Huis, Rumpold, Van Der Fels-Klerx, & Tomberlin, 2021). The export and import of edible insects in Southeast Asia and Africa is of great economic importance (Tanga et al., 2021). Although there are more than 1 million insect species worldwide, the insects that are particularly commercialized for human consumption are locusts and mealworms (FAO, 2021; Ponca-Reyes & Lessard, 2021; Andaç & Yılmaz Tuncel, 2023).

In Switzerland, where insects are considered food, insect-based hamburgers have become one of the accepted foods in the country as of 2017. In countries such as the USA and Canada, crackers and snacks made with insect flour are offered on the market (Van Huis, 2013). In Western countries, where insect consumption is associated with unhygienic or spoiled food; insects have never gained an important place in food cultures and are therefore not yet accepted as a source of protein (Megido et al., 2016). When insects are considered as food, two main different reactions occur in people. In countries where insects are traditionally consumed, insects are considered a valuable source of protein, while in Western cultures, insects are considered dirty, disgusting and dangerous (Jensen and Lieberoth, 2019). However, it has been reported that individuals are willing to change their thoughts about entomophagy if they are informed about its health and environmental benefits (Mancini et al., 2019).

Compared to traditional farm animals and poultry, insects support sustainability in terms of nutrition and environmental health due to reasons such as less greenhouse gas generation and less land and energy use (Muslu, 2020). Insects consume much less water compared to other animals. Production can be done in much smaller areas compared to the land used for raising farm animals (Smil, 2002; Ramos-Elorduy, 2008; Nelson et al., 2009; FAO, 2013; Van Huis, 2013; Gahukar, 2016; Halloran et al., 2016; Baş Aksoy and El, 2021). In addition, insects grow much more easily and in a shorter time than large animals and have a high fertility rate, which is important in terms of being a sustainable protein source. When the production of these two sources is compared, it has been reported that 2 kg of feed is spent to produce 1 kg of edible insects, while 25 kg of feed is spent to produce 1 kg of beef (Guine et al., 2021).

Since the consumption of insects as food causes concerns in terms of food safety, regulations should be made regarding the health effects of insects and their products, like other food products, and production hygiene (Van Huis et al., 2013). Microbiological, parasitological, chemical, toxicological and allergenic risks should be emphasized (Gahukar, 2011). Due to the high consumption of butterfly larvae, in a toxicological study conducted in Nigeria, untreated larvae showed toxic effects when given to mice. However, the possibility of neurotoxin effects was eliminated by boiling and drying the larvae in the sun (Akinnawo et al., 2002). Microbial risks associated with edible insects and their products can be significantly controlled by good hygiene practices to be applied during cultivation, harvesting, processing, storage and transportation (FAO, 2021). However, spores of pathogenic microorganisms, especially some genera such as Bacillus, may occur during production and cultivation (Osimani and Aquilanti, 2021). In addition, although the risks of foodborne viruses posed by the consumption of edible insects are limited, attention should be paid to the risk of virus contamination through feed. In addition, there are yeasts (Candida, etc.) and molds (Aspergillus, Alternaria, etc.) associated with edible insects (FAO, 2021).

The lack of a legal regulation that would allow the use of insects as food and feed is seen as the biggest obstacle to the industrial growth of this sector in developed countries. It is thought that the concept of “novel food” could pave the way for the use of insects as human food (Van Huis et al., 2013). Although some legal regulations and control mechanisms have been established regarding the hygiene and food safety of edible insects in countries such as the European Union, the United States of America and Canada, regulations on the subject are very rare or non-existent in continents such as Africa and Asia and in Mexico (Raheem et al., 2019; FAO, 2021; Andaç and Yılmaz Tuncel, 2023).

CONCLUSION

Today a significant portion of the animal protein demand worldwide is met through the traditional production of cattle, pigs and poultry. It does not seem possible to provide sufficient production due to the future population and demand growth of traditional production methods. In addition, it is understood that the negative results such as greenhouse gas emissions and high land and water usage caused by these low-yield traditional production methods may lead to major problems in the future. Adding edible insects and their products, which are environmentally friendly protein sources, to the diet is important in terms of meeting the increasing protein demand. However, insects will provide an alternative to animal proteins when produced on an industrial scale. For this purpose, it is necessary to increase the necessary research and development studies, to switch to industrial scale production, to eliminate food safety concerns and to make legal arrangements to provide a certain control mechanism. However, it should be taken into account that there are cultural differences regarding the consumption of edible insects in different regions.

NANOTECHNOLOGICAL APPLICATIONS in FOOD PACKAGING: IMPACT on FOOD SHELF LIFE

Hilal Soyocak , Nebahat Şule Üstün & Sadettin Turhan

Ondokuz Mayıs University / Department of Food Engineering

SUMMARY

Foods are packaged to protect them from various environmental influences such as heat, light, moisture, chemical and microbial contamination. Traditional packaging is a passive application that covers the food only to protect it from environmental influences. In this application, different materials are used to determine the most suitable packaging material for the food. Active packaging, which is a new approach in packaging, has been dveloped to extend shelf life of the food and to ensure minimum loss of food quality in this process. Nanotechnological applications, one of the latest strategies used in food packaging, is one of the active packaging methods. Nanotechnology is a field that deals with nano material with a size between 1-100 nm. Nanotechnologyical applications can be grouped as organic and inorganic according to their origin, as well as nanosheets, nanotubes and nanoparticle according to their size. Moisture and gas barrier properties and mechanical properties can be improved in edible films and coatings developed with nanotechnological applications. In addition, microbial and oxidative spoilage of foods can be prevened or delayed and thus the shelf life of foods can be extended. Nanoparticle added to the packaging material both improve the propeties of the food packaging material and ensure the sustained release of antioxidants and other active ingredients from the food surface. Metal nanoparticles such as silver, gold, titanium dioxide, magnessium oxide, zinc oxide are the most commonly used in packaging materials due to their antioxidant and antimicrobial properties. In this review, a broad summary of studies on the effect of nanotechnological processes applied to food packaging on the shelf life of various foods is presented.

Keywords: nanotechnology, nanoparticle, shelf life, active packaging

INTRODUCTION

Oxidation, which occurs during food storage and adversşy affects the shelf life, quality and nutritional value of the product, involves many complex chemical reactions. Various methods are used to eliminated thede negative effects and control oxidation. Elimination of pro-oxidants, addition of antioxidant agents, controlling storage conditions and using different packaging materials are examples of methods used to delay or prevent oxidation. Active packaging systems containing antioxidant agents to prevent food oxidations added directly to the product are more effective in preventing oxidation reactions that start on the food surface. Various nano materials are used to create antioxidant food packaging. These are nanoparticles, nano fibers, nano emulsions and nano crystals (Cheng et al., 2024). In foods packaged with edible films and coatings prepared with nanotechnological methods, even if the outer packaging material is opened, losses in properties such as nutrients, color and aroma of the food are reduced. The desired packaging property in food packaging is to have gas and moisture barrier properties an to be strong and biodegradable. Compounds such as bacteriocins and organic acids in packaging are obtained under diffucult conditions and have high sensitivity. Inorganic nanoparticles used in packaging Show strong antibacterial activity even at low concentrations and under extreme conditions. In the food industry, nanotechnology is used in food packaging to enhance packaging (improve physical properties), to create active packages (antioxidant, antimicrobial agents, etc.) and to create smart packages (pathogen detection, spoilage control, etc.). (Singh et al., 2017).

Active Packging in Food Packaging

We package food to protect it from various environmental influences such as heat, light, moisture, chemical and microbial contamination. Traditional packaging is a passive method of enclosing food to protect it from environmental factors. In these methods, different materials are used to determine the most suitable packaging material for the food. Avtive packaging, which is a new approach in packaging, has been developed to extend the shelf life of the food and to ensure minimum loss of food quality during this period. Active packaging systems are generally classified in two groups. These are active capture systems (absorbents) and active release systems (emitters) (Firous et al., 2021; Yıldırım et al., 2018).
Active packaging is defined by the European Comission as "the deliberate inclusion of ingredients that will release or absorb substances into the packaged food or the surrounding environment." Examples of ingredients included in the packaging material are antioxidants and antimicrobial agents. Traditionally, active ingredients are included in food. However, some disadvantages ocur in this case. For example, the ingredients added to the food have a negative sensory effect on the food or intraction between the added ingredient and the food components occurs, causeing the effect of the active ingredient to decrease. Active packaging aims to prevent such disadvantages. Some components used in active packaging can be listed as oxygen scavengers (iron, ascorbic acid, unsaturated hydrocarbon dienes, palladium, etc.), moisture scavengers, ethylene scavengers, antioxidants, carbon dioxide scavengers, antimicrobial agents and nanoparticle (Almasi et al., 2021; Firous et al., 2021; Yıldırım et al., 2018).
Different methods are used for active packaging of foods. (i) Placing pouches or pads containing the active ingredient in the package; this method is generally used for placing ingredients that are moisture retainers org as generators in the package. (ii) Coating the polymer surface with the active ingredient; this type of application is preferred in methods where heat sensitive components are used. The packaging material is coated with a thin layer of active ingredient. (iii) insertion of the active ingredient into the packaging polymer and the active ingredient. With the interaction between these functional groups, the active ingredients forms a strong bond with the polymer. However, there is a possibility of a decrease in the effect of the active ingredient in this method. (iv) polymers containing directly active ingredient; int his method, the active ingredients is added directly during the preparation of the polymer. Thus, the negative effect of the active ingredient is eliminated. Ths method is the most widely used method in active packaging. In packages prepared in this way, cotrolled release of the active ingredient is realized. All methods are schematized in Figure 1 (Almasi et al., 2021).

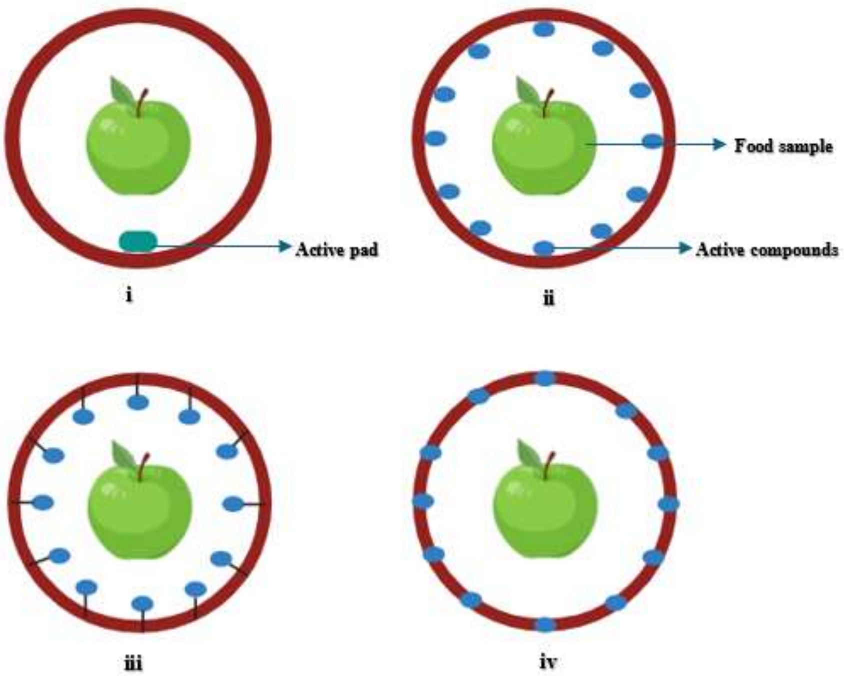

Figure 1. Active packaging methods

Nanotechnological Applications

Nanotechnological applications, one of the latest strategies used in food packaging, are gaining importance day by day. Nanotechnology is a field that deals with nano materials between 1-100 nm in size. Food packaging prepared with nanomaterials has many advantages compared to traditional methods. Nanoclays, one of the nanomaterials frequently studied by researchers, are preferred as food packaging due to their mechanical, thermal and barrier properties as well as their low cost. Nanoclays are composed of compounds such as montmorillonite, bentonite and kaolinite. Among these, montmorillonite and bentonite are recognized as GRAS by FDA (Almasi et al., 2021; He et al., 2019).
There are different classifications in nanotechnological applications. In the classsification accroding to their origin, they are divided into organic and inorganic, classification according to their size is in the form of nanosheets, nanotubes ans nanoparticle. With nano adible films and coatings developed with nanotechnological applications, it is desired to improve the moisture and gas barrier properties and mechanical properties of packaging. In addition, it is aimed to prevent or delay microbial and axidative spoilage of food and thus increase its shelf life. Nanotechnological applications are gaining importance especially fort he shelf life of fresh fruiys and vegetables that continue active respiration during transportation and storage efficiency in fruits and vegetables that continue active respiration. Studies of nano materials with features such as pesticide control, pathogen detection, toxin detection in active packaging with nanotechnology are carried out (Almasi et al., 2021; He et al, 2019).

The main reason for using nanotechnological applications is to improve the thermal, machanical and barrier properties of the developed packaging material. Active nanocomposite films are divide into two categories; (i) films containing nanostructured materials and (ii) films containing nanostructured materials as well as active components (Almasi et al., 2021):
Metal and metal oxide nanoparticles can be used in different applications in various fields. Nanoparticle synthesis can be categorized as physical, chemical and biological methods. Among biological synthesis methods, nanoparticle synthesis in plant extract media enables both the reduction of toxic by-products and the improvement of nanoparticle size tunng. Researchers believe that flavonoids in particular play an important role in the synthesis of many bioactive compounds found in plant extract media (Jeevanandam et al., 2016).
Biomedical and bioprocess applicaations are realized in the biological synthesis of nanoparticle. It has been determined that the toxic effect of metal nanoparticle obtained by this method is less. Three methods are used in the biological synthesis of nanoparticle. The first of these is the bacterial synthesis method. In this method, nanoparticle synthesis is carried out using different bacteria (Bacillus licheniformis, Pseudomonas meridiana, Lactobacillus casei, Shewanella alga, etc.). Researchers report that proteins, enzymes and other biochemicals play a role in nanoparticle synthesis in bacterial media. The biggest advantage of this method is that it allows the synthesis of large amounts of nanoparticles without the use of expensive and hazardous chemicals. However, it has the disadvantages of being time-consuming and not being able to control the properties of the nanoparticles such as size, shape and crystallinity. The second biological synthesis emthod is fungal synthesis. Fungi can be used as biological agents in the synthesis of metal and metal oxide nanoparticles thanks to their various intracellular enzymes. It has been determined that fungi have a higher ability to synthesize nanoparticle compared to bacteria. The advantages of nanoparticle synthesis by this method can be listed as having high metal retention capacity, producing high amounts of enzymes per biomass unit, and the growth of fungi on the surface of inorganic subsrates facilitates the dispersion of the metal. However, in addition to these advantages, the fact that it is time-consuming (fungal growth takes 24-120 hours) can be said to be a disadvantage compared to other methods. Nanoparticle synthesis in plant environment is the third group of biological methods. Plant biodiversity offers exciting biochemical and yield-specific resources for nanoparticle synthesis. Apart from bacteria and fungi, plant extracts are an important sources for nanoparticle synthesis. Studies on plant extract media have revealed the presence of many bioactive compounds such as alkaloids, amino acids, chelating proteins and these compounds enable the redustion of metal ions to nanoparticles. Nanoparticle synthesis from plant extracts takes under specific conditions. Temperature, pH and salt concentration are the main factors affectingnanoparticle synthesis (Jeevanandam et al., 2016).
Plant leaf extract are widely available, safe to use and have various metabolites that act as reducing agents in nanoparticle synthesis. The natüre of the plant leaf extract such as phytochemical concentration, metal salt concentration, pH, temperature and contact time are known to affect the nanoparticle production rate, production quantity, stability and quality. The main phytochemicals present in plant extract and responsible fort he synthesis of nanoparticle have been identified as terpenoids, flavones, ketones, aldehydes, amides and carboxylic acids (Jeevanandam et al., 2016).

Flavanoids are in the group of polyphenolic compounds and include compounds such as anthocyanins, isoflavonoids, flavonols. These compounds have the ability to actively chelate metal ions and reduce them to nanoparticles. Researchers predict that the flavonoid content in plant extracts serve as an important factor for the formation of metal oxide nanoparticles. Flavonoids stabilite the nanoparticles anda re important for reducing the toxicity of the nano-formulation. Since flavonoids possess antioxidant properties, the formation of reactive oxygen species produced by metal oxides can be reduced (Jeevanandam et al., 2016).

Nanotechnology has a wide range of applications in various fields of science and technology. Many nanoparticles attract the attention of various fields with their antimicrobial effect. Studies have shown that nanoparticles such as silver, silver oxide, titanium dioxide, silicon, copper oxide, zinc oxide, gold, calcium oxide and magnessium oxide have antimicrobial activity. For example, it has been determined that small nanoparticle have higher antimicrobial activity. Calcium oxide nanoparticle has a strong antimicrobial effect with its active oxygen and basicity (Dizaj et al., 2014).

Nanofibers, another nanotechnological method used in food packaging are linear materials with diameters less than 1000 nm and high length/diameter ratio. They can be prepared by methods such as high shear machanics, deep eutectic solvent and electrospinning. Among the nanofiber preparation methods, electrospinning is gaining importance due to its easy, continuous production and operation at room temperatures. Both natural polymers (gelatin, ethyl cellulose, starch, etc.) and chemically synthesized polymers (polyvinyl alcohol, policapro lactone, etc.) are suitable for nanofiber preparation by electrospinning (Cheng et al., 2024).

Effect of Nanıtechnological Applications on Shelf Life of Foods

Today, the interest in active packaging is increasing day by day in studies on the shelf life of foods. Active packaging plays an important role in maintaining the quality charecteristics of food, especially by protecting the food from environmental conditions. Bioactive packaging is being developed to protect various foods (vegetables, fruits, meat, fish, cheese, etc.) from both chemical and microbial spoilage. For this purpose, various herbal extract, essential oils were mostly used, but recently nanoparticles have also been frequently studied as preservatives (Hossen et al., 2022). In a study conducted bu Hosseini et al. (2022), they used cinnamaldehyde-coated chitosan nanoparticles in the packaging of fresh rainbow trout. At the end of the study, it was determined that trout coated with active packaging slowed down lipid oxidation and microbial growth. Zinc oxide nanoparticles (ZnO-NPs) and bamboo leaf extract were added to a chitosan-based film and it was determined that the prepared films have potential for use in food packaging. Bamboo leaf extract and ZnO-NPs showed synergistic effect and showed antibacterial properties especially against E.coli and S. aureus. It was stated that the active packaging prepared at the end of the study has the potential to increase the shekf life of foods (Liu et al., 2021). Iron oxide (FeO) and zinc oxide (ZnO) nanoparticles synthesized with clove extract were used in films prepared to increase the storage time of chicken meat. Films containing FeO-NPs had strong oxygen capture activity, while films containng ZnO-NPs were found to have high antimicrobial properties. Films containing nanoparticle improved the microbial, chemical and color properties of chicken meat stored at 4°C (Chandrasekar et al., 2024). Jamróz et al. (2019a) prepared an active package containing furcellaran, gelatin and Se-

AgNPs and applied it to kiwi samples bu dipping method. Samples coated with films containing 10% and 15% nanoparticles were compared with control and LDPE coated samples. At the end of 8 days, the control samples deteriorated more quickly than the coated samples containing nanoparticle. The elasticity and elongation at break values increased when the ratio of the added nanoparticle in the film increased. Nanoparticle added samples showed strong antibacterial effect against *S. aureus* and *E. coli*. A study was conducted to characterize furcellaran-based active composite films containig selenium nanoparticles, green tea and mate tea, and to investigate their antioxidant and antimicrobial effects. The antimicrobial activity of Se-NPs added films against *S. aureus* and *E. coli* was determined and the added green tea extract improved the antioxidant properties of the films. Films prepared as smart films were used to detect spoilage in fish. The changes occuring in the films placed in the packaging during storage were examined and it was determined that they have potential to be used as a smart label. After 72 hours of storage, a change in film color occured (Jamróz et al., 2019b). A study was conducted to investigate the effect of Se-NPs synthesized in nano turmeric (NC) environment against fish pathogenes (Aeromonas hydrophila, E. coli, Salmonella Thyhimurium, S. aureus) and NC/Se-NPs were found to have an effective inhibitory power against microorganism. Ampicillin and NC/Se-NPs formed a zone diameter of 24.3 and 24.6 mm against E.coli, respectively. When other microorganism were also examined, NC/Se-NPs showed higher zone diameter than the antibiotic. There was no significant difference between the minimum inhibition concentrations in E. coli ans S. Thphimurium (Gad et al., 2022).

Se-NPs were added to hazelnut and walnut packages and oxidative degradation was examined during 42 days of storage. When both samples were compared with the control groups, malondialdehyde (MDA) formation was less at the end of storage. In the same way, potato chips, pork, chicken and ready-to-eat meat meals were applied to the packaging material and MDA formation in each sample was less in Se-NPs added samples. It was determined that MDA formation was reduced bu 25%in these samples (Vera et al., 2018). Cid-Lopez et al. (2021) prepared coating solutions containing calcium oxide nanoparticle (CaO-NPs) and applied them to cucumbers on the day of harvest. It was determined that coatings containing nanoparticles has a positive effect on the appearance, pigment and antioxidant capacity of the sample. It was determined that the shelf life of cucumbers was extended by 24 days after harvest. In a study where seeds were treated with CaO-NPs, it was determined that it had a positive effect on seed growth (Ganhdi et al., 2021). In many studies, it has been determined that CaO-NPs have high antibacterial and antibiofilm properties. Emamifar et al. (2010) prepared films containing silver and zinc oxide nanoparticles and used these films fort he storage of fresh orange juice. Packages prepared with solutions containing nanoparticles were filled with fresh orange juice and the samples were stored at 4°C. At the end of the study, it was determined that the storage life of the samples compared to fresh orange juice stored in conventional packages exceeded 28 days. As a result, it was reported that packages containing silver and zinc oxide nanoparticles could be an alternative packaging method.

CONCLUSION

Many methods are used to increase the shelf life of foods and to maintain their quality characteristics. Nanotechnological methods, one of these methods, are gaining interst day by day. Nanotechnology, which plays an important role in active packaging used to ensure that foods do not löse their quality characteristics during storage; especially the use of nanoparticles in packaging is effective on the shelf life of foods. Various nanoparticles (silver, zinc oxide, selenium, calcium oxide, gold, etc.) added to food packages Show both antioxidant and antimicrobial properties. The use of these nanoparticles, which are effective against various pathogens, in food packaging shows positive result in many aspects. Studies on this subject, which has an important potential in food packaging, should be increased and their effects in model food applications should be investigated.

ABSTRACT

In this paper, the LC-ESI-MS/MS method is used to establish the phytochemical profile of the hydro-methanolic extract of pomegranate peels. Antioxidant activity was determined by two methods: 2,2-diphenyl-1-picrylhydrazyl (DPPH) against BHA and BHT standards and Ferric reducing antioxidant power assay FRAP against ascorbic acid and alpha tocopherol standards**.** The findings indicate the abundance of the hydro-methanolic peel extract in phenolic compounds where we could identify 22 compounds with a higher content of Riboflavin, Epicatechin, Oleanolic acid, Naringenin and p-Coumaric acid. The extract presents a substantial antioxidant activity at low concentrations in which we recorded an IC_{50} value of 5.79±0.15 µg/ml for DPPH and an $A_{0,5}$ value of 1.49±0.05 µg/ml for FRAP.
This study showed that the peel extract of *Punica granatum L* is an excellent antioxidant due to its richness in phenolic compounds. As a result, it opens up prospects in pharmaceutical and nutraceutical applications.

Key words: DPPH, FRAP, Hydro-methanolic extract, LC-ESI-MS/MS, *Punica granatum L*.

INTRODUCTION

Pomegranate is an ancient fruit originated from Iran and the Mediterranean basin belonging to the Lytheracea family REF. It is a shrub that produces a small ball shape fruits with red sweet arils from the inside and crunchy white seeds. Not only consumed as a fruit and molasses but also utilized historically as a remedy by using its bark in folk medicine to threat inflammations and gastric ulcers REF. The aim of this paper is to shed light on the beneficial effect of the pomegranate peel extract, its composition in bioactive compounds and its antioxidant capacity.

MATERIAL AND METHODS

- **Collection and preparation of the fruit (biological) material**

Fresh pomegranate fruits were collected from the local market, washed with tap water and peeled then the peels were cut into small pieces and let dried completely in shade after that they were grinded into powder and stocked in glass jars away from light till utilization.

- **Preparation of hydromethanolic extract**

100mg of the peel powder was weighted and a solution of methanol/water (70:30) was added. The mixture was kept in the dark for 48h with solvent renewal every 24h and under stirring. The solution was filtered through a filter paper. The filtrate was evaporated in a rotary evaporator at 50°C to obtain the crude extract.

- **Sample preparation for the LCMS analysis**

In order to optimize the samples for the LCMS/MS analysis and minimize the interferences a solid phase extraction (SPE) is a necessary step. First, about 1mg of the crude extracts were diluted in 1ml of methanol/water mixture, vortexed and centrifuged. After that, the samples were loaded in a chromatography column (ISOLUTE C18) then the lipids were eliminated with a hexane wash. Finally, the targeted molecules were eluted in clean tubes with methanol and filtered through a nylon syringe microfilters membrane of 13mm diameter, a pore size of 0,22µm. 100µl of the filtered solution is diluted in 1ml methanol.

- **Liquid chromatography-electrospray ionization-mass spectrometry analysis**

The LC-ESI-MS analysis is carried out in an UPLC system coupled with a tandem mass spectrometry and an ESI electro-spray ionization Shimadzu 8040 Ultra-High sensitivity with UFMS (Ultra-Fast Mass Spectrometry) technology and equipped with binary bump Nexera XR LC-20AD.

The mobile phase is used in the gradient mode on a Restek Ultra C_{18} column with 3µm diameter and 150x4.6mm dimensions and a fixed temperature of 40°C. The solvent A is water and 0,1 % formic acid and the solvent B is methanol. The flow rate is 0,2ml/min and the injection volume is 5 µL. The gradient elution and the conditions for electro spray ionization (ESI) were as follows:

0 min to 0.2min A 98 %
0.2 min to 7.5min A 25%
7.5 min to 12.5min A 0%
12.5 min to 17min A 0%
17 min to 18min A 98%
18 min to 21min A 98%

CID gas, 230 KPs; conversion dynode, −6.00 Kv◦C; DL temperature, 250 ◦C; nebulizing gas flow, 3.00 L/min; heat block, 400 ◦C; drying gas flow, 10L/min.

- **In vitro antioxidant activity measurement**

1. **DPPH free radical scavenging assay**

The free radical scavenging activity was determined according to **(Blois 1958)**. A stock solution of DPPH at 4% (4mg of DPPH in 100ml of methanol) stocked at -20°C in the dark and adjusted at 0,7 at 517nm. 40µl of the extract was mixed with 160µl of the stock solution. Results were read at 517nm in a microplate reader after 30min of incubation. Findings were compared with the antioxidant standards Butyl Hydroxy Anisole (BHA) and Butyl Hydroxy Toluene (BHT) and were expressed in 50% of the inhibition concentration in µg/ml (IC_{50}).

2. **Ferric reducing antioxidant power assay FRAP**

The ferric reducing antioxidant power activity was determined by the method of Oyaizu (1986) with slight modification. A solution of tri-chloro-acetic acid (TCA) at 10% was prepared by dissolving 1g of TCA in 10ml of distilled water. The reaction is carried out by mixing 10µl of the extract with 40µl of the phosphate buffer (pH 6,6) and 50µl of potassium ferricyanide Prussian red ($K_3Fe\ (CN))_6$ at 1%. The mixture was incubated at 50°C for 20mn then 50µl of TCA solution, 40µl of distilled water and 10µl of ferric chloride ($FeCl_3$) at 0,1% were added. The reading is done at 700nm. Results were compared with the antioxidant standards alpha tocopherol and ascorbic acid and were expressed as $A_{0,5}$ which indicates 50% of the inhibition concentration.

- **Statistical analysis**

All the experimental results are mentioned as a mean ± standard deviation of three trials.

Results and discussion

- **Liquid chromatography-electrospray ionization-mass spectrometry analysis**

According to the literature the pomegranate peel extract is reach in bioactive compounds with a wide range of polyphenols and flavonoids REF. In this study we were able to identify 22 different compounds by the LCMS analysis represented in **(Table1)** in which phenolic acids, flavonoids, phenolic aldehyde and vitamins and with a higher amount of Riboflavin, Epicatechin, Oleanolic acid, Naringenin and p-Coumaric acid respectively.

Table1: Phytochemical profile of *Punica granatum L*

ID #	Name	Molecular Formula	Molecular Weight	ESI Charge (+/-)	m/z	Ret. Time	Height	Area

- **In vitro antioxidant activity measurement**

The value of IC_{50} registered for the DPPH assay was 4,65±0,48 µg/ml compared to BHA and BHT standards (6,14±0,41and 12,99±0.41 µg/ml) and the value of $A_{0,5}$ registered for the FRAP assay was 1,49±0,05µg/ml compared to ascorbic acid and α–tocopherol standards (6.77±1.15 and 34.93±2.38 µg/ml) (Table2) which represent an excellent antioxidant capacity of the *Punica granatum.L* peel extract.

Table2: Antioxidant activity thehydromethanolic extract of *Punica granatum L* peels

	Punica granatum .L extracts	BHA	BHT	Alpha tocopherol	Ascorbic acid
DPPH assay IC_{50} (µg/ml)	4,65±0,48	6,14±0,41	12,99±0.41	NT	NT
Reducing power assay $A_{0.5}$ (µg/ml)	1,49±0,05	NT	NT	34.93±2.38	6.77±1.15

BHA: butyl hydroxy anisole, BHT: butyl hydroxy toluene, NT: not tested

CONCLUSION

The hydromethanolic extract of *Punica granatum.L* showed a very high antioxidant activity by the two methods tested and phytochemical screening confirms the abundance of multiple bioactive compounds. As a result, it opens up prospects in pharmaceutical and nutraceutical applications.

The Medicinal and Aromatic Plants (MAPs) industry is relevant for Albania covering approximately 20% of agricultural exports. Mostly high quality dried parts of MAPs are traded, while products not fulfilling quality criteria and non-tradable plant parts are often regarded as waste products, even though they contain valuable bioactive substances. This study evaluates the composition and biological activity of the essential oil (EO) fraction of wastes generated from the MAPs industy of *Juniperus communis* L. in Albania.
Juniperus communis L. was collected from Korçë area, dried, screened for trade quality berries in an industrial plant for MAPs, and the waste parts underwent hidrodistilation in industrial distilators. Chemical composition was performed using Gas Chromatography coupled with Mass Spectrometry and identified 50 compounds, where main components were α-Pinene (24.47%), Sabinene (12.4%), Germacrene D (3.2%) and β-Myrcene (1.6%). The antioxidant capacity of *J. communis* L.EO was determined by 2,2-diphenyl-1-picrylhydrazil (DPPH) and 2,2'-azino-bis(3-ethylbenzothiazoline-6-sulfonic acid) (ABTS) and expressed as Inhibitory Concentration of 50% of the free radical (IC_{50}) where values were IC_{50}= 155.4 µg/mL and IC_{50}= 163.2µg/mL for DPPH and ABTS respectively. Antimicrobial activity of *J. communis* L. EO was determined against five bacteria, *Escherichia coli ATCC 10535; Salmonella enteritidis, ATCC 49223, Pseudomonas aeruginosa, ATCC 9027; Micrococcus luteus, ATCC 10240; Stenotrophomonas maltophilia, ATCC 1363;*and one yeast, *Candida albicans, ATCC 10231* by microdilution method used to determine the minimum inhibitory concentration (MIC). The EO showed no antimicrobial activity against the first 3 bacterial strains, while it inhibited growth of *Micrococcus luteus* and *Candida albicans* at concentrations of 2.5 mg/mL and of *Stenotrophomonas maltophilia* at the maximum tested concentration of 5 mg/mL.

Keywords: *Juniperus communis* L , *antioxidant, antimicrobial, MIC*

1. INTRODUCTION

Albania has a long tradition in the production and export of medicinal and aromatic plants (MAPs), spanning more than 60 years, which is mainly based on the abundance of wild-grown MAPs. Compared to other agricultural subsectors, MAPs industry is primarily focused on exports, with over 95% of all MAPs exported, accounting for 20% of all agricultural exports (AASF, 2019). A considerable amount of post-harvest waste products are produced during the processing of MAPs, such as branches, leaves and fruits of lower quality (Routray. *et al.*, 2017), that are not suitable for commercial use (FAO/WHO Codex Alimentarius Commission On Spices and Culinary Herbs, 2021). Since these residual biomasses have the same components and characteristics as the finished product, they could be sources of bioactive chemicals (Navarrete *et al.*, 2011; Wang *et al.*, 2018). Most of these by-products are still treated as waste from the Albanian MAPs industry and discarted improperly or used as a burning material. Nevertheless MAPs by-products are a source of useful metabolites with significant biological characteristics that might give to finished products a unique quality (Sahaa. *et al.*, 2020).
One of the most prized aromatic plants in the world is juniper (*Juniperus* spp.), found also in Albania in two main species, red juniper (*Juniperus oxycedrus* L.) and black juniper (*Juniperus communis* L.) which possess antioxidant, anti-inflammatory, and antimicrobial properties due to the occurrence of several secondary metabolites, such as phenolic constituents, terpenoids, and flavonoids, in their extracts (Mërtiri *et al.*, 2024). Both spieces are employed for culinary and also essential oil (EO) uses, but there is a higher demand for the second, black juniper, in the Albanian MAPs industry. Also *J. communis* has been sold at higher prices in recent years in Albania due to domestic and international supply dynamics and higher domestic demand for essential oil production (Medicinal and Aromatic Plants Sector Study, 2021).
However, considerable quantities of *J. communis* herbal residues are formed during the post-harvest processing used to select the material to be marketed, and these residues can be used to extract its EO. While there are various ways to extract natural essential oils (EOs) from plants, steam distillation is the method most commonly employed in the industry today since it is easy to use and doesn't require the use of chemicals like solvents, which are often utilized in other extraction processes (Esteban *et al.*, 2023).

Due to the current issue with pathogenic bacteria whose resistance to antibiotics has grown over time, one of the main problems facing the pharmaceutical, food, and veterinary industries is discovering bioactive compounds to be employed as bactericides (Mancuso *et al.*, 2021). As many active organic compounds make up plant EOs, which act on microbial cells through different mechanisms, they do not induce microbial resistance (Rao *et al.*, 2019). Additionally, since customers are increasingly requesting natural products as alternatives to synthetic preservatives, it is necessary to look for antioxidant and anti-inflammatory active principles of natural origin. In this context, the US Code of Federal Regulation has classified juniper berries, essential oils, solvent-free oleoresins and natural extractives as Generally Recognized as Safe (GRAS) for their intended application (Code of Federal Regulation. Substances Generally Recognized as Safe, 2023).

The aim of this study was to characterize the chemical composition and assess the biological activity of the EO extracted from the by-products of *J. communis* MAPs industry, as a strong source of bioactive components for the creation of new products in food and pharmaceutical industry.

2. MATERIALS AND METHODS

2.1 Plant material and EO extraction

Juniperus communis L. was collected from Korçë district, Albania, from 10th of August until the end of September 2021, Albania, dried, screened for trade quality berries which are mainly intended for gin spirit and teas production in an industrial plant for MAPs (PETKUS Technologie GmbH), and the remaining by-product underwent hidrodistilation in industrial distilators at BioBes sh.p.k. company (Sopëz, Albania).

2.2 Reagents and microorganisms

Antioxidant radical screening reagents [20-diphenyl-1-picrylhydrazyl (DPPH) and 2,2'-azinobis(3-ethylbenzothiazoline-6-sulfonic acid) diammonium and potassium persulfate (ABTS)] were purchased from Alfa Aesar (Massachusetts, United States). Methanol was secured from VWR International (Fontenay-sous-Bois, France) and ethanol fromMerk KGaA (Darmstadt, Germany).

The bacterial and fungal ATCC strains [American type culture collection strain (ATCC) *Salmonella enteritidis* (ATCC:49223), *Escherichia coli* (ATCC:10535), *Pseudomonas aeruginosa* (ATCC:9027), *Stenotrophomonas maltophilia* (ATCC:13637). *Micrococcus luteus* (ATCC:10240), along with one fungal isolate *Candida albicans* (ATCC:10231) were procured from Microbiologics, Inc., (MinnesotaUnited States). 96-well plates were secured from Corning Inc. (New York, United States).

Blood agar medium and Muller Hinton Broth were procured from Remel Inc, (California, United States), 0.5 Polymer McFarland Standard from Thermo Fisher Scientific (Massachusetts, United States) and Dimethylsulfoxide (DMSO) from Sigma-Aldrich (Missouri, United States).

2.3 Gas Chromatography-Mass Spectrometry

Gas Chromatography-Mass Spectrometry Essential oil analyses were performed on a Shimadzu GC-2010-GCMSQP2010 system operating at 70 eV. The temperature program was from 60ºC to 250ºC, at a rate of 5ºC/min. Helium was used as a carrier gas at a flow rate of 1.0 ml/min. Injection volume of each sample was 1 μL. Retention indices for all compounds were determined according to Van den Dool and Kratz, 1963, using n-alkanes as standards. The identification of the components was based on comparison of their mass spectra with those of NIST21 and NIST107, Massada, 1976 and by comparison of their retention indices with literature data Adams, 2007. Component relative concentrations were calculated based on GC peak areas without using correction factors. Essential oils were often subjected to co-chromatography with authentic compounds (Fluka, Sigma).

2.4 Antioxidant activity

The free radical scavenging activity of the essential oils was measured *in vitro* by the 2,20-diphenyl-1-picrylhydrazyl (DPPH) and 2,2'-azinobis(3-ethylbenzothiazoline-6-sulfonic acid) diammonium and potassium persulfate (ABTS) assay according to Brand-Williams *et al.*, (1995) and to Re *et al.*, (1998) respectively. The stock solution for the DPPH assay was prepared by dissolving 24 mg of DPPH with 100 mL of methanol (and stored at 20°C. The working solution was obtained by diluting the DPPH stock solution with methanol to achieve an absorbance of about 0.98±0.02 at 517 nm using a spectrophotometer (Biochrom Ltd. Libra S22). The stock solution for the ABTS assay was prepared by dissolving ABTS in water at a concentration of 7 mM. The ABTS radical cation (ABTS•1) was obtained by combining ABTS stock solution with 2.45 mM potassium persulfate (final concentration) and thus allowing the mixture to stand in the dark at room temperature for 12–16 h before use. The working solution was obtained by diluting the ABTS stock solution with ethanol to achieve an absorbance of about 0.7±0.02 at 734 nm using a spectrophotometer.
Three ml portions of these solutions were mixed with 100 µL of the sample at 6 concentrations: 0.5, 1, 2, 5, 10, 20 mg/mL. The mixture was shaken well. For the DPPH assay it was incubated in the dark for 30 min at room temperature assay and then the absorbance was measured at 517 nm. For the ABTS assay the absorbance was measured at 734 nm after 5-6 minutes. The controls were prepared as above but without essential oil. The activity was evaluated based on the percentage of the DPPH and ABTS radical removed as the following equation:

Scavenging activity in % = {(absorbance of control - absorbance of sample) / (absorbance of control)} x 100.

Result was calculated as the concentration of essential oil that inhibits 50% of the free radical (Inhibition Concentration IC_{50}).

2.5 Evaluation of antimicrobial activity by Micro-dilution Broth Experiment

The Essential Oil (EO) antimicrobial activities were investigated against different clinical and food-borne pathogens using standard American type culture collection strain, five bacteria along with one fungal isolate. . The bacterial and fungal ATCC strains were stored at 4°C and sub-cultured for the experimental setup. Prior to the inoculation of the

strains with EOs, the microorganisms were grown at 28 or 37 °C (for fungus and for bacteria) for 18-20 h on blood agar medium.
The MIC (Minimum Inhibitory Concentration) of each EO was determined using a broth microdilution method in 96-well plate in accordance with the Clinical & Laboratory Standards Institute (CLSI) protocols [M100 Ed34, 2024]. In brief, bacterial suspensions were adjusted to a final concentration of 10^5 CFU/mL cells standardized by 0.5 McFarland in Muller Hinton Broth (MHB) media. EO stock concentration of 100 mg/ml was prepared by dissolving in DMSO. From this stock, a working concentration of 5 mg/ml was prepared (in MHB media) to be used in plate susceptibility testing, ensuring DMSO concentration less than 5%. This resulted in EO's concentration range of 5mg/ml to 0.0097 mg/ml on the plate. One hundred microliters of bacterial suspension were finally added to each well. The plate setup included the 11^{th} column as the media control (negative control), and the 12th column containing bacteria and media (positive control). Additionally, rows D and E were designated for solvent controls, with row D with only EO (solvent control) and row E for DMSO (conc. used to dissolve EO) and bacteria served as DMSO control. The plates were incubated at 37°C for 24 h. MIC was determined using Tecan I-control software (Infinite M Plex TECAN) to measure the OD (600nm) compared with positive control. Everything was kept constant for determining antifungal activity except incubation was done for 45-48h, with OD determined at 530nm. MIC was determined as the lowest concentration of EO that inhibited visible growth of the tested microorganism (Puškárová A *et al.* 2017).

3. RESULTS AND DISCUSSION

3.1 Plant material and EO extraction

The amount of by-product from different batches ranged from 10 to 20% of the total mass of *J. communis* L, with a mean value of 13%.The by-product is mainly composed of niddles and few berries on the top of the branch. The industrial hydrodistillation employed to extract the EO from *J. communis* L. by-product yielded 0.8% of the total mass of the plant material and the EO resulted in white-yellow colour.

3.2 Quantitative and qualitative analysis of the EO

GC-MS analysis (Figure 1) identified in total 49 different components, counting for 86.4% of the EO. Results are given in Table 1, where compound are listed according to their Arithmetic Index. The oil was composed mainly by the monoterpene fraction (62.3%) with α-Pinene (24.47%) being the most abundant compound, followed by Sabinene (12.4%), γ -Terpinene (4.6%), Limonene (4.1%). The sesquiterpene compounds constituted 24.1% of the essential oil with β-Caryophyllene (3.9%) and Germacrene B (3.8%) as main compounds. In general the EO composition was in compliance with ISO 8879 and The European Pharmacopoeia. 10th edition (Eur.Ph. 10^{th}) specifications, exept for α-Pinene being slightly lower than the specification of ISO 8879, and α-Phellandrene being above the maximum level set by Eur.Ph. 10th.

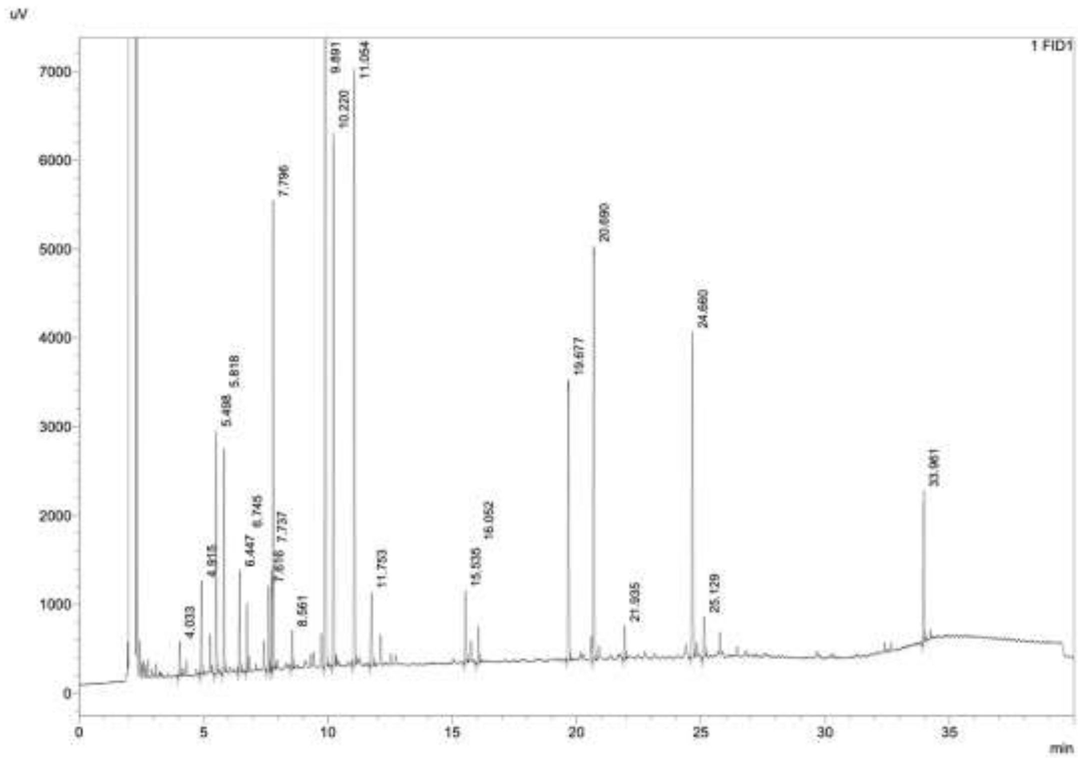

Figure 1. GC-MS chromatogram of EO from *J. communis*L. by-product.

Main components were in agreement with other reports from Albania (Salamon *et al.*, 2014; Buci *et al.*, 2018, Agastra *et al.*, 2021) and from other countries (Angioni *et al.*, 2003; Höferl *et al.*, 2014; Koukos *et al.*,1999) except for the concentration of β-Myrcene, where it is generally reported in higher concentrations as one of the main components. Similar β-Myrcene levels were found by Ainan *et al.*, (2022) with β-Myrcene *J. communis* L. harvested in Maroco. Probably this is due to high levels of leaves (niddles) in the by-product from *J. communis* L as the primary component that distinguishes berry oil from needle oil is myrcene, which may be found in berry oil at levels as high as 20% whereas it can only be found in needle oil at levels as low as 5% (Shamir *et al.*, 2003).

Table 1. Composition of the essential oil from *J.communis*L. by-product and reference values obtained for specific compounds considered in ISO 8879 and Eur.Ph. 10th edition.

3.3 Antioxidant activity

DPPH assay was one of the *in vitro* tests used in this study to determine the ability of juniper berry oil components to act as hydrogen atom donors. The EO Juniper by-product oil was a weak DPPH radical reducer with IC_{50} value of 155.4 µg/mL. This was expected as the main component in the EO, α-pinene, was found by Emami *et al.*, (2007) to show no antioxidant activity at all in relation to DPPH radicals. The same work established that γ-terpinene (17.74%) showed antiradical activity in relation to DPPH radicals. Also limonene in 10–50 µg/mL concentrations causes DPPH inhibition from 16% to 25% (Roberto *et al.*, 2010).
In relation with the ABTS radicals the result was similar with an IC_{50} value of 163.2µg/mL. The results are shown in table 2.

Table 2. Antioxidant activity of essential oil from *J. communis* L. by-product by DPPH and ABTS assays.

Assay	**IC_{50}*** *J. communis* **L. EO**	***St. Dev***
DPPH	155.4 µg/mL	±7,04
ABTS	163.2 µg/mL	±8,78

3.4 Antimicrobial activity

Table 3 shows the antibacterial activity of essential oil from *J. communis* L. by-product as Minimum Inhibitory Concentration. In tested concentrations the oil was not active against *E. coli, S. enteritidis* and *P. aeruginosa* bacterial strains while it resulted active against *M. luteus* and *S. maltophilia* with MIC 2.5 and 5mg/ml respectively. Similar results were reported from Sela *et al.*, (2013) where *J. communis* leaves and berries EO using broth dilution method showed no activity against *E. coli, S. enteritidis* and *P. aeruginosa*. The oil showed antifungal activity against *C. albicans* yeast with MIC 2.5 mg/ml. However According to Sela *et al.*, (2013) no MIC could be measured against *C. albicans* yeast from *J. communis* leaves and berries EO. Similar results were obtained from Angioni *et al.*, (2003) were *J. communis* EO tested was not active against *C. albicans*. To our knowledge this is the first report that shows the antibacterial activity of essential oil from *J. communis* on *S. maltophilia.*

Table 3. Minimum Inhibitory Concentration of essential oil from *J. communis* L. by-product.

Microorganism	**MIC *Juniperus communis* L. antimicrobial activity**
E. coli ATCC 10535	NO MIC
S. enteritidis ATCC 49223	NO MIC
P. aeruginosa ATCC 9027	NO MIC
M. luteus ATCC 10240	2.5 mg/ml
S. maltophilia ATCC 13637	5 mg/ml
C. albicans ATCC 10231	2.5 mg/ml

4. CONCLUSIONS

The purpose of this study was to assess the essential oil that was industrially extracted from *J. communis*L. by-product that was produced by the MAP industry by analyzing its chemical content and biological activity, in order to determine the potential value of this by-product.

The chemicals' presence is consistent with findings from the literature. Furthermore, proof of these compounds' existence in the EO supports the moderate free scavenging activity ascertained by the DPPH and ABTS assay, which is similar to EO isolated from *J. communis* L. primary material. Therefore, this industry by-product is appropriate to be used to produce EO that meets the general requirements for *J. communis* L. EO as established by ISO 8879 and Eur. Ph. 10th.

The terpenes and other volatile constituents found in the by-product plant material could be further utilized for the production of enriched aromatic beverages in which *J. communis* L finds wide applications (Enescu *et al.* 2016).

Considering all these findings, it is clear that the by-product plant material is a valuable source of bioactive compounds and that it could be used to produce novel nutritional products by as antioxidant, antimicrobial and flavoring additives to food.

ABSTRACT

Biopolymer-based materials are considered an alternative to petroleum-based plastics, which are responsible for much of the environmental pollution in food packaging. Biopolymers can be produced by microorganisms or derived from biomass. Starch, cellulose, chitin, chitosan, polylactic acid (PLA), and polyhydroxylalkanoates (PHAs) are biopolymers that are produced according to origin and method of production. These materials are used to produce biodegradable packaging, and these are preferred for sustainability, waste reduction and non-toxicity properties. However, high price, lower mechanical, thermal, and barrier properties against oxygen, water vapor, microbes, light, and conditions of high humidity compared to petroleum-based polymers limit their use in the food industry. Studies on biodegradable polymers coupled with various materials are expected to play an increasingly crucial role to improve these properties that restrict their industrial use. Ultimately, continued advancements and innovations in biopolymer technology holds promise for overcoming these challenges and fostering wider adoption of sustainable packaging solutions in the food industry. Here we review the benefits, chemistry and trends in biopolymer-based packaging materials for food applications.

Keywords: Biopolymer-based packaging materials, biodegradable packaging, biopolymers, sustainability

INTRODUCTION

Food packaging has a crucial role in the food industry to ensure the quality and safety of the food, as it helps not only to contain and carry goods from one place to another, but also to preserve, protect, present, market, and communicate with its mechanical and barrier properties (Ojha et al., 2015; Verma et al., 2021; Saha, 2023). Over a period, the packaging technology has evolved more to improve the shelf life of the product with ensured quality, using both modern technology and conventional methods.

Paper, plastic, metal, and glass are the materials used for packaging applications. Glass and metal, having high barrier properties, display insignificant interaction with the containment, whereas conventional petroleum-based plastics are preferred on the grounds of low cost, durability, resistance to degradation, high versatility, flexibility, transparency and heat sealability (Table 1) (Licciardello, 2017; Awulachew, 2022; Cheng et al., 2024). However, about 95-99% of plastics have been made from non-renewable sources and food packaging accounts for 50% of the plastics that have been made (Ncube et al., 2020; Shaikh et al., 2021). Food packaging plastics have half-lives ranging from 2 to more than 2500 years in the environment and that creates serious pollution (Amin et al., 2022) and approximately 70% of marine litter objects are single-use plastic items such as straws or food and drink containers (Omerović et al., 2021).

Table 1. Differences between plastics and bioplastics

Conventional plastics	Bioplastics
Produced from fossil fuels and petrochemicals	Produced from natural resources
Limited and nonsustainable resources	Sustainable and renewable resources
Almost all are non-biodegradable	Most are biodegradable
High mechanical strength, could withstand heavy load	Low mechanical strength
Low water permeability	High water permeability
High thermal stability	Low thermal stability
Low brittleness	High brittleness
Takes hundred years to degrade into smaller particles	Under controlled composting conditions biodegrades within 3–6 months
Eco-toxic and causes environmental pollution	Eco-friendly
High greenhouse gas emission	Emits fewer greenhouse gases and
Increases global warming	Considered as carbon neutral
More energy consumption during production	Less energy usage during production
Reduces soil fertility	Increases soil fertility
Technically mature production steps	Early stage of development, needs more study on production and recycling process

Since the food supply is expected to increase in parallel to the increase in the world's population, the demand for food packaging would also increase. The growing use of packaging materials and hurdles for natural recycling operations coupled with high costs had driven the need for renewable food packaging materials that have efficient physical, mechanical, and barrier properties (Ncube et al., 2020).

The emphasis is on developing packaging materials that are compatible with food products, eco-friendly, and lightweight for reducing the amount of material use, waste and as well as transportation costs. Therefore, plastics from biopolymers, known as biodegradable materials, are promising alternatives to fulfil this requirement as being compatible with foods and having sustainable properties to bring down the environmental impacts of food packaging. However, their use is mostly restricted due to high price and lower mechanical, thermal, and barrier properties against oxygen, water vapor, microorganisms, light, and conditions of high humidity. In order to improve these negativeness they mostly are combined with nanoparticles (Mekonnen et al. 2013; Jafarzadeh & Jafari, 2020; Wrona & Nerín, 2020; Zhao et al., 2020; Shaikh et al., 2021; Visco et al., 2022; Ghasemlou et al., 2024).

Biodegradable Packaging

Bioplastics are the materials derived directly from natural polymers with or without modifications, produced by microbial fermentations, and chemically synthesized from renewable raw materials, such as proteins, wood, potatoes, corn, vegetable oils, and food waste (Figure 1) (Abe et al., 2021; Xia et al., 2021; Keränen et al., 2022; Behera et al., 2022). In scientific literature two terms are described for bioplastics: bio-based and biodegradable. “Biobased” plastics are the materials that are wholly or partly substituted by renewable biomass, whereas “biodegradable” refers to materials that can naturally disintegrated or decomposted by microorganisms, resulting in carbon dioxide, water, and biomass (Ghasemi-Mobarakeh et al., 2019; Bhagwat et al., 2020; Bachleitner et al., 2023; Zhao et al., 2024).

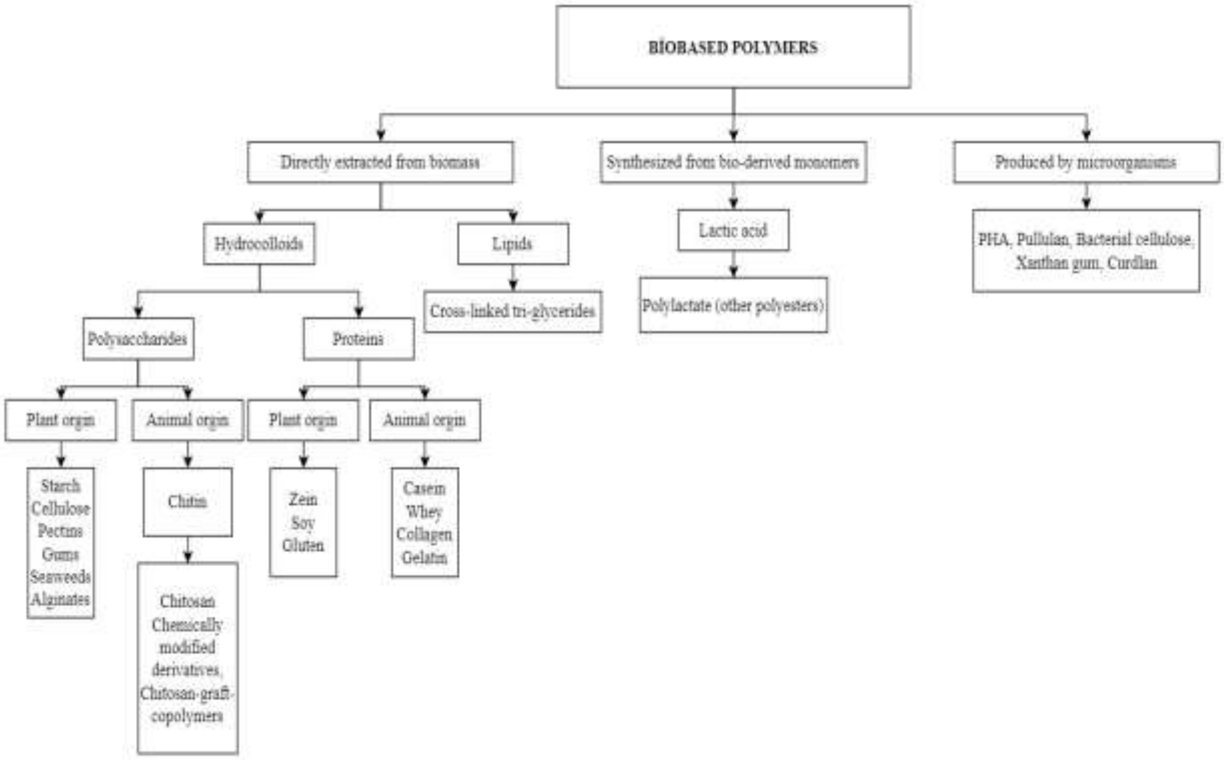

Figure 1. Types of biopolymers used in packaging

For a substance to be considered as "biodegradable" some studies find composting within 1-2 months is sufficient (Amin et al., 2022; Cheng et al., 2024); however, as stated by International Standard Organization (ISO), any substance could be considered as biodegradable if its initial mass is reduced by 90% after six months under compost conditions of 50^0C (ISO, 2018). Furthermore, The American Standard for Testing Materials (ASTM) accepts a composting rate of 60% for homopolymers and 90% for blends within 180 days (ASTM, 2024).
Biodegradable polymers at present only replace about 1% of the global plastic production, but its market is growing rapidly (Shaikh et al., 2021). In 2023, the global production capacities of biodegradable/biobased packaging materials were estimated as 2.18 million tonnes, which is forecasted to reach approximately 7.43 million tonnes in 2028.

Materials of Biodegradable Packaging

Naturally sourced biopolymers are the first choice when attempting to achieve a less toxic and more sustainable food packaging because of their biocompatibility, biodegradability, and nontoxicity (Omerović et al., 2021). Biodegradable plastics are the degradable plastics in which the degradation results from the action of living microorganisms such as bacteria, fungi, and algae into water, carbon dioxide, and biomass without the release of any toxic byproducts (Zhao et al., 2020). It is worth mentioning neither all bio-based plastics are biodegradable, nor all biodegradable plastics are bio-based. The biodegradable plastics comprised of bioplastics, whose building components are derived from renewable raw materials, and other plastics manufactured from the petrochemicals possess biodegradable additives. Thus, according to their degradation degree biodegradable plastics can be grouped as completely degradable or non-degradable (semi-degradable) (Ivanković et al., n.d.; Shaikh et al., 2021; Cheng et al., 2024).

It is important to note that non-degradable bioplastics are advantageous than biodegradable fossil fuel plastics. They have better recyclability, compatibility and low levels of carbon dioxide production than existing plastic processing systems. Starch, cellulose, chitin, chitosan, polylactic acid (PLA), polyhydroxyalkanoate (PHA), polyhydroxybutyrate (PHB), and polycaprolactone (PCL) are the mostly employed biopolymers for production of bottles, jars, cans, buckets, food containers, disposable cups, packaging films, and refuse bags (Pawar & Purwar, 2013; Jabeen et al., 2015; Nesic et al., 2020; Ncube et al., 2020).

Table 2. A summary of the types, form, applications and key features of starch and cellulose-based bioplastics from recent literature

Type of Polymer	Form of Packaging	Application	Key Features	References
Starch	Film	To improve bilayer food packaging films; PPS (Pure potato starch) and 3-APTMS (3-(Aminopropyl) Trimethoxy silane) crosslinked to make PPS-3APTMS films. These bilayer films were then made by solution casting the PPS-3APTMS with PLA.	Crosslinking reduced the hydrophilicity. PPS-3APTMS-PLA bilayer films improved thermal stability and mechanical properties. Tensile strength increased. Solubility, swelling ratio, water vapor permeability and transparency decreased. Crosslinked PPS-3APTMS bilayer film has 5.45% biodegradation. PPS-3APTMS-PLA bilayer film has 5.08% biodegradation.	(Cheng et al., 2024)

Chitosan/ Potato Starch	Film	Chitosan (CS)/ Potato Starch (PS) films cross-linked with citric acid (CA) at different concentration (5%-10%-15%-20%).	15% CA showed best comprehensive properties all among all films.Improved water resistance properties,	(Wu et al., 2019)
Cassava starch/ Chitosan	Active packaging	Cassava starch (CS) /chitosan (CH) film were combined with pitanga (Eugenia uniflora L.) leaf extract (PE) and/or natamycin (NA) in different formulations. (2.25 g PE/100g FFS, 1g NA/100g FFS, 2.25g PE+1g NA/100g FFS)	The addition of PE didn't affect mechanical properties, whereas NA significantly decreased the flexibility of films. While only the PE added film showed significant antioxidant activity, only NA added film showed antifungal effect against *Aspergillus flavus* and *Aspergillus parasiticus*.	(Sirisha Nallan Chakravartula et al., 2020)
Chitosan/ Starch	Active edible film	Chitosan/Starch film incorporated with nano titanium dioxide (TiO2-N) and clove oil (CO) in different concentrations.	TiO2-N improved the compactness of the film, increased the tensile strength (TS) and antioxidant activity, and decreased the water vapour permeability (WVP). CO decreased TS but increased the hydrophobicity, water vapour barrier antimicrobial and antioxidant properties.	(Li et al., 2019)
PLA/ Starch	Film	PLA/starch blends were loaded with cellulose nanofibers, cellulose nanocrystals and aqueous extract from coffee husk.	Adding extract from coffee husk didn't improve mechanical properties but reduced oxygen permability and showed antioxidant activity.	(Collazo-Bigliardi et al., 2019)

Cellulose/ Chitosan	Film	Prepared different 6 solution of composition of Cellulose/Chitosan and N-methylmorpholine-N-oxide (NMMO).	The tensile strength is the highest and has the smoothest surface with the solution containing 3% chitosan but at 5% chitosan reduces notably because of phase separation.	(Shih et al., 2009)
Hemicelluloses/ Chitosan	Edible film	Hemicelluloses/Chitosan films loaded with 5% cellulose nanofibers using different plasticizers. (10-20-30-40wt%/ glycerol, sorbitol, xylitol)	The film plasticized with sorbitol (20wt%) showed the highest tensile strength and glycerol (20 wt%) showed the highest tensile strain at break.	(Xu et al., 2019)
Bacterial cellulose/ Poly(3-hydroxybutyrate)	Active packaging	Bacterial cellulose (BC) were produced from *Gluconacetobacter hansenii,* Poly(3-hydroxybutyrate) (PHB) and clove essential oil (CLO) blended.	It was observed that adding 10wt% clove oil caused a 65% microbial reduction.	(Albuquerque et al., 2021)
Chitosan/ Cellulose acetate phthalate /Nano ZnO	Film	Chitosan (CS) /Cellulose acetate phthalate (CAP) loaded with nano ZnO.	The film loaded with 5 wt% ZnO nano particles showed low surface wettability, high tensile strength, and thermal and barrier properties compared to chitosan/ cellulose acetate phthalate films.	(Indumathi et al., 2019)
Corn Starch/ Chitosan	Active packaging	To see properties of different concentrations of Chitosan in active packaging, Corn starch (CS) and chitosan solutions in different chitosan	Increasing chitosan concentration increased film solubility, color change, tensile strength, and elongation at break, decreased water vapor permeability.	(Ren et al., 2017)

		concentrations (21, 41, 61, 81% of starch weight) blended.	Elongation at break peaked at 41% chitosan which decreased as concentration increased.	
Chitosan	Active packaging	The researchers prepared composite films by incorporating chitosan (CS) and polypyrrole(PPy) into microfibrillated cellulose (MFC).	Adding PPy increased surface uniformity and filled pores in the composite films. Antimicrobial and antioxidant activity increased. The MFC/CS/PPy composite films showed good thermal stability. The oxygen transmission rate was crucially reduced.	(Gao et al., 2020)
PBAT/TPS	Functional active packaging	PBAT (polybutylene adipate-co-terephthalate)/TPS polymer blended with ZnO nanoparticles (1-5%) for meat packaging.	PBAT/TPS films containing 4% ZnO showed superior microbial controls for total viable count, lactic acid bacteria and yeast and mold. The shelf life of meat packaged in PBAT/TPS films with 3% ZnO was extended by more than 3 days.	(Phothisarattana et al., 2022)
OP/LLDPE	Film	LLDPE/OP masterbatch pellets were produced and combined with neat LLDPE using specific processing parameters determined to produce blown LLDPE/OP composite films differing in OP	OP enhanced the UV and visible light blocking capacity. Composite films had reduced tensile strength and elongation at break. LLDPE/OP films with up to 11.5% OP had shown water vapor barrier	(Fehlberg et al., 2023)

		content (5, 10, 11.5, and 12.5%).	properties, crystallinity, and melting temperature compared to neat LLDPE films.	
PLA/PHB	Film	PLA-PHB blend films with 75 wt% PLA and 25 wt% PHB prepared and ternary blends with 15 wt % d-limonene added.	Improved oxygen barrier properties, surface water resistance, and thermal stability. The addition of d-limonene improved flexibility and elongation at break; improved processabilityIt decreased the glass transition temperature.	(Arrieta et al., 2014)

Starch and Celluloses

Starch, the main storage polysaccharide in the vegetal cells, is made of linear amylose and branched amylopectin molecules, of which have α-D-(l,6)-glucose monomers, and is insoluble in water and alcohol. When starch is gelatinized it loses its original conformation and forms a melted gel similar to synthetic thermoplastics (Gadhave et al., 2018; Ghasemlou et al., 2020, 2022). Starch is a key ingredient considered as a biodegradable polymer material for its availability, low cost, biodegradability, renewability, and eco-friendliness. Since starch is obtained from green plants, such as potatoes, corn, wheat and rice, due to its nontoxic nature it ensures safety in food, pharmaceuticals, and consumer products when it gets into direct contact (Henning et al., 2022; Hossain et al., 2024).
Starch is mostly regarded as an alternative to synthetic polymers as thermoplastic starch (TPS). TPS is highly sensitive to humidity and the thermal properties changes with the content of water. The amylose/amylopectin ratio of starch significantly impacts the structure and thermal stability of its bioplastics. The elongation and strength increase as the amylose content increases. Corn-starch is generally preferred as TPS for food packaging applications (Abe et al., 2021; Shaikh et al., 2021; Thulasisingh et al., 2022).
However, pure starch-based bioplastics are too brittle and fragile, and as a result of higher rate of crystallinity, strong intermolecular forces, and the presence of disordered granules their processability and mechanical strength is reduced. Thus, plasticization of starch, either by plasticizer effect of water or plasticizers, is the common way to improve its flexibility, and allow extrusion (Rao et al., 2022; Ghasemlou et al., 2024). Moreover, starch-based materials are prone to moisture sensitivity, which can lead to degradation

and microbial growth. To optimize the overall properties and amplify the processability and functional properties combining starch with aliphatic polyesters such as Polyglycolide (PGA), Polylactide (PLA), and Polycaprolactone (PCL) have been recommended (Encalada et al., 2018; Surendren et al., 2022). Blending starches with such before mentioned materials aims to reduce the production cost; to improve barrier properties and dimensional stability; to decrease the hydrophilic character of starch; and increase its biodegradability.

Further, starch derivatives, cellulose esters, cellulose acetate, nitrocellulose, and celluloid are available biodegradable polymers for packaging (Verma et al., 2021). Cellulose is composed of complex carbohydrates. It is a linear polysaccharide that depends on the type and treatment of the raw materials. Cellulosic polymeric materials are mostly available as bacterial cellulose, microcrystalline cellulose, cellulose nanocrystals or nano whiskers.

Cellulose-based bioplastics are sustainable, have barrier properties, work with current infrastructure, and break down over time. Cellulose properties encompass low density, high durability, non-toxicity, biocompatibility, biodegradability, transparency and good film-forming characteristics with exceptional mechanical, thermal and barrier properties, making cellulose as an ideal packaging material (Thulasisingh et al., 2022).

Regenerated cellulose film (RCF) is one of the first packaging films obtained from pure cellulose fiber derived from woods. Modified cellulose and different cellulose derivatives such as cellulose acetate and cellulose esters are predominant materials used in industry for molding, extrusion and film applications. However, have poor solubility and indigestibility. Cellulose can be transformed to various forms with its insolubility and low fluency (Shaikh et al., 2021), however, lacks antibacterial activity therefore it needs to blend with antimicrobial agents (Motelica et al., 2020). The naturally derived, high molecular weight cellulose can be made flexible by plasticizing with humectants (glycol-type compounds) (Saha et al., 2022).

Chitin and Chitosan

Crystalline chitin has low immunogenicity, biocompatibility, antimicrobial activity, environment-friendliness and biodegradability, which makes it highly attractive substrate for the biomaterial world. Chitin is the most abundant aminopolysaccharide polymer occurring in nature composed mainly of (1-4)-linked 2-acetamido-2-deoxy-β-D-glucose monomers. It is the main component of exoscheleton from crustacean such as crab, and shrimp and insects and cell walls of fungi and yeasts. Chitin acts as a structural material, similar to the role cellulose in plants forming crystalline nanofibrils or whiskers. This cellulose-like biopolymer is distinguished from other polisaccharides by its nitrogen content due to the replacement of glucose with N-acetylglucosamine. This allows increased hydrogen bonding between adjacent monomers, resulting in increased strength for the chitin-polymer matrix (Robertson, 2014; Azizati and Haqiki, 2021; Fuhrmann and Zuberer, 2021; Chen et al., 2023).

Chitosan is an approved food ingredient, however, it has limited industrial applicability due to low mechanical and thermal stability, as well as high sensitivity to water (Kumari et al., 2022). Therefore, chitosan derivatives to improve solubility or biodegradability have been produced to introduce new functions or properties. Chitosan oligomers are soluble over a wide pH range, from acidic to basic, compared to chitosan only being soluble in acidic aqueous media. Lack of solubility at neutral and basic pH has hindered the use of chitosan in some applications. Chitosan is the N-deacetylated derivative of chitin. This natural polysaccharide is produced from deacetylation by enzymatic preparations or treatment with hot alkali (Elieh-Ali-Komi and Hamblin, 2017; Ivanković et al., 2017; Azizati and Haqiqi, 2021; Lárez-Velásquez, 2023). As in the same manner of chitin the structure of chitosan is similar to cellulose except the glucose at position C-2 being replaced by acetamido and/or amino groups (Dutta et al., 2004; Rinaudo, 2006; Srinivasa and Tharanathan, 2007; Priyadarshi and Rhim, 2020). Owing to the specific intermolecular hydrogen bonding network of chitin, its solubility in water is very difficult. However, as chitosan being in deacetylated form can be readily dissolved in dilute acidic aqueous solutions.

The solubility, viscosity, film forming capacity, nontoxicity, bio-compostability, biodegradability, ion binding and antimicrobial properties make chitosan a multipurpose polymer for various food applications, including food packaging (Wang et al., 2018; Crini, 2022; Thulasisingh et al., 2022). The most they use as an edible coating to prolong the shelf- life of fresh fruits and vegetables Chitosan has very poor mechanical properties and resistance to water. Both chitin and chitosan and their derivatives exert biological activities such as antitumoral, antimicrobial, antioxidant, and anti-inflammatory activities, that designates them as therapeutic polymers. Chitin and chitosan showed good antimicrobial properties for various fungi, yeasts, and bacteria found in foods (Ivanković et al., 2017; Shaikh et al., 2021). Its film forming properties and biological activity invite new applications. Being soluble in aqueous solutions, this pseudonatural cationic polymer is largely used in different applications as solutions, gels, or films and fibers (Kaisler et al., 2020; Aranaz et al., 2021).

Polylactic acid (PLA)

Polylactic acid (PLA) is one of the most signified thermoplastic biopolymers made up of renewable resources, lactic acid which is produced either chemically through microbial fermentation or synthetically through the hydrolysis of lactonitrile. Mostly lactides and lactic acid monomers are depolymerized to give PLA. PLA has been acknowledged as safe for all industrial uses involving food packaging. It has been categorized as GRAS (generally recognized as safe) as the migration of LA from PLA packaging containers to food is insignificant (Scarfato et al., 2015; Castro-Aguirre et al., 2016; Nath et al., 2023; Ghasemlou et al., 2024).

In contrast to other biopolymers, PLA has garnered a greater degree of interest in the packaging industry because the existing technology utilized for conventional plastics can be employed for its processing without any modifications required. It can be processed by injection molding, thermoforming, film extrusion, and blow molding. PLA can be plasticized with monomers or oligomeric lactic acid (Aliotta et al., 2019; Mangaraj et al., 2019; Kumari et al., 2022). Its worth mentioning that it also has comparable mechanical characteristics with conventional polymers including PET, PS, and polycarbonate (PC). It is an eco-friendly biodegradable thermoplastic polyester since it slowly degrades over a period of months to two years whilst petroleum based plastics take more.

Polylactic acid has many desirable properties such as high transparency, easy fabrication, biocompatibility, biodegradability, recyclability, superior mechanical strength, non-toxicity and better thermal plasticity. Its main problem is its weak barrier property and oxygen can easily contact it (Motelica et al., 2020) and thermal resistance and high brittleness restrict its applications (Brdlík et al., 2021).

PLA is suitable for fresh foods and those that don't need protection from oxygen in the food packaging industry, it may also be used in food trays, bottles, candy wrappers, and cups. Also because of its high-water permeability, it is ideal for various packaging uses, including extending the shelf life of fresh fruit and bread (Nath et al., 2023). PLA products are preferred as mostly single-use primary packaging plastics such as cups, bottles, clam shells and wrappers for ready-to-eat meals. These packages have short service lifetime and easily find their way into the environment subsequently being thrown away after consumption. Hence their degradability is an important phenomenon to control environment pollution (Karamanlioglu et al. 2017; Imam et al., 2019; Silva et al., 2019; Ncube et al., 2020).

Polyhydroxyalkanoates (PHAs)

PHAs are a family of aliphatic polyesters generated through bacterial fermentations. A range of microorganisms can form and accumulate PHAs as storage materials when cultivated under low and unbalanced nutrient conditions. The production procedures of PHAs include microbial fermentation processes followed by extraction of the metabolite. The carbon source, microbial strain, and pretreatments are effective on the final physical and mechanical properties of PHAs obtained. They are recognized as nontoxic, nonsticky, and insoluble in water (Ghasemlou et al., 2024).

PHAs can be categorized according to their chain length as short-chain (3-5 carbon atoms), medium-chain (6-14 carbon atoms), and long-chain (15 or more carbon atoms) (Westlie et al., 2022). Poly (3-hydroxybutyrate-co-3-hydroxyvalerate) (PHBV) and poly (3-hydroxybutyrate-co-3-hydroxyhexanoate) (PHBH) are the two most well-known PHAs.

In addition to their biodegradable, biocompatible, and renewable nature, PHAs possess properties such as good ultra-violet resistance, high tensile strength, printability, grease and oil resistance, which make them ideal for use in the food packaging industry (Kumari et al., 2022). PHAs have thermo-mechanical properties similar to synthetic polymers such as polypropylene (Mangaraj et al., 2019). The soft and amorphous form of PHAs offers

better flexibility than crystalline or semi-crystalline forms of PHA, which are brittle (González-López et al., 2023; Ladhari et al., 2023).
PHAs exhibit diverse properties depending on the specific monomers incorporated during biosynthesis, offering a wide range of potential applications in food packaging. PHAs such as polyhydroxybutyrate (PHB) possess similar mechanical properties as PE, but their lamellar structure provides higher aroma barrier properties which are useful for short-term food packaging. Poly-3-hydroxybutyrate has comparable characteristics to some commonly used polyolefins such as polyethylene terephthalate, high-density polyethylene, low-density polyethylene and polypropylene in terms of high melting temperature, tensile strength, high resistance to ultraviolet radiation, glass transition temperature and crystallinity (Sirohi et al. 2021a,b).
PHA polymers can be molded into soft films or strong plastics by conventional processing methods to produce cups, jars, trays, or single-use packaging utensils (Rekhi et al., 2022), besides bottles, containers, sheets, films, laminates, fibers and coatings (Mangaraj et al., 2019). The PHA market share is less than 2% within all bioplastics, on the grounds of high production cost for large-scale up applications, almost ten times more than conventional plastics. Use of recombinant technology or mixed cultures, along with improvements in fermentation, recovery, and purification processes might help PHA commercialization. However, high brittleness, low impact strength and low melt viscosity are the other major hurdles which have negative impact on the technological feasibility of PHAs (Torabi et al., 2023), which might be reduced by the use of plasticizers, copolymerization, and blending with other polymers or the addition of inorganic or organic fillers.

Conclusion and Future Work

Bioplastics are sustainable, biodegrable and cost-effective polymers that exhibit comparable properties to conventional plastics with less environmental pollution impact. The waste management and recycling process of fossil-based plastics is hard and complex. Moreover, single-use plastics in food packaging industry display a significant environmental problem. Here bioplastics are considered as a potential solution to reduce the environmental threat for waste collection and recycling. However, biopolymers used for food packaging lack some technical, economic, and legislative deficiencies. Hence, to shift from conventional plastics to bio-based products more research and development is needed in processing and recycling techniques, mechanical properties, large-scale production, cost, durability, sustainability, greenhouse gas emissions and optimum biodegradation.

ABSTRACT

In ultrafiltration processes, membrane surface properties are one of the critical factors that directly affect filtration performance. Membrane fouling can be evaluated depending on the morphology, chemical composition and electrical charge of the membrane used. Furthermore, membrane modifications affect fouling tendencies and play a crucial role in membrane selection. Determination of membrane surface features contributes to the optimization of the ultrafiltration process. In this study, an investigation on membrane fouling characterization, membrane modifications and fouling trends was carried out focusing on surface analysis of ultrafiltration membranes. Various surface characterization techniques such as contact angle method, FTIR-ATR, SEM, AFM and surface load analysis are discussed and how these techniques determine membrane surface properties and their effects on fouling mechanisms are presented.

Keywords: Ultrafiltration membranes, Surface analysis, Membrane fouling

INTRODUCTION

In the food industry, ultrafiltration (UF) technology is used for concentration, clarification and separation of macromolecular solutions (Castro-Muñoz, Boczkaj, Gontarek, Cassano & Fíla, 2020). During UF, macro- and micro-components in the feed fluid accumulate in the porous structure or on the surface of the polymeric membrane, causing membrane fouling. This phenomenon brings many negative consequences.

Surface features of membranes like hydrophilicity/hydrophobicity, surface roughness and charge significantly affect fouling behavior (Xiao, Wang, Huang, Waite & Wen, 2011). Hydrophilic surfaces generally tend to be less fouled, while hydrophobic surfaces tend to be more fouled. Surface roughness affects the adsorption capacity of foulants, and rougher surfaces are generally subject to more fouling. Furthermore, surface load can also determine fouling behavior through electrostatic interactions (Breite, Went, Prager & Schulze, 2015). Various methods are used to analyze the fouling layer consisted on the surface of membranes. In this context, the use of contact angle, FTIR-ATR, SEM, AFM and surface load analysis for the characterization of membrane fouling in ultrafiltration processes was mentioned and membrane surface properties were examined.

CHARACTERIZATION OF ULTRAFILTRATION MEMBRANE SURFACES

Contact Angle Method

The contact angle method is used to identify the degree of hydrophilicity /hydrophobicity of the membrane surface. These measurements are made using a contact angle measuring device. Contact angle meters analyze the angle formed by a liquid drop with the membrane surface, using an optical system (Hebbar, Isloor & Ismail, 2017). In ultrafiltration technique, the surface properties of membranes significantly affect their processing performance. The tendency of the membrane surface to absorb or repel water can be determined by contact angle measurements. Generally, lower contact angles were observed in PES membranes with hydrophilic modifications, while high contact angles were observed in hydrophobic membranes (Otitoju, Ahmad & Ooi, 2018). As a result, it can be said that hydrophilic surfaces interact better with water and reduce fouling tendencies. As shown in Figure 1, it is stated that the membrane has a hydrophilic surface when the contact angle is smaller than 90˚, a hydrophobic surface when it is greater than 90˚, and a super hydrophobic surface above 150˚ (Yürekli, Polatoğlu & Baştürk, 2015). In the studies, it has been observed that lower contact angle values are obtained when the pore size of the membrane is increased (Susanto & Ulbricht, 2005). In summary, the contact angle method is important in terms of evaluating the effectiveness of modifications applied to membrane surfaces.

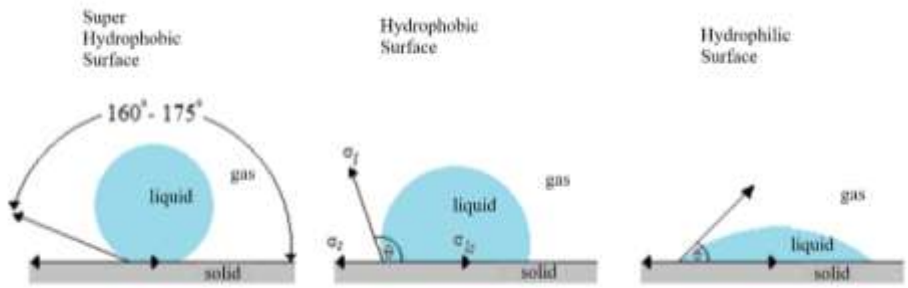

Figure 1. Contact angle results of different membrane surfaces (Yürekli, et al., 2015).

FTIR-ATR Analysis

Fourier Transform Infrared (FT-IR) spectroscopy and Attenuated Total Reflectance (ATR) method are used to analyze the chemical composition of fouling, and the layers formed on the membrane surface (Liu, Chen & Yu, 2020). The principle of the analysis is based on the reflection of infrared light sent to the sample surface (Glassford, Byrne & Kazarian, 2013), and the interaction between the ATR crystal and the surface shows how much the functional groups on the membrane surface absorb IR light. The ATR crystal is able to detect changes on the surface with a thickness of less than 1 micrometer (Yürekli, Polatoğlu & Baştürk, 2015). Phenolic compounds or other organic substances in the feed liquid used in ultrafiltration can be identified by this method. It has been reported that FT-IR spectra help to determine the functional groups and chemical bonds of organic and inorganic foulants (Gaffney, Marley & Jones, 2002). In a study investigating the chemical composition of clean and dirty UF membranes, the polymer structures of the clean membrane were first identified, so that the contaminant particles after the filtration process could be identified more easily with the help of the peaks obtained (Oldani & Schock, 1989). In a study investigating the surface characterization of membranes, it was observed that new bonds were formed in the FTIR spectra of modified membranes. It was reported that membranes with stronger properties were obtained with the bonds formed (Biederman, et al., 2001). As a result of all these, it is seen that FTIR-ATR analysis contributes to the optimization of the filtration process by determining the surface modifications and fouling mechanisms of membranes.

SEM Analysis

Scanning Electron Microscopy (SEM) is used to analyze the morphology and roughness of the membrane surface by imaging the surface topography in three dimensions at high resolution (Zhong, Li, Zhang & Xing, 2012). In SEM analysis, an electron beam is sent onto the sample, where it interacts with the electrons released on the surface. With the help of a detector, the electrons are collected and various images are created (Joy & Joy, 1996). It has been stated that the cross-sectional image obtained for ultrafiltration membranes provides information about the variation of porosity along the thickness, density and thickness of the upper layer otherwise, surface images provide information about membrane pore size and density (Yürekli, Polatoğlu & Baştürk, 2015). In various SEM analyses, it was observed that PES membranes with hydrophilic modification have smoother surfaces and less accumulation on the membrane surface. Conversely, the surfaces of membranes with hydrophobic character are rougher and more prone to fouling (Ahmad, Abdulkarim, Ooi & Ismail, 2013). In a study examining the surface properties of membranes with different polymeric structures, it was reported that more porous, ups and downs images were obtained in the membrane with a more hydrophilic structure (Gulec, Bagci & Bagci, 2017). Thus, SEM analysis helps to determine the fouling mechanisms by examining the morphological properties of foulants deposited on the membrane area.

AFM Analysis

Atomic Force Microscopy (AFM) is used to idetify surface roughness and nanometric structures on the surface (Russell, Batchelor & Thornton, 2001). AFM allows to obtain the topography of the surface of a sample by scanning over its surface with a very fine tip (probe). This probe moves up and down very close to the surface of the sample and the movements are measured with the help of a sensor (Sun, 2018). In this way, a detailed map of the membrane surface at the nanometer scale can be obtained. In ultrafiltration membranes, AFM is used to evaluate the surface roughness and to determine the size and shape of the pores on the area (Boussu, et al., 2005). In a study where a three-dimensional picture of the membrane surface was taken and the shadows were colored, it was reported that the higher areas were lighter and the lower areas were darker (Hilal, & Johnson, 2010). Surface roughness is an important factor in membrane fouling, and rougher surfaces can increase membrane fouling by facilitating the adhesion and deposition of particles. It has also been observed that the adhesion force of the AFM probe to the membrane area can determine the hydrophilic or hydrophobic properties of the surface (Brant & Childress, 2004). In studies, it is stated that hydrophilic surfaces generally have higher surface energy and reduce membrane fouling by causing water to spread more easily on the surface (Díez & Rosal, 2020). In addition, it has been observed that the cake layers formed on the surface can be examined in more detail using AFM in studies using UF (Li, et al., 2018). In summary, AFM is important in understanding the surface properties of ultrafiltration membranes and investigating the effects of these properties on membrane fouling.

Surface Load Analysis

Surface load analysis is used to specify the electrical charge of the membrane surface. To determine this electrical charge, zeta potential measurements are required (Nghiem, Schäfer & Elimelech, 2006). Zeta potential refers to the electrical potential difference in the double layer structure around a surface and varies depending on factors such as ionic strength, pH and chemical composition of the membrane surface (Attard, Antelmi & Larson, 2000). Surface load can be determined by zeta potential device. The device calculates the surface charge as zeta potential and shows the results graphically. In ultrafiltration membranes, the surface load can take positive, negative or neutral values depending on the chemical composition of the membrane material and surface modifications. It is stated that surfaces with high zeta potential generally reduce membrane fouling by repelling particles with the same charge, but this may alter depending on the fouling mechanism (Kochkodan, Johnson & Hilal, 2014). It has also been observed that in membranes with a more hydrophilic structure, foulants with the same charge electrostatically repel each other and the zeta potential takes negative values (Breite, Went, Prager & Schulze, 2015). Therefore, selecting a membrane surface that is appropriately loaded according to the nature of the foulant particles in the feed fluid has been reported to be an substantial factor in reducing membrane fouling (Kumar & Ismail, 2015). In a study showing that membrane fouling largely depends on the zeta potential and hydrophilicity of the surface, it was stated that membrane fouling can be avoided by changes in pH values and electrostatic repulsion forces (Breite, Went, Prager & Schulze, 2015). Thus, zeta potential helps to evaluate membrane fouling behavior by determining the electrostatic interactions between membrane and foulants and the charge density on the surface of particles.

CONCLUSIONS

The surface chemistry, morphology and charge properties of membranes directly affect their fouling behavior and filtration performance during the ultrafiltration process. The mentioned analysis methods ensure information about the chemical composition, physical structure and interactions of membrane fouling with the surface. The contact angle method determines the hydrophilic or hydrophobic nature of the membrane, while FT-IR and ATR analyze the chemical structure of the foulants. SEM and AFM visualize the morphology and surface roughness of the fouling layer. Zeta potential measurements determine the electrostatic interactions between the foulants and the membrane. The combination of these methods allows for a comprehensive characterization of membrane fouling. In this way, it may be possible to develop fouling prevention strategies and increase the efficiency of membrane systems.

FUNCTIONAL FOODS AND THEIR EFFECTS ON HEALTH

Kübra Demir, Orhan Onur AŞKIN

Kırklareli University

ABSTRACT

In recent years, there has been a significant increase in interest in natural products as individuals have become more health-conscious and aware of disease prevention. People are turning to functional foods to protect and improve their health, rather than relying on chemically-based medications. These foods are preferred more frequently due to their nutritional properties and their role in preventing diseases.

Functional foods can be defined as products that have positive effects on health thanks to certain biologically active components added to them. For example, adding ingredients such as omega-3 fatty acids, probiotics, fibers, and antioxidants to foods makes these products functional. These types of foods offer various benefits, such as strengthening the immune system, protecting heart health, ensuring proper digestive function, and generally enhancing quality of life by supporting specific metabolic processes in the body.

Another important feature of functional foods is that they do not contain synthetic ingredients. These foods can be included in a daily diet, consumed directly, or found in the form of food and beverages. While they serve as a part of the daily diet due to their nutritional qualities, they also stand out for their functions in reducing the risk of diseases and improving overall health. For this reason, functional foods occupy an important place in modern nutritional approaches.

In conclusion, functional foods play a significant role in supporting individual health and are increasingly finding a place in today's dietary habits. In an era where lifestyle diseases are on the rise, the consumption of such foods has great potential to protect individual health and improve public health levels.

Keywords: Functional foods, health benefits, nutraceuticals.

INTRODUCTION

Foods contain the nutrients required for an individual's survival, normal development, and growth. Recent advancements in food and nutrition science have demonstrated that foods not only meet the nutritional needs of individuals but also play a role in regulating various body functions and preventing certain diseases [1].

Foods have three primary functions: nutritional, sensory, and physiological. While nutritional and sensory functions are found in every food, only some foods possess physiological functions. However, with various technological processes applied in recent years, it has become possible to endow foods with physiological functions [1].

Functional foods are those that provide additional benefits beyond meeting the body's basic nutritional needs by exerting positive effects on human physiology and metabolic functions. As such, they play a role in disease prevention and promoting a healthier lifestyle. Functional foods can be natural, unprocessed food items, or they can be enriched with functional components or modified through genetic engineering methods to be consumed as part of the daily diet [2].

For food to be considered functional, it must contain active agents such as bioactive compounds, probiotic microorganisms, and prebiotic substances, and these agents must be adequately delivered to the relevant areas of the body. The effect of a bioactive compound should not be confused with the alleviation of symptoms caused by its deficiency; it should be based on the benefit it provides beyond its primary function [3].

Recent advancements in food science and technology have also led to the emergence of new terminologies such as novel foods, nutraceuticals, designer foods, pharmacofoods, and phytosceuticals. Nutraceuticals refer to both traditional and different forms of food components (such as tablets, capsules, etc.), while functional foods denote traditional food forms. Examples of functional foods include probiotic and prebiotic yogurts, margarines enriched with olive oil, various herbal teas and seeds (such as green tea, walnuts, flaxseed, etc.), certain seafood (rich in essential fatty acids), meat products enriched with fiber, antioxidant-rich foods, and low-cholesterol eggs [4].

Probiotics/Prebiotics

Probiotics are defined as live microbial food additives that provide beneficial effects on health by residing in the digestive system [5]. Probiotics contribute to the intestinal microbial balance by enhancing the flora, binding to receptors via competition to leave no space for pathogens, and facilitating their excretion through feces. Microorganisms used as probiotics include Lactobacillus acidophilus, GG, rhamnosum, lactis, Streptococcus thermophilus, and yeasts such as cerevisia and inigeroryze [6].

Prebiotics are non-digestible food ingredients that promote the growth of beneficial colon bacteria, which positively affect human and animal health. The most commonly known prebiotic substances are oligosaccharides. Oligosaccharides are non-digestible polysaccharides consisting of 3-10 sugar units linked by glycosidic bonds. As prebiotics, oligosaccharides have the ability to bind to fimbriae, which allow pathogenic microorganisms to adhere to the intestinal surface, thereby preventing colonization of pathogenic microorganisms and facilitating their excretion through feces [7].

Foods can be made functional with probiotics and/or prebiotics. Because bacteria such as lactic acid used in the production of various fermented dairy products like yogurt cannot survive in the digestive system, probiotics like Lactobacillus acidophilus and bifidobacteria are added to these products. In recent years, these bacteria have been sold in tablet form, as capsules, and by freeze-drying methods in the market. The presence of both prebiotics and probiotics in the same product as synbiotics enables the utilization of the beneficial functional effects of both when consumed [7].

The microflora in the digestive system plays a very important role in the health of humans and animals. The effects of lactobacilli on human health were first proposed by Metchnikoff at the beginning of this century. Probiotic bacteria are known to have antibacterial activities against pathogenic bacteria, and they have many positive effects on the immune system and anti-allergic responses [5]. According to the World Health Organization (WHO) and the Food and Agriculture Organization of the United Nations (FAO), probiotics are defined as live microorganisms that, when administered in adequate amounts, confer a health benefit on the host.

The consumption of probiotic-containing products has beneficial effects on health, strengthening gut and body health, and combating other diseases, and the benefits of these bacteria to human health have been known for a long time. The most important of these benefits is the regulation of the gastrointestinal system. However, they also contribute to the prevention and improvement of many other diseases. For example, probiotics are reported to have therapeutic applications such as preventing hypercholesterolemia, protecting against colon/bladder cancer, preventing osteoporosis, protecting against diarrhea, alleviating constipation, and preventing urogenital infections. Additionally, they have benefits like enhancing the immune system, protecting the normal intestinal microflora against pathogens, and lowering blood pressure [8].

Prebiotics, as fermentable carbohydrate sources for intestinal bacteria, play a significant role in reducing the risks of colon cancer by producing short-chain fatty acids and suppressing toxicogenic bacterial reactions. They lower intestinal pH, thereby increasing the solubility and absorption of minerals like calcium, magnesium, and iron ions. Moreover, the interaction between calcium and short-chain fatty acids also enhances mineral absorption. Long-term consumption reduces the risk of osteoporosis by increasing bone density. When they cause the intestinal environment to become acidic, they reduce the activity of procarcinogenic enzymes (7α-hydroxylase and nitroreductase). They are particularly effective in relieving intestinal problems like constipation in elderly individuals where Bifidobacterium species in the intestinal flora have decreased and been replaced by harmful bacteria. Prebiotics are effective in preventing food allergies in infants by increasing the number of probiotics. When prebiotics are used in conjunction with probiotic Bifidobacterium species, physiological and health effects are observed. Prebiotics promote the growth of bifidobacteria and are therefore important in manifesting the health benefits of bifidobacteria. Additionally, prebiotics inhibit the proliferation of pathogenic bacteria, have a laxative effect, reduce the risk of developing diarrhea, lower serum triglyceride levels, and reduce postprandial glucose and insulin levels in animal studies. Oligosaccharides themselves act like cell surface receptor analogs, binding pathogenic microorganisms and facilitating their excretion through feces [9].

Antioxidants

The primary sources of antioxidant substances are fruits and vegetables, which are widely consumed in daily diets. These foods contain essential nutrients such as water, various vitamins, minerals, polyphenolic compounds, and dietary fiber, and they are low in salt, making them one of the most important food groups in human nutrition. Recent epidemiological studies have shown that fruits and vegetables play a significant role in maintaining health and preventing diseases. High consumption of fruits and vegetables has been reported to help reduce the risk of chronic diseases such as cataracts, chronic lung diseases, hypertension, cardiovascular diseases, Alzheimer's, Parkinson's, and cancer. These benefits are attributed to the antioxidant components found in fruits and vegetables. Substances with antioxidant functions include vitamins C, E, and A, carotenoids, flavonoids, organic acids, melanoidins, and phenolic compounds. The antioxidant effects of especially vitamins E, C, and carotenoids have been demonstrated in numerous studies [10].

The primary effect of antioxidants on human health is their role as free radical scavengers. During metabolic activities, oxygen can be converted into reactive oxygen species, such as superoxide, hydrogen peroxide, singlet oxygen, and hydroxyl radicals, making oxygen highly toxic to living systems. In the presence of antioxidants, oxidative stress-related damage is significantly reduced in the body. Antioxidants act as hydrogen atom donors, converting chain-forming radicals into less reactive species. They prevent lipid peroxidation, cross-linking of proteins, and DNA mutations. Antioxidants neutralize oxidants through four different mechanisms:

- **Scavenging effect**: This occurs by converting oxidants into weaker molecules.
- **Quenching effect**: This involves neutralizing oxidant substances by transferring a hydrogen atom, primarily done by flavonoids.
- **Repair effect**: Antioxidants exert this effect by eliminating damage caused by oxidants.
- **Chain-breaking effect**: This effect, performed by hemoglobin and vitamin E, involves binding to oxidants and inhibiting their function [11].

Following the discovery of the beneficial effects of antioxidants, synthetic antioxidants were produced, but their use was associated with some side effects. This led to an increased preference for natural antioxidants. In one study, egg yolk, which is high in antioxidant content, was added to meatballs made from turkey meat. It was found that increasing the amount of egg yolk added to the meatballs correspondingly increased the antioxidant capacity [12].

Ice Creams

Ice cream is generally a dairy product enjoyed by people of all ages, made by processing a mixture (ice cream mix) of milk and dairy products (such as milk powder, cream), sweeteners, stabilizers, emulsifiers, colorants, and flavoring agents with added air in freezers [13].

Studies on functional dairy products hold an important place within research on functional food products. Due to their health benefits and their presence in almost every individual's daily diet, milk and dairy products are highly suitable for transformation into functional products. Functional ice cream is also an important component among functional dairy products. Besides its health benefits, the ease of modifying its composition and its popularity among people of all ages have increased research into making ice cream functional.

Ice cream is a high-nutrition product widely produced and consumed in almost all countries due to its significant nutritional content. In our country, it is mainly known as a dairy product consumed for pleasure, especially during hot summer days to cool off. Ice cream consumption per capita in our country is quite low compared to many other countries. However, the increasing number of modern ice cream-producing businesses, the rise in quality, and various educational activities have led to a growing trend in the consumption of this product during both summer and winter.

It is possible to make ice cream functional using various components. When considering the most commonly used methods, the types of functional ice creams can be listed as follows [14]:

- Probiotic, prebiotic, and synbiotic ice cream
- Ice cream enriched with whey
- Ice cream with reduced fat and/or sugar content
- Ice cream with increased antioxidant capacity
- Ice cream enriched with dietary fibers
- Ice cream enriched with omega-3 fatty acids
- Ice cream enriched with minerals
- Other functionally enhanced ice creams

•

Products containing probiotic bacteria and prebiotic substances hold an important place among functional foods because they help regulate the gastrointestinal system in individuals. Probiotics are live microorganisms that, when consumed in certain amounts, have positive effects on the gastrointestinal system of the individual [6]. It is known that probiotics present in the intestinal microflora have protective effects against various diseases, improve the immune system, have anti-carcinogenic properties, and lower serum cholesterol levels [5].

The combination of probiotics and prebiotics in a product is called synbiotic. If a probiotic bacterium utilizes a prebiotic present in the environment, a “synbiotic effect” occurs, and when a product containing both is consumed, the functional properties of both probiotics and prebiotics are utilized [5, 15].

There are numerous studies examining functional ice creams that result from the use of probiotics, prebiotics, or both, and their properties. In a study conducted by Alamprese et al. [16], the probiotic bacterium *Lactobacillus johnsonii* La1 was added to ice cream samples with varying fat and sugar contents, and various properties of the product were examined. The results showed that the probiotic bacteria used in ice cream production could maintain their presence at high levels for up to 8 months of storage, demonstrating that probiotic ice cream production is possible using the method in the study. In another study [17] where probiotic ice cream was produced from goat’s milk, the sample containing *Bifidobacterium animalis* subsp. *lactis* BLC1, a probiotic strain, was compared with a control sample without the bacteria in terms of various properties. The physical, chemical, and sensory analysis results indicated that producing probiotic ice cream from goat’s milk is feasible. Furthermore, in samples with bifidobacteria, approximately 7 log CFU/g of live microorganisms were detected within the first 24 hours after production, meaning 84.3% of the bacteria remained viable. During 120 days of storage under refrigeration, the number of live bacteria did not fall below 6.5 log CFU/g. In all studies, various microorganisms and components with probiotic or prebiotic properties were added to ice cream samples, and the physical, chemical, and sensory properties of these functional ice creams were examined. The results from all related studies demonstrated that the samples maintained their probiotic, prebiotic, or synbiotic properties throughout long storage periods.

Whey is the yellowish-green liquid portion separated when the curd is cut during cheese production [18]. Containing lactose, serum proteins, fat, minerals, and water-soluble vitamins, whey is a highly nutritious dairy byproduct. Due to its significant content of serum proteins with high biological value, whey has numerous health effects. Important biological effects of whey include antibacterial, antiviral, immune-supporting, antioxidant, anti-carcinogenic, and hypocholesterolemic effects. Research has also shown that it supports growth, bone development, and weight control [19, 20].

Milk fat has important functions, such as reducing the risk of heart disease and cancer, enhancing the immune system, and positively affecting bone health and body structure. Ice cream generally contains between 10-14% fat. Although milk fat has many positive effects, it is thought that consuming a product with such a high-fat content might pose health risks, especially for individuals with heart disease, cholesterol issues, and diabetes. In recent years, food products with reduced fat content have become more popular among individuals who need to consume less milk fat due to health problems and those who prioritize healthy eating. The sugar content of ice cream is also quite high, ranging between 15-17%. Consuming products with high sugar content is not suitable for individuals with conditions requiring reduced sugar intake, such as diabetes. People who care about their daily diet and want to lose weight also prefer food products with reduced sugar content.

Aime et al. [36] produced vanilla ice cream with reduced fat content using fat replacers to compensate for the textural defects caused by the reduction of milk fat. For this purpose, 5% pea starch was added as a fat replacer to each ice cream sample with varying fat levels (5%, 2.5%, and 0.4%) [21].

Antioxidants have protective and therapeutic effects on cells. Studies have shown that antioxidants exert a protective effect on cells by neutralizing free radicals [22]. Antioxidant compounds play a significant role in preventing many diseases, including cataracts, cancer, cardiovascular disorders, and neurological diseases. The most important natural antioxidant compounds include carotenoids, flavonoids, and other simple phenolic compounds found in cereals, fruits, and vegetables, along with vitamins A, C, and E [23]. Therefore, foods intended to be made functional with antioxidant properties often include various cereals, fruits, and vegetables high in these antioxidant compounds. There are several studies on the production of functional ice cream with increased antioxidant capacity and the investigation of its properties. For example, Hwang et al. [24] examined the effects of grape pomace on the rheological properties and antioxidant capacity of ice cream. As the amount of grape pomace added increased, the viscosity of the samples also increased, even surpassing that of samples with added stabilizers. Additionally, the melting rates of the samples significantly decreased with grape pomace addition. Another significant finding of the study was that the antioxidant capacity of ice cream samples increased due to the antioxidant content of grape pomace, and the antioxidant components remained stable during production.

Dietary fibers are food components primarily found in cereals, fruits, and vegetables that are highly resistant to digestive enzymes and are not digested in the small intestine but are partially or completely fermented in the large intestine. Fibers generally refer to the indigestible and relatively rigid parts of fruits and vegetables, such as peels, membranes, stems, and seeds. Dietary fibers, which have become increasingly prominent in low-energy diet products in recent years, are frequently used in functional foods due to their many positive health effects. It has been noted that dietary fiber components regulate large intestinal functions, have physiological effects on glucose and lipid metabolism and mineral absorption, and are known to have protective effects against constipation, hemorrhoids, colon cancer, obesity, diabetes, and cardiovascular diseases [25]. In a study conducted by Crizel et al. [26], some by-products obtained from oranges (peel, pomace, and seed fibers) rich in dietary fibers were used in ice cream, and various sensory properties of the samples were examined.

Functional foods enriched with products or components rich in omega-3 fatty acids can be placed at the forefront of foods that help reduce cardiovascular disorders. The most effective omega-3 fatty acids against these conditions are EPA (eicosapentaenoic acid) and DHA (docosahexaenoic acid), which are found exclusively in seafood and in trace amounts in other foods [27]. Besides cardiovascular benefits, EPA and DHA have numerous positive health effects. These fatty acids have been shown to prevent vascular blockage, gangrene, stroke, migraine, and allergic asthma, strengthen the immune system, and have protective and even therapeutic effects against various intestinal and skin diseases [28-29]. Due to these functional properties, the number of studies on products enriched with fish oil, especially, has been increasing. Additionally, the use of plant-based products rich in ALA (α-linolenic acid), another omega-3 fatty acid, such as flaxseed, purslane, spinach, soy, and canola, in foods is also possible. For the production of omega-3 enriched ice cream, Corradini et al. [30] used milk from cows fed with palm oil and coconut oil. Chromatographic analysis results showed that the milk from animals fed with palm oil contained more omega-3 fatty acids than milk from those fed with coconut oil, and the omega-3 fatty acid content of the ice cream samples mirrored the milk composition.

As previously mentioned, ice cream is a significant source of calcium and phosphorus [31]. However, as with almost all food products, the mineral enrichment of ice cream is a subject of study due to the important functions minerals serve. Minerals play general roles such as forming the basis of bone and tooth structure, being part of organic compounds like proteins and fats in muscles, organs, blood cells, and other soft tissues, and being involved in some enzyme systems, muscle and nerve stimulation, osmotic pressure, pH regulation, and acting as antioxidants. Various studies have been conducted on the mineral enrichment of ice cream due to these functional properties. In a study by Costa et al. [33], the effects of adding κ-carrageenan and calcium chloride on the structure and quality characteristics of ice cream were examined. The analysis results showed that calcium chloride addition caused growth in ice crystal size and partial coalescence in milk fat. Moreover, these effects were observed to be further enhanced with the addition of κ-carrageenan.

In addition to the various functional ice cream production methods mentioned above, research has also been conducted on ice cream enhanced with some natural flavoring agents, enriched with various fatty acids, and produced with reduced lactose content. For example, Trzecieski [34] conducted a study focused on reducing the lactose content of ice cream, which is often difficult for individuals with lactose intolerance to consume due to its high lactose content. In this study, lactase (β-galactosidase) enzyme preparation was added to the ice cream samples, facilitating the hydrolysis of lactose into glucose and galactose.

CONCLUSION

With changing living conditions, consumers' expectations from the foods they consume have evolved along with their eating habits. The desire for healthier eating, coupled with the growing demand to prevent diseases through diet, has increased significantly. Enhancing the functional properties of foods commonly consumed in daily diets, especially over the past decade, has become a frequently studied topic. The focus of these studies varies by country, with the type of food being functionalized or the aspect of functionality targeted based on the demands of individuals and the most common health issues in each region.

Prebiotics and probiotics are crucial for human digestive health, and many people prefer functional foods containing these beneficial bacteria because they need to include them in their daily intake. Antioxidants play an important role in metabolic processes and reactions. They act as hydrogen atom donors and convert chain-forming radicals into less reactive species, thereby preventing lipid peroxidation, protein cross-linking, and DNA mutations.

Ice cream has become a key focus for functional enhancement due to its nutritional value and its frequent inclusion in the diets of individuals of all ages. When examining the functional food groups consumed worldwide, functional dairy products are the most widely consumed in many countries, with ice cream holding a significant place within this category. Besides its high nutritional value, ice cream is a product enjoyed by people of all ages and, compared to other dairy products, is one of the easiest to modify in composition. This makes ice cream a popular subject of research for functional enhancement.

Educational activities for both producers and consumers regarding functional ice cream can further increase its consumption and lead to more focused research on this topic.

NEW TECHNOLOGIES AND TRENDS IN THE FOOD PRODUCT DEVELOPMENT PROCESS

Remziye Nur Gültekin, Orhan Onur AŞKIN

Kırklareli University

ABSTRACT

Today, manufacturing enterprises face numerous challenges, such as technological innovations, shortened product lifespans, increasing competition, and rapidly changing customer expectations. These challenges compel businesses to closely follow market developments and innovations, requiring them to adapt swiftly to maintain their competitive advantage. Especially with globalization, consumers have become more conscious and demand that food products are produced, processed, stored, transported, and distributed under safe conditions, emphasizing food safety. Customers prioritize not only the taste and quality of the products they purchase but also that these products are manufactured in a safe, healthy, and sustainable manner.

In this dynamic environment, businesses in the food industry are under pressure to prioritize food safety and nutritional quality while producing a diverse range of products that meet evolving customer needs. This pressure accelerates the new product development process in the industry and fosters the adoption of innovative approaches. In today’s food sector, the principle of sustainability is gaining increasing importance. In this context, environmentally friendly production methods, waste management, energy savings, and efficient use of natural resources are becoming key priorities for companies. New technologies and trends used in the food industry focus on extending shelf life while preserving the nutritional value of products, improving sensory characteristics such as taste and texture, and enhancing health-promoting functional components. These technologies include non-thermal food processing methods such as high-pressure processing, cold plasma technology, pulsed electric fields (PEF), ultrasonic and microwave processing, and other innovative techniques. Compared to traditional thermal processes, these methods better preserve the nutritional value of products and ensure food safety while causing less environmental harm.

Significant innovations are also observed in food packaging techniques. Solutions such as active and intelligent packaging, edible coatings, biodegradable packaging, and nanotechnology-enhanced packaging are being used to improve food quality and safety. These innovative packaging methods prevent food spoilage, reduce waste, and contribute to a more sustainable food system.

In conclusion, the new product development process in the food sector is shaped by innovative and advanced technological solutions that consider customer expectations and sustainability principles. These developments create a competitive advantage in the industry while supporting the community's access to healthy and safe food. Through these new technologies and sustainable practices, food manufacturers can respond more quickly to consumer demands, securing a strong position in the market.

Keywords: Food, new product, development, technology.

INTRODUCTION

The food sector holds a crucial position within the manufacturing industry due to the demand arising from one of the most fundamental human needs: nutrition. As it addresses the essential need for food products and is critically important for public health, the food sector is significant for both the economy and societal structure of a country. Additionally, the unique combination of both agricultural and industrial infrastructure within the food sector distinguishes it from other sectors.

The success of businesses in this field depends on enhancing the quality and reliability of the products they produce, expanding product variety, manufacturing in accordance with consumer orders, quickly meeting consumer needs and desires, and improving the services offered to customers. Achieving these objectives is possible only through the development of new products and their successful introduction to the market [1].

These are activities conducted to develop a new product or to produce an existing product more effectively or with improvements. For some, developing a new product means creating an entirely new product, while for others, it simply involves conducting scientific research. As the term "new product development" suggests, it involves initially conducting research to discover what has not yet been found and then enhancing or renewing the knowledge or product. It encompasses specialized activities aimed at making an existing product more effective or improved or developing a product that has never been produced but is planned for future production, with the goal of being a market leader in a particular field [2].

Innovative developments in food production systems contribute significantly to production efficiency. These innovations encompass a comprehensive process that begins with input procurement and extends through all production stages until the product reaches the consumer, even including after-sales activities. Both the public and private sectors have increasingly begun to invest efforts into the implementation of these innovative developments. The driving force behind this effort is the wave of innovation movements and globalization that have emerged worldwide in recent years. This ongoing transformation is evident in food production systems, and food production is increasingly becoming an integral part of industrial manufacturing [3].

The food sector is increasingly focusing on developing nutrient-rich, alternative, sustainable, and nanotechnological foods, as well as practices aimed at preventing waste, to keep pace with advancing technology. Among the developments aimed at meeting the growing demand for protein are alternative protein sources, such as lab-grown meat, insect-based proteins, and plant-based proteins. Following these developments, various plant-based protein products have emerged, including plant-based burgers, sausages, chicken, cheese, butter, eggs, and yogurt. Beyond these advancements, efforts are underway to meet the food needs of crews during space missions. Examples of such efforts include the development of long-shelf-life, nutrient-rich, and safe foods, often produced through freeze-drying methods [4].

1. Alternative Protein Sources

In recent years, the increasing human population and changing consumer preferences have led to a rise in research and biotechnological studies on alternative protein sources. It is estimated that with the growing human population, the demand for meat consumption will double, and animal production will reach its maximum capacity. Consequently, traditional methods are expected to fall short of meeting the rising demand, and production costs are anticipated to increase further. In this scenario, meat consumption is likely to be perceived as a luxury. Therefore, exploring new protein sources that can replace natural animal proteins, such as meat, is expected to have significant economic, nutritional, and environmental impacts and create substantial shifts in the meat industry [5].

The first commonly used alternative protein sources are plants and fungi [6]. Additionally, insects, seaweed, and cultured meat or in vitro meat also serve as significant protein sources [5].

1.1. Cultured Meat (In Vitro)

In vitro, or "cultured meat," also known as artificial or lab-grown meat, utilizes revolutionary technologies designed to address the challenges faced by the traditional meat industry [7]. Terms such as cultured meat, artificial meat, or clean meat are used for in vitro meat, which is derived from tissues and cells grown in a laboratory environment [5]. The development of artificial meat primarily focuses on two areas: cultured meat and plant-based meat alternatives. Several meat substitutes have been developed and are continuously being improved as alternatives to traditional meat [8]. For instance, meat substitutes made entirely from plant-based ingredients have gradually gained a small but growing market share [9]. Soy and wheat-based proteins are commonly selected for this production, providing efficient protein yields.

Although the technologies used to enhance the texture and taste of plant-based products are constantly evolving, replicating meat using plant-derived proteins, sugars, and fats remains challenging. Therefore, plant-based meat is predominantly used in processed meats such as burgers, sausages, and other minced products. Insects, on the other hand, are another natural protein source with high protein content in addition to sufficient minerals [8]. Insects contain between 38% and 77% protein by total dry weight. Many insect species, such as crickets (68.7%), have been reported to contain higher protein content per 100 g of dry weight than red meat (27.4%) or cod (28.5%) [10].

The potential benefits of cultured meat production include reducing greenhouse gases from animal production (especially methane), contributing to the prevention of global warming, preventing deforestation and land degradation, using agricultural land and crops to meet human nutritional needs, eliminating the necessity of slaughtering many animals, and meeting the protein needs of the growing human population [5]. Despite similarities to traditional red meat production, the acceptance of cultured meat by consumers remains controversial, as animals with artificially altered genomes in laboratories are considered artificial or human-made [7].

2. Nanotechnological Foods

The term nanotechnology is derived from the Greek prefix ‘nano,’ meaning ‘dwarf’ [11]. Food molecules found in nature exist on a micro or nanoscale. For instance, globular proteins in foods measure between 10-100 nm, and the 3-D crystalline structure of starch polysaccharides is 10 nm thick. In the food industry, many studies aim to create micro/nanoscale foods using top-down or bottom-up approaches. Nanotechnology is a relatively new field for the food industry. Nanotechnological applications in the food sector include nanoparticle delivery systems (such as micelles, liposomes, nanoemulsions, and biopolymeric nanoparticles), food safety, biosecurity (e.g., nanosensors), and nanotoxicology [12].

Nanofood is defined as foods derived through nanotechnological techniques or devices during soil processing, production, manufacturing, and packaging stages. Applications of nanotechnology in the food industry include improving food packaging systems to ensure quality and safe food production, enhancing traceability of food using biosensors, and developing active and intelligent packaging systems that allow the detection of bacteria [13].

One of the most common problems faced in the industry is the loss of freshness and quality of food before it reaches the consumer. One of the primary issues contributing to this is oxidation. Oxygen causes discoloration and spoilage of fats in cheese and meat. Polyamide-6 and ethylene vinyl alcohol can be used for food packaging; polyamide is suitable for less sensitive foods, while ethylene vinyl alcohol is ideal for highly sensitive foods. Some polymer researchers have developed a new nanocomposite plastic enriched with large-diameter silicate nanoparticles, known as a “hybrid system.” These hybrid systems have reduced oxygen permeability by 40% compared to conventional packaging materials. Nanotechnology plays a significant role in designing intelligent biosensors that can be packaged with food. These sensors, equipped with color-changing indicators, can inform consumers about the freshness of the food [12].

However, the use of nanoparticles in the food industry raises concerns among consumers. Due to the unknown effects of nanoparticles on human health and the lack of established maximum exposure limits, consumers are cautious about nanotechnology applications. It is believed that these concerns regarding the use of nanomaterials during food processing and packaging can be addressed through increased research, new approaches, and national and international legal and scientific regulations [13].

3. Space Food

Astronauts can face various nutritional deficiencies during space missions, making a healthy and nutritious diet a crucial factor for a successful space journey. Nutrition provides essential nutrients that help the body adapt to adverse environmental conditions (homeostasis), and nutrition in space differs from that on Earth due to the unique and harsh environment. Therefore, astronauts often encounter various nutrient deficiencies, including those required for their diets. To prevent these issues, space foods must be developed with critical parameters in mind. For example, these foods should have a longer shelf life and be produced to remain stable in zero-gravity conditions.

During space travel, astronauts must consume sufficient food not only to meet their nutritional needs but also to minimize the adverse effects of spaceflight on the body. Nutrition plays a vital role in countering the harmful effects of space travel on the human body, including oxidative stress, exposure to radiation, and bone and muscle loss [14].

Space food products typically contain reduced fiber and fat content and increased carbohydrates. The protein content is similar to that of Earth-based foods, but due to the absence of UV light, vitamin D intake is lower [14]. Changes in the body's biological clock and reduced food intake can alter taste perception, meaning that foods that taste good on Earth may not seem appealing in space [15]. To extend the shelf life of food and beverages in space, packaging must withstand pressure, external atmospheric conditions, and temperature while maintaining oxygen levels [16].

Flexible and soft packaging, suitable for sterilization, is often made from metal foil and flexible plastic laminates. These are used for packaging thermostabilized and irradiated foods, such as soups and dairy products, providing a long shelf life of up to 3-5 years, and serving as a replacement for rigid metal cans [14].

4. Three-Dimensional (3D) Food Production

Three-dimensional (3D) printers are increasingly gaining attention from both producers and consumers due to the innovations and advantages they offer. The primary reasons for this interest include the lack of need for special tools and equipment during production, reduction of labor, the ability to influence product quality characteristics (such as color, shape, texture, and aroma), and the ease of adjusting the raw material content as needed [17]. Today, raw materials developed specifically for this technology, as well as technologies that can process these materials appropriately, are commercially available [18].

In 3D food printers, the desired characteristic of raw materials is their ability to flow smoothly from the printer cartridge to the printing platform while maintaining a solid structure once deposited. Materials that can form hydrogel structures, such as starch and protein, as well as substances like cheese, chocolate, and hummus, can easily flow from the printer cartridge to the platform. In another study, sugar, starch, and mashed potatoes were used as raw materials, yielding positive results. It is worth noting that foods produced with these raw materials are generally in the snack or dessert category and are not suitable as main courses [17].

With materials that can be naturally printed in 3D printers, complete control can be achieved over taste, nutritional value, and texture. Although certain foods like meat, rice, fruits, and vegetables are inherently challenging to print, this limitation is being addressed. Aleph Farms, for instance, has developed a 3D bioprinting technology that uses animal cells to produce the world's first printed steak. To achieve a similar taste, tissues were taken from the steak portion of a cow and transformed into animal cells using incubators in a laboratory environment. Four different animal cells were obtained and prepared for use in the bio 3D printer. Regarding their produced steaks, the company stated, "The steak has a muscle structure and fat content similar to those of slaughtered cows and is as tender and delicious as meat you would buy from markets" [19].

These studies indicate the potential of 3D food printers. Today, consumer demand for boutique production and personalized food designs has reached significant levels. The industry's response to these demands, combined with expectations for precise and error-free production, the need to minimize raw material losses, and the requirement for skilled personnel, will form the basis for future developments in 3D food printers.

CONCLUSION

In the rapidly evolving food industry, innovations such as diverse food products, genetically modified foods, artificial meat and dairy products, edible insects, nanotechnology, 3D printers, and space food are contributing to meeting consumer needs and advancing existing technologies. These technological advancements not only cater to consumer demands but also offer significant benefits, such as improving product quality, reducing food waste, and providing alternative sources to address potential food access challenges arising from globalization.

It is anticipated that ongoing research and technological advancements in the coming years will further enhance these innovations, with consumers increasingly accepting and integrating the new developments brought about by these technologies into their daily lives.

ABSTRACT

Based on the increase of severe climate conditions in recent years, sustainability and sustainable development has become a very important topic of the global agenda. Within this scope, ecological footprint has started being used as a tool to evaluate the damage caused by economic and social activities of human beings. There are six areas that ecological footprint tracks such as cropland, grazing land, fishing grounds, built-up land, carbon demand on land, and forest area. The measurement on forest area, namely Forest Product Footprint (FPF), reveals the impact of consumption on worldwide forests. There are especially nine primary commodities such as palm oil, coffee, soybean, cocoa, timber, rubber, meat, paper, and cardboard that have high risk of deforestation.
Based on the importance of the case, this study aims to examine the evolution of global trade of these commodities from 2000 to 2023. Complex network tools will be used to examine the global trade networks. Complex network analysis enables us to reveal some topological properties of the network such as connectedness, transitivity, core-periphery structure, power-law degree distribution etc. Network tools also provide some centrality measurements in order to evaluate the systemic importance of countries in the network. An analysis covering the period from 2000 to 2023 will help to gain a dynamical perspective and evaluation. We also aim to evaluate these centrality measurements by comparing the position of countries in global agreements on environmental issues.

Keywords: Ecological footprint, Cropland footprint, Palm oil, Global trade network, Panel data analysis

INTRODUCTION

Sustainability has become so much popular especially with the increase of the felt effects of climate change recently. However, the main idea behind it goes back to 1987 when the Our Common Future Report was published by the UN. In this report, some reasons and hope to believe in the success of humanity are addressed such as falling infant mortality, increasing life expectancy, increasing literacy rate etc. However, there is also a strong emphasis on the environmental threats that put the lives of many species, including the human, into risk (UN, 1987). Thus, sustainable development, used first in this report, implies "to meet the needs of the present without compromising the ability of future generations to meet their own needs" (UN, 1987). In the current climate, it is estimated that only 16% of the Sustainable Development Goals (SDGs) could have been achieved. The remaining SDGs exhibit very limited progress or reversal. In the same report, the targets, that are off-track, are related to food systems, sustainable land use, biodiversity, strong institutions, and peace (Sachs et al., 2024). Following carbon footprint that has the 60% share, cropland footprint ranks second with the 19% share in ecological footprint (WWF, 2022). The literature on sustainable development includes many studies about the causes and effects of carbon footprint. However, the studies on cropland footprint is quite limited. Hence, the focus of the present study is cropland footprint in general and palm oil trade in specific.

Based on this motivation, we conducted a two-step analysis. First, we examined the palm oil trade network with network analysis tools for each year from 2000 to 2022. This methodology enables us to reveal the topological properties of the network with a dynamical approach, and also to obtain centrality scores for each country that represent their export impacts in the global trade of palm oil. Secondly, depending on these centrality scores, we selected the top 8 exporter countries. Then, we applied panel data analysis to test the relations between the export impact and cropland footprint of these countries. The present study makes contribution to the existing literature since it combines two methodologies.

Based on this motivation, the study is structured as follows: Some conceptual explanation is given in Section 2. The results obtained from the analyses are presented in Section 3. In Section 4, there is an evaluation and conclusion of the study.

MATERIAL AND METHOD

Ecological footprint concept was first used and quantified in the mid-1990s. based on the fact that everybody has an impact on the Earth as they consume the nature, Wackernagel et al. (1997) developed a method to calculate it. Ecological footprint focuses on two roles of productive areas: to provide resource supplies uninterruptedly, and to absorb the waste generated during this production using the technological opportunities. Thus, calculations are also based on a simple logic with two facts (Wackernagel et al., 1997): (i) monitoring most resources we consume and wastes we generate, (ii) conversion of these resources and waste flows into biologically productive areas to provide these functions properly. As land use contributes to produce different goods and services in a non-substitutable way, ecologically productive areas are divided into six categories such as arable land, forests, pasture, sea, built up area, and fossil energy land (Wackerhanel et al., 1997). Currently, we can reach the measurements of ecological footprint in total and also in these six categories, namely cropland footprint, grazing land footprint, forest products footprint, fishing grounds footprint, built-up land footprints and carbon footprint (Global Footprint Network, 2016). In the ecological footprint calculations, areas accepted 'unproductive for human purposes' (i.e. deserts and ice layer) are excluded (Lenzen and Murray, 2003). However, not all that biologically productive land area is available to human use since this area is also home to millions of spaces sharing this planet. Thus, it is stated that at least 12% of the ecological capacity should be preserved to protect the biodiversity (Wackernagel et al., 1997).

On the other hand, agricultural and forestry activities are accepted as the main causes of biodiversity loss. The demand for the products of these sectors increases as a result of increasing population and economic development (Marques et al., 2019). Therefore, the conversion of pasture to cropland area causes biodiversity loss. As a result of this loss, a planetary boundary is proposed for croplands as 15% of this productive land area (Ridoutt and Garcia, 2020).

The calculations indicate that carbon footprint has the highest impact on ecological footprint, and it is followed by cropland footprint (WWF, 2022). In cropland footprint, palm oil has a special importance as this sector contributes to high cropland loss among pulses and oil crops. Major producer countries exploit more land to fulfil their production targets (Malahayati, 2022).

Palm oil currently accounts for 41% of vegetable oil production around the world. As a result, it is criticised to be a major contributor to biodiversity loss and greenhouse gas emissions due to the conversion of lands (Beyer et al., 2020). It is documented that the global cultivation area for palm oil has increased almost 23% for the last five years (Patel, et al. 2022). Considering this increase of palm oil in the land area, more attention has been paid to the palm oil related economic activities such as, production, trade, consumption etc. Based on this, we analyse international trade of palm oil and its relation with cropland footprint.

For this purpose, this study has a two-step analysis. At the first step, network analysis has been applied to the international trade data of palm oil based on export from 2000 to 2022. This analysis enables us to examine the topological properties from a network perspective with a dynamical approach. This analysis also gives us centrality score (i.e. export impact score) for each country in the network. We selected top 8 countries with the highest centrality scores, and then built the panel data analysis on this scores. At the second step, we search for the cointegration between the export impact and cropland footprint.

RESULTS AND DISCUSSION

Network analysis results

Fig. 1. presents the trend of the density coefficient through the period. Density coefficient, which is the ratio of actual links among the nodes to the maximum possible number of the links (Newman, 2010), is low so that the international trade network of palm oil is a sparse network. However, an increasing trend is observed during the period.

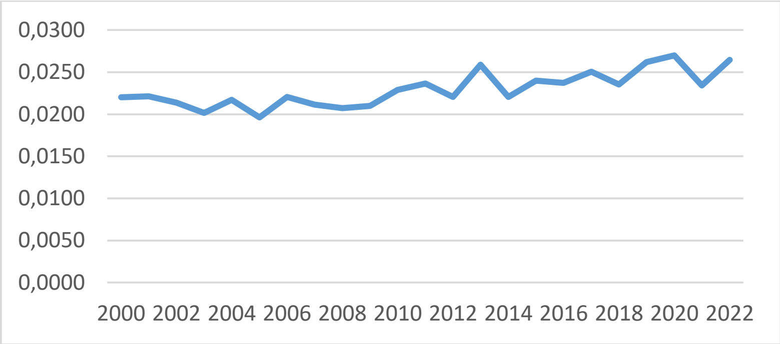

Fig. 1. Density coefficient

Source: Drawing is based on the author's calculation

Table 1 presents another important results from network analysis. Kolmogorov-Smirnov test is used to test whether the distribution of links follows a power-law distribution. If p-value is lower than 0.05, we reject the null hypothesis that it follows power-law (Igraph, 2020).

Table 1. Kolmogorov-Smirnov test results

Years	Skewness	Kurtosis	α	KS stats	KS p-value
2000	9.621	97.270	2.073	0.132	0.999
2001	7.288	56.910	1.371	0.125	0.773
2002	8.702	81.503	1.341	0.110	0.818
2003	8.533	78.676	1.235	0.124	0.441
2004	8.861	84.483	1.298	0.091	0.895
2005	9.603	98.318	1.263	0.095	0.834
2006	8.749	82.024	1.331	0.097	0.888
2007	9.905	104.386	1.230	0.107	0.605
2008	10.282	111.615	1.351	0.118	0.832
2009	10.440	114.826	1.395	0.138	0.705
2010	10.282	111.462	1.272	0.112	0.700
2011	9.543	97.626	1.170	0.138	0.218
2012	8.637	78.408	1.174	0.119	0.334
2013	8.277	72.867	1.749	0.121	0.995
2014	8.169	68.888	1.183	0.123	0.336
2015	8.260	71.439	1.208	0.111	0.505
2016	8.071	68.749	1.243	0.132	0.336
2017	9.633	100.223	1.253	0.121	0.416
2018	8.950	86.783	1.517	0.112	0.947
2019	8.807	83.891	1.210	0.128	0.383
2020	8.218	72.366	1.179	0.130	0.270
2021	8.728	84.004	1.190	0.128	0.237
2022	7.354	58.776	1.196	0.113	0.434

Source: Author's calculation.

It is observed that the international trade network of palm oil follows a power-law distribution for each year, so that the connectedness of the network is heterogeneous.

As an another important property, Fig. 2 includes results from core-periphery analysis. Following the methodology developed by Borgatti and Everett (1999), the values in Fig. 2 refer to the similarity of the network in question to an ideal core-periphery network. Accordingly, similarity to an ideal core-periphery network, meaning that there are some core countries strongly connected to one another and also peripheral countries while peripheral nodes are not connected themselves, has an increasing trend.

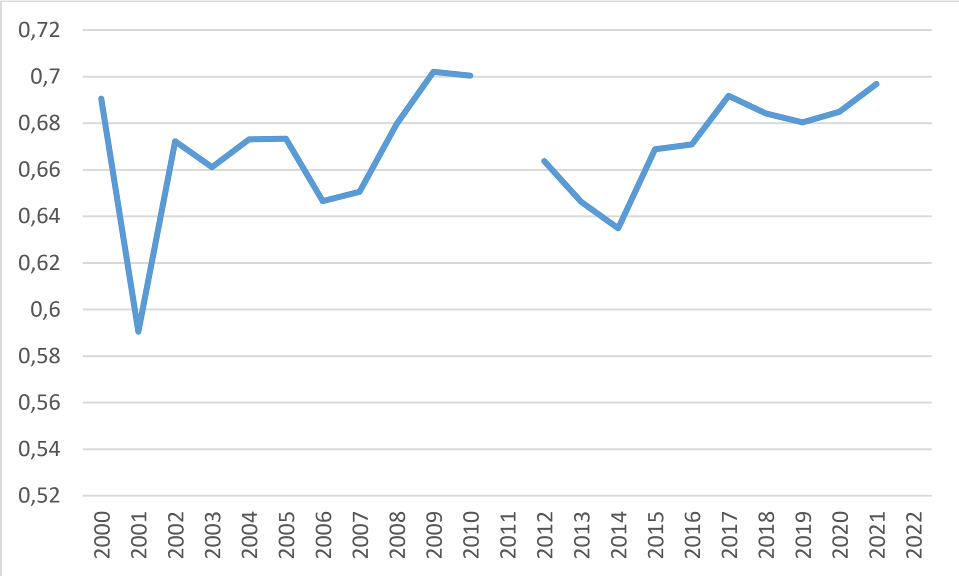

Fig. 2. Core-periphery fit correlation
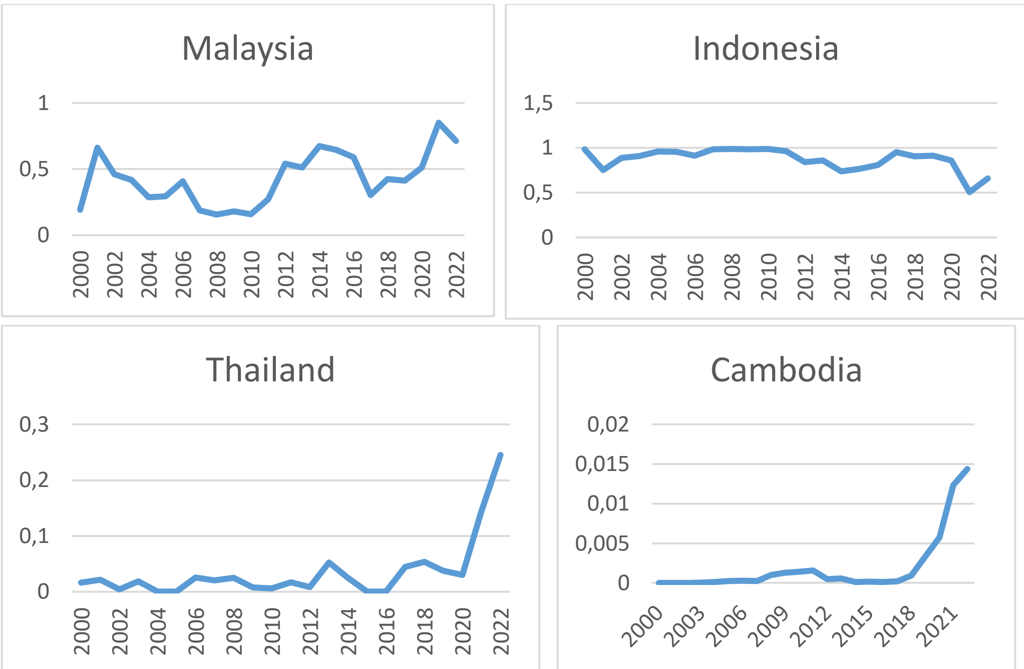
Source: Drawing is based on the author's calculation

As a final important part of a network analysis, we present centrality scores for top exporter countries. among many centrality measurement, we applied hub centrality developed by Kleinberg (1999). Hub centrality corresponds to 'export impact' for this network. The graphs in Fig. 3 indicate the export impacts of the top eight exporter countries. it is observed that all countries have an increasing export impact within the network except for Indonesia.



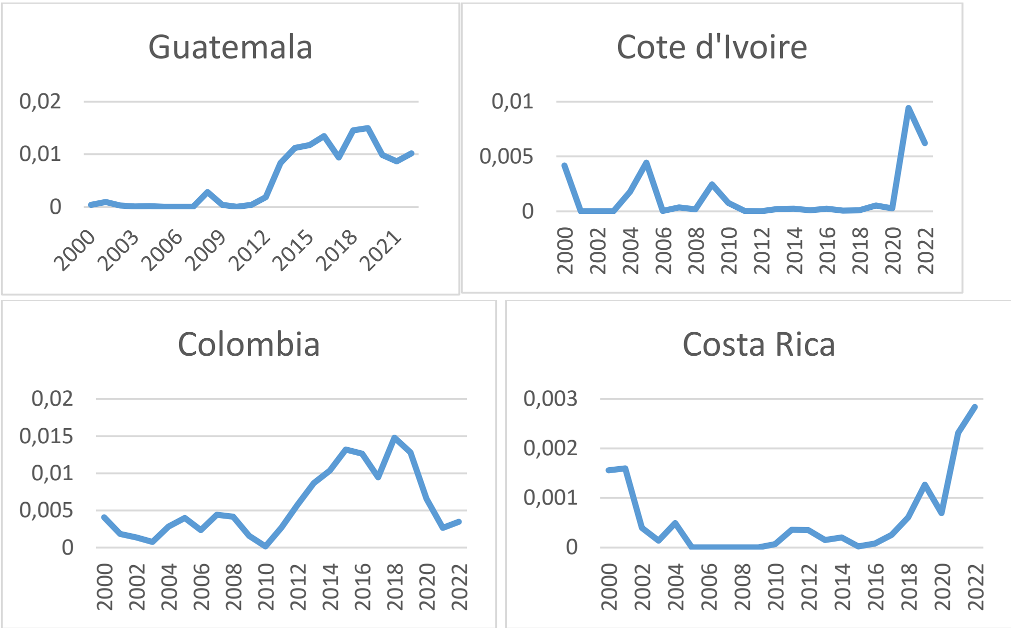


Fig. 3. Hub centralities based on export
Source: Drawing is based on the author's calculation

These findings give an idea about the network topology. However, these findings are also an input for the second step of the analysis. We searched for the long-run relationship between hub centralities (export impacts) of the countries and cropland footprint. The research question for the second part of the examination is whether export impact has an impact on cropland footprint in the long-run.

Panel Data results

The model we focus on in this part of the analysis is as follows:

$$\text{Crop=f (Hub)} \qquad (1)$$

However, we need to apply some preliminary tests before cointegration. First of all, we presented cross-section dependence test results for the variables. Accordingly, the null hypothesis of no cross-section dependence is rejected for each variable. Based on this results, we chose CADF test as a second generation unit-root test.

Table 2. Cross-section dependence test results for variables

Variables	CDLM 1	CDLM 2	CDLM adj
HUB	196.970	21.511	21.329
	(0.000)	(0.000)	(0.000)
CROP	165.638	17.324	17.142
	(0.000)	(0.000)	(0.000)

Unit-root test in Table 3 indicate that both variables have unit root at level, and become stationary at first difference. This result makes us consider whether there is a cointegration between these series.

Table 3. CADF panel unit-root test results

Variables	CIPS stats	
	Constant	Constant and trend
HUB	-1.281	-1.977
Δ HUB	-4.092***	-4.161***
CROP	-1.888	-3.180***
Δ CROP	-4.897***	-

Before testing cointegration, we applied a cross-section dependence test to the residuals of the model. The results are given in Appendix. Accordingly, we cannot reject the null hypothesis of no cross-section dependence. Based on this result, we applied first-generation version of Westerlund (2007) cointegration test. The results in Table 4 verify that there is cointegration between the variables in the model.

Table 4. Westerlund (2007) cointegration test results

Model	Statistics	Value	P-value
CROP = F (HUB)	Gt	-3.033***	(0.000)
	Ga	-10.489**	(0.043)
	Pt	-6.01**	(0.035)
	Pa	-6.825*	(0.064)

Before estimation of the coefficient, we first tested the homogeneity of the slope coefficients of the panel. The results obtain from the homogeneity test are given in Appendix. Accordingly, we reject the null hypothesis of homogeneity, meaning that coefficients are heterogeneous in the panel.

Table 5. Long-run coefficient estimates

Countries	DOLS			FMOLS			CCR		
	Beta (Variable: HUB)	Std. Error	t-stat	Beta (Variable: HUB)	Std. Error	t-stat	Beta (Variable: HUB)	Std. Error	t-stat
Malaysia	**1.69**	**0.26**	**6.4**	**1.57**	**0.2**	**7.71**	**1.56**	**0.2**	**7.89**
Indonesia	**0.48**	**0.02**	**25.38**	**0.5**	**0.03**	**16.28**	**0.5**	**0.03**	**16.29**
Thailand	**12.94**	**3.69**	**3.51**	**7.37**	**2.18**	**3.38**	**6.7**	**1.97**	**3.39**
Cambodia	375.5	251.82	1.49	**124.98**	**52.72**	**2.37**	**122.09**	**51.66**	**2.36**
Guatemala	33.94	23.1	1.47	39.8	20.33	1.96	39.4	20.24	1.96
Cot'e d'Ivoire	**231.8**	**111.08**	**2.09**	125.81	67.51	1.86	110.76	60.26	1.84
Colombia	**54.26**	**6.94**	**7.82**	**57.7**	**9.61**	**6**	**56.45**	**8.93**	**6.32**
Costa Rica	148.93	708.71	1.37	**134.1**	**574.19**	**2.35**	**115.1**	**48.68**	**2.37**
Model	274.07	17.51		213.35	14.82		186.11	15	

Then, long-run coefficients have been estimated by using FMOLS, DOLS and CCR methods that are first generation estimators. According to the results from DOLS estimator, export impact has a positive effect on cropland footprint in Malaysia, Indonesia, Thailand, Cot'e d'Ivoire and Colombia at 0,05 significance level. FMOLS and CCR results indicate that export impact has a positive effect on cropland footprint in Malaysia, Indonesia, Thailand, Cambodia, Colombia and Costa Rica at 0,05 significance level.

CONCLUSIONS

Cropland footprint has the second highest impact on ecological footprint following carbon footprint. In cropland footprint, palm oil has a special importance as it causes high cropland loss among all oil crops. Top exporters of this crop are claimed to convert more and more land to produce more palm oil. Hence, we aim to examine whether export centralities of top exporters affect their cropland footprint.

For his purpose, we first applied network analysis. Results obtained from network analysis indicate an increasing trend of connectedness and a trade structure clustered around some super hubs. This analysis also provides us centrality score for all countries that refers to export impacts of countries. Afterwards, we applied panel data analysis to examine whether a relation between export impact and cropland footprint in the long-run. The results approve the existence of such a long-run relationship between these variables. Accordingly, the effect of export centrality on cropland footprint is positive for top

exporters of this product. In the top three exporters, namely Malaysia, Indonesia and Thailand, an increase in the export impact also increases cropland footprint.
This result approves the argument mentioned in the literature. The conversion of other areas to cropland areas results in biodiversity loss and increasing greenhouse gas emissions, hence increase in cropland footprint. Considering the planetary boundary that is proposed for croplands as 15% of this productive land area, policy implementations are required to be taken urgently in order to prevent more biodiversity loss and cropland footprint.

EFFECT of ASPROSIN HORMONE on SKMEL-30 CELLS

Nebiye Pelin TURKER

[1] *Trakya University, Technology Research Development Application and Research Center (TÜTAGEM), Edirne, Turkey*
npelinturker@trakya.edu.tr

ABSTRACT

SKMEL-30 melanoma cancer is among the deadliest kind. Paying attention to SKMEL-30's altered energy metabolism and enhanced aerobic glycolysis is necessary. Insulin resistance and metabolic diseases are frequently accompanied by dysregulation of the glucogenic hormone asprosin. Its involvement in energy metabolism in the tumor microenvironment has not yet been studied, despite its link to metabolic diseases. Methods: MTT analysis, spectrophotometric measurement of sialic acid levels, and qRT-PCR for determining glycosyltransferase expression. Results: The ST8SIA-2 gene was significantly upregulated in the SKMEL-30 cell line after treatment with 50 nM asprosin ($p < 0.05$). It has been demonstrated that asprosin affects glucose and energy metabolism pathways as well as those linked to cell division and communication. Asprosin was found to lower the sialic acid level when sialic acid levels were examined at the control and 50 nm asprosin dose. In conclusion: Asprosin seems to control the glycosyltransferases' in vitro signaling pathway with regard to SKMEL-30. The Warburg effect, or aerobic glycolysis, is a role in the development of numerous malignancies, including SKMEL-30. Even in the presence of oxygen, the glycolytic pathway—which uses glucose for quick energy production and generates excess lactate—is frequently chosen over aerobic respiration and oxidative phosphorylation when dealing with excess glucose. It's common knowledge that breathing on its own can keep tumors alive. Oncogenesis begins with aberrant growth factor signaling regulation, which is a modifiable element in aerobic glycolysis. As a glucogenic hormone, asprosin is believed to play a part in this process and is a good subject for further study in the tumor microenvironment.

Keywords: SKMEL-30, Melanoma, Glycosyltrasnferases, Sialic Acid, Apoptosis

INTRODUCTION

Nowadays, the idea that cancer is a hereditary illness is starting to be viewed more and more as a metabolic disorder. Regardless of its cellular or tissue origin, emerging data is consistent with the overall idea that cancer is a disease in which cellular energy metabolism is disturbed (Hainaut and Plymoth; 2012). Due to specific metabolic processes that have been reprogrammed, cancer cells have unique characteristics such as dysregulated lipid metabolism and fast uptake of glucose (Jones and Thompson; 2009). Generally speaking, the primary adaptation mechanism that encourages tumor cell proliferation and survival is the Warburg effect (Figure 1). In this instance, preferential lactate generation coupled with an enhanced rate of glucose absorption permits unchecked growth and preservation of the tumor microenvironment even in the presence of aerobic glycolysis (Makale; 2008).

Numerous adipokines may stimulate cell migration and proliferation as well as other anti-apoptotic pathways, according to research investigations, which may accelerate the development of tumors and the spread of cancer (Booth et al.; 2015). On the other hand, there aren't many data on asprosin peptide levels in cancer. Remarkably, Kerslake et al. found that asprosin and its conjugated olfactory receptor OR4M1 were highly expressed in both malignant ovarian tissues and normal human ovaries, and they also showed that this had an effect on the tumor microenvironment. A recent in vitro investigation conducted by the same group on the ovarian cancer cell line SKOV-3 revealed differential regulation of genes after treatment with 100 nM asprosin (Kerslake et al.; 2022). Furthermore, asprosin changed several signaling pathways linked to cell division and communication as well as phosphorylated ERK1/2 (Kerslake et al.; 2022). It has previously been reported that the Warburg effect may have an effect on the tumor microenvironment in ovarian cancer. Other functionally expressed genes, such as Cadherin 11 (CDH11) and the Fc fragment of immunoglobulin G receptor IIa (FCGR2A), have been implicated in the regulation of metastatic progression and chemotherapeutic response in different cancers. (Wang et., 2017; Qian et al., 2021).

Cachexia syndrome (CACS) is a term for the starvation that many cancer patients may experience as their disease worsens. Depending on the type and stage of their tumor, CACS prevalence rates can range from 9% to 85%. Arends and Van Cutsem, 2005). According to Fearon et al. (2011), it is characterized by energy imbalance, systemic inflammation, and involuntary loss of lean body mass with or without adipose tissue wasting. Adipose tissue is decreased in anorexia as a result of caloric deprivation, whereas in CACS, skeletal muscle and adipose tissue degenerate (Tisdale, 1997). When compared to non-anorexic persons, cancer patients with anorexia showed significantly lower levels of asprosin, but not CACS (Du et al., 2021). To fully understand the potential function of asprosin in the initiation and spread of cancer, more research is required.

Our research aimed to understand how asprosin hormone affected sialic acid changes and signaling pathways in SKMEL-30 melanoma cancer cells. The LD50 dose of asprosin hormone was established by performing the MTT assay on SKMEL-30 cells at various doses. Next, qRT-PCR research was carried out to look into the genes for glycosyltransferase, apoptotic, and metastatic processes in order to assess the alterations brought about by the LD50 dose in the cell. Additionally, sialic acid levels were assessed by comparing them to the control group in order to look at the potential for SKMEL-30 cells treated with asprosin hormone to spread.

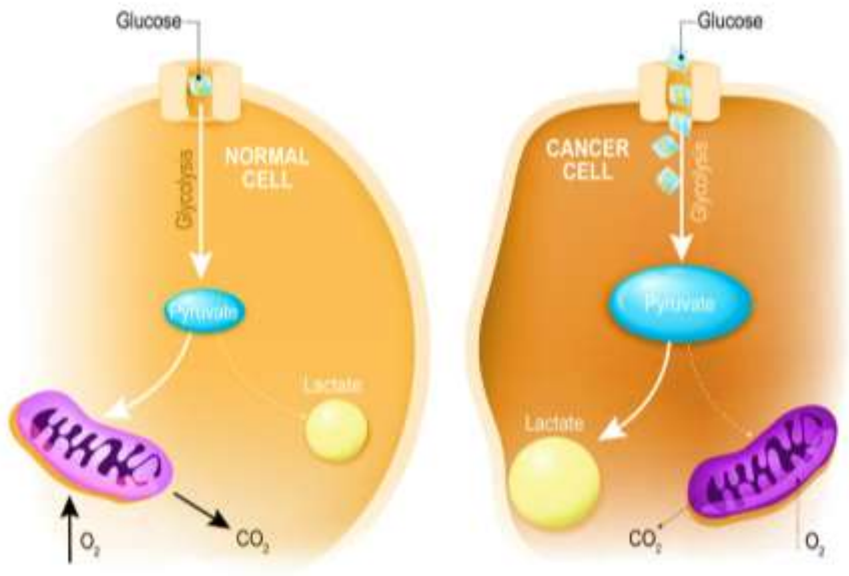

Figure 1. Warburg effect in healthy and cancerous cells

MATERIAL and METHODS

Cell Culture analysis

In this investigation, the melanoma (SKMEL-30) cell line was employed. The Safe Fast Elite (EN 12469 2000) flow chamber was used to cultivate the cell line. Bovine serum-containing media (MULTICELL (FBS-HI-IIA)) was used for cell passage and culture, together with DMEM, EMEM-HamsF-12 (MULTICELL), 1% L-glutamine (MULTICELL (609-065-E2), and 1% penicillin-streptomycin (MULTICELL (450-201-Z2)). The medium was kept at 37 °C and 5% CO2 in sterile incubators (PANASONIC). Up until the fifth passage, cultured cell lines were repeated; at that point, stocks were prepared for utilization. DMSO (MERCK 67-68-15) was frozen in liquid nitrogen, added to medium-containing cryotubes, and maintained at -150°C (PANASONIC). Every study project started at the fifth cell line passage and finished at the fifteenth. Using the MTT method, cell viability and proliferation were assessed. 2000 SKMEL-30 cells per well were seeded on cell culture plates in a 96-well plate. It was incubated for 24 hours in DMEM:EMEM:Ham's F12 medium to support cell adhesion. The range of dosages for asprosin hormone administration was identified by searching the literature. Irisin hormone was diluted serially in ultrapure water within the range of 3.75-120 nanoMolar (nM). During the course of a 24-hour incubation period, eight replicates of each dose were tested in treated cells. After that, each well received 20 microliters of MTT solution (5 mg/ml concentration), and each well was incubated for two hours at 37°C.

Measuring the Levels of Sialic Acid

Following the planting of SKMEL-30 cells on 6-plate plates, the cells were cultured for 24 hours at 37°C with 5% CO2. At the end of the interval, 30 nM asprosin hormone was added and the mixture was incubated for 24 hours. For five minutes, control and SKMEL-30 cells treated with 50 nM asprosin were homogenized in 0.1 M phosphate buffer (pH 7.4). After 0.2 ml of homogenized samples were collected, 1 ml of a 5% perchloric acid solution was added, and the samples were incubated for 5 minutes at 100°C. Phospholipid buffer (0.1 M–pH 7.4) was used to make a 2.5 mg/ml sialic acid (N-acetyl neuraminic acid) solution. The prepared stock solution was diluted, and standard operating procedures were developed. The samples were incubated with Ehrlich's reagent for four hours at 100°C after it was added to the calibration procedures. Graphs were made and the concentrations of sialic acid in the samples were determined in milligrams per milliliter based on spectrophotometric measurements obtained at 525 nm.

RNA isolation, cDNA synthesis and Real-Time PCR (qRT-PCR) Analysis

Using the Pure Link RNA isolation kit, total RNA was extracted from the SKMEL-30 cell line (Invitrogen TM-12183018A). The amount of RNA that was isolated was measured using NanoDrop (NanoQ Optizen). Applied Biosystems 00709629 cDNA Reverse Transcription Kit PCR circumstances The steps for completing cDNA synthesis were as follows: Step 1 was 25°C for 10 minutes; Step 2 was 37°C for 120 minutes; and Step 3 was 85°C for 5 minutes. A Quantstudio 6 Flex qRT-PCR system (Sybr Green Method (PowerSYBR Green-Applied Biosystems-1805575)) that reads 384-well microplates was used in this experiment. GAPDH was the endogenous gene used to analyze the samples.

Statistical analysis

The formula "Cell Viability%: (absorbance value of the substance applied wells / absorbance value of the control wells) × 100" was used to determine the amount of cells due to irisin application. The tool SPSS Regression Probit (IBM SPSS Statistics 22) was used to compute the LD50 doses. Gene expression changes resulting from three consecutive LD50 dosages were computed using the formula $2^{-\Delta\Delta cT}$. The statistical difference between the results was calculated using the SPSS-Anova (Duncan Test) with a p-value of less than 0.05. mRNA for GAPDH was employed as an internal control.

RESULTS AND DISCUSSION

Based on the study results, A 50 nm asprosin dosage in MTT measurement resulted in 50% of the cells dying. The ST8SIA-2 gene, particularly one of the glycosyltransferase genes, significantly increased in the SKMEL-30 cell line after treatment with 50 nM asprosin ($p < 0.05$). The asprosin group showed a 10,478-fold rise whereas the control group showed a 2,557-fold increase. Graphs of the glycosyltransferase and endoplasmic reticulum stress genes studied are presented in Figure 2. It has been demonstrated that asprosin affects glucose and energy metabolism pathways as well as those linked to cell division and communication. Asprosin was found to lower the sialic acid level when sialic acid levels were examined at the control and 50 nm asprosin dose. Asprosin seems to control the glycosyltransferases' in vitro signaling pathway with regard to SKMEL-30. As part of the study's parameters, the MTT test—which is covered in the Materials and Methods section—was employed to evaluate the effect of asprosin hormone on the 24-hour viability of SKMEL-30 melanoma cell lines. Asprosin hormone exposure for 24 hours resulted in dose-related mortality on cell viability for the SKMEL-30 cell line. The administration of asprosin hormone produced a 50 nM LD50 dose. A significant decrease in silicic acid levels (mean±std.) was observed between SKMEL-30 cells treated with 50 nM asprosin hormone and the control group. (It was determined as 0.4173 mg/mL in the control and 0.2456 mg/mL in the asprosin group). These results; This suggests that asprosin stops cell proliferation by suppressing the metastatic ability of SKMEL-30 cells.

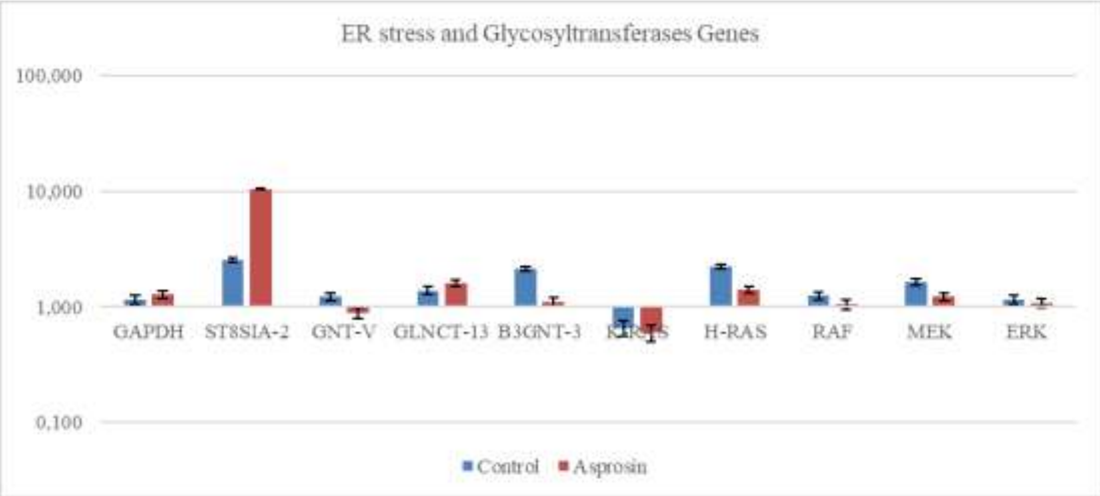

Figure 2. Results for glycosyltransferase and Endoplasmic reticulum stress genes.

Apoptosis genes: Cas-8 and Cas-9 showed a statistically significant increase ($p<0.05$). In the control and asprosin groups, the Cas-8 gene grew 11,165 and 84,755 times, respectively; in contrast, the Cas-9 gene increased 1,058 and 1,701 times, respectively. The flow cytometry data show that this rise is not, however, at a level that will cause the cells to undergo apoptosis. Metastasis genes: TIMP-1 and CDH-1 showed a statistically significant increase ($p<0.05$) in comparison to the control. While a rise of 0.695 and 1.622 times was seen in the CDH-1 gene, an increase of 0.816 and 1.279 folds was seen in the TIMP-1 gene. The results for apoptosis and metastasis genes are presented in Figure 3.

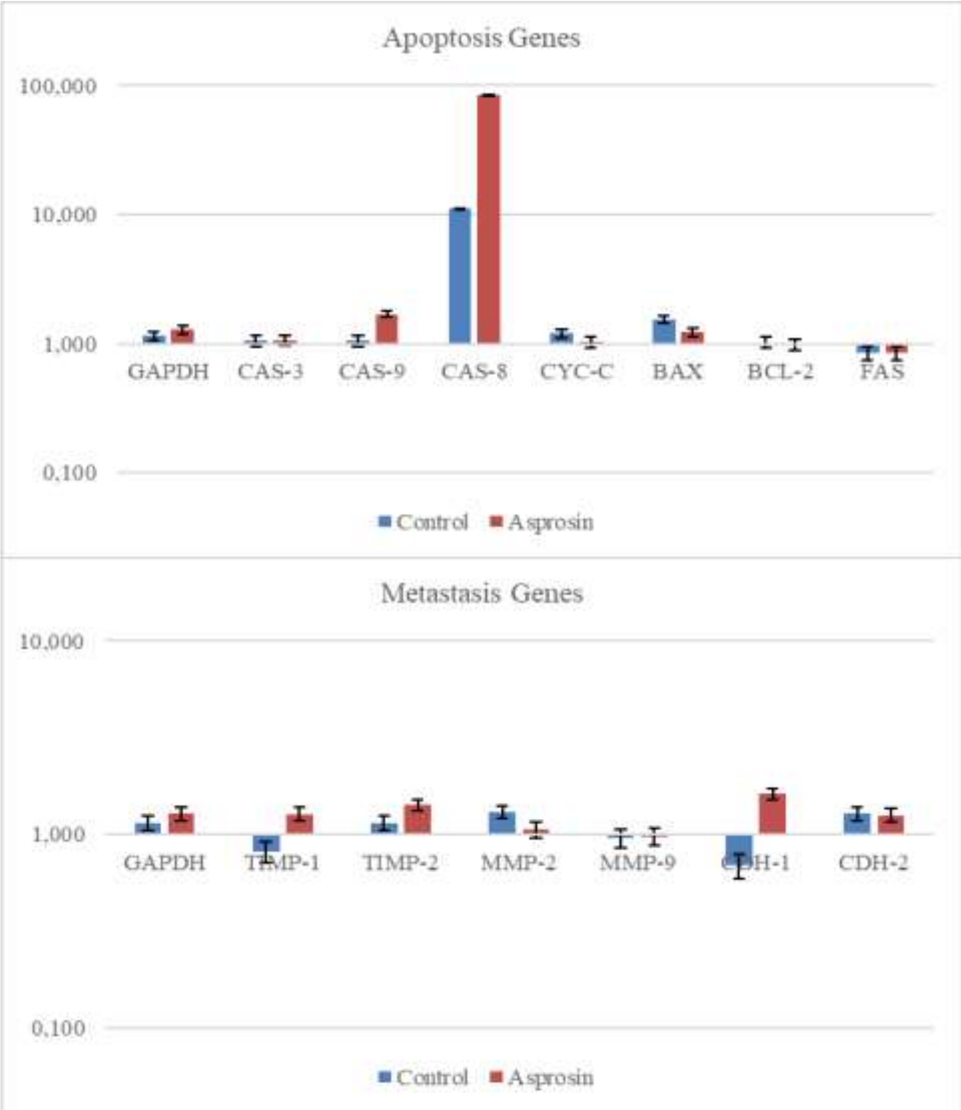

Figure 3. The results for apoptosis and metastasis genes.

Kocaman et al. discovered increased expression and positivity of asprosin when paraffin-embedded samples of the rare surface tumor known as malignant mesothelioma (MM) were compared to reactive mesothelial hyperplasia (RMH) samples as a control group (Kocaman and Artaş, 2020). In a subsequent study, the same author also proposed that asprosin might be used to distinguish between hair follicle-derived skin cancers known as hair follicle trichoblastoma (Kocaman et al., 2022) and basal cell carcinoma

(BCC). Trichoblastoma samples do not exhibit asprosin immunohistochemistry, while BCC samples exhibit a considerably higher level of asprosin immunoreactivity (Kocaman et al., 2022). As was already established, asprosin produces hyperinsulinemia and IR. These conditions can alter the equilibrium between antioxidants and oxidants and raise the production of Insulin-like growth factor 1 (IGF-1) (Du et al., 2021), which encourages the growth and metastasis of cancer (Ryu et al., 2014).

The Warburg effect, or aerobic glycolysis, is a role in the development of numerous malignancies, including SKMEL-30. Even in the presence of oxygen, the glycolytic pathway—which uses glucose for quick energy production and generates excess lactate—is frequently chosen over aerobic respiration and oxidative phosphorylation when dealing with excess glucose. It's common knowledge that breathing on its own can keep tumors alive. Oncogenesis begins with aberrant growth factor signaling regulation, which is a modifiable element in aerobic glycolysis. As a glucogenic hormone, asprosin is believed to play a part in this process and is a good subject for further study in the tumor microenvironment.

CONCLUSIONS

Based on the study, asprosin plays a critical role in the diagnosis, management, and prognosis of malignant malignancies. In the Melanoma cell line SKMEL-30 cells used in our investigation, asprosin hormone decreased the metastatic effects of the cells by lowering sialic acid levels; however, it had no effect on mitochondrial apoptosis.

ABSTRACT

One of the important complication of diabetes is diabetic foot infections accompanied by neuropathy and vascular problems. These infections, especially caused by resistant bacteria, are among the most important etiological causes of foot amputations. *Pseudomonas aeruginosa* is the most common cause of diabetic foot infections in our country. The widespread and multidrug resistance seen in this bacterium poses a global threat. In this study, the antibiotic resistance profile of 100 *Pseudomonas aeruginosa* strains isolated from diabetic foot infections was determined by E-test method. **Materials and Methods:** In our study, a total of 100 *Pseudomonas aeruginosa* strains isolated from diabetic foot infections were used. The susceptibilities of different antibiotics (piperacillin, piperacillin+tazobactam, ceftazidime, meropenem, ticarcillin+clavulanate, cefepime, cefpirome, aztreonam, imipinem, amikacin, ciprofloxacin and tigecycline) in *Pseudomonas aeruginosa* isolates were determined using the E-test method**. Results:** While two of the *Pseudomonas aeruginosa* strains isolated from diabetic foot infections were resistant to all the tested antibiotics, all the isolates except one of the isolate were found to be intermediate or resistant to at least one antibiotic. The most common resistance rate among *Pseudomonas aeruginosa* strains evaluated within the scope of our study was Ticarcillin-Clavulanate (60%), followed by Ciprofloxacin (48%), Aztreonam (45%), Piperacillin (30%), Piperacillin-Tazobactam (28%), Ceftazidime. (22%), Imipenem and Meropenem (15%), Amikacin (13%). The least resistance was found against Cefepime (4%). Since there is no breakpoint value in the CLSI data of tigecycline and cefpirome, the resistance rate could not be determined. **Discussion and Conclusion:** *Pseudomonas aeruginosa*, which has multidrug resistance, is being isolated at increasing rates from diabetic foot infections in our country. According to previous studies, although the resistance situation was generally similar, it was observed that sensitivity to carbapenems was higher and the resistance to cefepime was very low. Monitoring

sensitivity to antibiotics according to isolation locations is important in directing empirical treatments.

INTRODUCTION

Diabetes is a significant public health issue, and the number of people affected by the disease is increasing daily (Jneid et al., 2017). Diabetes can lead to various complications such as kidney failure, heart attack, blindness, stroke, and lower extremity amputations. Diabetic foot ulcers are a major global health concern and are one of the most common conditions among diabetic patients. Diabetic foot ulcer is a primary reason for the hospitalization of diabetic patients. Approximately 25% of infected wounds do not heal, which can result in the amputation of the lower leg (Iraj et al., 2013).

Recent studies indicate that the causative agents of diabetic foot infections (DFIs) vary by country and geographic location (Hatipoğlu et al., 2014). In Europe, Gram-positive bacteria such as *Staphylococcus aureus* are predominantly isolated from diabetic foot ulcers. In temperate climate regions, including our country, as well as Asia and Africa, *Pseudomonas aeruginosa* is the most frequently encountered pathogen in these infections (Ertuğrul et al., 2017). For example, in a large case series study from India covering data from 1991 to 2008, Gram-negative agents accounted for 57.1% (with *P. aeruginosa* at 16.9%, being the most frequently detected agent), while Gram-positive agents were found at 40.6% (Ramakant et al., 2011). Similarly, a study from Kuwait reported a Gram-negative/positive ratio of 51%/32%, with *P. aeruginosa* at a high rate of 17.4% (Al Benwan et al., 2012). Studies conducted in our country also show that *P. aeruginosa* constitutes a high proportion of DFI agents, ranging from 15% to 20% (Ertuğrul et al., 2008; Ertuğrul et al., 2012; Ertuğrul et al., 2017). The most significant challenge in treating infections caused by this agent is antibiotic resistance. Another study from our country indicates that the treatment failure rate for DFIs caused by resistant agents is five times higher, amputation rates are increased, hospital stays are prolonged, and treatment costs are approximately twice as high compared to infections caused by susceptible agents (Ertuğrul et al., 2012).

As with most microorganisms, antibiotic resistance in *Pseudomonas aeruginosa* is increasing day by day. It is thought that inadequate infection control measures and inappropriate antibiotic use contribute to the rising antibiotic resistance rates in *Pseudomonas spp*.; this acquired antimicrobial resistance limits treatment options and complicates the management of infections. In the antimicrobial treatment of pseudomonal infections; aminoglycosides, antipseudomal cephalosporins, carbapenems, fluoroquinolones, beta-lactam/beta-lactamase inhibitors, monobactams, phosphonic acids, polymyxins are used (Magiorakos et al.,2012). Resistance of *P.aeruginosa* to antimicrobials may vary depending on time period, country, different geographical regions, hospitals and clinics of the same country (Avcıoğlu et al.2019, Çakmaklıoğulları ve Kuru, 2019, Shortridge et. al.,2019, Erdoğan et. al.,2021).

In this study, the antibiotic resistance profile of 100 Pseudomonas aeruginosa strains isolated from diabetic wound sites was examined according to CLSI criteria using the E-test method.

MATERIALS AND METHODS

Isolates Used:
A total of 100 *P. aeruginosa* isolates of diabetic foot ulcers origin from the collection of the Nazlı-Selim Eren Chronic Wound and Chronic Wound Infection Treatment Unit at Aydın Adnan Menderes University Hospital were used in the study.
E-Test Procedure:
P. aeruginosa isolates were cultured in Tryptic Soy Broth (TSB) and incubated at 37ºC for 18-24 hours. The density of the bacteria to be tested was adjusted to 0.5 McFarland. For this purpose, 100 µl from an overnight culture was suspended in 10 ml of 0.9% sterile saline solution (FTS), and the bacteria adjusted to a 0.5 McFarland density were spread on the surface of Mueller-Hinton agar using a sterile swab. The plates were left to dry in an incubator at 37ºC for 10-15 minutes. Following this, E-test strips containing a specific antibiotic gradient (piperacillin, piperacillin + tazobactam, ceftazidime, meropenem, ticarcillin + clavulanic acid, cefepime, aztreonam, cefpirome, imipenem, amikacin, ciprofloxacin, and tigecycline) were placed on the agar surface with sterile forceps, with two different strips per plate. The plates were incubated at 37ºC for 18-24 hours. The next day, the Minimum Inhibitory Concentration (MIC) values were determined. The MIC value was considered the point where the inhibition ellipse intersected with the scale on the strip (Joyce et al., 1992).

RESULTS

E-test strips were used in determining the antibiotic sensitivities of *Pseudomonas aeruginosa* isolates in accordance with the manufacturer's instructions. MIC results of all tested antibiotics were obtained as examples shown in the picture (Figure 1). Critical values of antibiotics whose MIC values were determined by E-test according to CLSI 2023 are given in Table 1, and the E-test results performed with 100 *P. aeruginosa* are given in Table 2.

While two of the *Pseudomonas aeruginosa* strains isolated from diabetic foot infections were resistant to all tested antibiotics, all isolates except one were found to be intermediate or resistant to at least one antibiotic. The highest resistance rates among *P. aeruginosa* isolates were, Ticarcillin and Clavulanic acid (60%) respectively, It was determined as Ciprofloxacin (48%) and Aztreonam (45%). The highest sensitivity rates were found for the antibiotics cefepime (96%), meropenem (83%) and amikacin (81%), respectively (Table 3)

Table 3. Antibiotic sensitivity/resistance rates according to MIC results

DISCUSSION

Diabetes, with its rising prevalence and incidence, is considered as a global health problem, currently affecting around 171 million people worldwide and projected to reach 366 million by 2030 (Pedras et al.,2016). Diabetic patients have a higher rate of developing foot wound infections than non-diabetic individuals due to reasons such as deterioration of microvascular circulation, neuropathy, deterioration in immune capacity and anatomical changes. Therefore, one of the important complications of diabetes mellitus is diabetic foot ulcers (Abdulrazak et al.,2005). Diabetic neuropathy and peripheral arterial disease (PAD) play an important role in the development of foot ulcers complicated by infection and are also considered a strong indicator of amputation. Additionally, the high recurrence rate of diabetic foot ulcers, due to immune suppression and treatment costs ranging from $900 to $4,595 per episode in different countries, not only hampers the quality of life but also imposes a significant financial burden on patients (Mairghani et al.,2019).

It has been reported that over 50% of people with diabetic foot ulcers become infected by various types of microorganisms due to the damage to the protective skin layer. (Lipsky et al.,2012). Potential causative organisms of diabetic foot ulcers (DFUs) are believed to include *Staphylococcus, Streptococcus, Proteobacteria, Pseudomonas* *aeruginosa,* and coliform bacteria (Lipsky et al.,2015). Numerous studies have shown that *Staphylococcus aureus* is the predominant pathogen of diabetic foot ulcers in Western countries, while *Pseudomonas* is more common in Asian and African countries (Kwon and Armstrong,2018). Empiric antibiotic therapy is a crucial aspect of managing diabetic foot ulcers (DFUs). In recent years, the use of antimicrobial agents has become challenging due to the emergence of multi-drug resistant (MDR) bacteria, making the selection of appropriate antibiotics difficult. Antibiotic resistance rates have been increasing at an alarming rate in low- and middle-income countries. The rate of diabetic foot ulcers is increasing in developing countries due to inadequate knowledge about foot care among diabetic patients, an inefficient primary health care system, and low socio-economic status (Al-Rubeaan et al., 2015, Sharoni et al., 2017)

Aminoglycosides have a concentration-dependent bactericidal effect and are among the oldest antibiotics used in the treatment of infections caused by Gram-negative and some Gram-positive bacteria. While the amikacin resistance rate in *P. aeruginosa* varies between 0-29.5% in national studies, this rate is between 13.5-57% in international studies (Kara et al.,2014, Du et al.,2022, Öner et al.,2022, Makeri et al.,2023). The 13% resistance rate we obtained in our study is within the Türkiye and world average.

Ceftazidime, a third-generation cephalosporin, and cefepime, a fourth-generation cephalosporin, are antimicrobials with antipseudomal activity. In national studies, the cefepime resistance rate was reported as 24.2-42.3% and the ceftazidime resistance rate was reported as 11- 58,3 % (Aykan and Çiftçi, 2015, Avcıoğlu et al.,2019, Erdoğan et al.,2021). When *the P. aeruginosa* resistance data of the SENTRY antimicrobial surveillance program, which includes the Asia-Pacific region, Europe, Latin America and North America, was evaluated between 1997 and 2016, the cefepime resistance rate was reported as 20.7% and the ceftazidime resistance rate was reported as 22.5% (Shortridge et al.,2021). In the meta-analysis study conducted by Du et al. in China, the ceftazidime resistance rate was 33.9%, the cefepime resistance rate was 20% (Du et al., 2022). In meta-analysis studies conducted in Africa, resistance rates were found to be 48.48% for ceftazidime and 22% for cefepime (Makeri et al., 2023, Wada et al., 2023). Cefpirome, a broad-spectrum cephalosporin tested in our study, does not have a breakpoint value for *Pseudomonas aeruginosa* in CLSI data. *Pseudomonas aeruginosa* can develop resistance mechanisms to various antibiotics, especially to broad-spectrum cephalosporins such as cefpirome.

Ciprofloxacin, a member of the fluoroquinolone class of antibiotics, has been used successfully to treat a wide range of bacterial infections since 1987 and is included in the World Health Organization's list of essential medicines (Rehman et al.2018). Ciprofloxacin allows oral or intravenously, and recently an inhalable treatment of many infections that require parenteral treatment due to its bioavailability, good penetration into tissue, and low side effects (Şenol,2002, Kłodzińska et al.,2016). In national studies, the ciprofloxacin resistance rate has been reported as 7-48% (Gönüllü et. al., 2003, Gültekin et al.,2004). According to the results of meta-analysis conducted in China, Africa and

Iran, ciprofloxacin resistance in *Pseudomonas aeruginosa* was determined as 37.5%, 24.58% and 19.6%, respectively. (Shahrakh et al.,2021, Du et al.,2022, Wada et al.,2023). In our study, the ciprofloxacin resistance rate was found to be 48%. The resistance rate was higher than that mentioned studies .

The increasing level of carbapenem (imipenem/meropenem) resistance in *Pseudomonas aeruginosa* is an important public health problem. Resistance significantly limits treatment options. Significant differences are observed in the percentages of carbapenem-resistant *P. aeruginosa* across the WHO European Region. While resistance development of 5% or less was detected in only two of the countries where Central Asian and European Surveillance of Antimicrobial Resistance data were obtained, carbapenem resistance was found to be over 50% in 14 countries. Again, according to these data, the carbapenem resistance rate in Turkey is between 25-50% (WEB1, 2024). In our study, the carbapenem resistance rate was found to be 15% for both imipenem and meropenem, which showed lower percentage of resistance in comparison to other studies in Turkey and in many other countries..

Piperacillin extends the spectrum of activity of ampicillin to include most strains of *Pseudomonas aeruginosa*, *Enterobacteriaceae* (non-β-lactamase producing), many *Bacteroides* species, and *Escherichia faecalis*. (Pasifici,2023). In a study conducted in our country, the resistance rate to piperacillin was reported as 42.8%. According to the results of the meta-analysis conducted in China, piperacillin resistance rate was found to be 23,1% (Du et al., 2022).

The production of β-lactamases is the most common mechanism by which Gram-negative bacteria develop resistance to β-lactam antibiotics. A successful method to circumvent the threat of plasmid-encoded β-lactamases is to combine penicillin with inhibitors of these enzymes. Ticarcillin-clavulanate and piperacillin-tazobactam have the broadest spectra of activity, including effectiveness against *Pseudomonas aeruginosa*. Although ticarcillin-clavulanate and piperacillin-tazobactam have similar spectra of activity, they exhibit many differences. (Lister, 2000). In various studies conducted in our country, the resistance rate to ticarcillin clavulanate and piperacillin tazobactam in *Pseudomonas aeruginosa* was found to be approximately 38%. According to the results of the meta-analysis conducted in China, piperacillin resistance rate was found to be 15,4% (Du et al., 2022) Piperacillin/tazobactam, which is formed when combined with the β-lactamase inhibitor tazobactam, has a much broader antibacterial spectrum (Pasifici,2023).) In a study covering Western Europe, the piperacillin-tazobactam resistance rate was found to be 25,2%. In the same study, this resistance rate was found to be 88.9% in *Pseudomonas aeruginosa* with multidrug resistance (Karlowsky et al., 2023). In our study, the ticarcillin clavulanate resistance rate was found to be 60% and the piperacillin/tazobactam resistance rate was 28%. In our study, the resistance rate developing in piperacillin tazobactam was at a level similar to the studies conducted in Turkey and the world, while the resistance rate in ticarcillin clavulanate was found to be quite high.

Aztreonam is the first monobactam drug to enter antibacterial therapy. It is completely synthetic. It has a relatively narrow spectrum. It can be used instead of aminoglycosides in Gram (-) bacterial infections. It is an antibiotic that has not been used in the treatment of *Pseudomonas aeruginosa* in our country in recent years. The *Pseudomonas aeruginosa* aztreonam resistance rate in our country was found to be 49.6%. In a study covering France, Germany, Italy, Portugal, Spain and the United Kingdom, aztreonam resistance was found to be 19.1%, and in the examination of *Pseudomonas* with multidrug resistance in the same countries, the resistance rate was found to be 73.1% (Karlowsky et al., 2023). In meta-analysis studies conducted in China, the aztreonam resistance rate in *Pseudomonas* was found to be 45.2% (Du et. al.,2022). The 45% resistance rate we found in our study is within the Türkiye average. It is thought that the reason why aztreonam resistance is so common may be due to other antibiotic groups that can induce the synthesis of plasmid-controlled extended-spectrum β-lactamase (ESBL) and chromosomal inducible β-lactamase (IBL) seen in *Pseudomonas* species and are in active use in treatment (Baddal et.al.,2021).

Studies have shown that the majority of *Pseudomonas aeruginosa* strains exhibit natural resistance to tigecycline, making its use as a monotherapy in treating *Pseudomonas* infections limited (Zhanel et al., 2008). In another study conducted by Biedenbach and colleagues, the activity of tigecycline against pathogens isolated from patients with skin infections was examined, and it was found that *Pseudomonas aeruginosa* isolates exhibited high resistance to tigecycline (Biedenbach et al.,2005). In our study, evaluation could not be performed for tigecycline against *Pseudomonas aeruginosa* isolates due to the absence of a breakpoint value in the CLSI data. Among the 100 isolates evaluated, a MIC value of 256 or higher was detected in 52 isolates.

The resistance rates we observed in our study are generally consistent with those found in other similar studies conducted in our country. However, contrary to the general situation, we found a higher sensitivity to carbapenems and a significantly lower resistance to cefepime. Differences in antibiotic susceptibility results among hospitals vary depending on antibiotic use policies, the clinic where the patients from whom the strains were isolated were hospitalized, and the patients' underlying diseases. The observed differences in antibiotic resistance patterns highlight the need for ongoing surveillance and collection of localized resistance data to guide effective treatment strategies.

ABSTRACT

Achillea millefolium, commonly known as yarrow, is a perennial herb that belongs to the Asteraceae family. *A. millefolium* continues to be valued in modern herbal medicine for its broad spectrum of therapeutic applications, rooted in centuries-old traditional knowledge and validated by contemporary scientific research. The medicinal properties of *A. millefolium* are attributed to its complex phytochemical composition, which includes various classes of bioactive compounds. Essential oil of *A. millefolium* contains various compounds such as mono- and sesquiterpenoids, including pinenes, sabinene, phellandrene, terpinen-4-ol, alpha-terpineol, β-caryophyllene, bornyl acetate, azulene. These components contribute to the diverse pharmacological activities exhibited by *A. millefolium*. The objective of this study is to evaluate and identify the chemical components present in *A. millefolium* using supercritical CO_2 extraction.
The plant material was collected in May-July 2023 from 4 various regions in Albania (Elbasani, Librazhdi, Pogradeci, Korca) and then subjected to supercritical CO_2 extraction. The extracted compounds were analyzed using flame ionization gas chromatograph. The most abundant chemical components were 1.8-Cineole (6.2%-8.08%), b-Caryophyllene (19.8%- 24%), Germancene (11%-12.4%), Bornyl acetate (4.8%-6%), b-Pinene (6.2%-7.1%).

Keywords: *Achillea millefolium*, essential oil, supercritical CO_2 extraction.

INTRODUCTION

Achillea millefolium, commonly known as yarrow, is a perennial herb belonging to the Asteraceae family. It is found throughout Albania, from the northernmost to southernmost regions. This herbaceous plant has an unbranched stem that grows up to 80 cm tall and is characterized by its white, umbrella-shaped flowers and green to grey leaves. It is lightly aromatic with a bitter taste and blooms from June to November. *A. millefolium* is prevalent in meadows and mountainous areas, sometimes even in forests.

It is found at elevations starting from 500-600m above sea level and can reach up to 2400 m above sea level in mountain peaks. This plant has a long history of traditional medicinal use across various regions (Hassanzadeh-Kiabi & Negahdari, 2017). The medicinal properties of *A. millefolium* are attributed to its complex phytochemical composition, which includes various classes of bioactive compounds. Essential oil of *A. millefolium* contains various compounds such as mono- and sesquiterpenoids, including pinenes, sabinene, phellandrene, terpinene-4-ol, alpha-terpineol, β-caryophyllene, bornyl acetate, azulene. This herb has been utilized in traditional medicine for its anti-inflammatory, antioxidant, and immunological properties (Al-Ezzy et al., 2018). Studies have shown that A. millefolium exhibits a wide range of pharmacological effects, including anti-inflammatory, antipyretic, analgesic, and antioxidant activities (El-Sadek et al., 2007). Additionally, research has highlighted its potential as an antimicrobial agent against antibiotic-resistant bacteria (Aliasghari et al., 2017). The phytochemical composition of Achillea millefolium has been extensively studied, revealing the presence of bioactive components such as phenolic compounds with significant bioactivity (Vitalini et al., 2011). These compounds contribute to the herb's pharmacological profile, making it a valuable resource in herbal medicine (Satari et al., 2021). Furthermore, *A. millefolium* has been investigated for its potential to alleviate testicular damage, with studies demonstrating its ability to mitigate testicular oxidative stress and inflammatory responses (Okkay et al., 2021).

Moreover, *A. millefolium* has been explored for its effects on various health conditions, such as its use in mouthwash to prevent and treat oral mucositis induced by chemotherapy (Hajisalem et al., 2019). It has also shown promising effects in improving blood glucose levels, liver enzymes, and lipid profiles in diabetic rats (Rezaei et al., 2020).

Additionally, the herb has been associated with blood pressure-lowering, cardiovascular inhibitory, and bronchodilators actions, supporting its traditional use in treating cardiovascular and respiratory conditions (Khan & Gilani, 2010). The plant has also been investigated for its hepatoprotective effects and its ability to stimulate human skin fibroblast cells (Alzomor et al., 2022; Ghobadian et al., 2015) In recent years, numerous studies have been conducted in the field of nanotechnology utilizing *A. millefolium* as a component of nanoparticles. The results have shown promising effects of *A. millefolium* formulations as a practical distribution system. In conclusion, *Achillea millefolium* stands out as a versatile herb with a rich pharmacological profile, offering a wide array of potential health benefits. Its traditional uses are supported by modern scientific research, highlighting its importance in herbal medicine and pharmaceutical applications. The objective of this study is to evaluate and identify the chemical components present in *A. millefolium* in different regions of Albania using supercritical CO_2 extraction, as a suitable method for extracting valuable oils and some organic compounds from plants and explaining the pharmacological importance of the chemical components extracted from this plant. In other study the evaluation of the chemical composition of *A. millefolium* essential oil in Albania (in four different sampling sites: Kukësi, Tirana, Librazhdi and Përmeti) was conducted by the hydro distillation method and gas chromatography with a flame ionization detector. Evaluating borneol as the most noteworthy compound, with a percentage range of 19.62% to 20.72%. Cineole follows, with values ranging from 16.32% to 24.33%, succeeded by Azulenes with values ranging from 3.19% to 18.83%, (Kaloshi et al., 2023)

Supercritical-CO_2 (SC-CO_2) extraction is a suitable method for extracting valuable oils and some organic compounds from plants (Argun 2022). Carbon dioxide (CO_2) is used under supercritical conditions to extract the principal aromatics from plant materials without using organic solvents (DURAK et al., 2023). Supercritical fluid extraction (SFE) was developed for analytical application in the mid-1980s to reduce the use of organic solvents in the laboratory environment and is now a standard method for the extraction, fractionation, refinement, and deodorization of lipids or essential oils containing sample matrices at an industrial scale (Ferdosh et al., 2009). By using carbon dioxide in its supercritical state as a solvent, the method allows for extracting essential oils without leaving solvent residues, ensuring purer and safer extracts for various applications (Ahmadi, 2024). Followed by the separation between CO_2 fluids and extracted materials, CO_2 gas is returned, flowing into a low-pressure CO_2 tube to be reused (Argun, 2022). Supercritical CO_2 has been widely used due to its mild conditions, non-toxicity, and wide sources.

Supercritical fluid extraction using carbon dioxide (CO_2) has gained significant attention due to its numerous advantages. SC-CO_2 extraction offers benefits such as the ease of separating the solvent after extraction, leaving minimal residue in the processed material, its non-toxic and environmentally friendly nature, and its ability to operate at low temperatures, reducing thermal degradation of the extracted products (Jian-zhong & JianYing, 2014). This method is particularly attractive as CO_2 is a non-toxic solvent, recoverable at the end of the extraction process, and can be obtained as a byproduct of various industrial processes (Abdelfattah, 2023).

Supercritical fluid extraction (SFE) with CO_2 has shown promise in various applications, including the extraction of oils from different sources. This technology leverages the enhanced solvent power of supercritical fluids, allowing for the extraction of sensitive compounds under mild conditions, which is crucial for maintaining the stability of natural products (Ren & Zhu, 2011). Additionally, SC-CO_2 extraction ensures high precision and purity in extracting essential oils from aromatic, medicinal, and pharmaceutical plants (Ahmadi, 2024).

One of the key advantages of supercritical CO_2 extraction is its ability to extract thermally labile compounds at low temperatures, producing solvent residue-free extracts. This method is useful for extracting bioactive compounds from plant matrices, offering a green and efficient extraction technique (Vági et al., 2004). Furthermore, SC- CO_2 extraction has been highlighted for its practical advantages, such as being non-toxic, non-flammable, environmentally safe, cost-effective, and suitable for extracting natural compounds (Luksta, 2023).

In summary, supercritical fluid extraction with CO_2 presents a versatile and environmentally friendly approach for extracting a wide range of compounds from various sources. Its ability to operate at low temperatures, maintain product stability, and produce high-purity extracts makes it a valuable technique in industries such as food, pharmaceuticals, and cosmetics.

MATERIAL AND METHOD

The plant was collected between May and July 2023 in four distinct regions across Albania Elbasani, Librazhdi, Pogradeci, Korca).

Figure 1. Location of *Achillea millefollium* in Elbasani, Librazhdi, Pogradeci and Korca

The process begins with the air-drying of *Achillea millefolium* specimens to preserve their morphological and chemical properties. The integrity and health of the plant are carefully monitored using a humidity monitor and microscopic examination. The essential oils from the plant are extracted using a supercritical CO_2 extraction technique. The selection and milling of plants occur in a controlled, dry, and well-ventilated atmosphere. Plant integrity and health are assessed using precise humidity sensing and microscopic analysis. The plant's particle size is carefully controlled at 0.3 mm, and a maximum humidity level of 6% is maintained according to the standards of supercritical fluid extraction (SCFE) technology. Extraction of solids from ground materials, pellets, or granules is consistently carried out using food-grade carbon dioxide as a solvent. The equipment involved in the extraction consists of two separators for removing CO_2 from the extract before recycling, as well as two or more extractors operating above the CO_2 critical pressure. The extraction process involves raising the temperature and pressure of the carbon dioxide gas until it reaches the supercritical state.

This is facilitated by a heater and a high-pressure pump. The extractors contain organic raw material through which the supercritical CO_2 passes. After obtaining the entire CO_2 extract, it is diluted in n-hexane at a ratio of 1:2. The chemical composition of *Achillea millefolium* is then determined using Gas Chromatography with Flame Ionization Detector (GC-FID). This comprehensive method allows for precise analysis of the extracted essential oils.

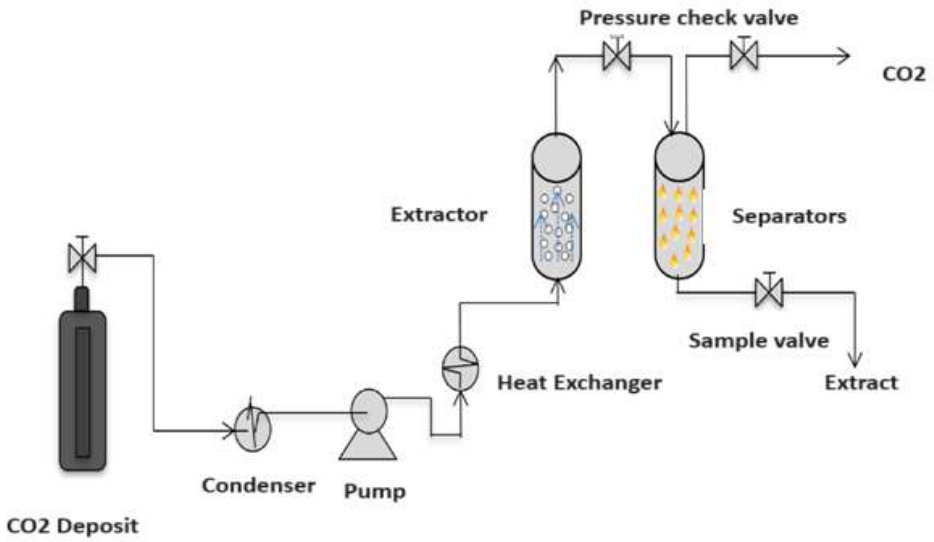

Figure 2. Scheme of CO_2 extractor

RESULTS AND DISCUSSION

Essential oil of *Achillea millefolium* samples from Pogradeci, Elbasani, Korca and Librazhdi were analyzed using GC/FID technique. According to GC- FID the results for chemical composition of Achillea millefolium are shown below for each region in percentage. Main chemical components are shown in the Table 1.

The main component of Achillea millefolium are the sequiterpenes: **β-Caryophyllene** from 19.8 % in Pogradeci to 24 % in Korca. **β-Caryophyllene** with anti-inflammatory, antimicrobial, antibacterial, and antioxidant properties (Scandiffio R, Geddo 2020). The second most abundant component is **Germancrene** from 11% in Librazhdi – 12.4 % in Korca. Germancrene has antibacterial and antifungal activities (Badalamenti, Natale 2022). **Cedrene** from 2,9 % in Librazhd and Pogradec – 4,31 % in Elbasan. Cedrene possesses antimicrobial properties, which can be beneficial in food preservation and in the development of natural antimicrobial agents (Yang, 2023).

Table 1. Percentage of chemical composition of *Achillea millefollium*

Chemical composition	**Elbasani (%)**	**Librazhdi (%)**	**Korca (%0**	**Pogradeci (%)**
a-Thujone	1.43	2.5	2.2	3
a-Pinene	2.21	2.8	1.6	2.2
Sabinene	6.7	6.4	4	3.6
1.8-Cineole	8.08	7	7.4	6.2
a-Phellandrene	1.39	2.1	1.2	4
p-Cymene	4.2	5.6	5.2	4.6
a-Terpinene	2.56	2.2	1.2	3.1
Terpinolene	1.26	1.9	1.4	2
Pinocarvone	1.84	2	1.2	1.9
Camphor	2.52	2.3	2.4	2
Linalol	2.9	3.2	2.4	1.9
Borneol	1.71	2.2	3.2	3.4
Geraniol	3.31	3.4	3.8	4
Dodecanol	1.69	3	3.4	3.2
Bornyl acetate	5.19	4.8	6	5.6
b-Caryophyllene	21.58	20	24	19.8
b-Pinene	7.1	6.4	6.2	6.4
Longipinene	1.95	2.1	2.1	2.1
Germancrene	11.3	11	12.4	11.9
Cedrene	4.31	2.9	3.2	2.9
Humulene	2.37	2.1	2.1	2.1
Cadinene	2.66	2.9	2.5	2.9
Caryophyllene oxide	1.72	1.2	0.9	1.2

The other chemical components of *A. millefolium* are the monoterpenes: **1,8 Cineole** 6.2% in Pogradec-8.08 % in Elbasani; 1.8 Cineole (eucalyptol) is a monoterpenoid that has many pharmacological effects, including anti-inflammatory and antioxidant properties. It has been used to treat respiratory and cardiovascular diseases and is clinically applied in rhinosinusitis, COPD, asthma, and bronchitis. (Cosima C. Hoch 2023). **β- pinene** is 6.2 % in Korce to the highest in Elbasan 7.1 %. A wide range of pharmacological activities have been reported, including antibiotic resistance modulation, anticoagulant, antitumor, antimicrobial, antimalarial, antioxidant, anti-inflammatory, anti-Leishmania, and analgesic effects (Salehi B, Upadhyay 2019). Geraniol 3.31% in Elbasani and 4% in Pogradeci. **Geraniol** has antioxidant and anti-inflammatory properties. In vitro and in vivo studies have shown the activity of geraniol against prostate, bowel, liver, kidney and skin cancer (Mączka W 2020). **Sabinene** (3.6 % in Pogradeci 6.7 % in Elbasani). The compound has been shown to exhibit anti-inflammatory properties (Kim, 2024; An et al., 2013). The antimicrobial properties of sabinene have also been documented, with studies showing its effectiveness against various bacterial strains, including **Streptococcus mutans*, where it inhibits growth and biofilm formation (Park et al., 2019). **Borneol** 1.71 % in Elbasani and 3.4 % in Pogradeci. Borneol has significant anti-inflammatory and analgesic effects. Research indicates that borneol can reduce nociceptive behavior and inflammatory responses in animal models, suggesting its potential as an analgesic agent (Almeida et al., 2013; Bansod et al., 2020). **Bornyl acetate** from 4.6 % in Librazhdi to 6% in Korca.

It is recognized for its diverse biological activities and potential applications in various fields, including medicine and agriculture. Bornyl acetate is a multifaceted compound with significant biological activities, including anti-inflammatory, antioxidant (Kim et al., 2013), and antimicrobial (Ivanova, 2023) effects. Its role as a precursor in the synthesis of camphor and its applications in cosmetics further emphasize its importance in both scientific research and practical applications. **Cymene** 4.2 % in Elbasani and 5.6% in Librazhdi. p-cymene exhibits notable antimicrobial properties. Research has shown that it can enhance the antimicrobial effects of other compounds, such as carvacrol and nisin, making it a valuable additive in food preservation and safety (Marchese et al., 2017).

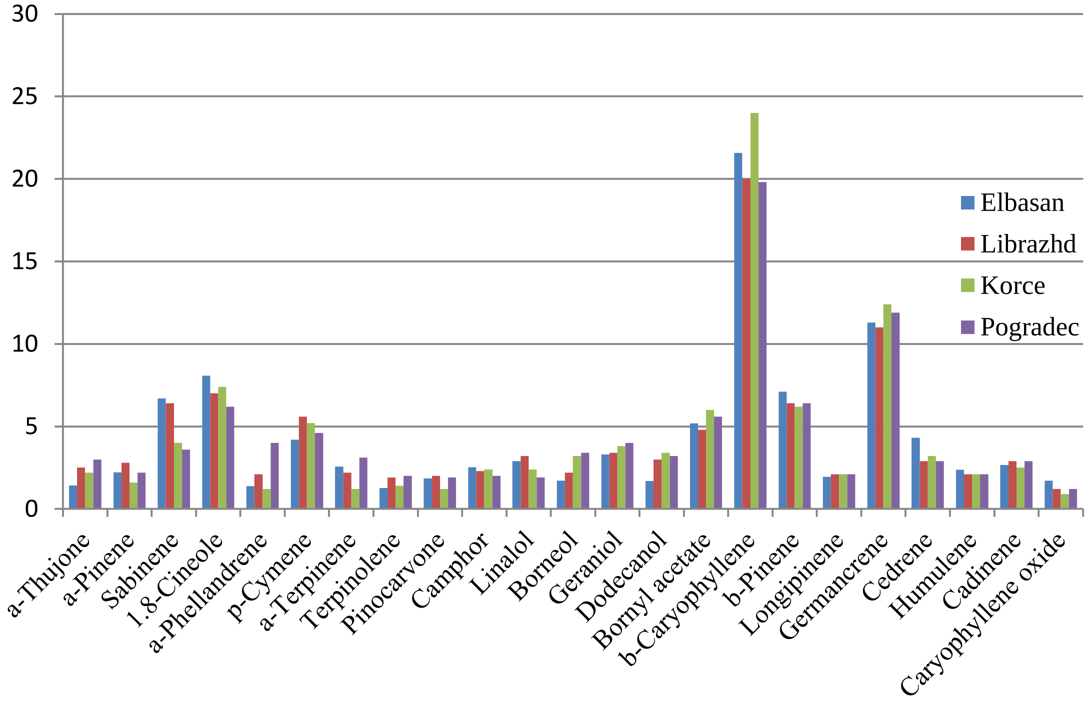

Figure 3. *Achillea millefolium* chemical composition in 4 different regions in Albania

CONCLUSIONS

Achillea millefolium, also known as yarrow, is a perennial herb from the Asteraceae family, widely found across Albania. Collected in four different Albanian regions

(Elbasani, Librazhdi, Pogradeci and Korca), bioactive compounds from *A. millefolium* are extracted using supercritical carbon dioxide (CO2) extraction (SFE- CO_2) and analyzed using GC/FID. The SFE- CO_2 method yields essential oils rich in monoterpenes such as 1.8-Cineole (6.2%-8.08%) and b-Pinene (6.2%-7.1%), as well as sesquiterpenes including Caryophyllene (19.8%-24%) and Germancrene (11%-12.4%). Variations in chemical composition percentages may be attributed to geographic and geological factors.

The SFE- CO2 extraction method has shown potential in producing high-quality extracts with enhanced therapeutic properties, offering advantages over traditional methods such as improved extraction efficiency and preservation of sensitive compounds. With its diverse biological activities and traditional medicinal uses, Achillea millefolium has garnered significant interest. Ongoing studies utilizing *A. millefolium* in nanotechnology have demonstrated promising effects, providing a practical distribution system. Further research into the composition and applications of *A. millefolium* extracts is likely to enhance their utility in medicine, agriculture, and the food industry.

ABSTRACT

In recent years, new therapeutic approaches that are non-toxic, lower cost and accelerate wound healing are needed. Considering the different medicinal benefits of mushrooms, mushroom extracts are gaining attention as wound healing agents. Fungi help in the wound healing process by stimulating the immune system, producing reactive oxygen species (ROS) and regulating various inflammatory intermediates. In this study, it was aimed to determine the cytotoxic activity of the edible wood fungus *Hohenbuehelia petaloides* (Bull.) Schulzer. in healthy 3T3 fibroblast cell line and its wound healing effect at a non-toxic concentration.

The collected mushroom material from Datça in Türkiye was identified and was turned into fungarium material at Muğla Sıtkı Koçman University, "Organic Chemistry and Natural Products Laboratory". *H. petalodies* was extracted (considering going from apolar to polar in the solvent system) with hot water (at about 85 °C by brewing) and the solvent of the extract was removed using a lyophilizer, respectively.

It was determined that *H. petaloides* water extract did not show toxic effect on healthy 3T3 fibroblast cell line treated for 24 and 48 hours (IC_{50}>1000 μg/mL). After 24 and 48 hours of application of *H. petaloides* water extract on healthy 3T3 fibroblast cell line, the wound area in the dose group decreased due to the increasing time compared to the control. It was determined that the wound area of 3T3 fibroblast cells treated with *H. petaloides* water extract closed at 66% and 95% in 24 and 48 hours, respectively, compared to the control group. In conclusion, in healthy 3T3 fibroblast cell line, the non-toxic dose of *H. petaloides* water extract caused 2-fold more cell migration in the wound area compared to the control at 24 and 48 hours.

Keywords: *Hohenbuehelia petaloides*, healthy 3T3 fibroblast, wound healing, cytotoxic activity

INTRODUCTION

Wounds can occur as a result of physical, chemical, thermal, microbial or immunologic events (Teymoorian et al., 2024). In recent years, there have been numerous attempts to develop new therapeutic approaches to accelerate wound healing at lower cost (Masson-Meyers et al., 2020). Chemical drugs are the common therapeutic approach to heal wounds. There are concerns about the side effects of chemical drugs because they can reach and affect non-target cells (Romano et al., 2022). And also some antiseptic solutions used in drugs, including hydrogen peroxide, chlorhexidine and povidone-iodine, have cytotoxicity effects on healthy cells and disrupt the healing process (Stan et al., 2021). Therefore, there is a need for natural products with fewer side effects and high efficacy.

Considering the different medicinal benefits of mushrooms, the use of medicinal mushroom extracts as wound healing agents is gaining popularity (Kaplan et al., 2021; Salem et al., 2022; Teymoorian et al., 2024). Studies have reported that medicinal mushrooms can help in the wound healing process by stimulating immune epithelial cells, promoting extracellular matrix formation, triggering cytokines and growth factors, producing reactive oxygen species (ROS) and regulating various inflammatory intermediates (Sharifi-Rad et al., 2020; Ge and Wang, 2023). In the study conducted by Zhao et al. (2021), the wound healing ability of different concentrations (0.02 - 0.2 μg/μL) of polysaccharides obtained from *Ganoderma amboinense* against NIH/3T3 cells at 24 and 48 hours was determined. In the study on the in-vivo and in-vitro wound healing and tissue repair effect of *Trametes versicolor* polysaccharide extract, it was determined that the wounds of treated mice, 100% and 60% of untreated mice healed within 14 days (Teymoorian et al., 2024).

In this study, it was aimed to determine the cytotoxic activity of the edible wood fungus *Hohenbuehelia petaloides* (Bull.) Schulzer. in healthy 3T3 fibroblast cell line and its wound healing effect at a non-toxic concentration.

MATERIAL AND METHOD

1. Mushroom Material

Hohenbuehelia petaloides (Bull.) Schulzer was freshly collected from mouse ear grass and woody tree remains in a mixed forest of red pine, pistachio pine and palm trees in Datça Peninsula, an ecotourism area in the Aegean Region of Anatolia. The collected fresh mushroom material was identified and some of them (about 5 grams, numbered with the code CK010) ws turned into fungarium material at Muğla Sıtkı Koçman University, "Organic Chemistry and Natural Products Laboratory".

2. Mushroom Extract

The dried 300 gram of mushroom was extracted with hot water (at about 85 °C by brewing) and the solvent of the extract was removed using a lyophilizer, respectively (considering going from apo to po in the solvent system).

3. Cytotoxic Activity

Healthy 3T3 fibroblast cell line was determined by MTT (3-(4,5-dimethylthiazol-2-yl)-2,5-dipenyltetrazolium bromide) assay (Plumb.,1997). Cells were plated in 96-well plates in triplicate with a density of 1000 cells/well. The cells were treated with water extract of *H. petaloides* (0-2000 µg/ mL) after culturing for 24 h followed by incubation for 24 and 48 h. Control group cells were left untreated. 3T3 fibroblast cell line was incubated in a humidified atmosphere of 5% CO_2 and 95% air at 37°C. IC_{50} value was determined using the AAT Bioquest. The data were expressed as the mean ± standard deviation (SD) of triplicate independent experiments and analyzed one sample t test using EXCEL PRO 2019-QI Macros. The percent of cytotoxicity was calculated in accordance with the following formula (Ugur et al., 2017).

% Cytotoxicty= [Control OD-Sample OD)/Control OD] x 100

4. Wound Healing Effect

90% confluent cells were passaged and $5x10^5$ cells were inoculated into 24-well cell culture dishes. The microscopic appearance of the 3T3 fibroblast cell line is given in Figure 1. Cells were incubated at 37 ºC, 5% CO2 and 98% humidity in an incubator for 20-24 hours. After incubation, a line (wound) was created in the center of each well with a 200 µl pipette tip. After the cells were washed twice with PBS, *H. petaloides* water extract was added at a concentration (500 µg/mL) at which it showed no toxic effect at 24 and 48 hours. During the incubation period, at 24 and 48 hours, the migration of cells along the gap formed by drawing a line was followed and photographed under an inverted microscope. Cell migration or wound healing was determined by observing the amount of cells migrating into the formed spaces. The wound area photographs obtained at the end of the studies were analyzed with ImageJ software. The percentage of wound healing is calculated by (C0 – C24)*100/C0, Whereas C0 = mean distance of wound at 0 h and C24 = mean distance of wound at 24h (Roy et al., 2023).

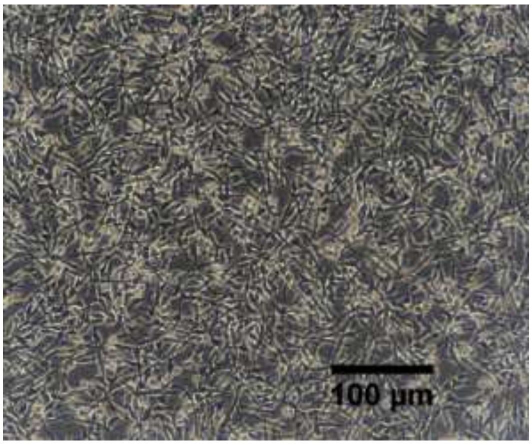

Figure 1. Microscopic view of healthy 3T3 fibroblast cell line

5. Statistical Analysis

The data were expressed as the mean ± standard deviation (SD) of triplicate independent experiments and analyzed via Two-ways analysis of variance (ANOVA) followed by using EXCEL PRO 2019-QI Macros, and GraphPad Prism version 8 Software. $p < 0.0001$ was considered to be statistically significant.

RESULTS AND DISCUSSION

It was determined that *H. petaloides* water extract did not show toxic effect on healthy 3T3 fibroblast cell line treated for 24 and 48 hours (IC_{50}>1000µg/mL). In recent studies on the wound healing effect of fungi, the antioxidant and proliferation effect of Talaromyces purpureogenus extract on cells was determined (Hu et al., 2023). In another study, the positive wound healing potential of Lignosus rhinoceros extract was determined (Yap et al., 2023).

In this study, a significant difference was detected in the wound area in the area where H. petaloides water extract (500µg/mL concentration) was applied compared to the control group ($p < 0.001$). When Table 1 is examined, after 24 and 48 hours of application of *H. petaloides* water extract in healthy 3T3 fibroblast cell line, the wound area in the dose group decreased with increasing time compared to the control. It was determined that the wound area of 3T3 fibroblast cells treated with *H. petaloides* water extract was closed by 66% and 95% at 24 and 48 hours, respectively, compared to the control group. In the control group, 34% and 45% of the wound area closed at 24 and 48 hours, respectively (Figure 2). Compared to the control group, the study was terminated at 48 hours in the area treated with *H. petaloides* water extract as it filled the wound area at 48 hours. In conclusion, *H. petaloides* water extract (500 µg /mL) at a non-toxic dose in healthy 3T3 fibroblast cell line caused 2-fold more cell migration in the wound area compared to the control at 24 and 48 hours. In this respect, it is a source of hope for future preclinical and adjuvant strategy research for fungal-based wound healing therapies that can help tissue regeneration and healing of skin wounds.

Table 1. The effect of 24 and 48 hours application of *H. petaloides* water extract on migration of healthy 3T3 fibroblast cell line

	Control	**Water extract of *H. petaloides***
0s		24s		
48s		

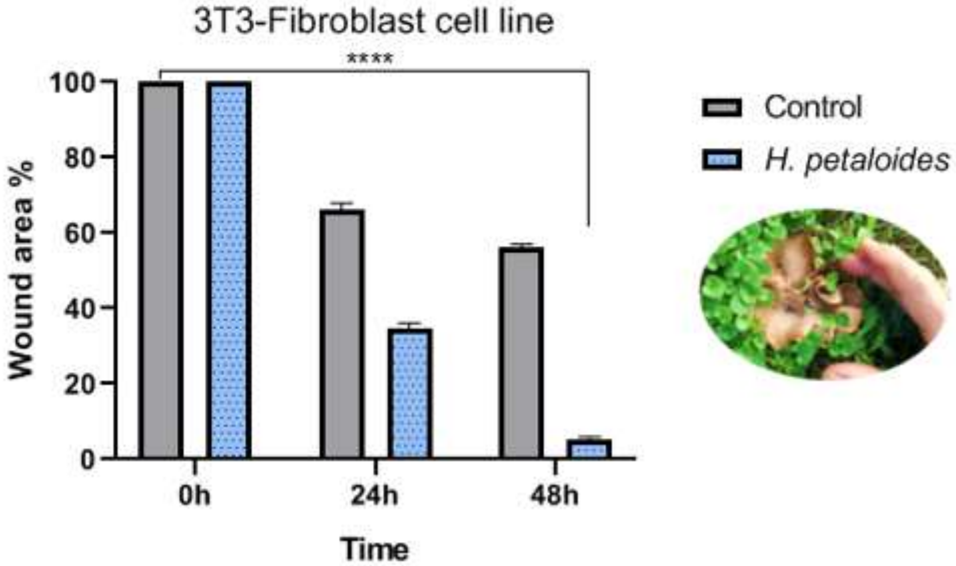

Figure 2. Percentage column graph of 24 and 48 hours application of *H. petaloides* water extract in healthy 3T3 fibroblast cell line
There was a significant difference in the wound area in the area where *H. petaloides* water extract was applied compared to the control group ($p < 0.001$).

CONCLUSIONS

H. petaloides water extract (500 µg /mL) at a non-toxic dose in healthy 3T3 fibroblast cell line caused 2-fold more cell migration in the wound area compared to the control at 24 and 48 hours. In this respect, it is a source of hope for future preclinical and adjuvant strategy research for fungal-based wound healing therapies that can help tissue regeneration and healing of skin wounds.

ABSTRACT

In Europe, potatoes (*Solanum tuberosum* L.) are regarded as one of the principal food crops, alongside wheat. The majority of potato production in Bulgaria is concentrated in the following regions: Pazardzhik, Plovdiv, Smolyan, Samokov and Blagoevgrad. It is established that in these regions, in the recent past, agricultural areas were predominantly cultivated for tobacco (*Nicotiana* sp. L.), which, along with potatoes, has a number of common pests and pathogens, including phytonematodes and particularly root-knot nematodes (*Meloidogyne* spp.). This represents a significant risk for potato growers, given the established presence of these pests in these areas and their capacity to infest a diverse range of hosts. The aim was to study the distribution of root-knot nematodes of the genus Meloidogyne in potato production areas where tobacco had been grown as a monoculture for decades.

The results presented in this study were obtained during the period 2022–2023. They are based on the monitoring of potato-producing areas, with a particular focus on 12 monitoring points occupied by potatoes. These points were selected due to the presence of preliminary information on root-knot nematode problems. The findings of the research indicate that root-knot nematodes are widespread in the potato fields in southwestern Bulgaria. A total of nine different genera of plant-parasitic nematodes were identified in the soil samples. The genera *Meloidogyne*, *Globodera*, *Pratylenchus*, *Paratylenchus*, *Tylenchorynchus*, *Tylenchus*, *Rotylenchus*, *Helicotylenchus* and *Hemicycliophora*, and those belonging to the Meloidogyne genus, were identified in 75% of the sampled fields. Potato tubers infected with nematodes of the genus Meloidogyne were found in 90% of the examined samples.

The information obtained is important to predict the spread of the infection and the preparation of an effective nematode management strategy.

Keywords: root-knot nematode, potato, tobacco

INTRODUCTION

The potato (*Solanum tuberosum* L.) is considered one of the principal food crops in Europe, along with wheat. The majority of potato production in Bulgaria is concentrated in the regions of Pazardzhik, Plovdiv, Smolyan, Samokov and Blagoevgrad. Semi-mountainous areas above 800-900 m and up to 1000-1500 m above sea level are considered suitable for growing seed potatoes, while areas at lower altitudes and on plains are suitable for growing early and mid-early varieties for consumption. It is known that, in the recent past, agricultural land in these areas was mainly occupied by tobacco (*Nicotiana* sp. L.), which shares with potatoes common pests, including plant parasitic nematodes and in particular root-knot nematodes (*Meloidogyne* spp.). This represents a significant risk to potato production given the established presence of these pests in the region and their documented ability to infest a wide range of host plants (Samaliev, 1990; Etropolski et al., 1994). Root-knot nematodes (*Meloidogyne* spp.) represent a significant economic threat to agriculture, with the potential to inflict substantial damage to potato crops (*Solanum tuberosum* L.) across a range of climatic zones, including temperate latitudes and tropical and subtropical regions (Bairwa et al., 2022; Abrantes et al., 2023). In the regions of Bulgaria where potatoes are cultivated for human consumption, the threat posed by root-knot nematodes remains underestimated. Notwithstanding the fact that considerable damage has been identified in certain potato-cultivating regions and the prevalence of root-knot nematodes is on the rise (Samaliev and Baicheva, 2010; Samaliev and Kalinova, 2013). It is important to note that certain species of the root-knot nematodes on potato, namely *Meloidogyne chitwoodi*, *M. enterolobii* and *M. fallax*, are currently classified as quarantine pests. No evidence exists to suggest that these species have been established in Bulgaria. Infected fields may be subject to direct and indirect damage caused by root-knot nematodes, which can have a detrimental impact on the potato crop. In addition to the considerable losses in the yield, the inferior quality of the resulting production limits the potential for its commercialisation. The decline in revenue is becoming increasingly pronounced, both within the domestic market and in international markets (Bairwa et al., 2022). The practice of monoculture farming provides a permanent habitat for these nematodes, resulting in the accumulation of *Meloidogyne* species over time and the establishment of a constant source of infection. In order to minimise the extent of losses incurred, it is imperative that farmers implement control measures.

The determination of the phytosanitary status of agrocenoses through monitoring represents a fundamental condition for the implementation of efficacious plant protection activities. The examination of soil and tubers to ascertain the extent of root-knot nematode infestation represents a crucial phase of the integrated plant protection system employed in Bulgarian potato cultivation.

The aim of the present study was to examine the distribution of root-knot nematodes belonging to the genus *Meloidogyne* in potato production areas where tobacco had been cultivated as a monoculture for decades.

MATERIALS AND METHODS

The findings of the present study were derived from the monitoring of areas dedicated to the cultivation of potatoes intended for human consumption and processing. The principal rationale for the selection of these areas was the cultivation of potatoes on agricultural land that had previously been used for tobacco production as a monoculture. A total of 12 monitoring points were selected in the following regions of southwestern Bulgaria: Sofia, Pernik, Kyustendil, Samokov, Pazardzhik, Blagoevgrad and Gotse Delchev during the period 2022-2023.

The samples were collected from the monitoring points at the conclusion of the vegetation period and/or at the time of harvest. The soil and tubers were subjected to analysis. The sampling was conducted in a specific sequence and pattern to ensure the consistency and comparability of the data across different fields. Soil samples were taken using a manual soil probe with a blade length of 20-30 cm and a diameter of 20-25 mm. In order to guarantee the representativeness of the aggregate sample, the number of samples taken was calculated in accordance with the dimensions of the area under investigation. The collected samples were placed in plastic bags and labelled in a clear and systematic manner. The tuber samples were collected concurrently with the soil samples and were placed in the same bag. Following the collection of the samples, they were placed in refrigerated containers. Prior to processing, the samples were stored in a refrigerator at 4°C for a maximum of two weeks. The subsequent phase of soil sample preparation for nematode extraction involved determining an average sample volume of 100 cm^3. The motile stages of the nematodes were extracted using two methods: the Cobb method and the modified Baermann funnel method (Tintori et al., 2022; Greco and Crozzoli, 2024). Following the extraction process, the samples were stored at a refrigerated temperature for a maximum of 10 days prior to the quantification and qualitative assay of the nematodes. The nematode fluid was diluted with water to 100 ml. This ensured that the total number of isolated individuals was accounted for. The resulting suspension was stirred with a magnetic stirrer and subsequently transferred to a modified Bogorov'scounting chamber. At 40× magnification under a stereomicroscope, the initial enumeration of nematodes is conducted. The plant parasitic nematodes were then excreted by a re-counting procedure. The mean number of nematodes that were extracted was determined according to the method of Peters (2013).

The available tuber material was investigated for the presence of nematode galls using a magnifying glass. The formations were separated using an entomological needle and then transferred with great care to a glass slide, where they were examined under a stereomicroscope. In addition to the aforementioned extraction methods, the detection of root-knot nematodes in plant tissues was also conducted through the use of staining techniques. The root-knot nematodes were identified morphologically in accordance with the identification keys of Jepson (1987), Karssen (2002), Perry et al. (2009) and other relevant sources.

RESULTS AND DISCUSSION

The results presented here were obtained from 12 monitoring points where tobacco was cultivated until 2010, during which time root-knot nematodes were reported (Samaliev et al., 1994).

Soil characteristics

The study areas were distinguished by a variety of soil types. Soil analyses showed that all samples had low humus content (Table 1). The soils were predominantly sandy. The lowest humus content was observed in the soil samples collected in the area of G. Delchev (0.7%), while the highest was noted in the samples from Dorkovo (2.6%). The soil samples collected in the Yundola and Velingrad region exhibited low pH values (5.1–5.9), whereas the pH of the soil samples from the Hadzhidimovo and Ognyanovo regions (6.3 and 6.9, respectively) and Samokov (Samokov and Alino) ranged from neutral to slightly alkaline (7.0–7.5).

Table 1. Soil characteristics of monitoring points in southwestern Bulgaria

	Monitoring points /Location	**crop**	**Soil type**	**Humus content, % 0–30cm**	**pH (KCl)**
1.	Gotse Delchev 41.569064, 23.760338	Potato	Eroded Choromic Cambisols	0.7	5.6
2.	Banichan 41.620586, 23.742062	Potato	Choromic Cambisols	0.95	5.1
3.	Ognyanovo 41.608738, 23.778636	Potato	Fluvisols/ Mollic Fluvisols	1.73	6.9
4.	Hadzhidimovo 41.520661, 23.859279	Potato	Eroded Choromic Cambisols	1,21	6.3
5.	Bansko 41.847361, 23.465952	Potato	Eroded Choromic Cambisols	1.2	5.9
6.	Rila 42.116994, 23.118583	Tobacco	Choromic Cambisols	1.6	6.2

Plant-parasitic nematodes in soil samples

The plant-parasitic nematodes detected in soil samples from the monitoring points were identified as belonging to nine different genera. The identified genera included *Meloidogyne*, *Globodera*, *Pratylenchus*, *Paratylenchus*, *Tylenchorynchus*, *Tylenchus*, *Rotylenchus*, *Helicotylenchus* and *Hemicycliophora*. It is notable that nematodes of the genus Meloidogyne were present at 90% of the monitoring points, while those of the genus Pratylenchus were identified at 50% of the same locations. Additionally, cyst-forming nematodes belonging to the genus *Globodera* were identified. (Table 2). The genus *Meloidogyne* was not identified in the samples from the Yundola, Bansko and Kostandovo locations.

Table 2. Plant parasitic nematodes in soil samples

	Monitoring points /Location	Crop	Established genera of plant-parasitic nematodes
1.	Gotse Delchev 41.569064, 23.760338	potato	*Meloidogyne*, *Globodera*
2.	Banichan 41.620586, 23.742062	potato	*Meloidogyne*, *Pratylenchus*
3.	Ognyanovo 41.608738, 23.778636	potato	*Meloidogyne*, *Pratylenchus*, *Paratylenchus*, *Hemicycliophora*
4.	Hadzhidimovo 41.520661, 23.859279	potato	*Meloidogyne*, *Globodera*, *Pratylenchus*, *Helicotylenchus*
5.	Bansko 41.847361, 23.465952	potato	*Tylenchorynchus*, *Tylenchus*, *Rotylenchus*
6.	Rila 42.116994, 23.118583	tobacco	*Meloidogyne*, *Rotylenchus*, *Tylenchorynchus*, *Tylenchus*

8.	Kostandovo 42.020043, 24.114994	potato	*Globodera*, *Tylenchus*, *Pratylenchus*
9.	Dorkovo 42.034816, 24.122245	potato	*Meloidogyne*, *Paratylenchus*, *Helicotylenchus*
10.	Yundola 42.066602, 23.840069	potato	*Rotylenchus*, *Hemicycliophora*
11.	Samokov 42.331305, 23.533564	potato	*Meloidogyne*, *Pratylenchus*
12.	Alino 42.380527, 23.397953	potato	*Meloidogyne*, *Pratylenchus*, *Paratylenchus*

Quantitative analysis of the motile stages of the genus Meloidogyne in soil samples

The number of motile juvenile stages (J2) and males of the genus Meloidogyne in the 9 monitoring points where their presence was identified ranged from 6 to 171.3 nematodes per 100 cm³ of soil. It should be noted that the number of nematodes in each sample, collected within the same area, varied considerably (Table 3). For instance, the density of nematodes in the samples from Gotse Delchev exceeded 150 per 100 cm³ of soil, reaching a maximum of 171.3 per 100 cm³. In contrast, the number of nematodes in the other monitoring points from the area was below 50 per 100 cm³. The density of nematodes in the Banichan samples was 23.1 per 100 cm3 soil, while in the Hadzhidimovo and Ognyanovo samples it was 21.3 per 100 cm3 soil and 39,7 nematodes/100 cm3 soil, respectively. The number of nematodes per 100 cm³ of soil was found to be below 100 in all other monitoring points. The lowest number of motile stages of root-knot nematodes was observed in the samples from Rila, with a count of 6.1 nematodes per 100 cm³ of soil.

Table 3. Presence of root-knot nematodes of the genus Meloidogyne in soil and potato tubers samples

	Monitoring points /Location	Crop /Cultivar	Nematodes ind./100 cm3 soil	Infected tubers, %, n=200
1.	Gotse Delchev 41.569064, 23.760338	Potato/Jelly	171.3	95.3
2.	Banichan 41.620586, 23.742062	Potato/Agata	23.1	19.1
3.	Ognyanovo 41.608738, 23.778636	Potato/Argos	39.7	29.6
4.	Hadzhidimovo 41.520661, 23.859279	Potato/Soraya	21.3	0
5.	Bansko 41.847361, 23.465952	Potato/Soraya	0	5.7
6.	Rila 42.116994, 23.118583	Tobacco/Rila 82	6.1	–
7.	Velingrad 42.020671, 24.004515	Potato/Jelly	95.3	89.1
8.	Kostandovo 42.020043, 24.114994	Potato/Jelly	0	12.3
9.	Dorkovo 42.034816, 24.122245	Potato/Soraya	61.6	16.6
10.	Yundola 42.066602, 23.840069	Potato/Agata	0	0
11.	Samokov 42.331305, 23.533564	Potato/Soraya	67.3	11.1
12.	Alino 42.380527, 23.397953	Potato/Soraya	59.1	7.3

Quantitative analysis of root-knot nematodes of the genus Meloidogyne isolated from potato tubers

Potato tubers infected with *Meloidogyne* sp. had malformations on the outer surface of the tuber caused by galls formed as a result of the vital activity of female nematodes. The female nematodes and egg masses were discovered within the fleshy part of the infected potato tubers. The investigation revealed that infected potato tubers were present in 90% of the samples. The percentage of infected tubers ranged from 0% in Yundola and

Hadzhidimovo to 95.3% in Gotse Delchev (Table 3). Notwithstanding the absence of root-knot nematodes in the soil samples from monitoring points Bansko and Kostandovo, the prevalence of infected tubers in these locations was 5.7 % and 12.3%, respectively. It is also noteworthy that, despite the presence of root-knot nematodes in the field in Hadzhidimovo, no infected tubers were identified. Infected potato tubers were identified in varios varieties: Argos, Soraya, Jelly and Agata, which are predominantly cultivated in this region of Bulgaria (Table 3). The Jelly variety had the highest infection rate (89.1-95.3 %). However, it was not possible to infer varietal susceptibility or resistance.

The frequency of infection with *Meloidogyne* spp. may have been influenced by a number of factors, including microclimatic conditions at the research points, varietal characteristics and the cultural and plant protection measures applied. The high percentage of fields and tubers infected with root-knot nematodes in the study areas can be explained not only by the long-term cultivation of host plants (tobacco, potatoes) in these areas, but also by local agricultural practices, where potatoes are grown in small fields, often using their own planting material. The transfer of nematodes from one field to another is facilitated by surface water and wind. Another contributing factor is the frequent absence of crop rotation and potato monoculture. Additionally, the climatic conditions and soil types prevalent in these regions of Bulgaria are conducive to the proliferation of nematodes belonging to the genus *Meloidogyne*. Furthermore, an examination of weed vegetation was conducted in the Gotse Delchev area. The majority of the collected weeds, including field mustard (*Sinapis arvensis* L.) and potato weed (*Galinsoga parviflora*), which have been documented to host root-knot nematodes (Suri and Jayasinghe, 2003, 2014), exhibited the presence of galls. The absence of root-knot nematode infestation in the Yundola region can also be attributed to the influence of temperature, soil type and altitude. The samples were obtained from an altitude of 1400 metres or above, which also corresponds to lower temperatures than those observed at other points. The authors Mutala'liah et al. (2019) observed the infection of Meloidogyne spp in areas situated at approximately 1300 m above sea level. However, no infestation was identified in areas above 1300 m above sea level, which is also related to the optimal temperature for the development of Meloidogyne spp. It is established that Meloidogyne spp. are unable to undergo complete development at low temperatures. The optimal temperature for the development of *M. javanica* and *M. arenaria* is 28 °C (Perry et al., 2009). At lower temperatures, *M. javanica* was unable to reproduce eggs (Bridge and Starr, 2007). *M. incognita* prefers a range of temperature between 25 and 30° C. The optimal temperature for hatching *M. incognita* eggs was reported to be between 15 and 30°C by Fu et al. (2012). The optimal temperature range for the penetration and development of *M. hapla* is 20–25 °C. A mean temperature of 28 °C may impede its development (Rusinque et al., 2022). In a study conducted by Asif et al. (2015), the impact of soil physicochemical attributes on the dispersion and infestation of two nematode species, namely *M. javanica* and *M. incognita*, was examined. The researchers found that physicochemical parameters, including soil temperature, soil pH, silt and clay, exerted a considerable influence on the nematode population. A negative linear correlation was observed in clay soils, whereas a positive correlation was evident in sandy loam soils with respect to root-knot nematode density.

In order to assess the risk posed by *Meloidogyne* species to potato crops, further research is needed on the species composition of root-knot nematodes in the potato-producing regions of southwestern Bulgaria. The results will contribute to a better understanding of the species composition and facilitate the development of strategies to mitigate the adverse effects. The present study revealed the presence of root-knot nematodes in association with cyst-forming nematodes in 3 of the investigated fields. It is possible that global climate change may result in the replacement of cyst nematodes by root-knot nematodes, which are better adapted to higher temperatures (da Conceição et al., 2009). The data yielded is of considerable importance in forecasting the dissemination of the infection and formulating an efficacious nematode management strategy.

CONCLUSIONS

The findings of the study indicate that root-knot nematodes are prevalent in potato crops cultivated in southwestern Bulgaria. Given the region's prominence in tobacco production, it is plausible that these nematodes have been present in these fields for an extended period.

A variety of methods are employed by farmers to control nematodes, including the use of chemicals, yet success is often limited. The disruption of the nematode life cycle through crop rotation and intercropping represents a significant challenge in this region. As a long-term strategy for the control of potato root-knot nematodes, the screening of new varieties imported from other countries or produced by the local breeding programme for resistance to Meloidogyne species should be initiated.

ABSTRACT

The Mediterranean climate that characterizes the northern region of the country allows for the establishment of the most verdant natural pastures in the country. These pastures are characterized by their floristic diversity, primarily composed of grasses and legumes, serving as feed for ruminant herbivores. However, these pastures face several challenges, such as overgrazing, desertification, and climate change. The preservation and sustainable management of natural pastures have become major issues to ensure the longevity of these valuable ecosystems.
Giving pastures a significant role again could help reduce the chronic forage deficit that Algeria has been experiencing for decades. One of the solutions would be to study these pastures and their forage potential to improve them and integrate them into livestock feed. The objective of this work is to evaluate, on one hand, the floristic composition and biomass produced in the spring of a pasture in the Dellys region (Wilaya of Boumerdes), and on the other hand, to determine the chemical composition and "*in vitro*" digestibility of organic matter (OMD) of the dominant species in the pasture. This study reveals that spring productivity is 5.31 tons, which remains variable from year to year. The floristic study shows an abundance of legumes with an abundance rate of 50%, where *Hedysarum flexuosum* (sulla) is the dominant species with a total abundance of 28.6%. Grasses represent 35.7%, and other species note an abundance of 14.2%. The results of the chemical composition show a highly significant difference between species, particularly for crude protein (CP) content (8 to 20%). *Hedysarum flexuosum* presents the highest value for legumes (20.5%), and Allopecurus pratensis (11.8%) for grasses. The *in vitro* measured digestibility of OM shows average to good levels, between 60 and 66% for grasses, and 63 to 67% for legumes.

Key words : natural pastures, Algeria, floristic composition, chemical composition, *in vitro* digestibility.

INTRODUCTION

Livestock feed is considered, after genetics, to be the most effective means of increasing animal production, but in Algeria it is undeniably one of the major constraints on the various livestock production systems. However, modern livestock farming needs to be well thought-out in order to adapt forage availability to animal requirements.

In Algeria, the availability of forage units and nitrogenous matter is insufficient, or a chronic deficit is recorded every year (3 to 4 billion FU depending on the year). Forage areas are estimated at 1,988,519 ha but represent only 2.6% of the area used for agriculture (MADR, 2014). Faced with this situation, rapid and sustainable solutions are needed.

Natural fodder such as natural grasslands are a significant source of energy and nitrogen for ruminants, despite the relentless reduction in their surface area, and the low level of human intervention to maintain and improve them.

Grasslands provide a number of important ecosystem goods and services. First and foremost, they provide fodder for livestock (Bailey et al., 1996; Schauer et al., 2005). They are also important food sources for insects. They help maintain soil moisture, purify water and prevent flooding, and their roots hold the soil in place.

Restoring the importance of grasslands could help reduce the chronic forage deficit that Algeria has been experiencing for decades. One solution would be to study these grasslands and their forage potential, so as to be able to improve them and integrate them into livestock feed.

This study is part of this approach. The aim is to study the forage potential (botanical composition and yields) and nutritional potential (chemical composition and *in vitro* digestibility) of the dominant species of a natural grassland in the central region of Algeria.

MATERIAL AND METHOD

1. Study area and climatic characteristics

The study was carried out in Dellys (Daira headquarters) in the wilaya of Boumerdes. Dellys is a coastal town 105 km east of the capital Algiers.

Its climate is Mediterranean, with cold, wet winters and hot, dry summers. The wet season lasts 08 months, from October to May, and the dry season lasts 04 months, from June to September.

During the study year, cumulative rainfall was 595 mm, with significant seasonal variation, and temperatures also varied between seasons, with a minimum of 8°C in January and a maximum of 37°C between July and August.

2. Study plot and sample collection

The study plot is located in the Thouabet locality (Dellys commune). It covers an area of 0.65 ha. Samples were taken in spring (early April, 2021). Each sample consists of a mixture of legumes, grasses and other plants. The development stage of the various species sampled is shown in Table 1.

Our samples are taken using the simplified method of Theau et al, (2010). This technique limits the time required to establish a vegetation survey on a given plot. The sampling principle is in the form of frames, which limits the number of observations while increasing the surface area studied. We decided to take 7 samples, using a 50 cm square frame (0.25m^2), along a transect zigzagging across the entire plot, as shown in Figure 1.

In each frame, the frequencies and abundances of the dominant species are determined using the scoring system suggested by De Vries (1959). The contents of each frame were then weighed to obtain the fresh yield, then dried for 48h at 60°C to obtain the dry matter (MS%) and dry yield (Qx/ha). Finally, we proceeded to separate the dominant species in each frame. After identification, we mixed the contents of the 7 frames. In total, we were able to count 7 samples for the most abundant species (Vulpia ciliata, Alopercurus pratensis, Bromus hordaceus, Avena sterilis, Hedysarum, Melilotus indica). All species were ground with a 1 mm grid hammer mill, preserved and labelled for later analysis 3.

Table 2.Development stage of species sampled.

Sample type	Dominant species	Spring sampling
Grasses	*Vulpia ciliata*	Emergence
	Alopecurus pratensis	
	Bromus hordaceus	
	Avena sterilis	
Legumes	*Hedysarum flexuosum*	Flowering
	Melilotus indica	
Others	*Chrysantemum myconis*	Flowering
	Galactites tomentosa	
	Stachys ocymastrum	
	Centaurea pullata	
	Convolvulus tricolor	
	Daucus carota	
	Malva parviflora	

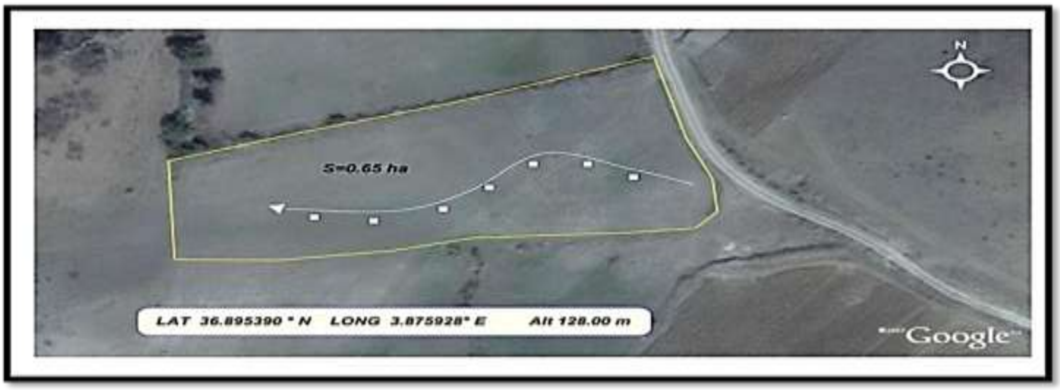

Figure 11.Location and method of sampling in the plot (Google earth, 2018).

3. Analysis and calculations

- For the agronomic study, frequency and abundance are calculated using the following formulas:

Abundance rate (B%) = (sum of scores for all frames/ n x 6).

Frequency (F) = number of times/ number of frames.

Frequency rate (F%) = (F / number of frames) x 100.

n : the number of frames used = 7

- Analysis of the chemical components: dry matter (DM); organic matter (OM); mineral matter (MM) and total nitrogenous matter (TNM) are carried out to AOAC (1990) standards, and total wall (NDF), lignocellulose (ADF) and lignin (ADL) by the sequential method of Van Soest and Wine (1963).

- Dry matter digestibility (DMD) and organic matter digestibility (OMD) are measured *in vitro* using the method of Tilley and Terry (1963). *In Vitro* digestibility of OM (per 100g DM) is calculated according to the following equation:

OMD (%) = (OM of sample - ROM) / OM of sample

With : ROM = Residual Organic Matter

The results are then corrected against a control (alfalfa hay of known digestibility).

All results were statistically processed by STATISTICA (version 6, 2003).

RESULTS AND DISCUSSION

1. **Floristic composition and biomass production**

2. According to the results obtained (Table 2), legumes were present at a rate of 50%, represented mainly by two species, *Hedysarum flexuosum* with an abundance rate of 28.6%, and Melilotus indica with 21.4%.

For grasses, the abundance rate is 35.71%, distributed between Avena sterilis (21.43%), Alopecurus pratensis (7.14%), Vulpia ciliata (4.76%) and Bromus hordaceus (2.38%). Avena sterilis is the representative grass species, with a frequency rate of 100%. On remarque également la présence d'autres espèces appartenant à différentes familles botaniques nommées dans la présente étude « autres » avec 14%, en grande partie occupée par l'espèce Galactites tomentosa avec une abondance de 4,76%. Table 2 shows the results of the frequency and abundance rates of the various dominant species on the plot during spring for the year under study.

Table 3.Frequency and abundance of dominant species in the Thouabet plot.

Genus	Dominant species	Frequency	Frequency rate	Total abundance	Abundance of each genus
Grass	***Vulpia ciliata***	**2**	**28,57%**	**4,76%**	**35,71%**
	Alopecurus pratensis	**3**	**42,85%**	**7,14%**	
	Bromus hordaceus	**1**	**14,29%**	**2,38%**	
	Avena sterilis	**7**	**100%**	**21,43%**	
Legume	***Hedysarum flexuosum***	**6**	**85,71%**	**28,57%**	**50%**

	Daucus carota	-	-	-	
	Malva parviflora	-	-	-	

According to Hubert and Pierre (2009), the dominant species (legumes or grasses) form what is frequently referred to as the "meadow base". These species ensure the biomass production of the plot. Ecological factors such as soil composition and climate have a major influence on the distribution of prairie species.

Among the most frequent species in Mediterranean regions, Avena sterilis provides the most ecological information. It is therefore an indicator species with a very wide ecological range (Kheddam and Adane, 1996).

Hedysarum flexuosum is a legume with an Ibero-North African distribution, endemic to north-central Algeria (Abdelguerfi et al, 1991), and thrives in regions with average rainfall of over 550 mm, in the humid and sub-humid bioclimatic zone (Abdelguerfi and Laouar, 1999).

According to some work carried out in Algeria, this legume is considered an excellent forage resource (Kadi et al, 2015).

According to Benjamin (2014), Melilotus indica is a forage plant of the legume family that has a wide natural range and grows in moderately saline areas.

Table 3 reports the fresh matter yield (RMF) and dry matter yield (RMS) of the various samples taken from the study plot.

Table 4.Yield (Qx/ha) of the Thouabet plot during spring.

Season	Frames	% DM at sampling	Fresh yield (Qx/ha)	Dry yield (Qx/ha)
Spring	1	14,63	328	48,00
	2	17,34	386	68,32
	3	14,21	366	52,00
	4	16,27	432	70,28
	5	19,17	240	46,00
	6	14,41	342	49,28
	7	10,32	370	38,20
Mean±SD		**15,19±2.80**	**353,14±60.41**	**53,15±11.84**

There was considerable variation between sampling points, with an average of 353.14 Qx/ha and 53.15 Qx/ha for fresh and dry yields respectively. DM content averaged 15.19%, with considerable inter-frame variability. DM yields depend on the floristic component of the meadow. They increase with wall content and plant height. Indeed, the results obtained by Lalmas and Bouchareb (2021) on the same plot show that *Hedysarum flexuosum* and Melilotus indica (legumes) represent the highest dry yields, thanks to the high weight and height of these species (103cm and 123cm respectively).

Huyghe et al (2015) report a ratio of 1 to 10 in the productivity of permanent grasslands between Portugal and Germany, mainly explained by soil and climate conditions, particularly the rainfall regime.

In Algeria, Salhi et al (2019) report that the fodder potential of the wasteland studied in the Chlef region stands at 38 Qx/ha, while DM content is 16.7 and 38.8%, which remain high compared with our results, due to the quality of the fodder produced. Adane and Kheddam (1996) found that grasslands on the Mitidja plain produced an average of 41 Qx DM/ha/year. The productivity of these grasslands is highly variable, ranging from 9 to 83 Qx DM/ha/year. According to these authors, these figures correspond to the quantity of forage harvested, and may be lower than the actual production of the grassland if it is under-exploited.

2. *In vitro* chemical composition and digestibility of the various species sampled

As mentioned above, the dominant and most representative species of the grassland were separated in order to determine their contribution to the forage value of the grassland.

Table 4 shows the results of the forage analysis and *in vitro* digestibility of the dominant species in the study meadow.

The results of the chemical composition show that there is a huge difference between the components, particularly for TN. These vary between 8% and 20% between the different species. For OM, they vary between 85 and 88%.

Table 5.Composition chimique et digestibilité In vitro des espèces dominantes de la prairie.

		% MS						%	
Species	**% DM**	**MM**	**OM**	**TN**	**NDF**	**ADF**	**ADL**	**DMD**	**OMD**
Melilotus indica	14,63	13,86	86,14	18,54	51,83	38,62	6,74	61,07	67,45
Hedysarum flexuosum	17,34	14,49	85,51	20,55	51,64	39,54	9,81	56,17	63,30
Vulpia ciliata	10,32	11,68	88,32	9,88	76,68	44,12	4,28	56,83	64,09
Avena sterilis	16,27	14,37	85,63	8,86	68,01	37,29	4,06	54,08	60,17

Bromus hordaceus	14,41	12,6	87,4	11,77	73,89	43,94	4,61	56,49	62,44
Autres espèces	14,21	13,41	86,59	8,25	77,6	47,6	4,37	55,40	63,68
P value		**0,001**	**0,001**	**<0,0001**	**<0,0001**	**0,003**	**0,001**	**>0,05**	**>0,05**

Hedysarum flexuosum and Melilotus indica are richer in TN than the other species. These different results for DM and TN are explained by the species' botanical family.

Analysis of variance revealed a highly significant difference for TN ($p<0.001$), indicating a large difference in this component between species. This difference can be explained by the influence of the species' botanical family, which explains why *Hedysarum flexuosum* and Melilotus indica species have a high nitrogen content, unlike grasses such as Avena sterilis and Vulpia ciliata, which have a low TN content.

According to Hoden (1973), nitrogen in the ration stimulates the activity of the microbial population, in particular its cellulotic activity, and also increases the rate of degradation of the forage's parietal constituents. It thus helps improve forage digestibility.

On the other hand, OM content varies from one species to another. According to Coppen et al, (1974) and Duru (1992), this difference can be explained by the fact that the absorption of mineral elements by the plant ceases as from heading.

Total wall density (NDF) varies between 54 and 77% for Alopecurus pratenis and Vulpia ciliata species respectively.

Lignin composition is the parameter that differentiates species the most, with 4% for Alopecurus pratenis and 9.8% for *Hedysarum flexuosum*, i.e. more than double for the latter species.

This difference observed for NDF and ADL is confirmed by the analysis of variance, which shows a highly significant difference (P< 0.0001) between species of the same season.

According to Jarrige (1988), variable NDF contents can be explained by a different evolution of the leaf/stem ratio, given that stems contain more walls. Arab et al (2009) report that ADF fibers are generally linked to the digestibility and energy value of forage. Indeed, the higher the ADF content of the forage, the lower the digestibility and energy content.

The average DM digestibility of legumes is 58.62%, varying between 56.17 and 61.07% between the two species. For grasses, DIV averaged 56.07%, with values varying between 54.80 and 56.83%. For other species, digestibility averaged 55.40%. Legumes are logically more digestible than grasses and “other” species.

Grass digestibility ranges from 54.80% to 56.83% for Avena sterilis and Vulpia ciliata respectively, making the latter the most digestible species.

Demarquilly (1989) indicates that the large differences in digestibility between selected and native grass species (Bruinenberg et al, 2002) are due to two processes. The first is when biomass is the same, the share of the structural compartment is higher for species with a resource conservation strategy.

The other is when the structural compartment digestibility of these same species is lower than that of resource-capture species. Thus, the average values for grasses with capture and conservation strategies are 58 and 49% respectively (Al Haj Khaled et al, 2006).

Among legumes, Melilotus indica is more digestible than *Hedysarum flexuosum*. According to Arab et al (2009), high lignin content tends to reduce forage digestibility. The lower the lignin content, the higher the digestibility of the plant, i.e. the animal will consume more easily if the feed is rich in nitrogen and low in lignin. Lignin has an effect on plant utilization, binding with nitrogen and preventing nitrogen from being used by the animal (Chabaca, 2004).

Rodrigues et al (2007), indicate that differences in digestibility between species depend on the time at which they are exploited. This is because plant phenology differs from one species to another.

Overall, the forage on this plot is considered average to good. It is the equivalent of Algerian alfalfa with an average digestibility of around 59% (Alane, 2017).

For OM digestibility, it was calculated from residues after passage through a muffle furnace according to the equation of Minson, Raymond and Harris (1960). Grass OMD varies between 58 and 66% for Bromus bordaceus and Alopecurus pratensis respectively. On average, the OMD of these grass species is 62%. Demarquilly (1989); Facker and Minson (1981), agree that in spring, digestibility decreases essentially in relation to the proportion of stems in the harvestable biomass, the latter being less digestible. For grasses, such a reduction is also observed at the leafy stage (Ducrocq and Duru, 1994).

Among legumes, Melilotus indica has the highest OMD at 67%, while *Hedysarum flexuosum* is less digestible at 60%. The average OMD is 64%. For the “others”, comparable BMDs were obtained, ranging from 53 to 78%, with an average of 63.68%.

According to BAUMONT et al (2007), the digestibility of organic matter is closely linked to the indigestible wall content of the forage, with grasses and legumes forming part of the same relationship. Wall content and digestibility evolve in the plant according to time-dependent processes. Over the course of a growth cycle, plant wall content increases with plant growth, and wall digestibility decreases with tissue ageing (review by DURU et al, 2008).

Ballard (2009b), notes that an increase in parietal constituents would imply a loss of 2 to 3 points in OMD. Similarly, Van Soest (1982) shows that cell wall richness has a negative influence on digestibility.

CONCLUSIONS AND RECOMMENDATIONS

At the end of this study, the following findings emerged:

The floristic composition of the Thouabet meadow is based on legumes, with a rate of 50% for spring (2021). The legume family is mainly represented by *Hedysarum flexuosum* and Melilotus indica for this plot. As for grasses, Avena sterilis remains the most abundant on the plot.

In terms of yield, the dry biomass produced by the same plot during the spring is 53 Qx/ha, which is lower than in previous years. With a dry matter content at harvest of 15%.

The species with the highest TN content was Hydesarum flexuosum, with 20.55% DM. In terms of chemical components, NDF, ADL and TN content show a difference between species.

However, Hydesarum flexuosum is also the richest in lignin, with a content of 9.81% DM.

The *in vitro* digestibility of the different species in our plot is higher for legumes (58.62%) than for grasses (56.07%), but overall the grassland is almost similar and shows no significant difference between species, as shown by the analysis of variance of the parameters studied ($p > 0.05$).

On the other hand, OMD also represents significant levels for practically all 6 species and “others”, with a maximum level for Melilotus indica (67.45%).

These results show that, despite their low maintenance (neither worked nor fertilized), natural grasslands have considerable fodder potential and can play a key role in diversifying and improving fodder supplies for ruminants.

Further studies are needed to better characterize this dormant resource, and improvement actions (introduction of species, fertilization, etc.) remain essential to enhance the nutritional value of these grasslands.

ABSTRACT

Our work is to study the quality of fodder resources of nutritional supports traditionally used by sheep. The study site is located in Tiaret, which is considered as a reception area for flocks and more precisely the M'kimen range. It is part of the High Plains steppes southeast of the city of Tiaret at an average altitude of 1,000 m with an area of 35,000 ha. The studied area offers more or less favourable conditions for the existence of a characteristic spontaneous flora which represents the available food source for the animals. The floristic study allowed us to identify 32 species belonging to different families represented by herbaceous and especially perennial plants. The analysis of the forage, of the total wall (AFNOR, 1985; Van Soest and Wine, 1967) and of the composition in phenolic substances by SPIR (Bertrand, 2002) of 7 samples among the 32 highlighted the great variability in chemical components between these different species. The DMD and OMD measured *in vitro* (Tilley and Terry, 1963) vary, for the extremes, respectively from 31 and 36% (*Artemesia Herba alba*) to 83 and 86% (*Peganum harmala*). These extreme values are explained by the extreme contents of total phenols of 9.3 and 5.0% as well as by the respective contents of TN (10 and 23%) and ADL (20.7 and 5.2%) for these same species. These results need to be reinforced by the study of other species collected and to know their level of palatability.

Keywords: livestock system, steppe, forage analysis; phenolic compounds; digestibility.

INTRODUCTION

Grazing land is the world's most important agricultural activity. Algeria is no exception to this land distribution statistic. With a total surface area of 238 million hectares, 41 million hectares (18%) are devoted to agriculture, including 33 million hectares to pasture. The latter is distributed as follows: 87.7% is occupied by steppe rangelands and grazing land; 10.6% by fallow land; 1.6% by forage crops and 0.17% by permanent grassland (Nedjraoui, 2002; Rami et al, 2021). Man has taken advantage of these vast areas of terrestrial grazing land, depending on the ecological and pedoclimatic characteristics of the ecozones and the endemic or imported herbivore species, by devising adapted production systems (FAO and L'ILRI ,2011).

Thanks to their many benefits, grazing areas can account for between 10% and 44% of gross domestic product in some poor countries (AU, 2010). They provide a livelihood for nearly 3 billion people. Numerous subsequent studies show that grazing lands are also effective carbon sinks, largely offsetting the 18% of GHG emissions from livestock production (FAO, 2009; Gac et al, 2010; Dollé et al, 2013). Their contribution has reduced this percentage to 14.5% (FAO, 2013).

To respond to this concern, we need to deepen our knowledge of the country's pastures in their entirety, in particular their productivity and the nutritional value of plant species in our grazing areas, in anticipation of their improvement, while being vigilant about the consequences of our actions on global warming (GW).

The present work deals with the nutritional value of some species found after the fencing of a parcel of land located in the Tiaret region, considered to be a herding area, and more specifically the M'kimen grazing area. The region is renowned for its ancestral pastoral vocation, with livestock farming providing the bulk of the local population's income.

MATERIAL AND METHOD

The study site is considered to be a herding area, more specifically the M'kimen grazing area. It is part of the Hautes-Plaines steppes to the south-east of the city of Tiaret, at an average altitude of 1,000 m and with a surface area of 35,000 ha.

The area studied offers more or less favorable conditions for the existence of a characteristic spontaneous flora, which represents the available food source for animals.

The species were harvested in late spring (2019), corresponding to the vegetative period for annual plants, after a period of defensing.

We analyzed 7 dominant perennial species in this steppe rangeland. These species (Table 1) dominate alone or in combination, forming several vegetation units.

After harvesting, the samples were air-dried, then ground in a hammer mill to a 1mm grid and stored for analysis.

Forage analysis: organic matter (OM), mineral matter (MM) and total nitrogen matter (TN) content was carried out in accordance with AOAC (1990) recommendations. Total wall (NDF), lignocellulose (ADF) and crude lignin (ADL) were determined according to Van Soest (1963). Phenolic composition is determined by SPIR (Bertrand, 2002). DMD and OMD are measured *in vitro* (Tilley and Terry, 1963). *In Vitro* digestibility of OM (per 100g DM) is calculated according to the following equation:

Div OM (%) = (OM of sample - ROM) / OM of sample

With : ROM = Residual Organic Matter

The results are then corrected against a control (alfalfa hay of known digestibility).

Calculation and statistical analysis of results

The results were statistically analyzed by means of regression calculations between variables. Calculations were performed using S-PLUS software version 4-5e (1998).

Table 6. Systematics of the 7 species collected on the M'kimen trail.

Samples	***Common name***		***Vernacular name(*)***	***Order***	***Family***	***Genus***
	French	**English**				
Artemisia Herba alba	Armoise blanche, Herbe blanche, Absinthe du desert	Wormwood	Chih (LT) ; Zazaré, Horasani (M. Orient) ; Kaysoum (Maroc) ; Izreg (berbere); La'anah (hebreux)	Asterales	Asteraceae	Artemisia
Atriplex canescens	Arroche	Fourwing saltbush	Guetaf	Caryiphillales	Chenopodiaceae	Atriplex
Lygeum spartum	Sparte	Lygeum	Senagh (LT) ; Gdin (RT)	Cyperales	Graminée	Lygeum
Peganum harmala	Rue sauvage	Harmala peganum	Harmel (LT) ; Tifri (RT)	Zygophyllales	Zygophyllaceae	Peganum
Plantago albicans	Plantain blanchissant	Chilean plantin	-	Plantaginales	Plantaginaceae	Plantago
Reseda lutea	Reseda jaune	Yellou mignonette	Denb el kharouf	Pareatales	Resedaceae	Reseda
Stipa paviflora	Stipe à petites fleurs	Normon needlegrass	Halfa	Cyperales	Graminée	Stippa

(*) LT: local phonetic transcription; RT: regional phonetic transcription ;

In addition to their role as a food resource for animals, these species are also of great ecological and economic importance. In fact, they are used for honey production, medicinal purposes (sedative, narcotic, antiasthmatic, bactericidal, insecticide, cosmetic) or to make handicrafts (Table 2). Often, the same plant species is used twice or even three times (for condiments, aromatic and medicinal purposes).

Table 7.Special properties of harvested plants.

Species	**Known properties**
Artemisia herba alba	Medicinal; essential oils; flavoring for tea and other beverages; condiment; vermifuge
Atriplex canescens	Medicinal; condiment
Lygeum spartum	Handcrafted (Ropes, baskets, soles)
Peganum harmala	Hallucinogenic properties (witchcraft)
Plantago albicans	Medicinal against constipation and dysentery, melliferous
Reseda lutea	Melliferous
Stipa paviflora	Handcrafted, rope and basket making

RESULTS AND DISCUSSION

Chemical composition of samples taken

All the chemical composition results are shown in Table 3.

Table 8.Average chemical composition of the 7 species in the M'kimen range.

Species	DM %		In % DM				
		MM	OM	TN	NDF	ADF	ADL
Artemisia herba alba	93,60	12,82	87,18	10,30	68,80	49,80	**20,67**
Atriplex canescens	94,75	16,72	83,28	10,71	60,48	31,30	9,66
Lygeum Spartum	95,10	6,11	93,89	**8,61**	**82,28**	**52,78**	6,52
Peganum harmala	92,05	13,26	86,74	**23,46**	**30,70**	**19,83**	**5,17**
Plantago Albicans	93,55	20,74	79,26	13,10	54,73	38,59	9,73
Réseda lutea	93,05	22,06	77,94	14,20	40,79	29,02	7,15
Stipa parviflora	95,55	5,61	94,39	11,47	81,95	40,03	8,16

OM varied between 78 and 94% for *Reseda lutea* and *Stipa parviflora* respectively. This large difference between species can be explained by the large difference in MM content between certain species. Steppe plants are certainly soiled by small particles of soil, but more likely by sand stored in plant organs such as hairs, which offer an adequate holding structure.

The average TN content is 13%, with a very wide range between the 7 species, as shown by the minimum of 8.6% (*Lygeum Spartum*) and the maximum of 23.5% (*Peganum harmala*), i.e. almost 3 times higher. However, this parameter remains within the range of TN contents of hay in Algeria (Chibani, 2013).

Sequential wall analysis in Table 3 shows a low average NDF total wall content of 60%, but the differences between the minimum of 31% (*Peganum harmala*) and the maximum of 82% (*Lygeum Spartum*) remain significant, with almost 3 times as much as for TN.

Lignin content appears to be the parameter that most discriminates the wall content of the species harvested, with a maximum of 21% and a minimum of 5.2% of DM, giving an average of 9.6%. This is the case for *Peganum hermala*, with the lowest ADL content, and *Artemisia herba alba*, with the highest. Lignin is known to be the main compound influencing the depreciation of indigestibility and digestibility of forages.

It has been reported that increasing temperature (the case in our study region) favors lignification. Indeed, rising temperatures can induce phenological (advanced flowering) and physiological (thicker cell walls and increased lignin concentrations) changes in plants

(Kering et al, 2011), and also favors species turnover by favoring taller, slower-growing species that invest more energy in structural support and defense, and less energy in leaf growth (Waghorn and Clark, 2004).

In general, fiber content is due to variations between plant species, maturity and environmental conditions. Similar results were reported by Boufennara et al (2012), who found that the high fiber content (ADF and lignin) of some forage species could be partly explained by ecological conditions - high temperature and low precipitation. This tended to increase the cell wall fraction and decrease the soluble content of the plants. This observation applies to our case (arid bioclimatic stage) where rainfall is low (around 200mm on average) and temperature high from spring to autumn (over 36°C on average).

In vitro digestibility of harvested species

Digestibility is considered the second step in forage evaluation after forage analysis. Variations in OMD results can be attributed to several factors, but mainly to differences in the chemical composition of feeds, (Tufarelli et al, 2010). In addition, values for total nitrogen matter, fiber content and digestibility are indicators of the nutritional quality of feeds for ruminants (Andualem et al, 2016).

The *in vitro* digestibility of our 7 harvested samples is reported in Table 4. Our OMD measurement results show an average of 56.5%, but ranges from 33% for *Artemisia herba alba* to 83% for *Peganum hermala*.

The lower lignin content (5%) and higher TN content (23%) of *Peganum hermala* could partly explain this extremely high digestibility result.

It can be seen that the lower the fiber content (Table 3), the higher the digestibility (*Peganum harmala*). These results can be explained by the total tannin content in the walls of certain species (Table 4). In fact, these components, even in a plant rich in OM, have a negative effect on OM digestibility, as shown by the *Artemisia herba alba* species with an OMD of only 33.4%.

In order to better understand and validate our observations, we established regressions between dMO and the different chemical components measured. Table 5 shows the results obtained.

The TT component was found to have a negative effect on OMD, accounting for 75% of its variations. Combined with ADF, the two parameters explain 96% of OMD ($p \leq 0.001$).

Tannins are said to form stable complexes with product proteins, insoluble in the rumen medium, and a large proportion of TN is thus rendered unavailable to the action of digestive enzymes (Larwence, 1983; Chabaca, 2004). These species confirm our observation that less total tannin favours a higher OMD (*Peganum* with 86%) and vice versa for *Lygeum* and *Stipa parviflora* (around 36%).

Foguekem et al (2011) suggested that OMD is strongly influenced by the amount of fiber represented by the levels of cellulose, hemicellulose and lignin in plant tissues. The results of our study are also in agreement with those of Ghulam et al (2017) who observed a negative correlation of OMD with NDF, ADF and lignin. In our study, ADF explained the most negative relationship with OMD (R^2 =0.92).

Table 9. Phenolic compounds and average in vitro digestibility of the 7 species of the M'kimen range.

CONCLUSIONS

Our data set reveals how different forage plant species growing in the same steppe rangeland can vary in their nutritional value for sheep flocks in particular and ruminants in general. Some forage plant species were highly nutritious, containing high concentrations of protein and low concentrations of fiber and lignin, but rich in total tannins. The characterization of forage qualities through laboratory trials is an essential step in long-term programs aimed at improving forage availability in pastoral and agro-pastoral environments. Experimental studies of the chemical composition of forage species, especially their total tannin content, have shown that restoring steppe ecosystems through fencing is a highly effective strategy, as several species have recorded good forage values.

Further work is needed to elucidate the effects of global environmental change on plant nutrient values, and also, through observations via surveys of livestock farmers, to find out whether or not these species are palatable to grazing animals.

ABSTRACT

Honey has been used as a natural sweetener for thousands of years, produced by bees (*Apis mellifera*) from either nectar or honeydew. Its chemical composition is influenced by factors such as processing methods, botanical origin, environmental conditions, and seasonal changes. Among the many valuable components of honey are phenolic compounds, such as naringenin, a flavonoid with several health-promoting properties, including nephroprotective, anti-inflammatory, antioxidant, and anticancer effects. This study aimed to quantify the naringenin content in nine honey samples from three honey types—sage, heather, and meadow—collected from three distinct locations in the Mostar region: Rujiste, Bijelo Polje, and Podvelezje. High-performance liquid chromatography (HPLC) was employed for the quantification. The results revealed the presence of naringenin in most samples from Rujište and Podvelezje, with no naringenin detected in meadow honey from Bijelo Polje.

Keywords: honey, naringenin, HPLC, functional food, Mostar

INTRODUCTION

Polyphenols, which consist of more than one phenolic hydroxyl group attached to benzene rings, are widely distributed in plants and foods (Vermerris & Nicholson, 2006). These include various derivatives such as flavonoids, phenolic acids, and stilbenes (Shahidi & Naczk, 2004). In honey, polyphenols play a significant role as antioxidants, contributing to its therapeutic benefits, which include protection against oxidative stress and chronic diseases such as heart disease, cancer, and neurodegenerative disorders. Due to the therapeutic benefits of honey, it is used to treat several illnesses because of its various pharmacologically active components, especially flavonoids and phenolic compounds. Kaempferol, chrysin, quercetin, pinobanksin, pinocembrin, genistein, luteolin, apigenin, naringenin, hesperetin, gallic acid, p-coumaric acid, ellagic acid, ferulic acid, caffeic acid, syringic acid, and vanillic acid are a few of the flavonoids and phenolic chemicals (Zullkiflee et al., 2022). In food, polyphenols may contribute to bitterness, astringency, color, flavor, and odor (Pandey and Rizvi, 2009). Naringenin, a flavonoid in the flavanone subclass (Salehi et al., 2019), is known for its potent antioxidant and anti-inflammatory properties, along with its effects on cholesterol regulation, blood pressure, and cancer cell proliferation. Naringenin is primarily found in citrus fruits but has also been detected in honey. Evidence supports the analgesic activity of naringenin in a wide range of inflammatory conditions. Naringenin can control body lipids by possessing hypocholesterolemic and hypolipidemic effects and anti-estrogenic activities. Principally, flavonoids have been investigated and found to be a major regulator of tumor cell growth, EC migration, and angiogenesis. Besides, naringenin also regulates blood pressure and has antagonistic activities against inflammation (Manchope et al., 2022).

This study aimed to quantify the naringenin content in 9 honey samples: 3 different types of honey (sage, heather, and meadow honey) from 3 different locations in Mostar: Rujiste, Bijelo Polje, and Podvelezje. These locations are at varying altitudes, which may influence the phenolic content in honey.

The HPLC method was used to determine naringin for the sampled types of honey.

Figure 1. Map of localities from which samples were taken (Bijedic A.)

MATERIALS AND METHODS

Sample Preparation

Honey samples (5 g) were homogenized with 10 mL of deionized water. The pH of the solution was adjusted to 3 using HCl. Solid-phase extraction was performed using BOND Elut Plexa cartridges, which were conditioned with 5 mL of methanol followed by 5 mL of acidified deionized water (pH 3.5). Samples were passed through the sorbent at a flow rate of 2 mL/min. Analytes were eluted with 5 mL of methanol, evaporated to dryness, and redissolved in 1 mL of a mobile phase consisting of 0.05% TFA in water (90:10, v/v). The extracts were filtered through 0.45 μm filters before HPLC analysis.

Chromatographic Conditions

Chromatographic separation was conducted on a UHPLC system (Merck Hitachi, Germany) equipped with a pump (L-2160U), UV detector (L-2400U), autosampler (L-2200), and a temperature-controlled column compartment (L-2350U). Data was processed using EZ Chrom Elite software. The separation was performed on a Zorbax 300SB-C18 analytical column (150 mm x 4.6 mm; 3.5 μm, Agilent Technologies) at 25°C. A binary gradient system with 0.05% TFA in water (solvent A) and acetonitrile (solvent B) was applied (Table 1). Naringenin was detected at 285 nm with a total analysis time of 12.5 minutes.

Table 1. Gradient Program

Time (min)	Mobile phase A (%)	Mobile phase B (%)	Flow rate (mL/min)
0	90	10	0.8
10	30	70	0.8
10.1	90	10	0.8
12.5	90	10	0.8

Polyphenols were identified by comparing retention times with standards and confirmed through standard addition.

RESULTS AND DISCUSSION

Table 2. Naringenin Content in Meadow Honey (µg/g)

Location	Naringenin (µg/g)	SD
Podveležje	0.73	0.01
Rujište	9.80	0.01
Bijelo Polje	ND	ND
ND: Not detected		

Meadow honey from Podvelezje showed a significantly higher naringenin content than that from Rujiste ($p<0.05$), while no naringenin was detected in honey from Bijelo Polje.

Table 3. Naringenin Content in Sage Honey (µg/g)

Location	Naringenin (µg/g)	SD
Podvelezje	7.92	0.01
Rujiste	6.64	0.014
Bijelo Polje	5.34	0.01

In sage honey, Podvelezje showed the highest naringenin content, with significant differences observed between all localities ($p<0.05$).

Table 4. Naringenin Content in Heather Honey (µg/g)

Location	Naringenin (µg/g)	SD
Podvelezje	3.67	0.01
Rujiste	11.91	0.01
Bijelo Polje	3.84	0.01

Heather honey from Rujiste exhibited the highest naringenin levels, significantly higher than those from Podvelezje and Bijelo Polje ($p<0.05$).

CONCLUSION

The analysis demonstrated that heather honey from the Rujiste location contained the highest concentration of naringenin, whereas meadow honey from the Podvelezje location exhibited the lowest levels. Notably, naringenin was not detected in meadow honey from the Bijelo Polje location.

The findings indicate that honey from the Mostar region, particularly samples from Rujiste and Podveležje, represents a significant source of naringenin. This compound, known for its potent antioxidant and anti-inflammatory properties, underscores honey's potential as a functional food with considerable health benefits. The results support the role of honey in promoting health beyond its nutritional value as a natural sweetener. Future research should focus on elucidating the environmental and botanical factors that influence naringenin content in honey to further understand the variability in its functional properties.

ABSTRACT

Seed germination and early seedling growth are the critical stage for species survival. Salinity affects the germination, seedling growth, and yield of several crop species, such as radish. The current study was carried out to reveal the effects of NaCl on seed germination and the early seedling stage of radish (*Raphanus sativus* L.). In order to study salinity stress on three radish cultivars, a laboratory experiment with a completely randomized design was conducted with three replications in the Department of Horticulture, Akdeniz University, Türkiye. To create salinity stress, sodium chloride (NaCl) at three levels of 0 (as control), 100, 200 and 300 mg L^{-1} were used. Results showed that there were statistical differences on final germination percentages (%), hypocotyl lengths, and root lengths in terms of cultivars. Accordingly, among the cultivars tested, the black radish variety showed better performance than the other cultivars regarding the parameters measured at different salinity levels.

Keywords: Radish, Salinity, Germination, Germination Percentage, Growth Parameters

INTRODUCTION

Throughout the world, radish (*Raphanus sativus* L.) is grown and consumed as a vegetable, making it one of the more significant species (Wang et al., 2013). It is well-known for its unique taste and fleshy root with a significant culinary component. It's rich in nutrients, including protein, carbs, crude fiber, and vitamin C (Lu et al., 2008). It also contains beneficial bioactive molecules such as isothiocyanate, polyphenols, and glucosinolates. Radish's characteristically strong taste comes from volatile isothiocyanates (Ghosh et al., 2014). Radish's ultimate yield and quality are determined by glucosesinolates, which also have a major effect on the vegetable's nutritional content and flavour (Kanjevac et al., 2021). As a species that is sensitive to salt, radishes are known to be inhibited in their growth by salinity. Stress due to salt has been shown to impact metabolic processes in seedlings and to produce chlorosis, morphological and anatomical abnormalities, and indications of nutritional inadequacy in matures in crops (Kanjevac et al., 2021). Numerous research findings demonstrated that salt stress has a detrimental impact on radish plant height, chlorophyll content, and fresh weight of the shoot and root.

The radish cultivars exhibited significant differences in germination and growth characteristics as a result of varying salinity treatments (Ghosh et al., 2014; Vishnu Priya et al., 2020; Kanjevac et al., 2021).

The most crucial stage of a plant's life cycle is the seed germination (Khan et al., 2000). The capacity of the seed to germinate in various environmental circumstances and to do so quickly and uniformly is important characteristics of radish, just like in the case of many other species. The germination and seedling growth phases of many plant species are very susceptible to salt stress (Khan et al., 2000). Normally, non-saline circumstances yield the maximum germination percentage, which then declines with increasing salt concentrations. The term "germination" refers to the rootlet's exit from the testa (Coopland and McDonald, 1995). Water intake initiates seed germination, whereas salt inhibits it (Othman, 2005). In salted circumstances, the seed is unable to germinate because of a reduction in water absorption, osmotically, and ion toxicity due to high concentration of Na and Cl ions around the seed (Murillo-Amador et al., 2002). Increasing salt concentrations delays the onset of germination, which not only prevents seeds germination but also extends the time needed for germination (Rahman et al., 2008).

Plant physiological and biochemical processes are impacted by salt stress, which lowers the biomass output (Ahmad and Sharma, 2012; Ahmad et al., 2012; Kanjevac et al., 2021). Plants are negatively impacted by salt stress throughout their whole life cycle. The ability of a species to withstand salt stress varies and is also dependent on the stage of plant growth (Ahmad and Sharma, 2012; Ahmad et al., 2012; Kanjevac et al., 2021). Compared to mature plants, seedlings, and immature plants are noticeably more vulnerable to salt stress. The demand to create crops that can withstand more salt has grown significantly in recent years as a result of global increases in salinity issues. In comparison to land without salt, radish yield is significantly reduced in saline soil. The technology involved in producing any crop, including radish, is complicated, and it gets much more under salinized conditions. Therefore, understanding how different salinities affect radish seed germination is crucial for achieving the ideal plant population and maximum output. Prolonging the germination period can be highly hazardous for a crop that is sown directly into the soil, as there is a greater chance of layer formation on the top layer of the soil, which could hinder or even completely prevent the emergence. Additionally, young seedlings and recently germinated seeds are particularly vulnerable to various pests and fungi (Cuartero and Fernandez-Munoz, 1999). For these reasons, it is necessary to improve the plants' resistance to salt to maximize the yield of cultivars grown in salted soils. Knowing the germination properties of the seeds at varying salt concentrations is crucial in this regard. The capacity of the seeds to germinate under salt-stress circumstances and their tolerance to salt during germination are investigated in present study. The seeds are from three different radish cultivars/types with varying salt concentrations. To serve the purpose, seeds of several radish cultivars are treated with salt concentrations of 0, (control), 100, 200, and 300 mg L^{-1}. After the experiment, germination percentage, final germination percentages (%), hypocotyl lengths (cm), and root lengths (cm) were measured and recorded.

MATERIAL AND METHOD

This study was designed to evaluate the germination characteristics of three different radish cultivars/types, namely black radish, radish Antep, and fındık radish, under laboratory conditions at the Department of Horticulture, Faculty of Agriculture, Akdeniz University in Turkey.

Preparation of seeds

The study was conducted in sterile cabins at every step. Following autoclave sterilization, glass petri dishes with a 90 mm diameter and filter papers within were employed. Seeds were surface sterilized for fifteen minutes in a 20% sodium hypochlorite solution. It was then ready for seeding in petri dishes after being washed four times with sterile distilled water. Each petri dish included ten seeds, and the study was conducted with three repetitions with three petri dishes included in each repetition.

NaCl Treatments

Three distinct concentrations of NaCl were employed for salinity applications (100, 200, and 300 mg L^{-1}). Pure water was utilized in the 0 (control) media, where NaCl was not added. Each petri dish received 10 ml of the liquids containing the control and all NaCl concentrations applied. Three different observations were obtained during the study's ten days. Among the characteristics recorded were the radicle length (mm), hypocotyl length (mm), germination percentage (%). Petri dishes were placed in completely dark conditions and allowed to germinate at 25±2ºC. After germination, the studies were carried out in the plant development chamber at the same temperature and with a light/dark photoperiod of 16/8 hours. The emergence of the radicle from the testa was considered as the basis for germination. Throughout the experiment, a small amount of liquid was supplied to moisten the seeds as needed, considering the filter papers' state of drying.

Germination percentage was calculated with down given formula:

Germination Percentage (%) = Germinated seeds / Total cultured seeds x 100 (Gosh et al., 2014)

Statistical Analyses

An entirely randomized factorial design with three replications was used to conduct the current experiment and the statistical software JMP version 5.0.1 (SAS Institute Inc., Cary, NC, USA) was used to analyse the data.

RESULTS AND DISCUSSION

The purpose of this study was to ascertain how salt stress affected the germination characteristics of radish cultivars/types. Positive (normal) germination was defined as the emergence of a 2 mm root segment from the seed coat. Figures 1 – 4 illustrate the variations' germination percentages, hypocotyl lengths, and root lengths in relation to the applied salt concentrations.

Germination percentage of Antep radish was adversely impacted by increasing the salt concentration. Black radish was the least impacted by the highest NaCl concentration regarding germination percentages. Fındık radish was heavily affected by the 200 mg L^{-1} NaCl concentration (Figure 1). Similar to Gosh et al. (2014), who examined the effects of salinity on the radish seed germination, development, and yield parameters, the current study also found that the effects of salt stress varied based on the radish cultivar/type. Additionally, the effects were found to depend on both the cultivar and the concentration of salt applied.

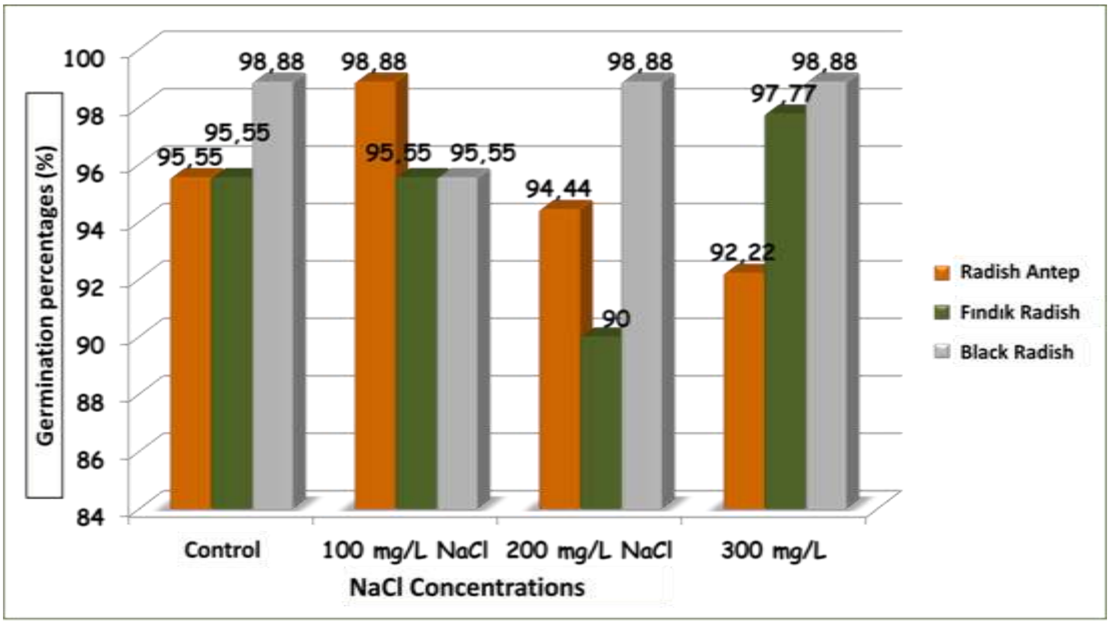

Figure 1. Germination percentages of three radish cultivars

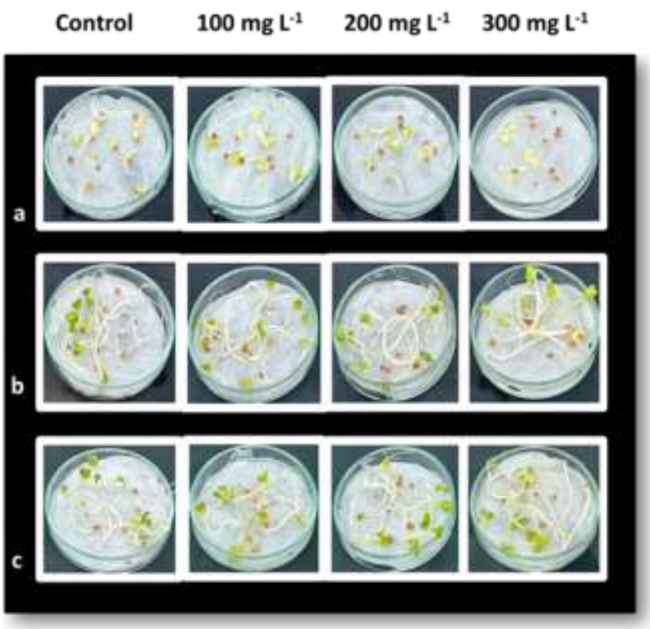

Figure 2. Germination characteristics of radish Antep under different NaCl concentrations; a. First measurement, b. Second measurement, c. Third measurement

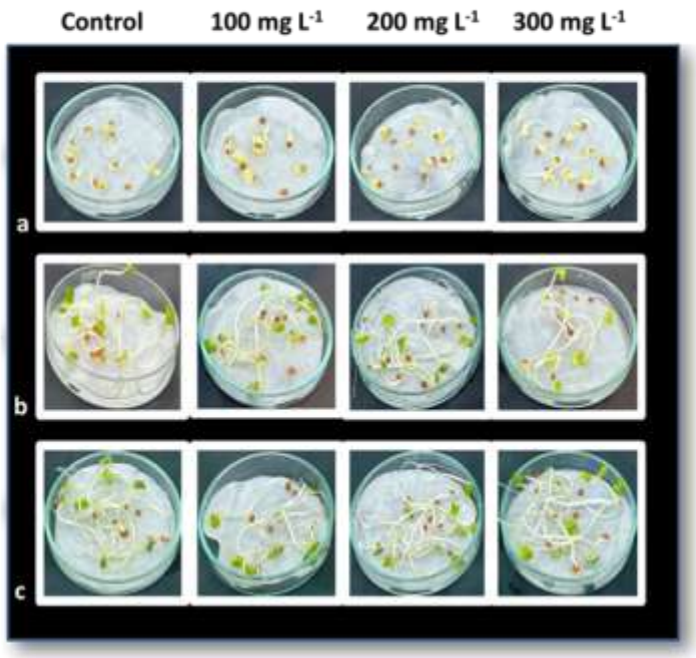

Figure 3. Germination characteristics of black radish under different NaCl concentrations; a. First measurement, b. Second measurement, c. Third measurement

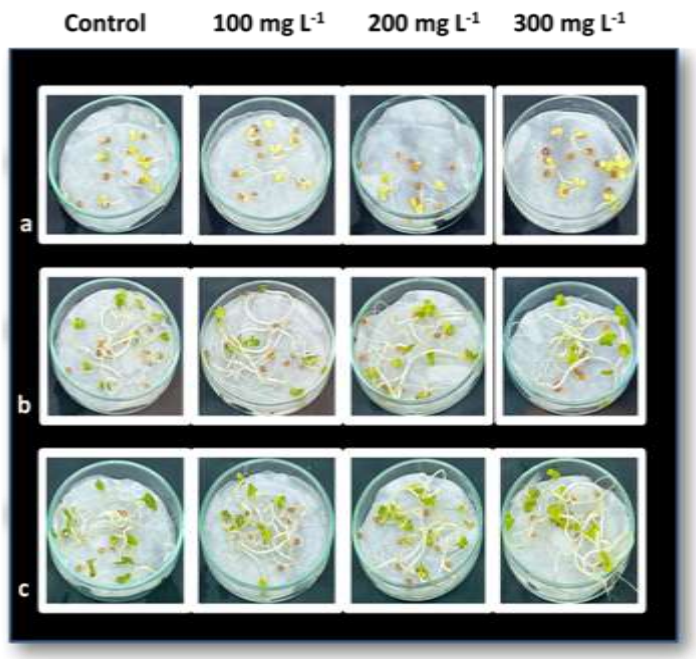

Figure 4. Germination characteristics of fındık radish under different NaCl concentrations; a. First measurement, b. Second measurement, c. Third measurement

Statistical differences in the number of seed germination within radish cultivars/types in terms of sodium chloride tolerance were observed upon evaluation of current findings as shown in Table 1. Therefore, it can be concluded that black radish has a better salt tolerance than fındık radish and Antep radish. Fındık and black radishes performed better than Antep radish when findings were evaluated in terms of root lengths, indicating statistically significant differences among the cultivars.

Table 1. Effect of NaCl concentrations on number of germinated seeds

Number of germinated seeds					
	NaCl Concentrations				Means of cultivars/types
Cultivar	Control	100 mg L^{-1} NaCl	200 mg L^{-1} NaCl	300 mg L^{-1} NaCl	
Antep Radish	9,66 ab	10,00 a	9,00 c	9,33 bc	9,50 *B*
Fındık Radish	9,33 bc	9,66 ab	9,00 c	10,00 a	9,50 *B*
Black radish	10,00 a	9,66 ab	10,00 a	10,00 a	9,91 *A*
Means of NaCl treatments	9,66 **AB**	9,77 **A**	9,33 **B**	9,77 **A**	
LSD Values	LSD cultivar= 0.313* LSD NaCl treat. = 0.361 LSD cult. x NaCl treat. = 0.626*				

*Different letters among cultivars and NaCl treatments denote significant differences (LSD test, $p<0.05$)

While the longest root length was recorded for black radish, the lowest root length was observed for radish Antep (Table 2). Cultivar/types differences in root length due to different NaCl concentrations were recorded in a number of previous researches. Similar results were also reported in some previous studies (Gupta et al., 1993; Zaman et al., 1995; Gosh et al., 2014).

Table 2. Effect of NaCl concentrations on root lengths

Root Length (mm)					
	NaCl Concentrations				Means of cultivars/types
Cultivar	Control	100 mg L^{-1} NaCl	200 mg L^{-1} NaCl	300 mg L^{-1} NaCl	
Radish Antep	63,72 c	78,27 abc	60,20 c	89,22 ab	72,85 *B*
Fındık Radish	88,38 ab	95,10 ab	79,94 abc	90,94 ab	88,59 *A*
Black Radish	93,88 ab	99,22 a	79,71 abc	73,44 bc	86,56 *A*
Means of NaCl treatments	82,00 **AB**	90,86 **A**	73,28 **B**	84,53 **AB**	
LSD Values	LSD cultivar= 12.06* LSD NaCl treat. = 13.93 LSD cult. x NaCl treat. = 24.13				

*Different letters among cultivars and NaCl treatments denote significant differences (LSD test, $p<0.05$)

Regarding hypocotyl lengths of cultivars/types, radish cultivars differed significantly in hypocotyl length after NaCl treatment. The highest hypocotyl length was found in radish Antep under the highest NaCl concentration whereas the control was had the lowest highest hypocotyl length (Table 3). Hypocotyl lengths differed greatly based on NaCl concentration levels. Similar results in cultivar differences in hypocotyl length were also reported by Zaman et al., 1995 and Gosh et al., 2014.

Table 3. Effect of NaCl concentrations on hypocotyl lengths

Hypocotyl Length (mm)					
	NaCl Concentrations				Means of cultivars/types
Cultivar	Control	100 mg L^{-1} NaCl	200 mg L^{-1} NaCl	300 mg L^{-1} NaCl	
Radish Antep	36,66 d	63,49 abc	60,24 bc	82,60 a	60,75
Fındık Radish	51,22 cd	67,10 abc	51,49 cd	64,94 abc	58,69
Black Radish	61,66 bc	72,49 ab	58,94 bc	69,27 abc	65,59
Means of NaCl treatments	49,84 **C**	67,70 **AB**	56,89 **BC**	72,27 **A**	
LSD Values	LSD cultivar= 9.58 LSD NaCl treat. = 11.07* LSD cult. x NaCl treat. = 19.26				

*Different letters among cultivars and NaCl treatments denote significant differences (LSD test, $p<0.05$)

CONCLUSIONS

In the current study, three different radish cultivars/types germination features in different NaCl concentrations were evaluated. Increasing the salt concentration impacted the germination percentage of radish cultivars/types differently. The black radish cultivar/type showed better tolerance to different NaCl concentrations. Root and hypocotyl lengths differed greatly based on NaCl concentration levels regarding cultivars/types, also. Fındık and black radishes performed better than Antep radish in terms of root lengths, while Antep radish showed the longest hypocotyl length. Based on the findings of the current study, different NaCl concentrations can be recommended to improve the tolerance of cultivated plants under conditions of increased soil salinity.

ABSTRACT

Orthoptera is an order of insects that may be found in several habitats. Additionally, they play a crucial function in the food chain. This study aimed to ascertain the taxonomic classification of species within various habitats in the Vlora geographical region over the period of June to September 2023. This study pertains to 18 species belonging to the order Orthoptera and 4 different families. The Tettigoniidae family has the greatest species variety, consisting of a total of 9 distinct species. At the same time, there is just one species that represents each of the families *Tetrigidae* and *Mogoplistidae*. The Sevaster station is represented by ten species, which is the most number. This station provides the most favorable circumstances 4 species belonging to the order Orthoptera.

Keywords: Orthoptera, Diversity, Grasshoppers, Ecosystem, Vlora

INTRODUCTION

State that the order Orthoptera, classified under the class Insecta, is among the most ancient assemblages of insects (Matthew et al. 2022). Have together established that grasshoppers are the most diverse and largest group of insects, capable of thriving in many conditions (Zahri et al. 2023; Bhowmik et al. 1982; Sageer et al. 2023). (Gardiner, 2018) asserts that orthoptera play a vital role in the functioning of the food chain. Have categorized them into two distinct categories: Caelifera, which refers to short-antennae shrimps, and Ensifera, which refers to long-antennae shrimps (Panhwar, 2015; Ali et al. 2017). According to (Gupta et al. 2016), both filiform and ensiform antennae are feasible. Have all recorded instances of large-scale outbreaks of species classified under the Order Orthoptera (Uvarov, 1966; Uvarov, 1977; Kasalo et al. 2024). This phenomena is widely recognized from both a biological and economic standpoint. (Kasalo et al. 2024) found that certain species of the Acrididae family (Caelifera) display seasonal polymorphism, or polyphenism, in several aspects such as their physical characteristics, growth, chemical makeup, and interaction with the environment.

Research undertaken by (Barsyte, 1999; Warchalowska-Sliwa et al. 2005; Guria, 2024) has shown that Orthoptera species may be used to assess the detrimental impacts of different environmental pollutants.

MATERIALS DHE METHODS

From June to September 2023, the species were collected in the Vlora area at three stations: Sevaster, Gumenicë, and Shesh (Vranisht).

Aerial ethnological nets (NETs) were used to collect species of the Order Orthoptera in different ecosystems. The collected species were placed in tubes with etheric acid, and each tube was associated with the corresponding label (Colas, 2000). In these tubes, they were transported to the laboratory. They were observed with a stereomicroscope (Prefix Sciences) for the taxonomic identification of the collected species based on external characteristics, and the keys and literature from the countries bordering Albania, which have habitats, were used like the Study Area (Willemse et al., 2018; Lemonnier–Darcemont et al., 2018) as well as previous publications on the Orthopeda Order of Albania (Csiki, 1922; Subashaj et al., 2024).

RESULTS AND DISCUSSIONS

In the present investigation, we make reference to the list of species belonging to the Order Orthoptera that is displayed in Table 1. This list is arranged in accordance with the stations Sevaster, Gumenicë, and Shesh (Vranisht).

Table 1: List of species for the Acrididae family

Nr	Scientific name	Sevaster	Gumenica	Shesh
1	**Family *Tettigoniidae*** Krauss, 1902			
1	*Decticus albifrons* Fabricius, 1775	+		
2	*Poecilimon jonicus F*ieber, 1853			+
3	*Acrometopa servillea macropoda* Burmeister, 1838			+
4	*Eupholidoptera schmidti* Fieber, 1861	+		+
5	*Tettigonia viridissima* Linnaeus, 1758			+
6	*Decticus verrucivorus* Linnaeus, 1758	+		
7	*Pholidoptera griseoaptera* De Geer, 1773	+		
8	*Pholidoptera femorata* Fieber, 1853	+		
9	*Pholidoptera aptera* Fabricius, 1793	+		
2	**Family *Acrididae*** MacLeay, 1819			
10	*Acrida ungarica mediterranea* Herbst, 1786	+		
11	*Acrotylus patruelis* Herrich-Schäffer, 1838		+	
12	*Calliptamus italicus* Linnaeus, 1758	+		
13	*Oedipoda caerulescens* Linnaeus, 1758	+	+	
14	*Chorthippus bornhalmi* Linnaeus, 1758			+
15	*Chorthippus biguttulus* Linnaeus, 1758			+
16	*Oedaleus decorus* Germar, 1825	+		
3	**Family *Tetrigidae*** Rambur, 1838			
17	*Paratettix meridionalis* Rambur, 1838		+	
4	**Family *Mogoplistidae*** Brunner von Wattenwyl, 1873			
18	*Arachnocephalus vestitus* Costa, 1855		+	

According to the taxonomic analysis of the Order Orthoptera, we were able to identify 18 species and 4 families in this study. These findings were based on the stations stated above, which were located in a variety of environments (Table 2).

Table 2 Distribution of the number of species and species frequency according to familie

Nr	**Family**	**Species' number**	**Species frequency**
1	*Tettigoniidae*	9	50 %
2	*Acrididae*	7	38.88 %
3	*Tetrigidae*	1	5.55 %
4	*Mogoplistidae*	1	5.55 %

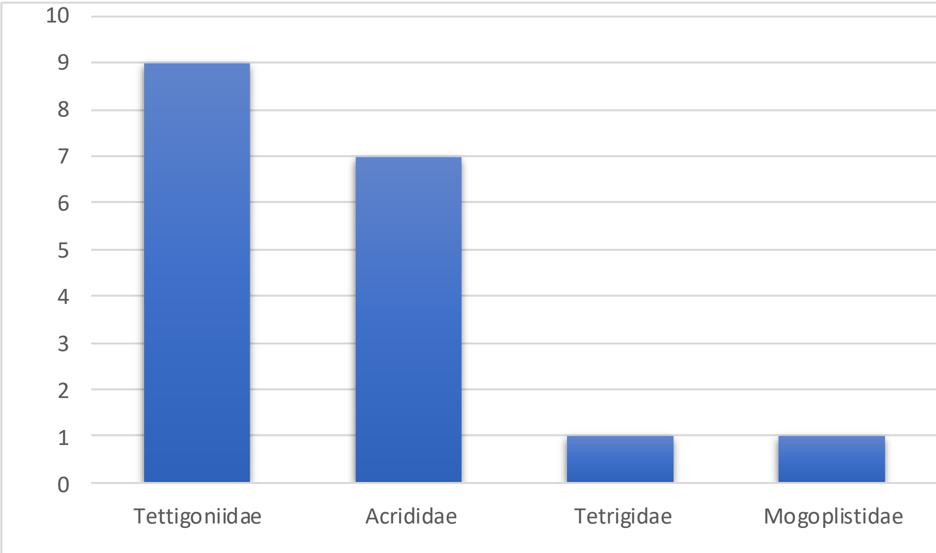

Figure 1 Distribution of the number of species by families

Upon examining the data shown in Table 2 and Figure 1, it is evident that the *Tettigoniidae* family has the highest level of species diversity. This family has a total of 9 species and has a species frequency of 50 %. The *Acrididae* family, with 7 distinct species, has a species frequency of 38.88 %. As previously mentioned, the *Tettigoniidae* and *Acrididae* species play a crucial role in creating optimal conditions within ecosystems. Conversely, the *Tetrigidae* and *Mogoplistidae* families each consist of only 1 species, and the frequency of these species within their respective families is 5.55 %.

Table 3 Number of species by station

Station	**Species number**	**species frequency**
Sevaster	10	55.55 %
Gumenicë	4	22.22 %
Shesh (Vranisht)	6	33.33 %

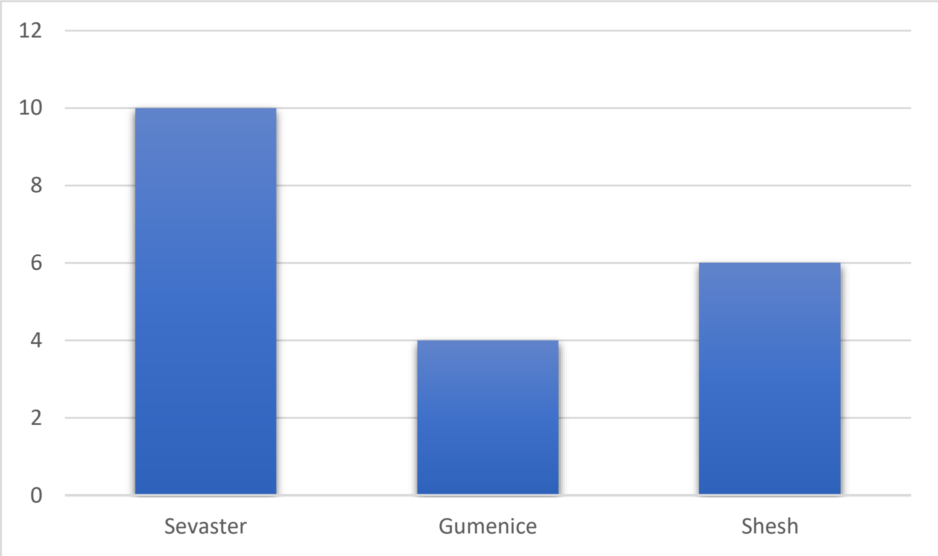

Figure 2 Distribution of species according to stations

The examination of habitat diversity in the examined region, as reported in Table 3 and Figure 2, shows that the Sevaster station is home to 10 out of the total number of species, representing a frequency of 55.55 %. Next in line is the station of Shesh (Vranisht), which is home to 6 different species. The species frequency at this station is 33.33 %. Following Shesh is the station of Gumenica, which has 4 species and a species frequency of 22.2 %. Interestingly, the species belonging to the Order Orthoptera are least likely to choose Gumenica as their habitat due to human activities in the area. During this time, the stations Sevaster and Shesh offer optimal conditions for the species belonging to the Order Orthoptera.

CONCLUSIONS

This research offers a thorough examination of the species belonging to the Order Orthoptera that inhabit the various habitats of the Vlora area. It provides significant information regarding their classification and geographical distribution. Our investigation indicates that there are 18 different species and 4 families within the Order Orthoptera in the Vlora area. This demonstrates the intricate and diverse nature of the ecosystems in this region.

The family *Tettigoniidae* has the highest number of species, with 9, followed by the family *Acrididae,* which has 7 species, making them the most diverse families within the Order Orthoptera. Both the families *Tettigoniidae* and *Mogoplistidae* consist of only one species apiece. The Tettigoniidae family, known for its extensive variety of species, has a substantial impact on this study.

The Sevaster station, which has 10 species from the whole spectrum of species variety, plays a significant role in this investigation. Based on the study's findings, this station provides the most advantageous environment for species belonging to the Order Orthoptera in comparison to the other stations.

ABSTRACT

This study intends to provide a comprehensive account of the species of Short-Horned Grasshoppers belonging to the family Acrididae (Orthoptera) that may be discovered in the various habitats of the Vlora region, which is located in the southern part of Albania. A well-defined seasonal pattern that includes a cold and rainy winter and a warm and arid summer is characteristic of the climate in this region, which shows some characteristics that are typical of the Mediterranean climate. On a worldwide scale, this region represents a discovery that is both extraordinarily valuable and one of a kind. Following an examination of the data, it has been determined that the genera *Calliptamus*, *Chorthippus*, and *Oedipoda* are known to exist, with two species belonging to each of these genera. It is estimated that 13.33% of each species is present. For the purpose of establishing whether or not these species are present in this region, the Llogara and Armen National Parks were both investigated. According to the conclusions of the study, these parks, which each include six species and have a species frequency of forty percent, offer the best possible environment for the species in question.

Keywords: Orthoptera, Acrididae, Habitat, Biodiversity, Vlora, Southwestern Albania

INTRODUCTION

The Acrididae family, is a diversified group within the Orthoptera order. These grasshoppers are generally referred to as short-horned grasshoppers (Memon et al. 2021). According to (Riffat, 2015; Shaikh et al. 2018), the agricultural crops that they infest are considered to be pests if they occur. In addition to wetland environments, they may be discovered in a wide variety of habitats, including as grasslands, shrublands, herbaceous regions, and woods. (Dempster, 1963; Uvarov, 1966; Shaikh et al. 2018) all came to the conclusion that the majority of the species that belong to the Acrididae family are herbivorous insects.

The findings of the study conducted by (Akwanjoh, 2020) suggest that they have the potential to function as helpful bio-indicators for identifying changes in the environment. According to (Song et al. 2018), the family Acrididae is comprised of a wide variety of species that fall within the order Orthoptera and the suborder Caelifera.

Each and every member of the Acrididea family contains a pair of antennae that are extremely small and very thin. In contrast to the tympanum, which is situated on the lateral sides of the first abdominal segment, the tarsi are composed of three segments. The research conducted by (Smith et al. 2014) revealed that certain adult species have wings, whereas others either do not have wings at all or have wings that are severely reduced. In this paper, we provide the results of our taxonomic investigation into the species belonging to the Acrididae family that were found in the Vlora region.

MATERIALS AND METHODS

During the years 2022 and 2023, the species were gathered from a variety of locations within the Vlora region, including National Park Llogara, Armen, and Selenica. The different species were gathered by the utilization of aerial entomological nets (NET). In order to maintain the color, the species were placed in tubes that contained ether (Colas, 2000; Halimi et al., 2023). Each tube was then labeled with the appropriate information, which included the date, location, coordinates, and altitude from the data collection. Notes were recorded in a journal regarding the vegetation, as well as any particular traits that were considered to be unique to particular species. For the taxonomic identification, the species were observed with a stereomicroscope (Perfex Sciences), and the keys from the publications for the countries bordering Albania, which offer similar climatic conditions and habitats to our study area, were used (Eades et al., 2014; Willemse et al. al., 2018; Willemes, 1985) as well as previous publications on the Order Orthopetra of Albania (Csiki, 1922; Ebner, 1910; Lemonnier – Darcemont & Darcemont, 2015; Subashaj, 2024).

RESULTS AND DISCUSSIONS

This study presents the species of the Acrididae family, which are listed in Table 1 according to the stations (Llogara, Armen, and Sevaster National Parks) in the habitats of the Vlora area, which is situated in the southwestern part of Albania, across the Ionian Sea, and in the southern Adriatic Sea. The Vlora area is located in the southern Adriatic Sea.

Table 1. List of species of the Acrididae family

13	*Calliptamus italicus* Linnaeus, 1758			+
11	**Genus Oedaleus**			
14	*Oedaleus decorus* Germar, 1825			+
12	**Genus Acrida**			
15	*Acrida ungarica mediterranea* Herbest, 1786			+

Twelve genera and fifteen species are included in the collection of species belonging to the Acrididae family that was collected from three different sites (Table 2, Figure 1).

Table 2. Species and genus enlisted

Genus	Species number	Species frequency
Acrida	1	6.66%
Acrotylus	1	6.66%
Acryptera	1	6.66%
Calliptamus	2	13.33
Chorthippus	2	13.33
Euchorthippus	1	6.66%
Oedaleus	1	6.66%
Oedipoda	2	13.33
Paracaloptenus	1	6.66%
Pezotetix	1	6.66%
Pseudochorthippus	1	6.66%
Sphingonotus	1	6.66%

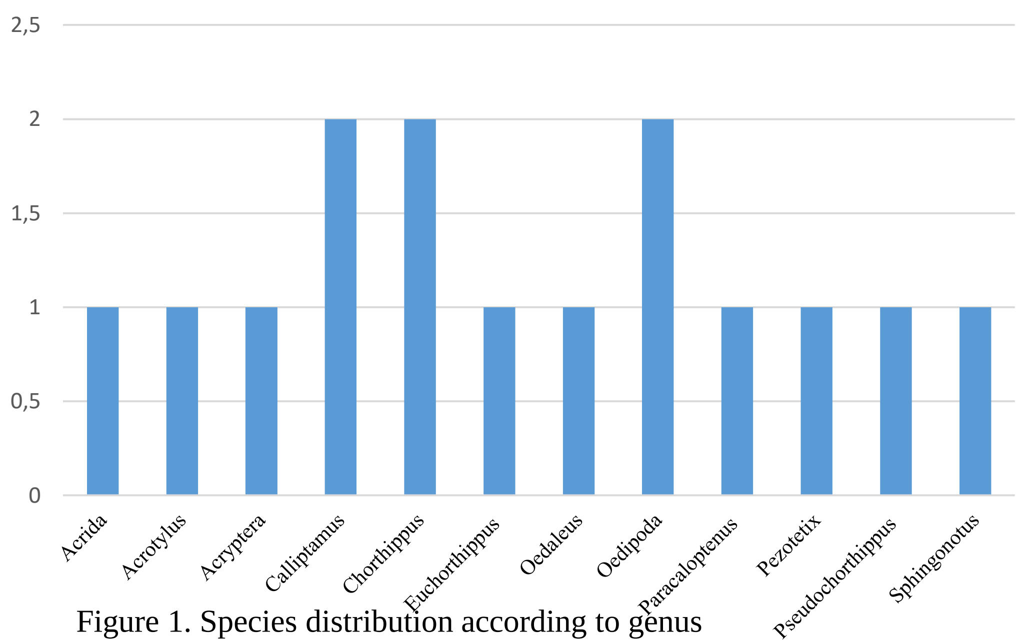

Figure 1. Species distribution according to genus

Based on the data, it can be deduced that the genera *Calliptamus*, *Chorthippus*, and *Oedipoda* are responsible for two species out of the total number of species. Thirteen point three percent of the total number of species in the entire collection is accounted for by these genera. The genera *Acrida*, *Acrotylus*, *Acryptera*, *Euchorthippus*, *Oedaleus*, *Paracaloptenus*, *Pezotetix*, *Pseudochorthippus*, and *Sphingonotus* are the ones that come in close succession after them. Due to the fact that each of these genera has one species, the total number of species that may be found in each of these genera is one. The frequency of each species within each genus is found to be six point six percent. According to the findings of the inquiry into the diversity of stations, which are shown in table 3 and figure 2, the Llogara and Armen National Park stations each include six species, which accounts for forty percent of the total number of species. These findings are presented in the table and figure respectively. Each of the five unique species that make the Sevasteri station their home has a frequency of 33.33 percent, and the station is home to all five of these species. The stations in Llogara and Armen National Park offer the most optimal environments for species that are members of the Acrididae family. As a consequence, the amount of disturbance that is generated by human activities is reduced to the greatest extent possible.

Table 3. Species according to the surveyed stations

Station	**Species number**	**Species frequency**
Parku Kombetar Llogara	6	40 %
Armen	6	40 %
Sevaster	5	33.33 %

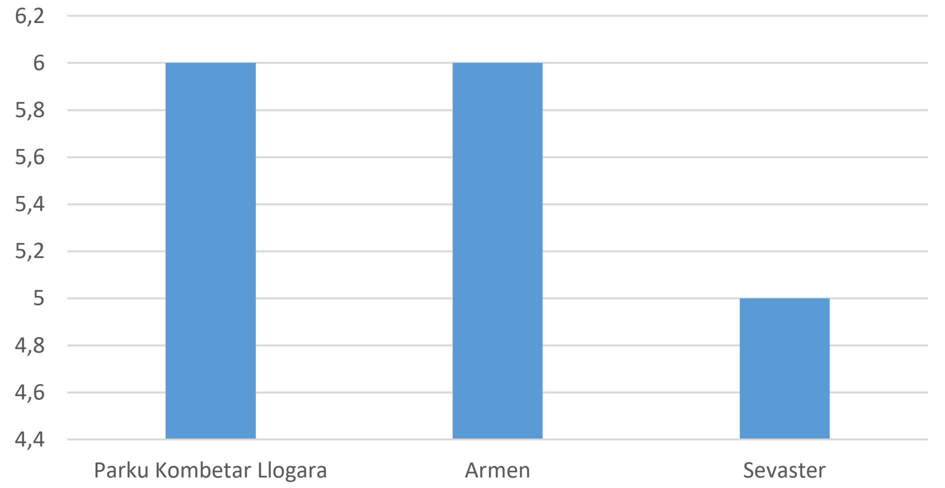

Figure 2. Species distribution according to studied

CONCLUSIONS

This research presents a complete analysis of the species that belong to the Acrididae family and are found in the ecosystems of the Vlora region. These species are found in the Vlora region. According to the parameters of this inquiry, we are discussing a total of twelve different genera and fifteen different species. A great degree of species diversity can be found within the Acrididae family, notably among the genera *Calliptamus*, *Chorthippus*, and *Oedipoda*, each of which has two different species. Acrididae is a family of insects. These three genera collectively are responsible for thirteen-point three percent of the total number of species that have ever been discovered. With a total of six species, the stations in Llogara and Armen National Park have the most species diversity of all of the stations in the park. This represents forty percent of the total species diversity count.

According to the information shown here, it is possible to draw the conclusion that these stations provide the conditions that are most favorable for the species that belong to the Acrididae family.

ACKNOWLEDGMENTS

The authors wish to thank their French colleagues, M. Darcemont-Lemonnier and Ch. Darcemont, for their invaluable assistance in preparing this publication. Additionally, the University of Tirana provided support for this project through the "*UT-Search, Excellence, and Innovation—REI2023*" program.

NEW OIL-YIELDING BULGARIAN SUNFLOWER HYBRID "KRASI"CLP" (HELIANTHUS ANNUUS L.)

Georgi Georgiev, Nina Nenova, Galin Georgiev

Dobrudzha Agricultural Institute - city G. Toshevo
Corresponding author: Georgi Georgiev, E-mail: georgi_d4@abv.bg

ABSTRACT

Hybrid Krasi CLP is a new Bulgarian two-line sunflower hybrid suitable for cultivation according to Clearfield Plus technology, obtained by inter-line hybridization. The hybridization involved the maternal sterile line 1111A as a component and the fertility restorer line GTS 51R. The two parental lines have very good general and specific combinatorial ability. Hybrid Krasi is medium-early with a vegetation period of 109-111 days, seed diameter 19-21cm, mass of 1000 seeds 62g, kernel content %-77%. The production potential, depending on the conditions of the year, varies from 328 kg to 350 kg. The oil is of the linoleic type and its content varies from 49-51%. The hybrid is characterized by good drought tolerance, resistance to downy mildew 731, phoma, phomopsis, alternaria and blue wrist. The hybrid was recognized by the Minister of Agriculture of the Republic of Bulgaria under the RHS with order RD-12-3/17.03.2023. The hybrid was tested at IASAS for two years in three locations.

Keywords: Sunflower, Drought tolerance, Hybrid, Yield traits, Yield performance,

INTRODUCTION

Seed yield in sunflower is a quantitatively heritable component strongly influenced by environmental factors. However, the yield also depends on the genetic potential of the hybrids and on other components related to seed yield such as seed mass, kernel diameter, mass per 1000 seeds, leaf area, plant height. The yield of the oil-bearing sunflower is also determined by the agrometeorological conditions of the periods of the individual phenophases: sprouting-budding, sprouting-mass flowering, flowering period and vegetation period. Sunflower breeders should pay attention to these important seed yield components when evaluating experimental hybrids. A major factor determining the achievement of a high and quality sunflower yield is the selection of hybrids suitable for the area, providing high seed yield, combined with high oil content, resistance or tolerance to the most important diseases, enemies and parasites (Georgiev et al., 2012; Georgiev, 2016). It is very difficult and almost impossible to collect all these indicators in a single hybrid.

The aim of the present study is to make a complete characterization of their newly created tolerant Bulgarian hybrid Krasi CLP, created at the Dobrudzhan Agricultural Institute - General Toshevo. Hybrida is recognized by the Minister of Agriculture of the Republic of Bulgaria under RHS with order RD-12-3/17.03.2023. The hybrid was tested at IASAS for two years in three locations.

In recent years, high-yielding parental lines and hybrids with a complex of valuable quantitative and qualitative indicators have been created at the Dobrudzhan Agricultural

Institute - G. Toshevo. The newly created sunflower hybrids showed very good stability to abiotic and biotic environmental factors. With these sunflower hybrids, very good results of seed yield kg/ha were obtained in different regions of Europe and in no way inferior to the hybrids from other countries.
In sunflower, seed yield and oil content are complex characteristics that are influenced by different factors that may act individually or collectively. The study of a complex of traits is a crucial approach to increase seed yield. (Chandirakala et al., 2015) [5]. The effectiveness of selection depends mainly on the direction and magnitude of the relationship between yields and its components. Correlation describes the mutual relationship between variables and helps to improve different features simultaneously. An attempt was therefore made to estimate a correlation between yield and yield components. We have and maintain the largest collection of wild sunflower species on the Balkan Peninsula, including annual and perennial forms (Valkova et al., 2015; Valkova et al., 2016).

MATERIAL AND METHODS

Hybrid Krasi CLP is a new Bulgarian two-line sunflower hybrid suitable for cultivation according to Clearfield Plus technology, obtained by inter-line hybridization. The hybridization involved the maternal sterile line 1111A as a component and the fertility restorer line GTS 51R. The two parental lines have very good general and specific combinatorial ability. Hybrid Krasi is medium-early with a vegetation period of 109-111 days, seed diameter 19-21cm, mass of 1000 seeds 62g, kernel content %-77%. The production potential, depending on the conditions of the year, varies from 328 kg to 350 kg. The oil is of the linoleic type and its content varies from 49-51%. The hybrid is characterized by good drought tolerance, resistance to downy mildew 731, phoma, phomopsis, alternaria and blue wrist. The hybrid was recognized by the Minister of Agriculture of the Republic of Bulgaria under the RHS with order RD-12-3/17.03.2023. The hybrid was tested at IASAS for two years in three locations.

RESULTS AND DISCUSSION

Biological and economic qualities of hybrid Krasi CLP
The Krasi CLP hybrid has been tested three years in a row in a competitive varietal experiment on the fields of the DZI. It showed an excess compared to the average standard in terms of seed yield and oil yield per hectare (Table 1).

Table 1. Results of Krasi CLP hybrid testing in KSO - 2020, 2021.

Seed yiled kg/da	**% of Average Standard % of average standard**	**Oil content %**	**Oil yield кg/da**	**% of Average Standard % of average standard**
2020				
359,6	103.7	48.1	159.3	106.8
2021				
337,8	104.2	47.6	168.8	107.7

After a two-year trial in KSO, the Krasi CLP hybrid was included in the Single Variety Trial in DZI in 2018. The results showed that this year the seed yield was 368.7 kg/da, which was 6.6% higher than the average standard, and the content of oil in the seeds is 51.7%. The amount of oil per hectare is 176.5 kg/da or 109% exceeding the standard.
Hybrid Krasi CLP was tested for biological and economic qualities in the experimental fields of IASAS for two years - 2020 and 2021. On average for the period of the test, 336 kg/da of seeds were obtained on average for the two years of the test.

Table 2. Results of the Krasi CLP hybrid test in IASAS - 2020, 2021.

№	Hybrid	Year of testing	Selanovci			Brashlen			Radnevo			Average	
			kg/da		%	kg/da		%	kg/da		%	kg/da	%
3	**Krasi CLP**	**2**	359	-	100,0	339	-	100,5	287	oo	88,3	**328**	96,4

Results of a varietal test for biological and economic qualities of the Krasi CLP hybrid

Table 3. Results of a varietal test for biological and economic qualities of the Krasi CLP hybrid

Hybrid / KRASI CLP	**PH**	**HD**	**LP**	**BRL**	**MS1P**	**M1000S**	**NS1P**	**VEGP**	**PBUT**	**PNC**	**PCAF**
	164	21	7830	28	114,6	60,5	2445,6	110	38	70	13

Legend: PH-Height of plant cm, HD-Diameter of pita cm, LP-Leaf area cm2 ,BRL-Number of leaves per plant, MS1P-Weight of seeds per plant, M1000S-Weight of 1000 seeds, NS1P-Number of seeds per pita , VEGP.- Vegetation period/ number of days, PBUT-Period from emergence to budding/number of days, PNC-Period from emergence to phase beginning of flowering/number of days, PCAF-Period from emergence to mass flowering phase/number of days .
The Krasi CLP hybrid is characterized (table 3, figure 1.) by a plant height of 164 cm, a seed diameter of 21 cm. The leaf area of the hybrid has an area of 2445.6 cm2 and 28 asymmetrically arranged leaves. The mass of 1000 seeds is 60.5 g, with a plant mass of 114.6 g and 2245 seeds per pita. The hybrid is medium-early with a vegetation period of 110 days, the period from germination to budding is 38 days and 70 days is the period from germination to mass flowering. The flowering period from the beginning to the end of flowering is 13 days. The production potential depends on the conditions of the year and varies from 328kg to 350kg. The hybrid is characterized by good drought tolerance, resistance to downy mildew 731, phoma, phomopsis, alternaria and Orobanche cumana.

Figure 1. Hybrid Krasi CLP

Biochemical and phytopathological characteristics of Krasi CLP hybrid

Table 4. Biochemical and phytopathological characteristics of Krasi CLP hybrid

Hibyd/ Krasi CLP	***Plasmopara helianthi* /731/ attack %**	***Phoma macdonaldii* %**	***Phomopsis helianthi* attack %**	**Sclerotinia sclerotiorum attack root, stem%**	**Sclerotinia sclerotiorum attack head %**	***Orobanche cummana* attack % %**
	8,8	31,2	4	18,4	0	18,9

From the phytopathological studies (table 4.) of the hybrid Krasi CLP in IASAS, the hybrid is characterized by very good resistance to downy mildew /731/ 8.8%, Phomopsis - 4%, sclerotinia attack pita - 0%, and average resistance to sclerotinia root and stem 18, 4%, phoma-31.2% and to the blue wrist parasite-18.9%.

CONCLUSIONS

Hybrid Krasi CLP was created at the Dobrudja Agricultural Institute - General Toshevo and was approved for recognition and registration in the Republic of Bulgaria under the RHS by order RD-12-3/17.03.2023. in the official variety list of the country by order. of the Minister of MFA of the Republic of Bulgaria. Hybrid Krasi CLP is a new Bulgarian two-line sunflower hybrid suitable for cultivation according to Clearfield Plus technology, obtained by inter-line hybridization. The hybridization involved the maternal sterile line 1111A as a component and the fertility restorer line GTS 51R. The two parental lines have very good general and specific combinatorial ability. Hybrid Krasi is medium-early with a vegetation period of 109-111 days, seed diameter 19-21cm, mass of 1000 seeds 62g, kernel content %-77%. The production potential, depending on the conditions of the year, varies from 328 kg to 350 kg. The oil is of the linoleic type and its content varies from 49-51%. The hybrid features good drought resistance, resistance to downy mildew 731, phoma, phomopsis, Alternaria and Orobance Cumana.

ABSTRACT

The current trend of decline in the ability of agroecosystems (e.g. organic farming) to provide ecosystem services is a major threat to food security worldwide. In 2022, the total area of organic agriculture in Türkiye totaled about 310.584 ha from 24 million ha of agriculture area. On the other hand, Türkiye is facing environmental problems such as soil degradation, deforestation, climate change, loss of biodiversity, etc, which pose major threats to human safety, health, environment, and productivity. Therefore, organic farming can provide important services to the environment and society. Basically, the function of organic farming systems plays an important role in both ecological and economic aspects by improving livelihoods, protecting biodiversity and increasing soil fertility and health. The development of organic farming is possible for the use of its services such as provisioning, regulating, cultural, and supporting services. For example, organic farming provides a systems approach to reducing greenhouse gases (GHG) emissions and increasing soil carbon sequestration while maintaining healthy soils and protecting biodiversity. This can reduce the world's agricultural GHG emissions by about 20%. Furthermore, this agricultural system may cut soil erosion by 22%, which is an issue that Turkiye's agricultural lands are facing. In general, organic farming reduces negative impacts on nature-related ecosystems while simultaneously providing ecosystem services. In this article, we will address this issue, how can the development of organic agriculture minimize the environmental problems of Türkiye by providing ecosystem services.

Keywords: Agriculture, biodiversity, ecosystem services, organic farming, Türkiye.

INTRODUCTION

By 2050, the world's food production will need to rise by 60% due to an expanding population, present food distribution patterns, and food consumption habits (United Nations Environment Programme, 2012). Agricultural practices can assist in achieving the goals by reducing trade-offs between output and the environment and by identifying and increasing the ecosystem services (ES) from farmlands (United Nations Environment Programme, 2014). Ecosystem services (ES) like organic farming are essential to the ongoing provision of food to an expanding global population, yet food and nutritional security are under risk due to the rising use of chemical fertilizers globally. Organic agriculture is essentially a method of farming that stays away from artificial fertilizers, pesticides, and genetically modified organisms. Rather, it depends on organic techniques like crop rotation and composting to preserve soil fertility and biological pest management (Daylam et al., 2023). The performance of organic farming systems plays an important role in both ecological and economic aspects by improving livelihoods, protecting biodiversity, increasing soil fertility and reducing poverty. In 2022, the total area of organic agriculture in Türkiye estimated about 310.584 ha from 24 million ha of agriculture area (Anonymous, 2024). Turkiye is dealing with environmental issues including deforestation, soil degradation, climate change, biodiversity loss, etc. These issues pose serious risks to people's health, safety, and productivity and impede the pursuit of sustainable development. Thus, organic farming in Turkiye may offer significant benefits to both the environment and society.

The aim of the paper was the assessment of ecosystem services of organic agriculture to the environment and society of Türkiye. In this paper, we answer this question, how can the development of organic agriculture minimize the environmental problems of Türkiye by providing ecosystem services.

MATERIALS AND METHODS

We first investigated the state of agriculture in Türkiye based on official reports, statistics, and available sources. Then, we recorded the problems in the agricultural sector of this country. Next, we looked at the scientific literature on organic farming and determined the environmental services it provides. In the end, to solve the existing problems in Türkiye, we suggested some solutions based on organic agriculture services and linked them together.

To address our research objective, we reviewed the literature and analyzed the assessment of ecosystem services related to organic farming. Scientific databases like Science Direct and Scopus were used to gather publications, which were then investigated and categorized. All data was calculated and classified into 4 groups, including provisioning, regulating, supporting, and culture services.

RESULTS AND DISCUSSION

The growth of organic agriculture in Türkiye is possible through the use of its services such as provisioning, regulating, cultural, and supporting services Table 1). The country is facing major environmental problems such as soil degradation, deforestation, climate change, loss of biodiversity, etc, which pose major threats to human safety, health, environment, and productivity. Therefore, organic farming in this country can provide important services to the environment and society. For example, organic agriculture can improve the quality and health of Türkiye's agricultural products, which in turn improves the health of the society. Agriculture continues to be a significant economic sector in Türkiye. Wheat, sugar beet, milk, poultry, cotton, hazelnuts, apricots, oregano, vegetables, and fruits are the main goods (IFAD, 2023: ITA, 2022). Sustainable food and fiber production in agriculture depends on ecosystem services like pollination, soil formation, biological control, and nutrient cycling. In order to provide ecosystem services, organic agriculture needs a comprehensive approach that acknowledges the interdependencies between ecological processes, agricultural output, and human welfare. Therefore, maintaining and promoting organic agriculture is important to achieve sustainable production and economic conditions (Padmavathy and Poyyamoli, 2011).

Table 1. Services by organic farming to agriculture of Türkiye

Services by organic farming	Service type	Problems related to agriculture
High quality food	Provisioning	Food production with low quality
Healthy food	Provisioning	Unhealthy food production
Help to food security	Provisioning	Food with pesticide remains
Help to pollination	Regulating	Decrease of pollinators
Soil protect	Regulating	Soil erosion
Biodiversity protect	Supporting	Loss biodiversity
Soil fertility	Regulating	Low organic matter
Soil healthy	Regulating	Land degradation
Protect of water bodies	Regulating	Water pollution
Carbon sequestration	Regulating	Greenhouse gases emission
Protect of environment	Regulating	Environmental pollution
Pest control without chemicals	Regulating	High consumption of pesticides
Increase of soil organic matter	Regulating	High consumption of chemical fertilizer
Agrotourism	Culture	Low income

Turkiye reported 558 Mt of GHG emissions for 2022, which is higher than what a global carbon budget would permit. Additionally, the country's gross domestic product in 2022 was 6.6 t, greater than the global average (Turkstat, 2024; Ritchie and Roser, 2020). Additionally, research conducted in Turkiye calculated that almost one-third of all national emissions are related to food production (Üçtuğet al., 2021). The agriculture industry in Turkey has a part to play in either escalating or resolving this worldwide challenge. Organic farming, on the other hand, provides a systems approach to lowering greenhouse gas (GHG) emissions and raising soil carbon sequestration while preserving biodiversity and healthy soils. This has the potential to cut global agriculture GHG emissions by almost 20% (IFOAM, 2022).

Soil erosion is a challenge faced by Turkish farmers (Table 1), with estimates of moderate to severe erosion being 59% in agricultural regions, 54% in forest lands, and 64% in rangelands.

Because of its geographical position and different climate characteristics, Türkiye is one of the countries most affected by drought and desertification (General Directorate of Combating Desertification and Erosion, 2021). According to the findings of research, Turkiye has lost almost 287.5 million tons of soil in a year (Berberoglu, et al., 2020). There are many reports that organic farming helps to control soil erosion by conserving water and soil resources. Organic agricultural systems can reduce soil erosion by 22% and protect water resources by lowering nitrate leaching. Generally, enhancing soil structure in organic farming makes it more resistant to climate change, less prone to erosion, and supportive of plant health (IFAOM, 2022). Therefore, this agricultural system offers beneficial services while minimizing detrimental effects on ecosystems connected to nature including soil protection and biodiversity.

In the year 2023, Türkiye's agriculture sector utilized 57.8 thousand tons of pesticides. Over 19,600 tons of fungicides were utilized this year, making them the most popular kind of pesticide. Herbicides come next, with over 15,000 tons of usage in 2023 (Statista, 2024). The main environmental concerns related to pesticides are contamination of soil, water, and air damage to non-target organisms, and the health of humans. Also, these conventional agriculture systems have negative impacts on neighboring natural ecosystems. According to reports, the ban on synthetic fertilizers and pesticides along with biodiversity-boosting practices like varied crop rotations including legumes, landscape features, and less tillage, leads to an average of 30% greater species and 50% more individuals residing in organically managed areas (IFAOM, 2022). In organic farming, biological control of pests and diseases, as opposed to chemical pesticides, is the most sustainable and environmentally friendly technique to manage agricultural fields. Thus, organic farming provides advantages like biodiversity, environmental protection, and human health while simultaneously lessening harm to ecosystems that are a part of the natural world (Kuhling and Trautz, 2013).

With a nearly 34% endemism rate, Türkiye boasts the most diverse flora of any temperate region. This richness is increasing even more with the newly identified plant species. Approximately one thousand endemic plant species are included in the endangered species list. Also, 305 key biodiversity areas are identified in Türkiye (Türkiye’s Biodiversity, 2024). The current agriculture practices have led to a decrease in biodiversity in Türkiye (Table 1). Loss of biodiversity may have hidden consequences that make ecosystems more vulnerable to a variety of biotic and abiotic stressors (Winqvist et al., 2012). Organic farming has led to a rise in the quantity and species richness of many common species; nevertheless, the effects are often species-specific and tissue- or trait-dependent. Furthermore, maintaining a sustainable agricultural system and promoting biodiversity and high-quality soil through land management methods are key components of organic agriculture's sustainable food production strategy. Feledyn-Szewczyk et al. (2016) criticized the stepping up production and increased use of chemical pesticides, fertilizers, energy, and water in agricultural ecosystems. They reported that agricultural lands globally need further biological and agronomic methods to produce food and fiber. Principally, biodiversity conservation is important for the suitable function of ecosystems and the provision of services. A high level of biodiversity in agricultural ecosystems contributes to the sustainability and economic viability of agricultural output.

In this paper, we addressed the subject of how ecosystem services provided by organic agriculture might help to mitigate Turkiye's environmental issues. The performance of organic farming in this country can play important roles in the ecological, environmental, and economic aspects by improving livelihoods, protecting biodiversity, increasing soil fertility and health, and reducing pollution and poverty.

EFFECT OF IRRIGATION REGIME, NITRATE NITROGEN FERTILIZATION, APPLICATION PHASE AND GENOTYPE ON QUALITATIVE AND QUANTITATIVE PARAMETERS IN COMMON WHEAT FOR INCLUSION IN AN ALGORITHM OF THE SYSTEM FOR INTELLIGENT MANAGEMENT OF AGRICULTURAL PROCESSES

Evgeniy DIMITROV, Stanislav STAMATOV, Teodora ANGELOVA, Zlatina UHR
IPGR "K. Malkov", Sadovo, Agricultural Academy, Bulgaria

ABSTRACT

The drip irrigation has been used in recent years as a water and fertilizer saving technology. A three-year field experiment was conducted in the selection field of IPGR, Sadovo, in the period 2021-2023. The response of the two varieties of wheat to different irrigation rates and levels of nitrate nitrogen fertilization was tested. Eighteen fertilizing treatments were used in the experiment, including one-time, two-time and three-time application of the nitrogen fertilizer rate (17 kg N) in combination with a different irrigation regime - 10, 20 and 30 mm. Fertilizer and irrigation rates were applied in the stages of tillering, end of tillering, beginning of stem elongation and stem elongation. Grain virtuousness response and wet gluten yield were monitored. The obtained results show that the highest values of the virtuousness trait were obtained in the varieties Geya 1 and Sachets with an irrigation rate of 20 mm in combination with single and double application of nitrogen fertilization. In the wet gluten yield and its quality characteristics, the best results are available with the Sachets variety in the version with three times the application of the fertilizer and the maximum irrigation rate. The greatest influence on the traits of vitreousness and gluten relaxation is exerted by the interaction of genotype x the tested factors, with the rest - yield of wet gluten, dry gluten yield - the influence of the genotype is the leading factor. The year of cultivation is decisive for the number of baker's strength. Quality traits in wheat are controlled by a smaller number of genes, and the influence of nitrogen fertilization and irrigation rates in the set periods is weaker on their expression. The mathematical processing of the data was carried out using the program Microsoft Excel for Windows. The obtained results will be integrated into an algorithm of the system for intelligent management of agricultural processes.

Key words: Smart farming, Common winter wheat, quality, Vitreous, Wet gluten yield

INTRODUCTION

The wheat (*Triticum aestivum* L.) is one of the main cereal crops cultivated worldwide (Allami, et al., 2020; Bielski, et al., 2021; Erenstein, et al., 2022; Reinhardt, et al., 2022). It is a major source of plant proteins that depend on the unique characteristics of grain storage proteins (Shewry et al., 2009). Provides the human diet with essential amino acids, minerals, vitamins, as well as beneficial dietary fiber (Khalid et al., 2023)

Due to its high plasticity and easy adaptation to different environmental conditions, wheat has a significant advantage in terms of global food security over other cereals, as it can be grown under different climatic conditions. However, biotic and abiotic factors strongly influence wheat grain yield and quality (Allami et al., 2020; Pawlak et al., 2020; Behnassi et al., 2022; Mottaleb et al., 2022; https://ec.europa.eu/eurostat/statistics-explained/). Dry seasons, high temperatures, water deficit are the main abiotic factors that reduce yield and affect the quality of wheat grain. In the context of global water scarcity and climate change, the sustainability of wheat cropping systems is a major challenge for scientists and farmers (Ding et al., 2018; De Oliveira Silva et al., 2020b; Zubair et al., 2021; Zingale et al., 2022).

In dry land areas, which cover approximately 41% of the earth's surface, water stress has a significant negative impact on the crop (Zain et al., 2023; Amirahmadi et al., 2024). It is the second most irrigated cereal crop. after the rice (Frenken and Gillet, 2012). Nevertheless, the large amounts of water used in conventional irrigation methods lead to an irrational use of limited water resources.

Their shortage and unwise application of nitrogen fertilizers is a problem in wheat production (Yao et al., 2023). The application and appropriate management of nitrogen (N) fertilizer is also critical for wheat plant growth and yield formation and improvement of quality (Peng et al., 2006; Dalin et al., 2017; Shahdany et al., 2018). Soil water and nitrogen resources suffer from overuse. Management of these resources is therefore necessary for sustainable agricultural productivity (Yao et al., 2023).

Studies on the physiological and biochemical processes of common winter wheat under different levels of irrigation and nitrogen fertilization are needed to better understand winter wheat growth and yield pattern and quality change under different soil and environmental conditions (Zain et al., 2023).

Therefore, various irrigation systems have been applied to further improve wheat yield and quality characteristics and water use efficiency, such as one-time pre-sowing irrigation (Sun et al., 2019), supplementary irrigation based on moisture content measurement (Meng et al., 2015), integration of micro-sprinkler irrigation (Li et al., 2019b), use of drip irrigation systems (Hoff et al., 2018; Qu et al., 2022; Bouazzama et al., 2024).

Irrigation systems used and nitrogen (N) fertilization regimes have complex effects on wheat physiology, growth and development, leading to regulation of wheat grain yield and quality (Hamani, et al., 2024).

The use of drip irrigation is recommended to deal with water shortage problems. It appears to be highly effective in regulating soil moisture at a capacity of 50-60% (Wang et al., 2013; Zhang et al., 2013), and compared to surface irrigation methods, it can improve water use efficiency (Mehmood et al., 2019). Wang et al. (2013) reported a 5–13% improvement in wheat grain yield obtained with drip irrigation compared to gravity.

In the current climate challenges, an integrated approach of applying water and nitrogen through a drip irrigation system is crucial (Hamani, et al., 2024). Common winter wheat grown for consumption should be characterized by yield and high technological quality (Guerrini et al., 2020; Dilmurodovich et al., 2022). The suitability of the grain for processing is determined by the quality characteristics of the grain; the physical properties of the grain that affect its milling (vitreousness, hardness, bulk density, weight of 1000 grains and the protein complex (Rasheed et al., 2014; Lachutta et al., 2024) The protein content of the grain has a significant influence on the quality of the flour (Li et al., 2018; Kumar et al., 2021).

Storage proteins (gliadins and glutenins) play an important role during dough formation and are responsible for the baking qualities of wheat flour (Zhang et al., 2007; Li et al., 2008; Li et al., 2021; Hao et al., 2023). These two proteins during the mechanical kneading of flour in the presence of water combine to form a viscous and elastic mass and a plastic mass -gluten. Gluten determines the water absorption capacity of the flour and therefore the elasticity and plasticity of the resulting dough (Wieser et al., 2007; Dizlek et al., 2022; Zhang, et al., 2022)

MATERIAL AND METHOD

Plant material

Two of the institute's varieties participated in the test - Geya 1 - medium-strength wheat (Group B) and Sashets - strong wheat (Group A).

Setting up the experiment

The experiment was carried out on an experimental field of IPGR, Sadovo in the 2021 - 2023 harvest years. The response of two varieties of common winter wheat to three applications of nitrogen fertilization and different application rates was tested.

The reaction of grain vitreous,% (BDS 13378:1976), wet gluten yield, % (BDS EN ISO 21415-1:2007), gluten release, mm (BDS 13375:1990/Amendment 1:1993), was monitored. number number of bakery strength, acc. unit (BDS 13375:1990/Amendment 1:1993) and dry glugen (%) BDS EN ISO 21415-4:2007.

The nitrogen fertilizer rate (17 kg nitrate nitrogen) was applied once, twice and three times in combination with three different irrigation rates – 10, 20 and 30 mm. Fertilizer and irrigation rates were applied in the stages of tillering, end of tillering, beginning of stem elongation and elongation.

The two varieties of the institute were fertilized with ammonium nitrate at a dose of 17 kg/da and distributed as follows:

1. The entire amount introduced in the tillering-beginning of stem elongation phase.
2. ½ of the amount entered in the tillering-beginning of stem elongation phase, and ½ entered in the stem elongation phase.
3. 1/3 of the amount entered in the tillering-beginning of stem elongation phase, 1/3 entered in the tillering phase and 1/3 entered in the heading phase.

The amount of water supplied to the experimental variants was 10, 20 and 30 l/m2 in the stages of twining - beginning of spinning and leveling. The experience set in this way formed 18 test plots with a total harvest area of 1 da.

By means of the coefficient of variation, the variation of some indicators was determined (Dimova and Marinkov, 1999) as: weak - up to 10%, medium - greater than 10% and less than 20%, strong - over 20%.

RESULTS AND DISCUSSION

The Table 1 presents the obtained results for the vitreousness of the grain. The vitreousness of the grain is one of the main quality indicators. It is related to its density, reflects the structural-mechanical properties of endosperm and the ratio of protein to starch. Differences in endosperm structures were found in vitreous and mealy grains. Vitreousness is a physical indicator that is extremely influenced by the climatic conditions during the year of cultivation, the genotype, as well as the method of cultivation and their interaction. (Filipov, 2004; Cacak-Pietrzak, 2008; 2011; Brankovic et al., 2014; Mitura et al., 2023).
On average for the study period, the best values of the indicator were obtained with the Geya 1 variety, variants with three times the fertilizer rate and irrigation, both with 10 and 20 mm of water. In the case of variety Sachets /group A/, they are the highest when nitrogen is applied twice and 20 mm of water, as well as when feeding three times and thirty mm of water. Vitrification is an indicator that is most influenced by environmental conditions (Angelova et al., 2023). A decrease in the values of the indicator is observed when the irrigation rate is increased. The lowest values were recorded for the Sachets variety with a single application of the fertilizer and the highest irrigation rate of 30 mm. The coefficient of variation of the indicator is average according to the scale of Dimova and Marinkov, - 10.9%.

Table 1. Vitreousness of grain for the period 2021-2023

Stand. deviation					4.8				
Coeff. of variation					10.				
Stand. error of mean					1.1				

On average for the period, we report the highest values of wet gluten yield and dry gluten (Table 2) for the Sachets variety with the triple nitrogen application and irrigation regime with 20 and 30 mm of water - option 16 and 18., and for Gaia 1 with option 11 and option 17. The lowest results are for Sachets variant with single fertilization and maximum irrigation rate. The variation in the yield of wet gluten is low and that of dry gluten is medium. This study showed that the water use efficiency of medium-gluten wheat increased with the increase in fertilization frequency, while that of high-gluten wheat was the opposite and was in confirmation of that obtained by Hao et al., 2023. In mature wheat grains, gliadins and glutenins are the main water-insoluble proteins forming the gluten complex (gluten). They represent 80 - 85% of wheat proteins (Van Der Broght, 2005; Zlateva, 2010). They are responsible for the elasticity and extensibility of the dough, which in turn determines the processing qualities of various end products.(Rasheed et al., 2014). Wet gluten in wheat grain depends on a number of factors, such as genotype, environmental conditions during pouring and ripening of the grain. (Karadzhov et al., 1998), Ivanova and Kirchev, 2018; Biel et al., 2020; Campesi et al., 2023; Altenbach et al., 2012; Zhen et al., 2020). Irrigation has a significant impact on the yield and quality of wheat. Supplemental irrigation at critical growth stages of wheat increased crop yield to face extreme drought events (Campesi et al., 2023; Zhang et al., 2019). Flour protein content increases significantly under water deficit, especially total gluten content, due to higher nitrogen accumulation and lower carbohydrate accumulation (Liu, et al., 2022).

The physical properties of the dough largely depend on the quantity and quality of gluten (Hristov, 1967). The quality of the wet gluten of wheat is determined by the relaxation of the wet gluten. It represents the difference (in mm) between the initial and final diameter of the gluten ball with a mass of 4g after a 60-minute stay at a temperature of 30°C (Zlateva, 2010). A good allowance for breadmaking is 6 to 10 mm. In the present study, the release of gluten in both varieties, as well as in the three years of the study, was above the norms, i.e. higher than the maximum value of 10 mm. The release of the gluten of the Geya 1 and Sashets varieties for the period is from 12.7 - 19.5 mm (Table 3). The highest values were recorded with a single fertilization and watering of 20 mm in both varieties. The trait number of bakery strength ensures the level of bakery quality - volumetric yield of bread with good dimensional stability (Belcheva, 2018). The number of bakery strength as a complex indicator expressing the quantity and quality of gluten, although weaker, also changes depending on mineral fertilization (Nenova and Stoyanova, 2011).

Table 3. Gluten release and number of bakery strength values for the period 2021-2023

Vitreousness is an traait that is not significantly affected by the amount of irrigation water (Figure 1). This is evident from the resulting linear equation of the empirical data, it was obtained with a low coefficient of determination. The exponential equation shows that at a water supply between 20 and 25 mm, the vitreousness values are the highest for both varieties.

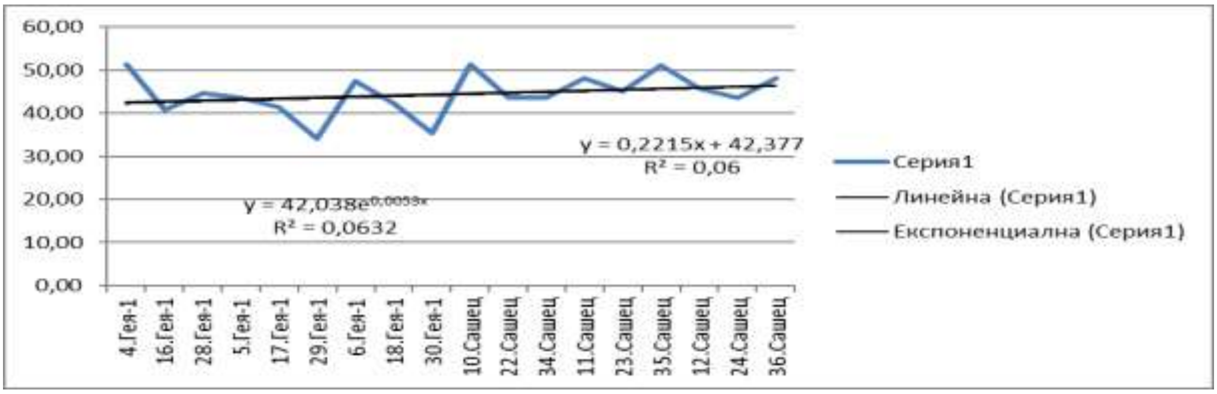

Figure 1. Effect of irrigation on vitreousness

The yield of wet gluten increases with an increase in the amount of water in the irrigation rates (Figure 2). The increase is linear, and the resulting equation is provided with a sufficiently high coefficient of determinant. The exponential growth of the index with increasing irrigation rate is shown in the graph, the resulting equation is highly deterministic and it can be seen that it is between 25-30 mm for both varieties.

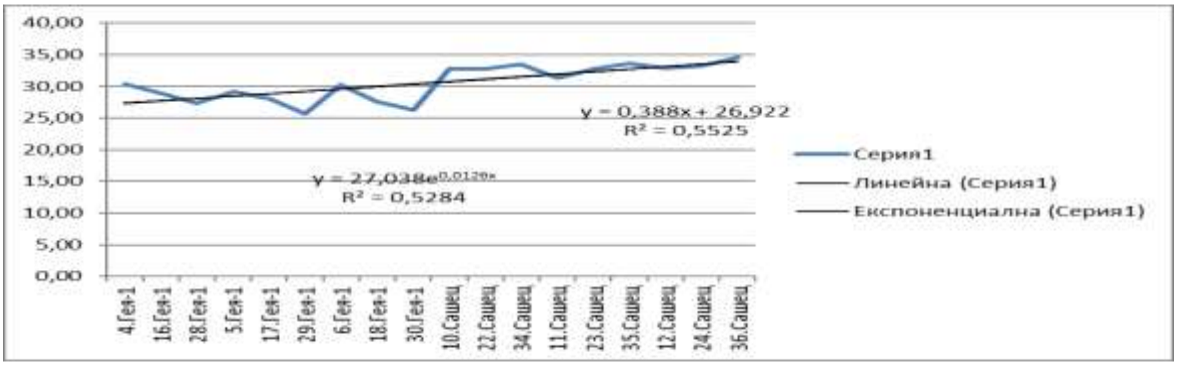

Figure 2. Effect of irrigation on wet gluten yield

Gluten release decreases with an increase in the amount of water and this decrease has a linear character with a sufficiently high degree of the determinant (Figure 3). The resulting exponential equation from the empirical data shows that the increase in the irrigation rate above 10 mm leads to a decrease in trait with the assurance of the equation with a high coefficient of the determinant.

Figure 3. Effect of irrigation on gluten release

The bakery power number is an trait that increases linearly with an increase in the amount of irrigation water (Figure 4). Empirical data show that the resulting equation has a high degree of the determinant and is sufficiently assured. The exponential curve shows that the highest values of this trait can be expected at 10 and 15 mm of water in the irrigation rate. The resulting equation has a high coefficient of determination

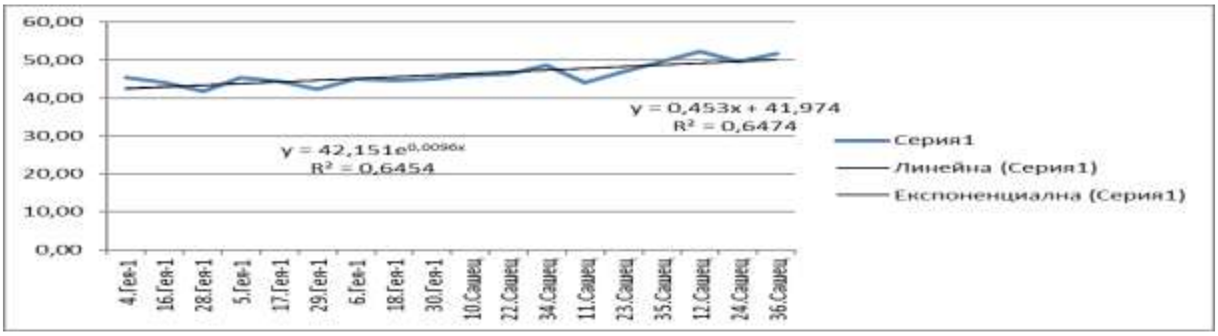

Figure 4. Effect of irrigation on bakery power number

The dry gluten also increased linearly with increasing amount of water used in both cultivars involved in the test (Figure 5). The linear equation derived from the empirical data has a high coefficient of determination. From the resulting exponential curve, we can conclude that the highest values of the trait are obtained when using an irrigation rate in the range of 10-20 mm.

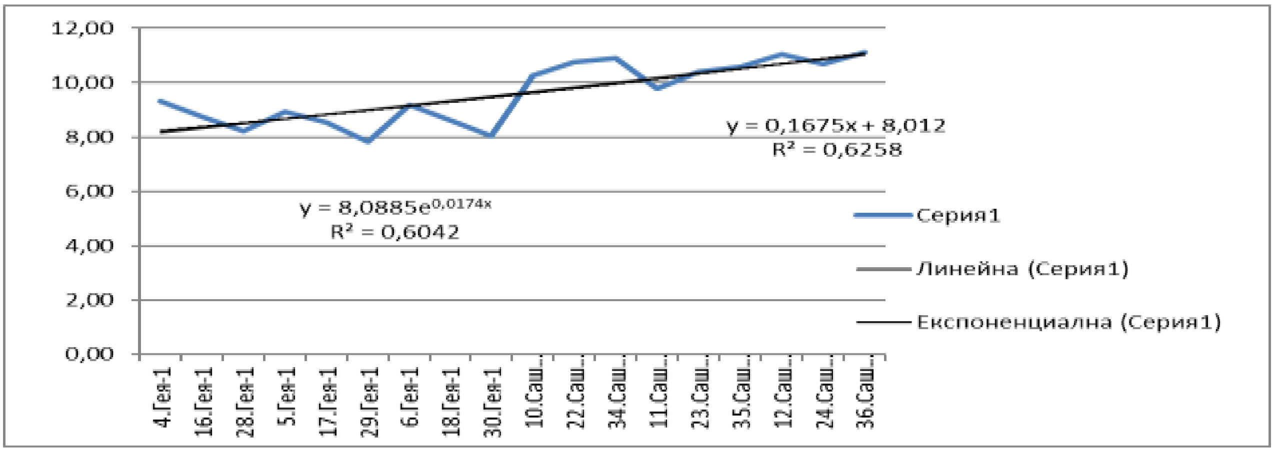

Figure 5 Effect of irrigation on dry gluten

Table 4 shows the influence of the genotype, the conditions of the year and the interaction between them on the studied traits. From the data in the table, it is clear that the interaction between genotype and environmental conditions has the highest influence on vitreousness, the genotype is second in importance. The genotype has the strongest influence on wet gluten yield, and the environmental conditions and the interaction between the two significant factors are equal. Gluten release has influence from the interaction conditions of year and genotype.

CONCLUSIONS

1. Average variation in the varieties Geya1 and Sachets in the variants of fertilizer application and irrigation rates based on the coefficients of variation was found for vitreousness, dry gluten and gluten release, and it was weak in the yield of wet gluten and number of bakery strength.

2. The influence of the genotype factor is decisive for the yield of wet gluten, and the interaction between genotype and weather conditions for the vitreousness and the gluten release

3. The influence of the investigated factors and their interaction on the dry gluten trait has not been proven.

4. The established optimal number of application of the fertilizer rate by phases and the amount of water for irrigation for each studied trait will be included in an algorithm of

the system for intelligent management of agricultural processes in the cultivation of common winter wheat.

STABILITY OF QUALITY TRAITS IN COMMON WINTER WHEAT GENOTYPES GROWN UNDER DIFFERENT NUTRITIONAL AND IRRIGATION REGIMES FOR INCLUSION IN AN ALGORITHM OF THE SYSTEM FOR INTELLIGENT MANAGEMENT OF AGRICULTURAL PROCESSES

Evgeniy DIMITROV, Stanislav STAMATOV, Teodora ANGELOVA, Zlatina UHR

IPGR "K. Malkov", Sadovo, Agricultural Academy, Bulgaria

ABSTRACT

In the experimental field of the IPGR, Sadovo town. A three-year experiment with two varieties of common winter wheat grown under different nutritional and irrigation regimes was conducted in the field of IPGR, Sadovo, in the period 2021-2023. Eighteen fertilizing treatments were used in the experiment including single, double and triple application of nitrogen fertilizer (17 kg N) in combination with different irrigation rates of 10, 20 and 30 mm. The fertilizer and irrigation rates were applied at the tillering, end-tillage beginning-tillage and tillering phases. Grain vitreousness, wet gluten yield, gluten release, baking strength number and dry gluten were used to assess grain quality. The stability of the studied traits of two wheat cultivars, Geya 1 and Sashets, was evaluated by the stability variants σi^2 and Si^2 according to Shukla (1972), the ecovalance Wi according to Wricke (1962) and the phenotypic stability criterion (Ysi) according to Kang (1993). IPCSSVKYSI (Interactive program for calculating Shukla's stability index (Ysi)) developed by Kang and Magari (1995) was used to determine the stability index. The most stable value for the parameters vitreousness, gluten release and dry gluten was characterized by the cultivar Sashetz under the variation with double fertilizer application rate and irrigation rate of 10 mm. Stability of the trait baking strength number was reported in Geya 1 in combination with double nitrogen application and minimum irrigation. Cultivar Sashets realized the highest stability of the trait wet gluten yield in the variant with single fertilizer application and maximum irrigation rate. The obtained results are useful from the breeding point of view for increasing the stability of quality traits. The data obtained from the different nutrient regimes can be incorporated into the algorithm of the intelligent agricultural process control system to achieve a consistency in the values of the studied parameters.

Key words: Smart farming, Common winter wheat, Stability, Quality indicators

INTRODUCTION

In today's context of steadily increasing population and changing climate, increasing the yield and improving the quality of winter wheat grain is becoming increasingly important worldwide. This requires the introduction of varieties with high productivity and ecological plasticity to the environmental conditions in which they are grown. There is a need for in-depth research on the yield and quality potential of varieties under different agro-ecological conditions, so each element of wheat crop technology has been studied by a number of researchers (Sevov and Delibaltova, 2013; Kuneva et al., 2014; Barakova et al., 2018; Delchev and Angelova, 2019; Stoyanova et al., 2020; Van Frank et al.,2020; Minoli et al., 2022).

One of the main tasks of breeding programs is the introduction of varieties with high ecological plasticity, quality characteristics and with good stability varieties. Any variety can have high grain yield and high ecological plasticity, regardless of its quality potential (Tsenov and Atanasova, 2015; Stoyanova et al., 2020).

The problem of wheat grain quality is an integrative indicator of the interaction between the genotype of the variety, natural and ecological features, agrotechnical and organizational and economic conditions of cultivation (Rozbicki, 2014; Krystkowiak, 2016; Пахотина et al., 2020; Fomenko, 2018). It is considered that the leading factor influencing the quality of wheat grain is the hereditary characteristics of the variety (Смирнова, 2018).

The results show that the influence of genotype and its interaction with the surrounding environment has been demonstrated in all observed traits (Reckling et al., 2021; Dimitrov et al., 2023).

The increasing demand for high technological quality in wheat necessitates the need to increase protein and gluten content, improving dough strength and stability (Blandino et al., 2016).

As a consequence of global climate change, the sustainability of cropping systems in agriculture is decreasing. There is a decline in cereal production, which has also been reported for wheat in Europe (Kahiluoto, H., 2019; Kahiluoto et al., 2019; Piepho, 2019;).

As temperature increases, wheat yields are expected to decrease by 6% for every 1°C increase in temperature. Therefore, wheat grain yields must increase by 60% by 2050 to meet the needs of a growing world population (https://www.fao.org/worldfoodsituation/csdb/en; Asseng et al., 2015; Uhr et al., 2023). In this regard, the study of crop response to water deficit is important in areas where water resources are limited. Many of them in which wheat is grown are characterized by low humidity and insufficient rainfall (Bouazzama, 2024).

Wheat is one of the majornon-grain crops in irrigated farming systems (Frenken and Gillet, 2012; De Oliveira Silva et al., 2020b; Leghari et al.,2024).

Different primes are used for its irrigation. Conventional surface irrigation methods use large amounts of water, resulting in irrational use of limited water resources.

According to the literature, among all the irrigation methods used, drip irrigation is the most efficient and can be successfully practiced for irrigating a wide range of crops (Bouazzama, 2024). It potentially saves more than 20% of irrigation water compared to surface irrigation (Karrou et al., 2011)

Scarcity of water resources and unwise application of nitrogen fertilizers appear to be a problem in wheat production.(Yao, 2023).

Hence proper water management and use of nitrogen fertilizers by conducting studies on their application is necessary to achieve good productivity (Zain, 2023).

Yao et al. (2023) investigated the application of irrigation and nitrogen nutrition regimen to simultaneously improve wheat grain yield, its quality, water and nitrogen use efficiency and clarify its improvement mechanism. The results showed that increasing the nitrogen fertilization ratio significantly improved the chlorophyll content, net photosynthetic rate, glutamine synthetase, nitrate reductase activity and soluble protein content during grain pouring (Yao et al., 2023).

It has been found that, unwise use of nitrogen fertilizers leads to environmental problems such as water eutrophication, nitrate contamination in groundwater, greenhouse gas emissions etc (Axinte et al., 2015; Tedone et al., 2018).

Because of this obstacle, proper nitrogen fertilizer management is very important for high yield, high quality and environmentally friendly production of common winter wheat. Scientists devise the most effective N fertilizer management methods by separating the application of N fertilizer in different crop development phases,as well as changing the form of N fertilizer itself and so on (Shi et al., 2012; Li et al., 2018; Zhang et al., 2021; Wan et al., 2021; Lyu et al., 2022).

Nitrogen is an important factor influencing the protein and wet gluten content of wheat (Blandino, 2016), and the quality of wheat dough and pasta is largely influenced by the protein content and gluten quality Gluten is a protein that has elastic and plastic properties after hydration and mixing by hand or machine (Edwards, 1999; Morris, 2016; Zubair, 2021; Trevisan, 2022).

Stability is the ability of varieties to express their genetic potential under a wide range of growing conditions (Ann icchiarico, 2002). Stable expression of varieties and their wide adaptation in terms of yield and quality traits is the goal of many breeding programs (Atanasova et al., 2008; Aminzadeh, 2010; Parveen et al., 2010, Stoyanova et al., 2020; Bondarenko and Nazarenko, 2020; Uhr et al., 2021).

Different parameters are known to assess phenotypic stability (Eberhard and Russell, 1966; Shukla, 1972), but the most reliable method for simultaneous stability assessment is Kang's (1993) Ysi parameter.

Through this criterion, the value of each variety is presented, taking into account both the value of the indicator and the stability of the variant. The value of this criterion is that, using non-parametric methods and statistical evidence of differences, a summary score is obtained, ranking the variants according to their economic value.

Irrigation methods and nitrogen (N) fertilization regimes have complex effects on wheat physiology, growth, and development, resulting in regulation of wheat grain yield and quality.

The purpose of the study is the selection of an effective nutritional regimen to achieve high and stable results of the studied traits, as the data obtained from the study will be included in an algorithm of the system for intelligent management of agricultural processes.

MATERIAL AND METHOD

The experiment was carried out in the breeding field of IRGR, Sofia. Sadovo in the period 2021-2023. Bulgarian varieties Geya 1 - medium strength wheat (Group B) and Sashetz - strong wheat (Group B) were used in the experiment.

The response of grain vitreousness, % (BDS 13378:1976), wet gluten yield, % (BDS EN ISO 21415-1:2007), gluten relaxation, mm (BDS 13375:1990/Amendment 1:1993), baking strength number, AU (BDS 13375:1990/Amendment 1:1993) and dry gluten (%) BDS EN ISO 21415-4:2007 was monitored.

The technology under which the varieties were grown consisted of eighteen feeding treatments involving single, double and triple application of the nitrogen fertiliser rate (17 kg N) in the following scheme:

-The total amount applied at the tillering-early spindling stage.

-½ of the amount applied in the tillering phase-early stem elongation phase and ½ applied in the stem elongation phase.

-1/3 of the quantity imported in the tillering phase - start of stem elongation, 1/3 imported in the stem elongation phase and 1/3 imported in the heading phase.

Application is in combination with different irrigation rates of 10, 20 and 30 mm. The irrigation rates were applied in the tillering, end-till-early tillering and stem elongation phases.

The mathematical processing of the data was performed using Microsoft Excel for Windows.

RESULTS AND DISCUSSION

The results of the qualitative indices studied and their stability under different diets are presented in Tables 1, 2, 3 and 4. It is evident from the data that the highest value of the trait vitreousness (Table 1) during the study period was obtained in cultivars Geya 1 and Sashchets, variant №1 and variant №10. In variant №1, the nitrogen fertilizer rate was applied once in combination with an irrigation rate of 10 mm, while variant №10 included a double fertilizer application and an irrigation rate of 20 mm. The lowest value of the trait vitreousness is characterised by the variety Sashetz (№6), where the nitrogen fertiliser rate was applied once in combination with the maximum irrigation rate.

Regarding the stability of the studied parameters, genotypes showing lower values under the different diets are estimated to be more stable because they interact less with the environmental conditions. Negative values of the σi^2 and Si^2 indicators are assumed to be 0. For reliably high values of either σi^2 or Si^2, genotypes are considered unstable. In Wricke's equilibrium Wi, the higher the parameter values at different feeding levels, the lower their stability. In our study, the results showed that the highest vitreous stability (Table 1) was reported for variant 8 (two nitrogen and 20 mm water application) and variant 2 (two nitrogen and 30 mm water application). In these variants, the differences in vitreous values between years were smaller. As not stable, it can be pointed out that feeding variants

№9 and №14 show the highest variation between the values of the indicator during the years of the study

Very useful information on the value of genotypes is provided by Kang's YSi indicator for simultaneous assessment of qualitative indicators and their stability, the indicator being based on the reliability of differences between different values and the variance of interaction with the environment. The value of this criterion is that using non-parametric methods and statistical evidence of differences, we obtain a summary score ranking genotypes in descending order of their economic value. In our study, the most valuable varieties were Geya 1 (variant №12) and Sashez (variant №18) in which nitrogen fertilizer was applied twice (variant №12) and three times (variant №12) with a maximum irrigation rate of 30 mm.

σ^2_i – Shukla's stability variance; s^2_i – deviation from redression; W_i^2 – Wricke's ecovalence; YSi – Kang's rank-sum;

The highest values of wet gluten yield (Table 2) was recorded in variants 18 and 15 in which there was a triple nitrogen application with 30 and 20 mm amount of water. The lowest result was recorded in variety Sashetz (variant № 6) involving a single application of fertilizer and an irrigation rate of 30 mm.

The calculated stability indices of wet gluten yield show us that high stability was recorded in feeding variants №5 and №8, while low stability over the years was present in feeding regimes №1 and №11. According to Kang's YSi index, we can assume that the variant №18 is evaluated as the most efficient since it showed high yield wet gluten values in all three years of the study.

The data obtained for gluten release (Table 3) show us that the most efficient regime is the one with a single application of the entire nitrogen rate with 20 mm of water (variant 4). Variant 16 was characterized as not effective and with the lowest value in the indicator of gluten release. High stability of the studied indicator was found in the fertilizing variants 8 and 12, and as not stable were evaluated the fertilizing №9. The most valuable according to the YSi index was variant №3, which showed a combination of high and relatively constant values of the studied indicator during the test period.

For the baking strength number (Table 4), the values of the different options ranged from 41.7 (variant) to 52.3 (variant16). The calculated stability indices (σ^2_i, W_i^2) show us that the most stable values were obtained under a fertilazimg regime involving a double application of the fertilizer rate combined with an irrigation rate of 20 mm of water (variant 7). Low stability of the indicator was recorded in the cultivar Sachets involving a threefold application of the fertilizer rate and a maximum irrigation rate (variant 17). A combination of high and stable values according to the YSi index was obtained in variants 11 and 12, both involving a two-fold fertilizer application and an irrigation rate of 30 mm of water.

The dry gluten values (Table 5) ranged from 7.8 (variant 6) to 11.1 (variant 18). In this indicator, the regularity was observed that the results obtained with a single application of nitrogen were lower compared to two and three applications of the fertilizer rate. The data obtained from the stability indices show us that the highest stability was obtained with variant №8, while the stability reported with variant No. 1 was poor. According to the YSi index as the most effective fertilazing regime we can determine variant №17, including triple application of nitrogen fertilizer and maximum irrigation rate.

Table 5. Dry gluten of winter common wheat for the period 2021-2023

σ^2_i – Shukla's stability variance; s^2_i – deviation from redression; W_i^2 – Wricke's ecovalence; YSi – Kang's rank-sum;

According to the calculated coefficients of variation of the qualitative indicators studied, we can summarize that the use of different fertilazing levels did not significantly affect the values obtained for the traits studied. For example, the variation in the number of baking strength and wet gluten yield was estimated to be low, with CV% values of 6.5 and 9.1%, respectively. Variation in vitreousness (10.9%), dry gluten (11.9%) and gluten release (13.8%) was moderate. Slight to moderate variation in qualitative traits has also been found in our previous studies (; Dimitrov et al., 2020; Uhr et al., 2020).

Table 6 presents the analysis of variance of the results, in which the influence of the factors genotype (factor A), growing conditions (factor B) and their interaction (AxB) on the studied quality indicators was evaluated.

Analysis of genotypex interaction is particularly important for the breeding process (Yan and Hunt, 2001). Very often, high stability of a given trait is associated with low levels of manifestation and vice versa (Tsenov et al., 2004; Atanasova et al., 2010).

The proven influence of the genotype x environment factors for all traits studied gives us reason to accept as reliable the data presented in the previous tables on the stability of genotypes grown at different levels of nutrition. From Table 6 it is evident that the interaction of the factors AxB, e had the strongest influence on vitreousness (52.6%) and gluten relaease (43.5%). The genotype factor was decisive in wet gluten yield (45.7%) and dry gluten, while the influence of different fertilazing levels was of primary importance on baking strength number (39.0%).

CONCLUSIONS

The highest stability of the quality parameters vitreousness, gluten release and dry gluten during the study period was realized by the variety Sashetz at two times application of the nitrogen fertilizer rate combined with an irrigation rate of 10 mm water. High stability of results in wet gluten yield was characterized by Geya 1 with a fertilazing regime involving the use of a single application of fertilizer and a maximum irrigation rate of 30 mm of water. In baking strength number, stability of results obtained was recorded in variety Geya 1 by using twice nitrogen rate and minimum water application.

A combination between high values and stability of the obtained results of quality parameters during each of the years of the study were obtained with the following diets:

- vitreousness, baking strength number: double application of nitrogen fertilizer with 10 mm irrigation rate
- wet gluten yield: three applications of nitrogen fertiliser at 30 mm irrigation rate
- gluten release: single application of nitrogen fertiliser at 20 mm irrigation rate

dry gluten: three applications of nitrogen fertiliser at 30 mm irrigation rate

The results of the research will help the breeding process to achieve stability and high values of the studied quality indicators by using effective nutritional regimes.

ABSTRACT

The use of *Nigella sativa* L., commonly known as black cumin, in traditional and medicinal practices is well-documented, due to the wide range of its biological activities. In light of its significance, this study investigates the efficacy of various seed priming treatments, specifically Gibberellic Acid (GA3) and different priming durations, under laboratory conditions to enhance the germination stages of *Nigella sativa* L. The objective of these priming treatments is to improve germination rates, the germination index, and average germination time, with the potential to increase agricultural productivity.
The findings of this study demonstrate that priming durations and gibberellic acid doses have a significant impact on germination parameters under controlled conditions. These results provide valuable insights into the potential of these treatments to optimise crop growth. It can be concluded that appropriate seed priming can effectively enhance the early growth stages of *Nigella sativa* L., contributing to better crop establishment and yield.

Keywords: Nigella sativa L., Seed priming, Gibberellic Acid (GA_3), Germination rates, Germination index

INTRODUCTION

Medicinal plants, especially those with a broad spectrum of biological activities, have attracted considerable attention in both the scientific and medical fields. *Nigella sativa* L., commonly known as black cumin or black seed and belonging to the Ranunculaceae family, is notable for its widespread use in culinary and medicinal contexts (Mohamed et al., 2014; Kiralan et al., 2016). Its medicinal use has attracted worldwide interest, largely due to its efficacy in the treatment of numerous conditions. Historical accounts, including those attributed to the Prophet Muhammad, have enhanced the reputation of black seed as a remedy for various ailments, except death itself (Islam et al., 2019).

Traditionally, *Nigella sativa* seeds have been used to treat conditions such as fatigue, persistent headaches and melancholy. Roasted seeds mixed with honey or butter have been suggested to relieve colic and coughs, while the seeds are known for their lactogenic and antiseptic properties, particularly in the treatment of eye infections. The emergence of COVID-19 has further sparked interest in potential antiviral treatments, with studies investigating Nigella sativa extracts for their ability to inhibit coronavirus replication and affect TRP gene expression during infection (Ulasli et al., 2014). The results suggest that *Nigella sativa* has a significant effect on viral load and gene expression associated with CoV infection, enhancing its therapeutic potential (Yimam et al., 2015).

The genus Nigella includes around 20 species, 14 of which are found in Türkiye (Nemtinov et al., 2022). It is cultivated globally, from Southern Europe to the Middle East and South Asia, and is particularly widespread in regions like Thrace, Northern Anatolia, and the Mediterranean in Türkiye, especially in provinces like Burdur, Afyon, Isparta, and Gaziantep (Inan et al., 2022).

Seed priming, a cost-effective method to promote early crop growth and uniform emergence, is a common agricultural practice. This involves treating seeds with osmotic solutions or plant growth promoters such as salicylic acid and gibberellic acid, or inorganic salts like KNO_3 and $CaCl_2$ (Farooq et al., 2008; Rehman et al., 2011). Priming typically accelerates germination, improves stand establishment, and enhances crop yield and quality. For example, KNO_3 priming not only speeds up germination and strengthens seedlings but also boosts yield and protein content when combined with other priming methods (Rehman, 2014).

A substantial body of research has demonstrated that a variety of priming techniques can positively influence seed germination and seedling growth (Paparella et al., 2015; Sharma et al., 2014; Khalaki et al., 2020). The primary objective of this study is to determine the optimal dose and duration of gibberellic acid (GA3) application for seed priming in Nigella sativa, with the aim of enhancing seed germination. While the study also aims to explore whether these optimal conditions observed in controlled laboratory settings can be effectively applied in field conditions, the central focus remains on identifying the most effective GA3 treatment parameters to improve seed germination.

MATERIAL AND METHOD

This study examines the impact of , Gibberellic Acid (GA_3), priming treatments on Nigella sativa L. seeds under controlled laboratory conditions. The seeds were subjected to germination tests, placed on four layers of moistened filter paper, and incubated in darkness at a constant temperature of 22°C. Germination was assessed by the emergence of a 1 mm radicle and monitored over a 10-day period. No signs of microbial contamination were observed during the experiment (Kamal et al., 2010).
For priming, there are four dose; Control dose, 100 ppm GA, 200 ppm GA and 300 ppm GA; three priming duration; 12 hour Priming, 24 hour Priming and 36 hour Priming applications. The experimental design was arranged in a completely randomized design with 4 replications of 25 seeds in the germination stage The seeds were placed in 10 × 10 cm plastic boxes lined with blotting paper.

Germination Rate (%): It is calculated as Scott et al., 1984.

$$GR = \frac{Number\ of\ germinated\ seeds}{Total\ number\ of\ seeds} * 100$$

Germination Index: The germination index is calculated by dividing the number of germinated seeds by the number of days to the first count, and adding that to the number of germinated seeds divided by the number of days to the final count (Benech Arnold et al., 1991).
Mean germination time (Day): It is calculated as Ellis &Roberts, 1981.

$$MGT = \frac{\Sigma(Dn)}{\Sigma n}$$

n : number of seeds germinated on day D,
D: number of days counted from the beginning of the germination the lightest seeds,
The obtained data were analyzed separately and differences were determined using the analysis of variance (one-way ANOVA). Variance analyses were performed using JMP Pro v.16 software. Statistically significant factors were grouped using the LSD (Least Significant Difference) test. Factors that were not significant in the LSD test were compared based on mean tables.

RESULTS AND DISCUSSION

The ANOVA analysis results highlight the significant effects of GA_3 (gibberellic acid) dosage and application time on the germination performance of Nigella sativa seeds. The results show that both factors have statistically significant impacts on parameters such as germination rate, germination index, and mean germination time. The GA_3 dosage has a highly significant effect on the germination rate at the 1% level ($p < 0.01$). Different GA_3 concentrations lead to noticeable differences in the seeds' germination success. Additionally, application time also significantly affects germination rate at the 1% level ($p < 0.01$), indicating that the duration of exposure to GA_3 plays an important role. However, the interaction between dosage and time was not statistically significant ($p > 0.05$), suggesting that the combined application of these two factors does not create a synergistic effect. GA_3 dosage significantly affects the germination index at the 5% level ($p < 0.05$), meaning that varying doses impact the rate of germination, though not as dramatically as for germination rate. On the other hand, application time did not significantly influence the germination index ($p > 0.05$), indicating that time does not largely affect germination speed. GA_3 dosage significantly affects the mean germination time at the 1% level ($p < 0.01$), showing that optimal dosages can shorten the time it takes for seeds to germinate. Similarly, application time also has a significant effect on the mean germination time at the 1% level ($p < 0.01$), indicating that longer exposure to GA3 can alter the germination process. However, the interaction between dosage and time did not significantly affect this parameter ($p > 0.05$) (Table 1).

These findings suggest that both GA_3 dosage and application time should be optimized independently to improve the germination performance of Nigella sativa seeds. The lack of a significant interaction between the two factors means that their combined application does not offer additional advantages, so it is important to focus on each factor separately for better results.

Table 1. Significance levels in variance analysis for the GA_3 priming dose applications and priming durations in *Nigella sativa* L. Plant.

Source of Variation	**Df**	**Mean of Square**		
		Germination Rate	**Germination Index**	**Mean germination time (Day)**
Rep.	**2**	21.33	0.127	0.048
Dose	**3**	564.74**	1.369*	0.173**
Time	**2**	112**	0.098	0.497**
Dose*Time	**6**	40.29	0.151	0.131
Error	**22**	21.33	0.9	0.053
Total	**35**			

The results presented in Table 2 show the effects of different GA3 doses and priming times on the germination parameters of mean value *Nigella sativa* seeds.

The 300 ppm GA_3 dose consistently yielded the highest germination rates across all priming times, with an average of 92.00%, significantly outperforming the control (72.88%) and lower GA_3 doses. The dose of 300 ppm GA_3 resulted in significantly higher germination compared to the other treatments ($p < 0.01$). When considering priming duration, 36-hour priming resulted in the highest average germination rate of 85.32%, followed by 12-hour (81.33%) and 24-hour (79.33%). The effect of the priming time was significant, indicating longer priming times positively influence germination rates. A similar trend is observed with the germination index. The highest index (4.05) was found in seeds primed with 300 ppm GA_3, indicating faster and more successful germination compared to the control (3.14) and other GA_3 concentrations. The effect of the dose on the germination index was statistically significant ($p < 0.05$). Among the priming durations, the 12-hour priming time slightly outperformed others with an average germination index of 3.57, though the differences between priming times were not as pronounced. Regarding the average germination day, seeds primed with 300 ppm GA_3 also exhibited the fastest germination, averaging 6.08 days. This was significantly faster compared to seeds primed with 200 ppm GA_3 (6.40 days) and the control (6.18 days). The effect of GA_3 dose on germination time was significant at $p < 0.01$. The longest germination time was recorded at the 36-hour priming duration (6.45 days), suggesting that longer priming may slow down the germination process, while shorter priming durations (12 and 24 hours) resulted in quicker germination.

Table 2. Effect of GA_3 priming dose applications and priming durations in *Nigella sativa* L. plant germination parameters.

GA Dose and Priming Time	**Germination Rate**				**Germination Index**				**Avarage Germination Day**			
	12 hour Priming	**24 hour Priming**	**36 hour Priming**	**Avg.**	**12 hour Priming**	**24 hour Priming**	**36 hour Priming**	**Avg.**	**12 hour Priming**	**24 hour Priming**	**36 hour Priming**	**Avg.**

CONCLUSION

The results of the analysis of GA_3 priming doses and durations on *Nigella sativa* seeds provide several key insights for optimising germination performance. The highest germination rates, germination index values and shortest average germination times were achieved with a GA_3 concentration of 300 ppm. This dose significantly improved germination performance compared to lower doses and the control, demonstrating its effectiveness in promoting faster and more successful seed germination. Of the different priming durations, 36 hours priming resulted in the highest average germination rate, but also resulted in a slightly longer average germination time. This suggests that while longer priming durations may improve the overall germination rate, they may also increase the time taken for seeds to germinate. Conversely, shorter priming durations (12 and 24 hours) tended to speed up the germination process, but with less pronounced improvements in germination index compared to the 36 hour priming.The results suggest that the GA_3 dose of 300 ppm combined with a 12- or 24-hour priming period may be the most balanced approach, providing high germination rates and relatively short germination times. The effect of the interaction between dose and priming time was not as significant as the individual effects of each factor.In conclusion, a GA_3 dose of 300 ppm is highly recommended to enhance the germination of *Nigella sativa* seeds, with 12 h or 24 h priming preferred for faster germination. Longer soaking times may be beneficial for overall germination rates but may slightly delay the germination process. Balancing these factors according to the specific needs of the seed and the desired results can lead to optimum germination performance.

With a well-planned and socially responsible business policy, Solana d.d. Tuzla, founded in 1885, has established itself as a key producer of salt on the Southeast European market. The process of producing salt, NaCl, is created by evaporating salt water in a four-stage vacuum evaporation battery. Raw salt water (SSV) is supplied to the saltwater pipelines circuit through a DN 250 pipe from the source of salt water in Tetima.
The aim of this research is to process all stages of the salt production process integrating all the requirements of the implemented standards. This paper will show the process approach and all the benefits of process management using GFSI principles.
When all the input parameters of the production process are satisfied, one of the most important process steps is the purification of raw salt water, which obtains a high-quality and safe essential product with all the required parameters. The purification process takes place in reactor 1DC/1,2. The process is based on the reduction of Ca^{+2} and Mg^{+2} ions within the permissible limits. The purification process itself takes place by mixing the salt water in the central pipe with the reagents Na_2CO_3 and NaOH, depending on the composition of the raw salt water. Purified salt water of satisfactory quality produced by process and laboratory monitoring is further transported to the vacuum evaporation plant and continues with the process stages of centrifugation, iodization, drying and screening of iodized salt.
The investigation confirmed that Solana d.d. Tuzla manages the process and the implemented requirements of the standards, ensuring traceability and the possibility of monitoring products in the complete chain of production and distribution. It bases its process management on the principles of sustainable technology using mother liquor as a by-product for further purpose and use.

Keywords: raw salt water, purified salt water, vacuum evaporation, mother liquor, iodization, traceability, sustainable technology, FSSC 22000

INTRODUCTION

Sodium chloride is one of the most common salts in nature. In crystalline form, it appears as rock salt in all geological formations. In Europe, large deposits of rock salt are found in Romania, Poland, Germany, France, England, Spain, and in Bosnia and Herzegovina in the territory of Tuzla. Exploitation of underground deposits is done by simply pumping out raw salt water through previously made wells, the composition of which can be variable. Raw salt water is transported by pipeline from the salt wells "Tetima" from the Tuzla Salt Mine and comes to the raw salt water receiving tank, then it is transported to the salt water purification plant by means of a pump through a meter using a pipeline. The process of purifying raw salt water is the removal of Ca^{2+} and Mg^{2+} ions within the permissible limits, and is carried out by the use of the reagents Na2CO3 and NaOH. The mixture of Na_2CO_3 and NaOH together with salt water passes through the already formed layer of sludge in the reactor, so that clear salt water (purified) from the top of the reactor goes into the salt water receiving tanks and goes directly to the four-stage vacuum evaporation station.
The process of purifying raw salt water and the continuation of all further processes is subject to monitoring and control based on GFSI principles. The salty slurry created by the process of vacuum evaporation is separated from the apparatus into the mixer, and from there it is transported to the concentrators by means of pumps and pipelines. Process control includes concentrator control and centrifuge operation control. Centrifuged salt is released from centrifuges on vibro - i.e. belt conveyors by which it is transported to the iodization drive. Salt is iodized at this plant. KJ or KJO_3 solution and an anti-caking agent are added to the salt. From the iodization plant, the salt from the belts falls into the dryer (vibrating dryer with a fluidizing layer), where the remaining moisture from the salt is extracted. Iodization of salt is carried out in order to prevent the occurrence of goiter in humans, domestic animals and livestock, which is caused by a lack of iodine. The process step of iodination is represented by CCP in the Production Plant itself. A by-product of salt production is mother liquor with a certain concentration of NaCl and Na_2SO_4. The mother liquor is discharged from the process when the concentration of Na2SO4 reaches the eutonic range, i.e. simultaneous crystallization of NaCl and Na_2SO_4.
The aim of the paper is to present the correlation between the GFSI principle and the basic step, i.e. purification of raw salt water through the traceability of the use of raw materials, reagents, additives and all the way to the finished product. In addition to the production of healthy and safe iodized salt, the goal is to point out the possibility of using mother liquor as a by-product of the salt production process.

MATERIAL AND METHODS

For experimental tests, raw salt water (SSV) was used, which was sampled at the discharge pipe of the snow pipeline in Solana, the composition of which is shown in Table 1.

Table 1. Raw salt water Solana d.d. Tuzla

Components	***NaCl (g/l)***	***Ca (g/l)***	***Mg (g/l)***	***HCO_3 (g/l)***	**SO_4^{2-} (g/l)**	***H_2S (mg/l)***
Reference values	***300-310***	***0,70-0,90***	***0,02-0,03***	***0,17-0,20***	***1,50-2,30***	***< 1***
Analysis results	*308,59*	*0,72*	*0,036*	*0,18*	1,39	0,44

If you look at the composition of raw salt water, Ca+2 and Mg+2 represent the carriers of hardness that must be reduced to the permitted limits because they affect the shift in the balance in the solution and reduce the coefficient of utilization of reactive NaCl, during the production of salt itself.
The amount of Na2CO3 and NaOH reagents is determined depending on the quality of the raw salt water, after the analysis as shown in Table 1. In the first stage of raw salt water purification, the reagents sodium hydroxide (NaOH) and sodium carbonate (Na2CO3) are used, and the process itself is called the soda-soda process.
The purification process takes place according to the following reaction mechanism:

$$Ca^{+2} + Na_2CO_3 \rightarrow CaCO_3 \downarrow + 2Na^+$$

$$Mg^{+2} + 2NaOH \rightarrow 2Na^+ + Mg(OH)_2 \downarrow$$

The reagents are prepared in a mixer where Na2CO3 and NaOH are dosed depending on the composition of the raw salt water and the flow rate, and they are transported by pump to the reactor where the salt water is purified. In the reactor with a contact layer, Ca2+ and Mg2+ are separated by mixing the salt water in the central pipe with the reactants Na2CO3 and NaOH, depending on the composition of the raw salt water. The mixture of Na2CO3 + NaOH together with salt water passes through the already formed layer of sludge in the reactor, so that from the top of the reactor the clear salt water (purified) goes to the receiving tanks of salt water and/or directly to the vacuum evaporation plant.
Iodization of salt is carried out in order to prevent the occurrence of goiter in humans, domestic animals and livestock, which is caused by a lack of iodine. Iodination is performed with a KJ or KJO3 solution in the range of 15 - 110 mg/kg of salt, depending on the customer's requirements. The iodination process is carried out according to the liquid-liquid principle, prepared solution of KJ or KJO3 on centrifuged salt. During salt production, the iodine content is monitored using iodometric titration according to the established sampling plan. The prescribed salt quality control methods according to the Codex standard for salt for human consumption are:

- Determination of NaCl content
- Determination of the content of insoluble substances in water/mineral acids
- Determination of sulfate content
- Determination of Ca^{2+} and Mg^{2+}
- Determination of H_2O content
- Determination of K^+ content

- Determination of heavy metal content - Cu (2.0 mg/kg)
- Determination of the content of heavy metals - As (0.5 mg/kg)
- Determination of the content of heavy metals - Hg (0.1 mg/kg)
- Determination of heavy metal content - Pb (2.0 mg/kg)
- Determination of heavy metal content - Cd (0.5 mg/kg)
- Determination of iodine content

One of the most important waste streams in salt production is mother liquor, and for these reasons, the treatment of mother liquor before its discharge and the possibility of using it in the process is of great importance for the sustainability of the salt production process. Table 2 shows the composition of raw salt water and mother liquor.

Table 2. Chemical composition and concentrations of raw salt water and mother liquor

Chemical composition	Raw salt water	Mother liquor
NaCl	308,59 gr/l	295,41 gr/l
Ca^{+2}	0,720 gr/l	63,01 gr/l
Mg^{+2}	0,03gr/l	0,198 gr/l
HCO_3^-	0,18 gr/l	1,14 gr/l
SO_4^{-2}	1,39 gr/l	1,06 gr/l

All tests were done so that the obtained results correspond to real systems.

RESULTS AND DISCUSSION

The process of purification of raw salt water after the dosing of reactants corresponds to the chemical composition shown in Table 3.

Table 3. Purified salt water

Components	***Ca* (mg/l)**	***Mg* (mg/l)**	***Na_2CO_3* (g/l)**	***NaOH* (g/l)**
Reference values	***30***	***5***	***0,30-0,40***	***0,10-0,15***
Analysis results	10	-	0,27	0,08

Since the process of purification of raw salt water is very important for the process of vacuum evaporation of salt water, great attention is paid to the control of purification, that is, analyzes of purified salt water. If we look at the reference values of purified salt water, and the values obtained after the purification procedure, we can conclude that the further process of vacuum evaporation will take place without inconsistencies in the process regarding the quality parameter of purified salt water.

Table 4. Chemical analysis of purified salt water produced by the applied purification method (mother liquor)[1]

Chemical composition	PSV after purification with ML
NaCl	306,66 gr/l
Na_2SO_4	19,88 gr/l
Na_2CO_3	0,90 gr/l
NaOH	0,017 gr/l
Ca^{+2}	0,0194 gr/l
Mg^{+2}	0,0021 gr/l
pH	9,63

Chemical analysis shows in Table 4 that all the parameters of the multicomponent system, such as purified salt water, are within the allowed limits, which confirmed the theoretical and experimental claims that part of the excess can be provided from the mother liquor.

After the production process is completed, the iodized table salt is transported to the silos from where it is mechanically packed. The quality of the packaging is visually controlled by the immediate machine operators (dispersion, var, declaration, date of packaging), and during the packaging, the weight and visual control of the packaged product is carried out by the packaging controller, while the physico-chemical characteristics are monitored in the test laboratories.

DATA ON QUALITY			
No.	***Data***	***Quality conditions according to the rulebook***	***Analysis results***
1.	Content of pure NaCl on a dry basis	min. 97%	99,72
2.	Moisture content	max. 0.5%	0.03
3.	Foreign impurities visible to the naked eye	does not contain	No
4.	The smell	does not contain	No
5.	Color	White or slightly noticeable shade of another color	satisfies
6.	Mineral admixtures insoluble in hydrochloric acid	max. 0.05%	satisfies
7.	20% solution	Neutral to the litmus test	satisfies
8.	Contents of KJ or KJO3	Iodine mg/kg salt 15-23	19,04
9.	Granulation	min. 90% salt through a sieve with hole size 1.25 mm square	satisfies
10.	E - 536	max. 10 mg/kg	satisfies

According to the data presented in Table 5, the produced salt satisfies the quality and can be delivered to the final customer.

CONCLUSION

Based on the conducted analyses, following documentation and processes according to GFSI principles and in correlation with sustainable development standards, it is possible to conclude that Solana d.d. Tuzla adopted a business strategy that recognizes the necessity of adapting its business to the challenges posed by climate change and harmonizing with the global goals of sustainable development by 2030.

In the process of purifying raw salt water, the applied soda-soda process provides premium quality brine that allows the further flow of the process to take place without inconsistencies. The proportion of Ca^{+2} and Mg^{+2} is within the reference defined values, so that incrustations that affect the efficiency of the production process do not occur.

One of the critical control points is iodination. By meeting the iodine limits for exporting countries, Solana d.d. Tuzla represents a socially responsible company, because it markets a health-safe and safe product if we take into account that the state limits for all exporters range from 15 to 110 mgI/kg of salt. On the basis of the presented results in the part of the utilization of the mother liquor stream, it is clear that some basic requirements of the ESG strategy in the part of sustainable systems in the part of environmental protection are being respected.

This way of working, clear traceability in the process, utilization and use of own production process flows and returning to the system, it is possible that Solana d.d. Tuzla has competitiveness on the domestic and foreign markets and excellent business results, while at the same time respecting the social environment and the environmental component, striving to stop or minimize the harmful effects of its activities on the environment.

ABSTRACT

Food packaging material poly (ethylene terephthalate) (PET) is a polyester polymer that causes environmental pollution because it does not decompose for decades due to its inert and stable molecular structure. Synthesis of PET polymer with acid-end groups can help form a new material by allowing biodegradable polymers to be attached to this group. In this study, PET with acid-end group polymer was synthesized by esterification and polycondensation reactions by taking ethylene glycol (EG) and terephthalic acid (TPA) monomers in a 19:20 ratio and the obtained copolymer was characterized by Fourier Transform Infrared Spectroscopy (FTIR) and *Differential Scanning Calorimeters* (DSC). The FTIR spectrum displayed a prominent ester carbonyl (C=O) stretching peak at 1715 cm^{-1}. The melting temperature of the acid-end group PET copolymer was measured as 204.5 ºC and the melting enthalpy as 48.1 J/g. Based on the obtained results, PET polymer could be converted into a new generation polyester polymer with acid-end group.

Keywords: Food packaging material, poly (ethylene terephthalate), acid-end group, terephthalic acid, ethylene glycol

INTRODUCTION

Polyethylene terephthalate (PET) has become the ideal material for water and beverage bottles in the food industry and worldwide, with its unbreakable, lightweight and transparent properties, as well as its barrier properties against moisture and oxygen (Welle, 2011). PET production occurs in two different initial reactions: esterification of TPA and EG at temperatures between 240°C and 260°C and pressures between 300 and 500 kPa, and trans-esterification of dimethyl terephthalate (DMT) and EG at 150°C (Brydson, 1995). PET material is a thermally stable plastic material with good mechanical properties, chemical resistance, clarity, process ability and acceptability, as well as tensile and impact strength (Jankauskaite et al., 2008).

The world's plastic production, which was approximately 5 million tons/year in the 1950s, is now more than 280 million tons (Thompson et al., 2009; PlasticsEurope, 2011). Plastics and plastic waste, which are being monitored seriously today, have reached a point where they endanger marine biodiversity and the food chain, and therefore animal and human health (Thompson, 2015). Naturally microorganisms and genetically modified microorganisms may play a role in the degradation process of PET (Benavides et al., 2022).

PET's properties such as high crystallinity (30%-50%), high molecular weight, strong C-C bonds and hydrophobic surface are the main reasons for preventing biodegradation (Amobonye et al., 2021). The aromatic component of PET is important in its biodegradability and increases stability, chemical inertness and longevity (Yoshida et al., 2016). In the presence of microbial enzymes such as PET hydrolase, ester bond hydrolysis can break down PET into the simple form (Boneta et al., 2021; Gao et al., 2022). Additionally, some commercial lipases and esterases such as Rhizopus (Rh.) delemarlipase can hydrolyze some types of polyesters (Tokiwa et al., 1977) . The acid-end group PET polymer can be coupled to biodegradable polymers such as poly (ethylene glycol)(Güngör Ertuğral, 2016). In this study, acid-end group PET copolymer was obtained from EG and TPA monomers and characterized by FTIR and DSC.

MATERIAL AND METHOD

Preparation of acid-end group poly (ethylene terephthalate) copolymer

The esterification and polycondensation reactions of EG/TPA at the ratio of 19:20 were carried out in the acid-end group PET copolymer synthesis apparatus system and under nitrogen atmosphere with antimony trioxide (Sb_2O_3) as catalyst, respectively. The reaction was carried out in a four-necked flask placed in an oil bath and heated on the magnetic stirrer. In the first stage of the reaction, Sb_2O_3 was dissolved in EG and transferred to a four-necked flask and then TPA was added. The reaction was started at 60°C and the temperature of the mixture, which became homogeneous at 60 rpm at 30-50 psi pressure for 30 min, was increased to 160°C in 2.5 hours and then slowly to 280°C. Finally, a vacuum was applied to the system for 30 min. (Güngör Ertuğral, 2016).

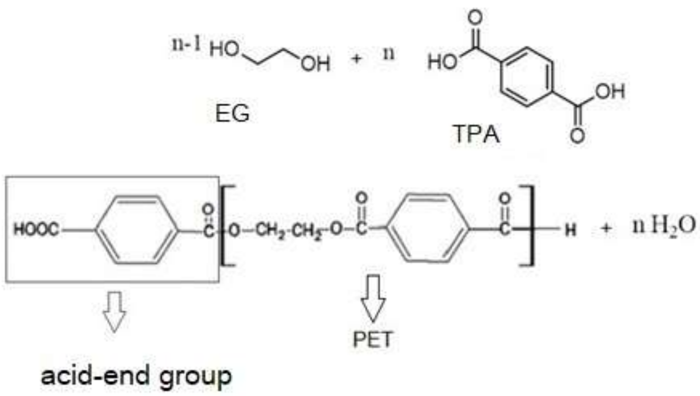

Figure1. Synthesis formula of acid-end group PET copolymer (Güngör Ertuğral, 2016).

DSC Analysis

Thermal properties of acid-end group PET were determined with a DSC Q2000 V24.11 Build 124 (TA Instruments, New Castle, Delaware, USA). 7 mg sample was prepared and heated and cooled at 5°C min-1 under nitrogen atmosphere between -28°C and 292°C (Chen et al., 2013; Sanchez-Silva et al., 2010).

FTIR Analysis

FTIR spectra were performed with a Perkin-Elmer FTIR Spectrum One B spectrometer (Waltham, Massachusetts, USA) and copolymer were recorded in transmission mode in a wavenumber range of 4000–600 cm^{-1} with a spectral resolution of 4 cm^{-1} (Chen et al., 2013; Khan et al., 2018).

RESULTS AND DISCUSSION

The obtained polymers were characterized by FTIR and DSC.

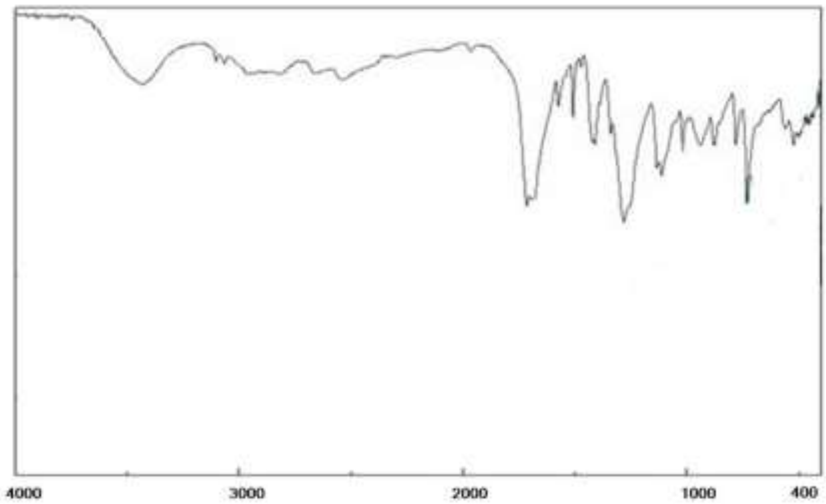

Figure1. FTIR spectrum of acid-end group PET

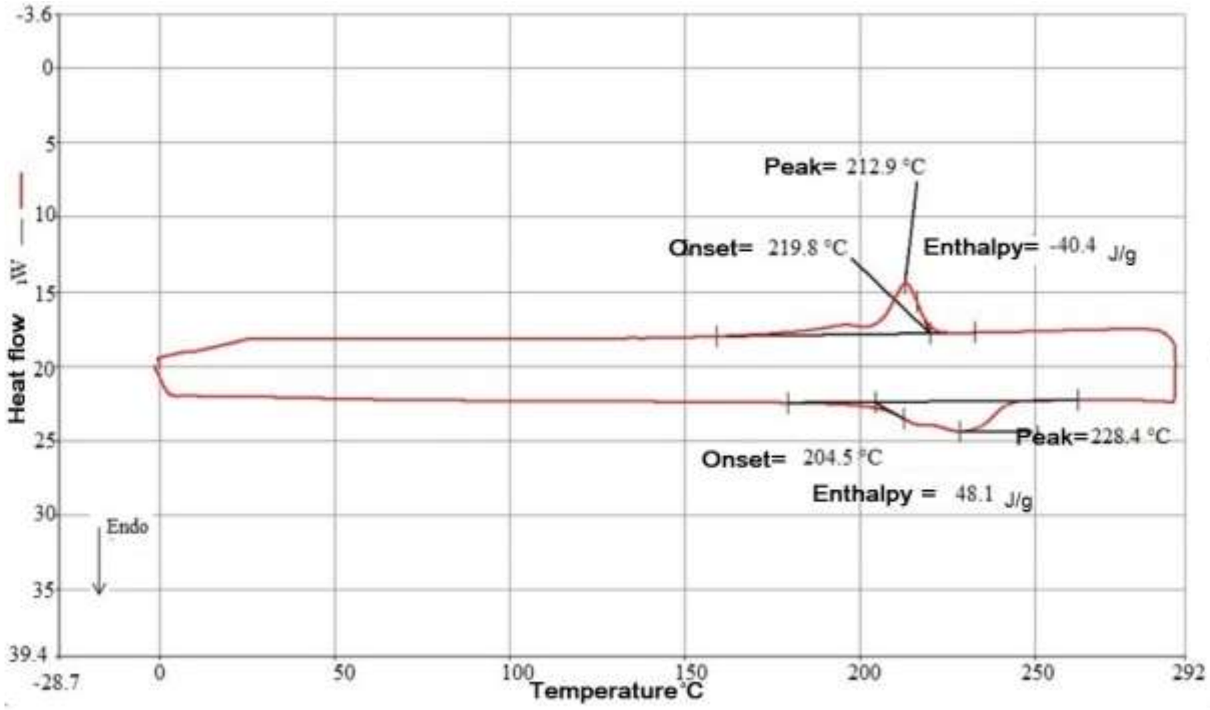

Figure 2. DSC curve of acid-end group PET

In the FTIR spectrum in Figure 1, a distinct ester carbonyl (C=O) stretching peak at 1715 cm^{-1} and a C-H stretching peak at 2870 cm^{-1} are clearly seen. According to the DSC curves in Figure 2, melting temperature of the acid-end group PET is 204.5°C and solidification temperature is 219.8°C, melting enthalpy is 48.1 J/g and solidification enthalpy is -40.4 J/g (Table 1).

Table1. Thermal properties of acid-end PET copolymers

Copolymer	Melting Temperature ºC	Melting Enthalpy(J/g)	Solidification Temperature ºC	Solidification Enthalpy(J/g)
Acid-end group PET	204.5	48.1	219.8	-40.4

CONCLUSIONS

In this study, acid-end group PET copolymer was successfully synthesized. The degradation of PET polyester polymer with its resistant molecular structure takes decades and causes serious environmental pollution. When biodegradable polymers are attached to the synthesized acid-terminated PET copolymer, new generation environmentally friendly materials can be obtained.

ABSTRACT

Pomegranate (Punica granatum L.) is a perennial plant belonging to the Punica genus of the Lythraceae family, with a cultivation history dating back to 3000 BCE. It is native to Iran and is known to grow in the Middle East, the Caucasus, and northern India, encompassing tropical and subtropical climates, including the southern and southeastern regions of Turkey. The pomegranate is consumed fresh but can also be processed into products such as juice, juice concentrate, jam, wine, and liqueur, and used as a coloring and flavoring agent in various foods. After processing, approximately half of the fruit is discarded as waste, consisting of pulp, rind, and seeds. It is known that production wastes are rich in phenolic compounds and dietary fiber. This study determined some physical and chemical properties of dietary supplements pressed using a single-punch tablet press machine with pomegranate juice production waste powders of three different particle sizes (<500, <710, <1000 µm) and three different ratios of binder (20%, 30%, 40% Polyethylene Glycol (PEG) 4000). The bulk densities of the powder mixtures ranged from 0.67 to 0.72 g/cm³, the tapped densities ranged from 0.78 to 0.86 g/cm³, Carr Index values ranged from 10.71 to 17.24, Hausner ratios were between 1.12 and 1.21, angle of repose ranged from 32.23° to 35.74°, flow rates were between 0.90 and 1.97 mm/s, and water absorption varied from 70.99% to 122.29%. The hardness of the dietary supplements (429 - 4849 g force) increased with the PEG 4000 ratio, with the highest hardness observed at 40% PEG 4000 and particle size of <710 µm. The friability of the tablets ranged from 0.45% to 2.76%, with the lowest friability (0.45%) observed at 40% PEG 4000 and <710 µm particle size, as expected with the highest hardness. Notably, under conditions of reduced PEG 4000 ratio and particle size (<500 µm), the lowest hardness and highest friability were observed. Considering the significant quality indicators of high hardness and low friability, it was concluded that the highest quality tablets were obtained using 40% PEG 4000 with pomegranate juice production waste powder particle size of <710 µm.

Keywords: pomegranate, waste, dietary supplement, tablet quality

INTRODUCTION

Today, nearly all process wastes are either destroyed or repurposed as fertilizer or animal feed. Among these, the waste generated from pomegranate juice production, which has limited economic value, constitutes a significant portion. Approximately 50% of the waste produced from pomegranate processing consists of peel, pulp, and seeds (Figure 1-3), with the peel accounting for 33-40% of the fruit's total weight, although this proportion can vary depending on the fruit variety (Topkaya, 2012). Recently, pomegranates have garnered considerable attention from researchers due to their high content of phenolic compounds. Consequently, there has been a growing interest in utilizing pomegranate peel in food applications, particularly as a functional ingredient due to its potential as a natural antioxidant.

Figure 1. Pomegranate

Figure 2. Pomegranate peels

Figure 3. Pomegranate juice pulp

It has been reported that wastes generated from pomegranate juice production possess higher antioxidant activity, phenolic components, and bioaccessibility compared to pomegranate fruit itself, making them suitable for use as functional ingredients in food supplements or food products (Surek and Nilüfer-Erdil, 2016). Specifically, pomegranate peel is characterized by a composition of 70% moisture, 4% protein, 31% sugar, 28% fiber, and 5% ash on a dry weight basis (Uca, 2019). Chemical composition of pomegranate peel constitutes carbohydrates (80,50–94,90 g/100 g DM (dry matter)), crude fibers (11,22–34,00 g/100 g DM), crude protein (1.30–8.72 g/100 g DM, crude fat (0,50-9,40 g/100 g DM), ash (3,0–5,00 g/100 g DM). Pomegranate peels are notably rich in secondary metabolites, particularly phenolic compounds such as phenolic acids, flavonoids, and hydrolyzable tannins. These include a variety of bioactive compounds like condensed tannins, ellagitannins, gallotannins, ellagic acid, gallic acid, anthocyanins, kaempferol, luteolin, and naringin (Kaderides et al. 2021, Uca, 2019). The peel is packed with vital minerals like potassium (K), calcium (Ca), phosphorus (P), and sodium (Na), along with notable levels of iron (Fe), zinc (Zn), copper (Cu), and selenium (Se). It is also good source of vitamins such as B1 (thiamine), B2 (riboflavin), C (l-ascorbic acid), E (α-tocopherol), and A (retinol) (Rowayshed et al., 2013). The concentrations and quantities of these compounds vary with fruit ripening, environmental conditions, and the pomegranate variety.

Modern medical research provides evidence supporting the potential use of pomegranates in treating a range of conditions, including cancer, cardiovascular disease, diabetes, Alzheimer's disease, infertility, arthritis, and obesity, as well as for protection against ultraviolet (UV) radiation. The health benefits are believed to arise from the synergistic interactions of various bioactive compounds present in pomegranates and their derivatives (Jurenka, 2008).

Food supplements encompass a variety of components including vitamins, minerals, amino acids, and herbal ingredients, all of which are intended to support an individual's dietary intake. These products often contain elements such as antioxidants derived from fruits and vegetables, fiber from grains, and proteins from dairy sources. While food supplements are not classified as pharmaceuticals, their appropriate use can contribute positively to health (Kazaz, 2020) and these supplements are formulated in various oral forms, including tablets, capsules, and liquids (Atalay and Erge, 2018). Specifically, tablets are produced by compressing homogeneous powder mixtures of active ingredients and excipients using specialized machinery. Tablets are the one of the mostly used pharmaceutical dosage form in the drug industry due to their advantages, including cost-effective mass production from solid active ingredients, ease of use, precise dosing accuracy, and flexibility in terms of shape, color, and flavor. They also offer long shelf life, ease of packaging, transport, and storage, with the possibility of modifying active ingredient release through diverse formulations and production techniques (Kumar et al., 2002).

This study aims to evaluate the feasibility of using pomegranate peel as a functional ingredient for food supplements by investigating its chemical composition and physical properties in tablet formulations. It focuses on optimizing the effects of Polyethylene Glycol (PEG) 4000 ratios and peel powder particle sizes on tablet quality, including bulk density, flowability, tablet hardness and friability. The findings will provide insights into sustainable use of pomegranate peel and its potential in developing antioxidant-rich supplements. The next part of the study can be to analyze the nutritional value of the tablets, emphasizing dietary fiber, phenolic content, antioxidant capacity, and bioacceptability.

MATERIAL and METHOD

Materials

The pomegranate juice by-products (peels) used in the study were obtained from Semes Gıda San ve Tic. Ltd. Şti, Izmir, Turkey immediately after pomegranate juice production.
,

Pomegranate Peel Powder Production

The pomegranate juice production by-products were dried at 40°C in a tray dryer (Figure 4), ground into powder, and sieved (Figure 5) to obtain particle sizes determined by preliminary trials (<500, <710, and <1000 µm). The resulting pomegranate peel powder, with a moisture content of 7,05%, ash content of 2,98%, dietary fiber content of 14,1%, and protein content of 3,52%, was stored at +4°C for physical and chemical analyses.

Figure 4. Dried pomegranate peels

Figure 5. Pomegranate peel powder

Directly Compressed Tablet Production

Polyethylene glycol 4000 (PEG 4000) was utilized as the binder in the formulation process. Based on preliminary trials, it was determined that PEG 4000 should be used in particle sizes smaller than 1000 µm for all samples. Additionally, pomegranate peel particles were categorized into three distinct sizes: <500 µm, <720 µm, and <1000 µm. The optimal PEG 4000 concentration was established at 20%, 30%, and 40% through preliminary testing.

The tableting process for the mixtures (PEG 4000 and pomegranate peel powder) was performed manually using the direct compression method with a single-punch tablet press machine (Renas Machinery, Istanbul), located in the Food Engineering Laboratory at Manisa Celal Bayar University (Figure 6). A minimum of 50 tablets were produced from each sample. Each tablet was manufactured to have a weight of 1,25 ± 0,05 g. Following production, the tablets were stored in airtight glass jars for subsequent analysis.

Figure 6. Single punch tablet press

Tablet (Mixture) Powder Analyses

Color

The CIE L* (lightness), a* (red/green), and b* (yellow/blue) values of the pomegranate peel powders were determined using a Konica Minolta CR5 Chromameter (Japan) with a D65 light source and a 100-degree measurement angle. Color analysis was conducted by measuring at five different points over three separate repetitions, and the results were averaged (Ho et al., 2013).

Bulk Density and Tapped Density

The bulk density was determined by transferring a known mass of pomegranate peel (average 2 grams) into a 10 mL graduated cylinder from a specific height and measuring the volume it occupied. The bulk density was then calculated by dividing the mass of the pomegranate peel by the volume it occupied. For the tapped density, a known mass of pomegranate peel (average 2 gr) was placed into a 10 mL graduated cylinder. The powder was compacted using a glass rod until the volume it occupied remained constant at a fixed time and speed. The minimum volume occupied by the powder was then measured. The tapped density and volume were calculated considering the weight of the powder (Jinapong et al., 2008).

Carr's Compressibility Index (Carr Index) and Hausner Ratio (HR)

The Carr's compressibility index and Hausner ratio are rapid, simple, and cost-effective indirect methods used to determine the flow properties of powder granules. In this study, the Carr Index and Hausner Ratio were calculated to assess the flowability and cohesiveness of the powder samples (Jinapong et al., 2008). The compressibility of the powder is significant in tablet production as it influences tablet thickness (Ofori-Kwakye et al. 2010).

Carr Index was calculated according to the equation below. CI% between 5-12% corresponds to perfect powder flow, whereas 13-16% indicates good powder flow properties. A Carr Index bigger than 36% represents a very poor flow ability of a powder (Gandhi, 2012).

CI%= [(powder volume before compression - compressed powder volume)/powder volume before compression)] x100

Hausner ratio (HR) was calculated according to the equation below. A Hausner ratio <1.25 indicates that powders have good flow properties, while a Hausner ratio >1.25 indicates that powders have poor flow properties (Gandhi, 2012).

HR= tapped density/bulk density (Jinapong et al., 2008).

Flow Rate and Angle of Repose

Powders of known weight were poured from a certain height with the help of a funnel. Flow time was measured with a stopwatch (mm/s). The analysis was repeated 10 times. Angle of repose was determined by flowing the powder granules down a funnel fixed at a height of 5 cm from the ground (so that the tip of the funnel was 5 cm). Angle of repose indicates the cohesive property of a powder, and there is an inverse relationship between the angle of repose and flowability. The angle of repose (θ) was calculated on the equation below by measuring the height (h) and radius (r) of the dust accumulation (Aslani and Daliri, 2016).

$\tan \theta = (h / r)$ where θ is the angle of repose, h is the height, r is the radius.

Moisture and Ash Content

Moisture content was determined in accordance with the AACC 44-15.02 method and calculated as the weight difference after drying/total peel powder *100. Ash and dietary fiber contents were determined according to the mehods AACC 08-01.01 and 32-05-01 (AACC 2010) and calculated as % dry matter.

Tablet Analyses

Diameter, Thickness, and Weight

The average diameter, thickness, and weight of the tablets were analyzed according to the method described by Bushra et al. (2008). Twenty randomly selected tablets were weighed using a precision scale to determine the average tablet weight. The thickness and diameter of the 20 tablets were measured with an electronic caliper, and the average tablet thickness and diameter were calculated. The resulting values are reported as the mean values in millimeters (mm).

Color

The CIE L* (lightness), a* (red/green), and b* (yellow/blue) values of the tablets were determined using a Konica Minolta CR5 Chromameter (Japan) with a D65 light source and a 100-degree measurement angle. Color analysis was performed by measuring at five different points across three separate repetitions, and the results were averaged (Ho et al., 2013).

Tablet Hardness and Friability

The hardness of the tablets was assessed using a Texture Analysis Device (TA-XT Plus Texture Analyzer, Stable Micro Systems, Godalming, England) with a 30 kg load cell. Tablets were placed in a vertical position under a 25 mm cylindrical probe and compressed at a rate of 0,03 mm/s over a distance of 1 mm. The maximum force at the point of tablet fracture (g force) was used to represent the tablet hardness. The analysis was conducted on 20 tablets to determine the average tablet hardness, with the values reported as the mean values in g force.

Friability in tablets can develop due to friction and mechanical impact. Friability is directly related to tablet hardness; increased hardness can reduce durability and increase wear. The analysis was conducted as a service provided by the Pharmaceutical Sciences Research Laboratory (FABAL) at the Faculty of Pharmacy, Ege University, following the method of (Osei-Yeboah and Sun, 2015).

RESULTS AND DISCUSSION

Moisture and Ash Content of Tablet Powders

After the pomegranate peel was dried and crushed into powder, chemical composition analysis revealed that the moisture content was 7,05%, the protein content was 3,52%, the ash content was 2,98% and the dietary fiber content was 14,1%. Kushwaha et al. (2013) determined the ash, protein, and crude fiber content of the pomegranate peel to be 5,49%, 3,95%, and 12,61%, respectively, which is in line with our findings, considering the differences in climate and soil conditions.

Table 1 presents the moisture and ash content of powders with varying PEG 4000 ratios and pomegranate peel particle sizes. High moisture content can affect the flowability and stickiness of a powdered product. The obtained tablet powders, with moisture levels between 4,43% and 7,37%, were found to be sufficiently dry. Increasing the ratio of PEG 4000 resulted in a lower moisture and ash contents in the powders. On the other hand, the moisture content reached its maximum at the largest peel powder particle size (hereafter referred to as "particle size").

Table 1. Effect of PEG 4000 ratio and pomegranate peel powder particle size on moisture, ash contents and color values of the tablet powder

Sample #	PEG ratio (%)	Peel powder particle size (µm)	Moisture (%)	Ash (%)	*L**	*a**	*b**
1	20	<500	6,57	3,15	57,21	12,16	25,87
2	30	<500	5,95	2,53	57,77	11,80	25,05
3	40	<500	4,82	2,03	58,74	11,49	24,62
4	20	<710	6,04	2,74	58,53	11,34	24,16
5	30	<710	5,38	2,49	58,21	10,29	21,93
6	40	<710	4,43	2,00	58,65	10,91	22,48
7	20	<1000	7,37	3,00	54,86	11,38	23,48
8	30	<1000	6,46	2,52	54,80	11,75	23,30
9	40	<1000	5,68	2,49	56,38	10,81	22,04

Color Values of Tablet Powders

The L^* (lightness) values of the samples ranged between 54.80 and 58.74. The lowest lightness values were observed for the samples having the pomegranate peel powders with the largest particle size (<1000 µm). The PEG ratio and particle size had no significant effect on the a^* and b^* color values (Table 1.)

Physical Properties of Tablet Powders

Determining the flowability and adhesion behavior of powdered products is important for processes such as packaging, processing, storage, dosing, and mixing. High moisture content affects the flowability of the powdered product. Additionally, products with a high degree of adhesion tend to experience flowability issues. The bulk and tapped density results provide important insights into the compressibility of powder mixtures during tablet production and also offer valuable information regarding the strength of the tablets. Therefore, it is expected that the tablet mixtures will have an adequate level of density.

The bulk and tapped density of the powder mixtures reached their highest values in tablet powders containing the smallest peel particle sizes (Table 2). A similar effect was observed by Zhong et al. (2016) in pomegranate peel powders ground and sieved into different sizes, where the bulk density ranged from 0.653 to 0.751 g/mL. Low molecular weight PEGs undergo greater densification and form compacts of low porosity which results in increased hardness (Larhrib et al., 1997). However, in this study PEG ratio did not pose a significant effect on the density of the tablets.

Table 2. Effect of PEG 4000 ratio and pomegranate peel powder particle size on the physical properties of the tablet powder.

Sample #	**PEG ratio (%)**	**Peel powder particle size (µm)**	**Bulk density (g/cm^3)**	**Tapped density (g/cm^3)**	**Carr index (CI%)**	**Hausner ratio (HR)**	**Angle of repose (θ)**	**Flow rate (mm/s)**
1	20	<500	0,70	0,81	13,79	1,16	32,91	1,75
2	30	<500	0,68	0,82	16,67	1,20	33,78	0,90
3	40	<500	0,71	0,86	17,24	1,21	34,12	1,29
4	20	<710	0,71	0,85	15,79	1,19	32,23	1,18
5	30	<710	0,70	0,81	13,79	1,16	33,41	1,87
6	40	<710	0,72	0,81	10,71	1,12	35,03	1,85
7	20	<1000	0,69	0,81	13,79	1,16	35,74	1,97
8	30	<1000	0,67	0,78	13,33	1,15	34,92	1,87
9	40	<1000	0,68	0,78	13,33	1,15	34,36	1,71

The Carr Index (CI%) indicates the flowability of the powder, while the Hausner Ratio provides information on the powder's cohesiveness, which in turn affects its flowability. A high cohesiveness in a powder typically implies poor flowability (Koç et al., 2011). Jinapong et al. (2008) stated that powders with a Carr Index below 15 have very good flowability, while those with a Carr Index between 15 and 20 have good flowability. The results obtained in this study indicate that the flowability of all pomegranate peel powders is classified as either good or very good. Powders with a Hausner Ratio below 1,2 are categorized as having low cohesiveness, those between 1,2 and 1,4 have moderate cohesiveness, and those above 1.4 are classified as having high cohesiveness. The cohesiveness values obtained in this study, except for sample 3, are below 1,2, indicating that the powders have low cohesiveness. As the particle size of the peel powder increased from 500 to 1000 µm, both the Carr Index and Hausner Ratio values decreased, and flow rate increased, indicating an improvement in flowability (Table 2). Similarly, Metiner et al. (2023) reported that pomegranate peel powders dried under different microwave powers and drying temperatures exhibited very good flowability and low cohesiveness.

Gandhi (2012) defined powder flowability as follows: excellent for powders with an angle of repose below 20º, good for those between 20º and 30º, fair for those between 30º and 40º, and poor for those above 40º. In our study, all samples were found to be flowable enough based on their angle of repose (34,055 º, in average).

Post-compression Properties of the Tablets

Weight, Diameter, and Thickness of the Tablets

In the production (compression), the tablets were adjusted to a weight of 1.25 ± 0.05 g, and it was verified that their weights fell within this range (Table 3). The diameters of the tablets ranged from 13.32 to 13.47 mm, and their thicknesses varied from 8.66 to 8.90 mm. Overall, there appears to be no significant effect of PEG ratio or pomegranate peel particle size on the thickness of the tablets.

Hardness and Friability of the Tablets

Table 3 displays the hardness and friability of the direct compression tablets. Tablet hardness is a parameter that varies depending on the characteristics of the final powder and the compression force of the tablet press (Canbağı et al., 2016). It provides information about the tablet's durability and significantly affects the tablet's disintegration time and, consequently, the dissolution rate of the active ingredient. Tablet friability is the tendency of a tablet to lose component particles due to abrasion, friction, or mechanical shock. Ideally, ≤1% weight loss is acceptable for an existing compressed and uncoated tablet product (Osei-Yeboah and Sun, 2015). Friability also provides information about the tablets' durability under conditions such as handling, storage, and transport.

An increase in the PEG 4000 ratio resulted in greater tablet hardness and reduced friability. The results of the study indicate that the tablets with suitable friability values (that is ≤1%) are those with sample codes 5, 6, and 9. None of the samples with pomegranate peel particle sizes of 500 µm or less, and those with a PEG 4000 ratio of 20%, had an accepted friability value. Therefore, it was determined that a PEG 4000 ratio of 40% or higher was appropriate for pomegranate peel powder tablets, with particle sizes below 710 µm and 1000 µm, including medium and large particles.

Tablets with these characteristics not only exhibit physical durability but also have the potential to be dietary supplements due to their content of dietary fiber, total phenolic compounds, and high antioxidant capacity.

Table 3. Effect of PEG 4000 ratio and pomegranate peel powder particle size on the post-compression properties of the tablets.

Sample #	PEG ratio (%)	Peel powder particle size (µm)	Weight (g)	Diameter (mm)	Thickness (mm)	Hardness (g force)	Friability (%)
1	20	<500	1,22	13,47	8,89	429	2,76
2	30	<500	1,27	13,45	8,78	1490	1,47
3	40	<500	1,27	13,38	8,66	2941	1,15
4	20	<710	1,29	13,44	8,85	1386	1,45
5	30	<710	1,30	13,39	8,79	3169	0,68
6	40	<710	1,30	13,35	8,83	4849	0,45
7	20	<1000	1,29	13,43	8,89	2111	1,12
8	30	<1000	1,29	13,37	8,90	2919	1,10
9	40	<1000	1,26	13,32	8,69	4140	0,50

Color Values of Tablets

Table 4. documented the impact of PEG 4000 ratio and pomegranate peel particle size on the color values of the tablets. The results were consistent with those of the powder mixtures. As the tablets were manufactured by compressing the powder mixtures, similar outcomes were anticipated.

Table 4. Effect of PEG 4000 ratio and pomegranate peel powder particle size on the color of the tablets.

Sample #	PEG ratio (%)	Peel powder particle size (µm)	***L****	***a****	***b****
1	20	<500	57,10	12,43	25,76
2	30	<500	57,46	11,98	25,14
3	40	<500	58,55	11,54	24,54
4	20	<710	58,24	11,76	24,23
5	30	<710	58,78	10,43	21,88
6	40	<710	58,74	10,76	22,56
7	20	<1000	54,65	11,43	23,65
8	30	<1000	54,90	11,76	23,21
9	40	<1000	56,45	10,76	22,12

CONCLUSIONS

In conclusion, this study identified the potential use of pomegranate peel powder in the dietary supplement sector and established that the binder ratio and pomegranate peel particle size are significant factors in the production of dietary supplements. Powder blends of pomegranate peel powder and polyethylene glycol 4000 (PEG 4000) with low moisture content, good flowability, and low cohesiveness were successfully produced for tablet manufacturing. Considering the significant quality indicators like hardness and friability, it was concluded that the highest quality tablets were obtained using 40% PEG 4000 with pomegranate peel powder particle size of <710 µm. The findings will provide insights into sustainable use of pomegranate peel and its potential in developing antioxidant-rich supplements. The next part of the study can be to analyze the nutritional value of the tablets, emphasizing dietary fiber, phenolic content, antioxidant capacity, and bioacceptability of vitamins and other bioactive compounds.

ABSTRACT

The brown peach aphid *Pterochloroides persicae* distributes in Southern Europe, North Africa, Southwest and Central Asia, Indonesia, Türkiye, India, and Pakistan. This aphid species cause serious damage to *Prunus* members (*Prunus persica, P. dulcis, P. domestica, P. armeniaca, P. salicina*). Although they show both holocyclic and anholocyclic life cycles, this species shows monoecious holocyclic life cycles in cooler climates. In recent years, it gradually widened its geographic distribution and prompted more financial destruction, becoming an important threat to peach and almond trees. So far, there is no study has been conducted in Türkiye with *P. persicae* related to its host plant preference or agricultural importance. The speciation process of *P.persicae* populations might occur based on their host plant preferences. In this context, this study aimed to find out morphometric variations of *P.persicae* depending on host plant usage. The study was conducted in Adıyaman, Malatya, Şanlıurfa, Afyonkarahisar, Kütahya, Uşak, Antalya, Muğla, Karaman, Erzurum, and Nigde provinces, and the samples collected from *Prunus* spp. The 25 morphometric characters were evaluated for statistical analyses from 228 aptera individuals of *P. persicae*. As a result of the study, 23 morphometric characters. It was determined that host plant preference plays an important role in morphological variations observed in *Pterochloroides persicae* populations.

Keywords: Morphological variation, *Prunus* spp, *Pterochloroides persicae*, Türkiye

INTRODUCTION

Aphids are obligate phytophagous insects that feed on plant sap. They have economic importance in terms of direct damage to the plant and indirectly as carriers of various plant viruses. Therefore, aphids are closely related to the host plant (Blackman and Eastop, 2023). Aphids show a great deal of phenotypic plasticity. Phenotypic plasticity has been shown to be very important for aphids to adapt to new host plants, to bring about new reproductive strategies and especially in the speciation of aphids (Görür, 2005). In aphids, the state of physiological and morphological characteristics of the host species, its locality, the effects of biotic and abiotic conditions may cause morphological differences in the same species. Studies have shown that aphids can show differences in morphological characters to adapt to environmental conditions (Hales et al., 2010; Siddiqui et al. 2019; Nibouche et al., 2021).

Brown peach aphid *Pterochloroides persicae* is a pest of *Prunus* spp. Although they show both holocyclic and anholocyclic life cycles depending on environmental conditions, this species shows monoecious holocyclic life cycles in colder climates (Talhouk, 1977; Blackman and Eastop, 2023). It is distributed in southern Europe, North Africa, south-west and central Asia, India, Pakistan and Indonesia and has recently increased its distribution and has become a significant threat to peach and almond trees in Romania and Tunisia (Blackman and Eastop, 2023). *P. persicae* has caused weakening of young fruit trees, drying of branches, reduction in yield and mould formation due to honeydew (Cross and Poswal, 1996; Moya, 2014; Mdellel, 2015). In addition, biotic and abiotic factors have caused changes in the growth and development period of *P. persicae* (Müller et al. 2001; Mdellel et al. 2011). The effect of host plant on the morphology of *P. persicae* has been reported in studies (Mdellel and Kamel, 2015; Mdellel et al, 2011).

In this study, it was aimed to reveal possible morphological differences due to different host preferences of *Pterochloroides persicae* feeding on *Prunus* spp. (*P. persica, P. dulcis, P. domestica, P. armeniaca, P. salicina).*

MATERIAL AND METHOD

Samples of *Pterochloroides persicae* preferring *Prunus persica, P. dulcis, P. domestica, P. armeniaca* and *P. salicina* host plants distributed in Adıyaman, Malatya, Şanlıurfa, Afyonkarahisar, Kütahya, Uşak, Antalya, Muğla, Karaman, Erzurum and Niğde provinces were performed. The samples were taken in eppendorf tubes containing 96 % ethyl alcohol and then prepared according to Martin (1983). After, the identification of the specimens was made according to the identification keys offered by Blackman and Eastop, 2023. Morphometric measurements of 3-4 wingless adult individuals suitable for morphometric analysis from each of the colonies in 5 different host plants were made under OLYMPUS BX51 brand microscope. Measurements of 25 morphological characters belonging to a total of 228 individuals were carried out. Measured characters are;

Body Length (BL), Body Width (BW), Total Antenna Length (AL), Antenna 1st segment length (A1L), Antenna 2 st segment length (A2L), Antenna 3 st segment length (A3L), Antenna 4 st segment length (A4L), Antenna 5 st segment length (A5L), Length of the 6 st Antenna Segment Processus Terminalis (A6PT), Length of the 6 st Antennal Segment Base (A6BASE), Length of segments IV and V of the rostrum (URSL), Rostrum segment IV width (URSW), Cauda length (CL), Caud Width (CW), Diameter of Siphunculi (SIP BD), Hind tarsus I. segment length (HTI), Hind tarsus II. segment length (HTII), Hind Femur Length (HFL), Hind Femur Width (HFW), Fore Femur Length (FFL), Fore Femur Width (FFW), Hind Tibia Length (HTL), Longest hair length of antennal 3 st segment (A3HL), Antenna 5 primary rhinaria width (A5RW), Antenna 6 primary rhinaria width (A6RW)

Canonical Analysis of Variance (CVA) was performed to determine the principal components of variation in morphological data. One-way Analysis of Variance (ANOVA) and Multiple Comparison Analysis (Tukey-HSD Test) were evaluated to determine the possible effects of the host plant on the morphological characteristics of *Pterochloroides persicae* members. SPSS ver 26.0 package programme was used for statistical analyses.

RESULTS AND DISCUSSION

Measurements of 25 morphological characters of 228 individuals of *Pterochloroides persicae* collected from 5 different host plants (*Prunus persica, P. dulcis, P. domestica, P. armeniaca, P. salicina*) were carried out.

Morphometric variations depending on the host plant

As a result of the evaluation of the obtained morphological characters, it was determined that the measured characters of the population sampled in the *Prunus armeniaca* host were shorter than other populations characters. These variations among *P. persicae* populations were tested by applying One-Way Analysis of Variance (ANOVA). In 22 of the 25 characters measured, it was observed that the host plant caused statistically significant differences on *P. persicae* populations (Table 1).

Following the differences detected by applying ANOVA, Multiple Comparison Analysis (Tukey-HSD test) was performed. Especially, morphological features of the *Pterochloroides persicae* population collected on *Prunus armeniaca* differed from other populations. In addition to the overall differences in BL, there are also differences between *P. armeniaca* and *P. dulcis* (Tukey HSD[37.72]=-0.34, P=0.010), differences in BW between *P. armeniaca* and *P. domestica* populations (Tukey HSD[37.72]=-0.25, P=0.023), differences in AL between *P. armeniaca* and *P. salicina* (Tukey HSD[35.91]=-0,11, P=0.008) respectively. Moreover, there are differences in HTI between *P. armeniaca* and *P. dulcis* populations (Tukey HSD[34.63]=-0,00, P=0.001) and differences in HFL between *P. armeniaca* and *P. persica* (Tukey HSD[35.67]=-0,14, P=0.007). Furthermore, Canonical Vector obtained according to Wilk's lambda analysis is significant with P=0.00 and P=0.11 values and Function 1 (CV1) accounts for 39.5% of the variances; Function 2 (CV2) explains 35% of variances indicating strong host plant effects on morphological features of the *P. persicae* populations. Standardised Canonical Analysis of Variance (CVA) was also performed to determine the relative significance of the characters used to separate the populations related with host plant usage. According to Canonical Vector 1 (CV1), the highest values belong to HFL (1,381), FFL (0,988), HFW (0,842); according to Canonical Vector 2 (CV2), the highest values belong to AL (1,058), A3L (0,604) and A5L (0,689).

The host plant influences on the morphometric characters was given graphically by discriminant function analysis. It was observed that *P. persisae* populations differed in morphometric characters depending on host plant preference, especially *P. armeniaca* clearly separated from others (Figure 1).

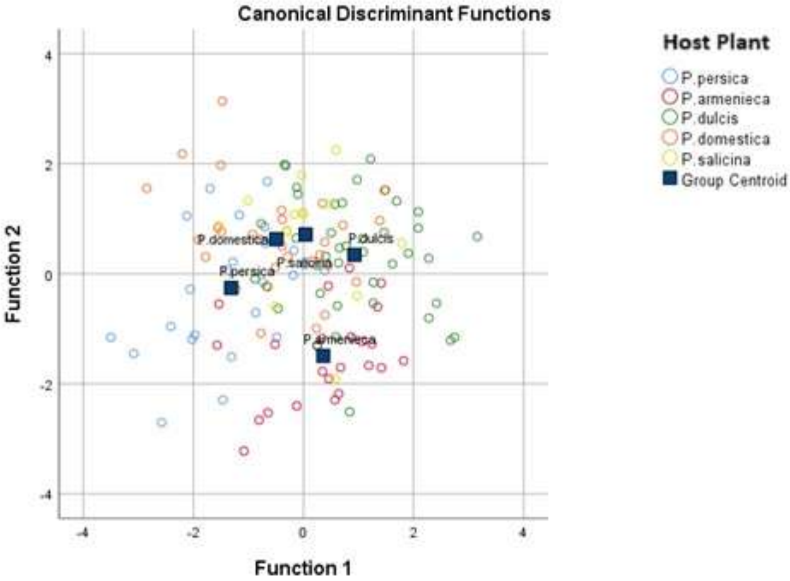

Figure 1. Classification of *Pterochloroides persicae* populations according to canonical discriminant function depending on host plant

CONCLUSIONS

In this study, *Pterochloroides persicae* populations feeding on 5 different host plants (*P. persica, P. armeniaca, P. dulcis, P. domestica, P. salicina*) were evaluated to reveal morphometric variations related with the host plant utilization. According to the results of ANOVA analyses, there are significant differences in 23 morphometric characters of the P. persicae populations sampled from 5 different host plants, *Prunus* spp. Hind femur length, total antenna length, fore femur length, hind femur width, antenna 3 and 5 length were the most differentiated characters in the differentiation of *P. persicae* populations on *Prunus* spp. Among 23 measured characters, 9 of the morphometric characters were incorporated for the first time when comparing *P. persicae* populations collected from different host plants. Findings of the presented study shown similar host plant effects with the previous studies. Adouani et al. (2021) measured 16 morphometric characters and among these characters, body length, body width, total antennal length, hind femur length showed a significant difference. Mdellel and Kamel (2015), 13 morphological characters were determined by ANOVA. Among them, there were significant differences in the length of antenna segments I, IV and V, body length and siphunculi diameter. Mdellel and Kamel (2015a), measured 12 morphometric characters and showed differences in 1 antennal segment, body length and cauda length. The host plant appears to play an effective role in the morphology of the *P. persicae* population. This study is the first morphometric study on *P. persicae* populations, which is one of the important agricultural pests in Türkiye.

ABSTRACT

Aeromonas hydrophila is an important fish pathogen and causes serious economic losses especially in freshwater and brackish water under culture conditions. The aim of the present study was to determine the antibacterial effect of astaxanthin on the strains of *A. hydrophila*. The MIC values of astaxanthin were compared using different solvents. These included ethanol, water, and 2-propanol. Sick rainbow trout (*Oncorhynchus mykiss*) samples used in the study were obtained from a commercial trout farm. Body weights of the fish varied between 56 g and 225 g. After external findings observed in the fish were recorded, necropsy was performed on the fish and the findings detected in the internal organs were recorded. For bacteriological studies, liver, spleen, and kidney were inoculated onto petri dishes containing Brain Heart Infusion Agar (BHIA). After 72 h of incubation at 24 ± 2 °C, subcultures were made from the bacterial colonies that grown in the dishes. According to the morphological, physiological, and biochemical test results and API 20E rapid diagnostic kit results, 6 strains were identified as *A. hydrophila*. In the study, the commercial form of astaxanthin was used for the determination of its antibacterial effect. For this purpose, astaxanthin solutions were prepared using water, ethanol, and 2-propanol. The value at which bacterial growth was not observed was evaluated as Minimal Inhibition Concentration (MIC). According to the results of the study, it was determined that the solution of astaxanthin prepared with 2-propanol was effective on *A. hydrophila*, while the solution prepared with water did not have effective.

INTRODUCTION

Aquaculture is on a continuous growth trend worldwide to fulfil the global for edible fish. This growth can cause fish to be kept in intensive production, resulting in severe stress that can adversely affect the development, growth, and immune systems of fish, and subsequently various disease outbreaks (Korni and Khalil, 2017, Preena et al., 2021). Bacterial diseases, which are among the infectious diseases, cause low growth rate, low meat quality, morbidity/mortality, and reduce fish production.This situation results in a decrease in the profit, margins of fish farms and as a result, significant economic loss for aquaculture sector (Jeeva et al., 2013, Salem et al., 2020, Yassen et al., 2022).

Motile *Aeromonas* septicemia (MAS) is a bacterial infection caused by certain species of the genus *Aeromonas*, mainly *Aeromonas hydrophila* (Preena et al., 2021, Yassen et al., 2022). The disease is commonly observed in fish species and can result in high mortality rates (Korni and Khalil, 2017, Abraham and Bardhan, 2019). Fish species affected by MAS include edible fish such as Nile tilapia (*Oreochromis niloticus*), rainbow trout (*Oncorhynchus mykiss*), common carp (*Cyprinus carpio*) and channel catfish (*Ictalurus punctatus*) (Ashraf et al., 2018, Cao et al., 2020, Dien et al., 2023) and ornamental fish species such as guppy (*Poecilia reticulata*), zebrafish (*Danio rerio*), and goldfish (*Carassius auratus*) (Perreta et al., 2018; Hossain et al., 2019, 2020). Clinical signs associated with *Aeromonas* infections include exophthalmos, hemorrhage, ulceration, fin rot, lethargy, scale loss, skin discoloration, and hemorrhagic/necrotic viscera. In some cases, acute mortality has been observed, with fish dying rapidly before developing symptoms of the disease (Kumar et al., 2016, Azzam-Sayati et al., 2021).

Antibiotic treatment is used in human medicine as well as in the treatment and control of bacterial infections (Stratev and Odeyemi, 2017). With the expansion of aquaculture worldwide, the use of antibiotics for the treatment of bacterial infections as well as the use of antibiotics for prophylactic purposes has increased (Stratev and Odeyemi, 2017, Scarano et al., 2018). The Multiple Antibiotic Resistance (MAR) has been reported in *A. hydrophila* strains (Le et al., 2018). This resistance can be attributed to the misuse and overuse of antibiotics and to the genetic adaptability of *A. hydrophila* (Hossain and Heo, 2020) and occurs through conjugation, mutation, or horizontal gene transfer in the natural environment (Watts et al., 2017). Indeed, antimicrobial resistance in *A. hydrophila* is often mediated by genes on the bacterial chromosome, plasmids or integrons that confer resistance to most beta-lactam antimicrobials (Abdulhasan et al., 2019). The emergence of antimicrobial resistance in *A. hydrophila* poses a significant challenge to the effective treatment of infections caused by this bacterium. This situation also highlights the need for responsible use of antibiotics and non-antibiotic infection control measures to prevent the further spread of drug-resistant strains (Stratev and Odeyemi, 2017). Therefore, alternative methods have been developed to prevent and/or treat *A. hydrophila* infections. These methods include probiotics, vaccination, and phytobiotics (Stratev and Odeyemi, 2017).

Astaxanthin (3,3´-dihydroxy-β, β-carotone-4, 4´-dione) was discovered in 1970 by the English chemist Professor Basil Churles Weeden. Astaxanthin is a naturally occurring carotenoid found in marine organisms such as microalgae, salmon, trout, krill, shrimp, crabs, and crustaceans. The green microalgae, *Haematococcus pluvialis* is a rich source of astaxanthin. *Chlorella zofingiensis*, *Chlolococcum* spp. and other microalgae such as *Botryococcus braunii* contain astaxanthin (Köksal, 2008). Carotenoids are a class of bioactive natural products synthesized exclusively by plants, phytoplankton, algae, bacteria, and some fungal species (Lim et al., 2018, Brotosudarma et al., 2020). Due to factors such as the high chemical diversity of carotenoids and the host protection of some carotenoids from oxidation and related damage, scientific and commercial interest in carotenoids has increased in recent years (Galasso et al., 2018, Brotosudarma et al., 2020).

Astaxanthin is the most important carotenoid used in aquaculture (Lim et al., 2018). This important carotenoid pigment is used to make rainbow trout and salmon flesh more reddish (Lim et al., 2018). Other effects of astaxanthin that make it important aquaculture are that it is a growth promoter and can increase the survival rate and antioxidant capacity of fish (Saleh et al., 2018). Saleh et al. (2018) found an increase in some immune parameters as well as a decrease in the effects of stress factors in sea bass (*Dicentrarchus labrax*) fed with astaxanthin-supplemented diets. Tizkar et al. (2015) reported an increase in sperm concentration in goldfish (*C. auratus*) fed with 150 mg/kg astaxanthin-supplemented diets.

The aim of this study was to determine the antibacterial effects of astaxanthin, used in the coloring of rainbow trout carcasses in Türkiye, on *A. hydrophila* strains. The MIC values of astaxanthin using different solvents including ethanol, water, and 2-propanol were compared.

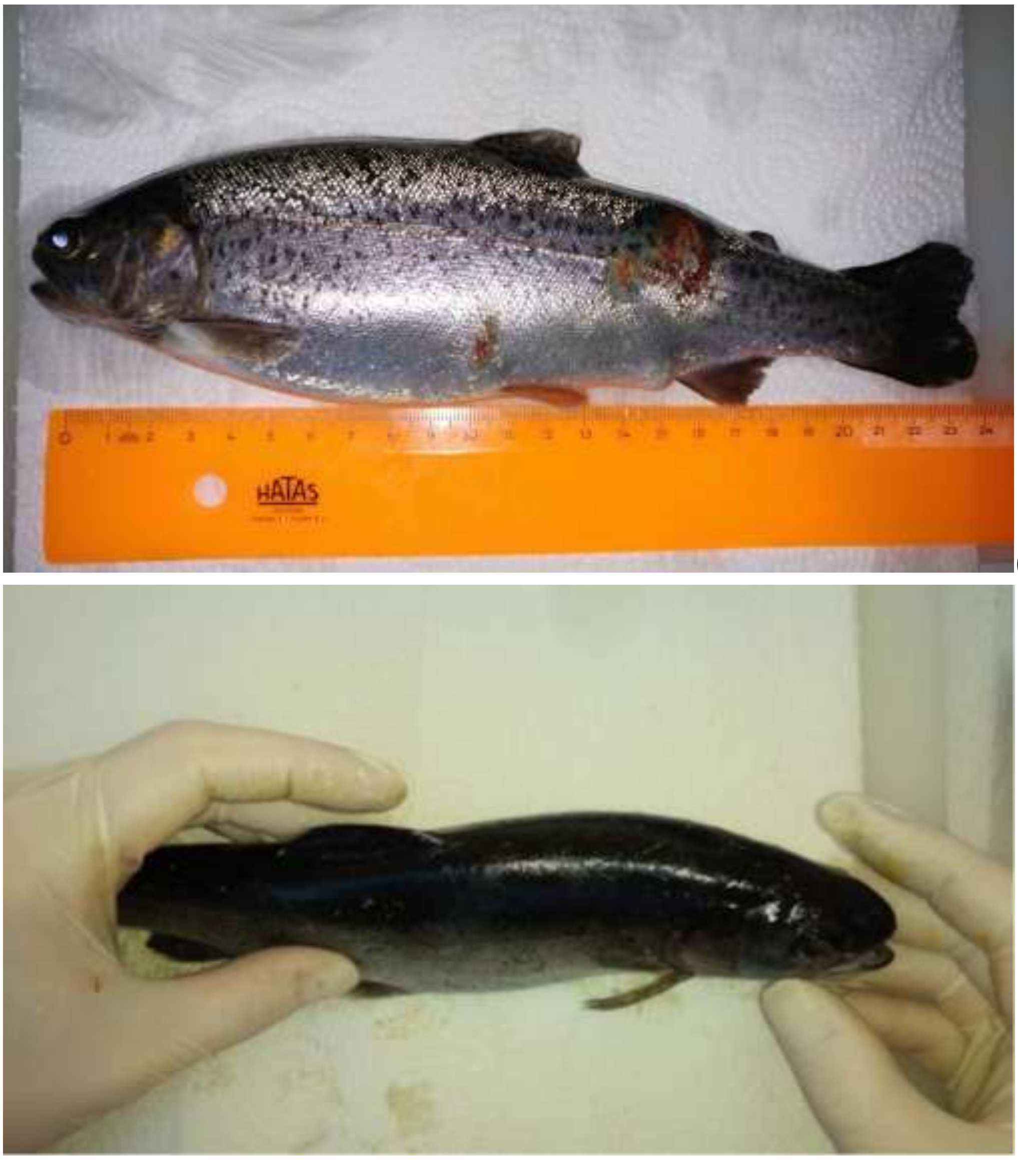
MATERIAL AND METHOD

The diseased fish samples (from 56 to 225 g) used in the study were obtained from commercial trout farms in Antalya (Türkiye) and necropsy was performed on the fish. Samples of liver, spleen, and kidney from the fish were inoculated on Brain Heart Infusion Agar (BHIA) for bacteriological analysis. All plates were incubated at 24 ± 2 °C for 72 h (Austin and Austin, 2012). The necessary permissions were obtained from the local ethics committee for animal experiments of Akdeniz University (744/2018.03.003). After the incubation period at 24 ± 2 °C for 72 h, the morphology and color of the bacterial colonies on BHIA plates were examined and then subcultures of the isolates were made. A series of physiological and biochemical tests including cytochrome oxidase, catalase, O/F (Leifson) fermentation, H_2S production, growth at different temperature degrees, growth in different salt concentrations, methyl red and Voges-Proskauer (VP), indole production citrate utilization, starch hydrolysis, NO_2 production, acid production from sugars and growth on MacConkey agar (Austin and Austin, 2012). The API 20E kit (BioMerieux, France) was also used for the identification of strains isolated from diseased fish. The kit was prepared according to the manufacturer's instructions and it was incubated at 24 ± 2 °C for 24-48 h. At the end of the incubation period, the reagents were added to the kit and the results were read using the APIWEB identification software.

The antibacterial effects of astaxanthin were determined by using the macro dilution method. For this purpose, solutions of astaxanthin were prepared with ethanol, water, and 2-propanol. Commercial astaxanthin powders (Roche) of 1 mg, 0.5 mg, and 0.1 mg were used in the study. For 1 mg/ml stock solution, 10 mg of astaxanthin was dissolved in 10 ml of ethanol, water, and 2-propanol. For 0.5 mg/ml stock solution, 10 mg astaxanthin was dissolved in 20 ml ethanol, water, and 2-propanol. For 0.1 mg/ml stock solution, 10 mg astaxanthin was dissolved in 100 ml of ethanol, water, and 2-porpanol (Erdağlı, 2011). The stock solutions were sterilized before use by means of 0.2 µm disposable membrane filters. Then 1 ml of cation-adjusted Mueller-Hinton broth (CMHB) (CLSI, 2006) was added to each tube. Starting from the first tube, twofold dilutions were made, and the inoculated tubes were incubated at 24 ± 2 °C for 16-24 h. At the end of the incubation period, it was determined from which tube bacterial growth started and the micro values of astaxanthin were determined in terms of % concentrations. The lowest concentration at which turbidity was not observed was taken as the minimum inhibitory concentration (MIC) for that strain. The inoculated bacterial solution was used as control.

RESULTS AND DISCUSSION

In the study, behavioral findings such as lethargy, swimming near to the water surface, loss of appetite, and reduced feed intake were detected in sick fish. Exophthalmos, abdominal dropsy, loss of scales, and skin lesions (Figure 1a), darkening of skin color (Figure 1b), paleness of gills, adhesion and melting at the ends of gill filaments, hemorrhages under the jaw and on the fins were observed.



(a)

(b)

Figure 1. (a) Abdominal dropsy, loss of scales and skin lesions caused by *Aeromonas hydrophila* (b) Darkening of the skin in sick fish

At necropsy, hemorrhage in the mouth and muscle tissue, pyloric seka, paleness of the liver (Figure 2), swelling and hemorrhage in the air bladder, splenomegaly and melting of the kidneys were detected.

Figure 2. Paleness of the liver, hemorrhages in pyloric seka and muscle in sick fish

Fish infected with *A. hydrophila* may show symptoms of loss of appetite, pallor of the gills and skin ulcers. Gills, kidney, liver, spleen, pancreas, and skeletal muscle are among the organs frequently affected by the disease (Swam and White, 2014). The findings observed in the disease depend on the virulence of the bacterium, the resistance of the fish to infection, the presence or absence of bacteremia or septicemia and other stress factors related to fish (Swan and White, 2014). Wamala et al. (2018) reported that *A. hydrophila* isolated from Nile tilapia (*O. niloticus*) and African catfish (*Clarias gariepinus*) caused hemorrhages and ulcers on the skin, exophthalmos, swollen abdomen, and acidic fluid accumulation in the abdomen. In addition, fin rot was observed in tilapia, while mortalities were observed in both species. Laith and Najiah (2013) informed lethargy, shallow hemorrhagic ulcers as well as deep ulcers exposing muscle tissue in *C. gariepinus* naturally infected with *A. hydrophila*. In some fish, hemorrhages were observed at the base of the fins and in the anus. At necropsy, pale liver and gills enlarged kidney and accumulation of yellowish fluid in the body cavity was also detected. Timur et al. (2010) reported that *A. hydrophila* was isolated from young Russian sturgeon (*Acipenser gueldenstaedtii*) cultured in concrete ponds in 2002-2003 as a single causative species or as a mixed infection with *Flavobacterium hydatis* and reported that these disease agents caused bacterial hemorrhagic septicemia in fish, resulting in low mortality. In the present study, lethargy, decreased feed intake, swimming near to the water surface, darkening of the skin color, exophthalmos, abdominal dropsy, pallor of the gills, skin lesions and loss of scales in sick fish were observed and these findings were like the other researchers' findings (Timur et al., 2010; Laith and Najiah, 2014; Wamala et al., 2018).

As a result of bacteriological studies, cream-colored, motile, fermentative, cytochrome oxidase and catalase positive, rod-shaped six bacterial strains were isolated from the liver, spleen, and kidney of the sick fish. The strains were indole-producing, arginine dihydrolase positive and hydrolyzed starch. The strains grew on MacConkey agar. The biochemical properties of the strains are given in Table 1.

Table 1. Biochemical test results of *A. hydrophila* strains

Tests	Strains (N=6 strains)	Abbott et al., (2003) (N=25 strains)
Motility	+	+
Cytochrome oxidase	+	+
Catalase	+	+
Indole	+	96% positive

MOB	Motility	+
McC	Mac Conkey medium growth	+
OF-F	Fermentation	+
OF-O	Oxidation	+

+: positive, -: negative

Nahar et al. (2016) used API 20E rapid diagnostic kit to identify 10 *A. hydrophila* strains isolated in their study. The researchers reported that the strains reacted positively to beta-galactosidase, arginine dihydrolase, lysine decarboxylase, sodium citrate, urea, tryptophan deaminase, sodium pyruvate, gelatinase, glucose, mannitol, sucrose, melibiose, amygdalin, and arabinose. However, the test results of ornithine decarboxylase, sorbitol, and rhamnose were negative. The *A. hydrophila* isolated in our study were found to be positive for beta-galactosidase, arginine dihydrolase, glucose, mannitol, amygdalin in the API 20E kit, but urea production, arabinose, and TDA results were found to be different from the results reported by Nahar et al. (2016). In the present study, ornithine decarboxylase, sorbitol, and rhamnose test results of the strains were found to be as negative. These results agreed with the results reported by Nahar et al. (2016).

MIC values were determined using solutions of astaxanthin prepared with different solvents. It was determined that astaxanthin did not have antibacterial activity against *A. hydrophila* when water was used as solvent. However, the solution prepared with 2-propanol was more antibacterial activity than the solution prepared with ethanol. Also, 7.8125 µg/ml, 15.625 µg/ml and 31.25 µg/ml concentrations of ethanol did not have antibacterial effect on the strains. It was determined that there was not bacterial growth at concentrations ranging from 62.5 µg/ml to 500 µg/ml. In the study, it was found that 2-propanol was not effective on strains at 7.8125 µg/ml, while it was effective at 62.5 µg/ml and 500 µg/ml.

Poor water quality, inadequate feed, and a suppressed immune system contribute to infection by opportunistic fish pathogens such as *A. hydrophila* and antimicrobials are often used to treat and control bacterial diseases (Mahanty et al., 2013). However, antimicrobials used to treat bacterial fish diseases may result in the emergence of drug resistance bacterial strains (Harikrishnan and Balasundaran, 2005). This situation has led researchers to search for alternatives to antibiotics. These alternatives include prebiotics, probiotics as well as the use of medical and local plants (Bhuvaneswari and Balasundaram, 2006; Tareq et al., 2014). In the present study, solutions of astaxanthin prepared with different solvents were used on *A. hydrophila* strains isolated from sick rainbow trout. According to the test results, it was found that water was not effective, but 2-propanol was effective.

CONCLUSIONS

Aeromonas hydrophila is one of the most important bacterial infectious agents affecting the aquaculture of marine, ornamental, and freshwater including rainbow trout. Until today, antimicrobial drugs have been used in the treatment of bacterial fish diseases. Intensive and random use of drugs may lead to the development of resistance to these drugs in bacterial species. For this reason, the research and use of alternatives to antimicrobial agents, especially antibiotics, has come to the spotlight. Today, more than one study is being carried out on this subject and solutions are being tried. Astaxanthin is known to have strong antioxidant properties. In this study, it was investigated *in vitro* whether astaxanthin has antibacterial properties as an alternative to antibiotics on *A. hydrophila* strains, which is frequently isolated in cases of motile *Aeromonas* septicemia caused by stress in rainbow trout farms. For this purpose, the antibacterial effect of different solvents of astaxanthin prepared with water, ethanol, and 2-propanol on *A. hydrophila* was studied and it was found that among the solutions of astaxanthin prepared with different solvents, especially 2-propanol was effective while water was ineffective. The present study is a basic study for astaxanthin. Therefore, it is thought that the results of the *in vitro* study of astaxanthin may be the basis of for further *in vivo* studies.

PROSPECTS OF USE OF BUFFALO BREED BULGARIAN MURRAH IN UKRAINE

Igor Goncharenko

National University of Life and Environmental Sciences of Ukraine. Kyiv
igorgoncharenko2711@gmail.com

The development of buffalo breeding is extremely promising for Ukrainian agriculture. In particular, the prospects are good for the dairy industry: Murrah buffaloes have better milk yields than other buffalo breeds. Buffaloes are quite durable and cheap in feed consumption. They are highly resistant to blood-borne diseases. They have satisfactory slaughter qualities - 48-55% meat yield. Indicators of fat, protein and dry matter content in buffalo milk show us that it can become the basic basis for children's nutrition and production of food products of high biological quality, which are highly valued abroad. The meat productivity of Murrah buffaloes is also quite high. We have an excellent example of using this breed of buffalo in Bulgaria, which gives us a fair right to repeat their success, adapting it to the realities of the Ukrainian agricultural market. Thus, all these advantages can be used to improve the level of the export market, which will also have a positive impact on Ukraine's economic potential. To do this, a number of changes should be made. In particular, it is necessary to create scientific and production breeding and genetic state associations for buffalo breeding in Ukraine, it is necessary to separate buffaloes from the cattle population into a separate group, to set a standard and a wholesale price for buffalo products. In addition, it is necessary to create special programs to preserve the buffalo gene pool, with the allocation of appropriate state funding and attraction of foreign investment. The perspectives for the use of Bulgarian Murrah buffaloes in Ukraine are very high, but only if appropriate steps are taken. Otherwise, unfortunately, we should expect t he gradual extinction of buffaloes in Ukraine, and along with them the potential to improve the condition of a rather important part of our agricultural industry.

Key words: buffalo breeding, Bulgarian Murra, buffalo selection in Ukraine

INTRODUCTION

The use of buffalos in Bulgaria has its origins in their economic activities. Since the beginning of the twentieth century, buffaloes have been used for agricultural work, in particular, as a source of meat, as well as draft animals: they have a speed of 3 km/h and can pull a load of 900-1500 kg. According to A. Agabeyli, the number of buffaloes in Bulgaria at the beginning of the twentieth century was 500 thousand [1].

During the Soviet period, Ukraine did not attribute due importance to the prospects of using these animals in agriculture; they were not even separated from the cattle population. There was also no special standard and no wholesale price for buffalo products. These problems have not been addressed in independent Ukraine either. Today, we can observe the irrational use of very powerful cattle in farms of various forms of ownership, the lack of an appropriate buffalo register and common standards for their valuation in Ukraine.

An excellent example of the use of buffaloes is their selection and breeding in Bulgaria. The Bulgarian breeders in 1962 asked themselves how they could further improve the efficiency of using these animals, in particular their milk production? The solution was to import Indian sires of the high-yielding Murrah breed. This was the beginning of the creation of a new dairy breed, the Bulgarian Murrah. Coordination of the breeding of the Bulgarian Murrah breed was carried out under the scientific guidance of the Buffalo Research Institute in Shumen and the National Center for Animal Breeding. In order to optimize the genetic improvement of the Bulgarian buffalo population, to increase milk production, selectors have developed measures and programs to improve the Bulgarian buffalo, and introduced artificial insemination. As a result of these measures, the type of local Bulgarian buffalo has evolved into the dairy type of the Murrah buffalo. Today in Bulgaria 80% of the buffaloes belong to this breed and most of the animals are raised in individual farms [4]. What are the advantages of Murrah buffalo breeding and what should we implement in Ukrainian agriculture today?

RESEARCH RESULTS

The Murrah buffalo is a large animal, with a live weight of 800-950 kg for males and 500-780 kg for females (see picture). The duration of pregnancy is 290-340 days. The average age at first calving is between 32 and 40 months. The inter-calving period is 436 to 505 days, depending on the genotype, feeding and keeping conditions.

Under satisfactory feeding and housing conditions, buffaloes are inseminated at 17-20 months, although under optimal conditions, economic maturity occurs at 10-12 months. The animals are long-lived - some live up to 60 years, even at the age of 45-55 years a buffalo can mate and give birth to viable offspring, however they are kept until 25-30 years of age. Murrah buffaloes have well-developed, rounded udders, so they are well suited for machine milking. Additional evidence of the high genetic potential of Bulgarian Murrah buffaloes for high quality milk production is that many buffaloes have milk yields above 2500-3000 kg, and some of them produce more than 4500 kg of milk per lactation. The highest milk yields were obtained from F2 crosses - 5349 kg of milk with a fat content of 6.64% for 305 days of lactation [5].

At the same time, the milk productivity of other buffalo breeds used in Ukraine is lower, at about 1500 liters of milk per 270-280 days of lactation, so Murrah buffaloes are more productive for dairy products. It should be noted that the production of buffalo milk is cheaper than cow's milk.

Fig. Buffaloes of the Bulgarian Murrah breed in the indoor and outdoor environment

On average, it contains 7-8% fat (6.5-10.5) and 4.3-5.1% protein, up to 23% dry matter, and up to 5.1% lactose. Buffalo milk is homogenized abroad to improve its quality and taste, and fermented milk products such as mazzoni, cream, butter, and mozzarella cheese have excellent taste and are in great demand in the area where they are bred, and therefore can become a very important attribute of the Ukrainian export market.

The main source of buffalo meat is bulls. Studies conducted on the growing qualities of young buffaloes show significant differences compared to conventional cattle. The average daily weight gain of young buffaloes is 650-1083 g. The most effective slaughter weight is recognized as a live weight of 400 kg.

Murrah buffalo meat is used to produce excellent raw dried products, which mature 10-11 days faster than other cattle meat.

Another advantage of Murrah buffaloes is their digestive system, which is much larger than that of other cattle (the length of the intestine is 31 times longer than the length of the body). The most intensive absorption of nutrients in Murrah buffaloes takes place in the small intestine (55.8-62.5%), which indicates a high level of feed digestibility. They usually consume cheap, rough fodder, including fern, quinoa, nettles, burdocks, sedge, ordinary corn stalks without preparation for feeding, cereal and legume straw, branch fodder and fodder from marsh vegetation. During the summer, buffaloes mainly eat only foot fodder, and occasionally their owners feed them [2, 3].

Thus, the development of buffalo breeding is extremely promising for Ukrainian agriculture. In particular, the prospects are good for the dairy industry: Murrah buffaloes have better milk yields than other buffalo breeds. Buffaloes are quite durable and cheap in feed consumption. They are highly resistant to blood-borne diseases. They have satisfactory slaughter qualities - 48-55% meat yield. Indicators of fat, protein and dry matter content in buffalo milk show us that it can become the basic basis for children's nutrition and production of food products of high biological quality, which are highly valued abroad. The meat productivity of Murrah buffaloes is also quite high. We have an excellent example of using this breed of buffalo in Bulgaria, which gives us a fair right to repeat their success, adapting it to the realities of the Ukrainian agricultural market.

CONCLUSION

Thus, all these advantages can be used to improve the level of the export market, which will also have a positive impact on Ukraine's economic potential. To do this, a number of changes should be made. In particular, it is necessary to create scientific and production breeding and genetic state associations for buffalo breeding in Ukraine, it is necessary to separate buffaloes from the cattle population into a separate group, to set a standard and a wholesale price for buffalo products. In addition, it is necessary to create special programs to preserve the buffalo gene pool, with the allocation of appropriate state funding and attraction of foreign investment. The perspectives for the use of Bulgarian Murrah buffaloes in Ukraine are very high, but only if appropriate steps are taken. Otherwise, unfortunately, we should expect t he gradual extinction of buffaloes in Ukraine, and along with them the potential to improve the condition of a rather important part of our agricultural industry.

ABSTRACT

The use of waste mushroom compost (MC) in the establishment of lawns can have a positive effect on reducing the heavy metal content of turfgrass and MC can effectively immobilize the uptake of heavy metals by plants. The waste mushroom compost can affect the heavy metal content in perennial ryegrass grown by mixing different ratios into soils. In this study, the use possibilities of mushroom waste compost for lawn establishment were evaluated. The research was established in the randomized block design in the form of a pot trial in field conditions in Ordu province. Mushroom compost (MC) and soil (S) were mixed in various rates (100% S, 75% S + 25% MC, 50% S + 50% MC, 75% S + 25% MC and 100% MC) and applied as cover material after sowing. In the experiment, dry perennial ryegrass yield and aluminum (Al), cadmium (Cd), cobalt (Co), chromium (Cr), nickel (Ni) and lead (Pb) contents of perennial ryegrass plants were determined. According to the results, it was determined that 50% S + 50% MC mixture was more effective on the dry herbage yield of perennial ryegrass plants in cover materials prepared by mixing mushroom compost with soil. The application of cover materials prepared at different rates caused differences in Al, Cd, Co, Cr, Ni and Pb contents of perennial ryegrass plants. Heavy metal contents of perennial ryegrass plants grown in 100% MC application increased compared to 100%S treatment (control). Al, Cr and Pb contents decreased by 4-fold, 2.5-fold and 3.5-fold, respectively, when perennial ryegrass was grown in 50% Soil + 50% mushroom compost mixture compared to 100%S (control) treatment. In this mixture, Cd content increased to 0.07 mg kg^{-1} from 0.05 mg kg^{-1} in the control. Similarly, Ni content increased from 0.91 to 1.51 mg kg^{-1}. In our results, it is recommended that waste mushroom compost should be applied as a mixture with soil since the use of 100% of waste mushroom compost as a cover material in the creation of perennial ryegrass area causes a decrease in dry perennial ryegrass yield and an increase in heavy metal content.

INTRODUCTION

Heavy metals such as cadmium and lead can accumulate in agricultural soils through industrial activities, mining and contaminated fertilizer. After entering the soil, heavy metals can be taken up by plants, potentially entering the food chain and posing a risk to human and animal health (Kabata-Pendias, 2011). To reduce soil pollution, organic-based media such as mushroom compost can be used as soil amendments. This by-product of mushroom cultivation can increase soil fertility and improve plant health by reducing heavy metal bioavailability (Amir et al., 2005). Adding compost to the soil can also influence heavy metal accumulation in perennial ryegrass plants. Compost can improve the physical and chemical properties of the soil, leading to perennial ryegrass growth and higher heavy metal accumulation in the plant. The addition of compost can enhance microbial activity in the soil, which can increase the degradation of organic pollutants and increase the solubility of mineral nutrients, making them more accessible to the plant. The addition of substances of organic origin to the soil can increase the cation exchange capacity (CEC) of the soil, which can lead to immobilization of heavy metals and decrease their uptake by plants (Bolan et al., 2003). Benitez et al. (2005) found that the addition of mushroom compost to a heavy metal contaminated soil reduced the bioavailability of Cd, Pb and zinc (Zn) and reduced their uptake by ryegrass (*Lolium perenne* L.). Similarly, Amir et al. (2005) reported that application of mushroom compost to a Pb-contaminated soil reduced Pb concentration in shoots and roots of ryegrass. The tolerance of plants to heavy metals is impacted by several physiological and biochemical processes, involving the production of antioxidants and the activation of stress response pathways. There is limited information on the specific effects of mushroom compost on the uptake of Al, Cd, Co, Cr, Ni and Pb by perennial ryegrass. The aim of this research was to investigate the effects on heavy metal content of perennial ryegrass grown in soil with the application of different proportions of mushroom compost and to determine the optimum proportion of mushroom compost to maintain acceptable growth and biomass production and to reduce the uptake of heavy metals.

MATERIAL AND METHOD

The research was carried out in Ordu University Research and Application land under field conditions in baton type pots numbered 12. The waste mushroom compost used in the experiment was obtained from Antalya-Korkuteli Gülat mushroom compost company. Perennial ryegrass (*Lolium perenne* L.) was used as grass plant in the experiment. The results of the analyses of some properties of the soil (Table 1) and waste mushroom compost (Table 2) are given. In experiment, air dry 6 kg of soil sieved through a 4 mm sieve was added to each pot. After the mushroom compost added to the pots, each pot was equalized to 8 kg. The experiment was carried out according to the random plots experimental design with 3 replications.

Plants Growth

After sowing in pots, the pots were watered with 60-70% of the water in the field capacities of the soils when needed until harvesting under open field conditions. The harvest of green parts of the perennial ryegrass was determined depending on the level of growth retardation. Accordingly, the plants were harvested 1 cm above the soil level before flowering. Harvested plants were washed with pure water and dried at 65 ^{0}C for 48 hours. Dry weights of the dried plants were determined, and dry matter yields were determined.

Soil and Plant Analyses

Texture of the soil used in the experiment: According to hydrometer method (Bouyocous, 1951); Soil pH (Soil Reaction) using soil/water 1:2.5 ratio, determination of EC in Soil: Total salt by EC-meter (Richards, 1954) in 1:2.5 soil/water ratio suspension. Lime ($CaCO_3$) measurement using 1:3 HCl/water ratio (Allison & Moodie 1965). Organic matter Walkley & Black (1934); Plant-available phosphorus Bray & Kurtz (1945). Plant-available potassium, calcium and magnesium were determined according to Pratt (1965); Plant-available iron, copper, manganese and zinc were determined according to Lindsay & Norvell (1978).

For the determination of mineral elements in perennial ryegrass samples, 0.25 g of the plant samples were weighed and burnt in a muffle furnace at 550 °C to ash. Then, it was boiled with 10 N HNO_3 (2 ml), and it was completed to 50 ml with pure water and filtered through Whatman blue band filter paper. Cd, Co, Cr and Pb were determined by ICP-OES (Perkin Elmer 2100V).

All data used the means among treatments were compared with excell. Results were given in the form of mean±std.

RESULT AND DISCUSSION

Dry Grass Yield

It was determined that there were differences in the effects on dry perennial ryegrass yield with the application of waste mushroom compost at different ratios as a cover material in perennial ryegrass field formation. While the dry perennial ryegrass yield was 165 kg da^{-1} in 100% soil application, it increased approximately 2.5 fold in 50% S + 50% MC environment and was obtained as 364 kg da^{-1}. Under 100% waste mushroom compost application alone, it was determined that 83 kg dry perennial ryegrass yield was obtained per decare with a 2-fold decrease (Table 3). The use of waste mushroom compost (MC) as a soil amendment can significantly increase the dry matter yield of perennial ryegrass plants in turf areas. Several studies have shown the beneficial effects of MC on the growth and productivity of various perennial ryegrass species. In a study by Jankowski et al., (2018) it was found that supplementing MC with minerals increased the biomass yield of lawn perennial ryegrass in turf areas. In addition, MC can increase soil organic matter content, improve soil structure, and improve water retention capacity. The use of waste mushroom compost is a promising approach to increase the dry matter yield and quality of perennial ryegrass plants in lawn fields. Its nutrient-rich composition and ability to improve soil properties make it an attractive alternative to synthetic fertilizers. However, it has been shown that the use of waste mushroom compost alone is not sufficient for hay yield and quality, and it shows that better results can be obtained with mixtures with soil in certain proportions.

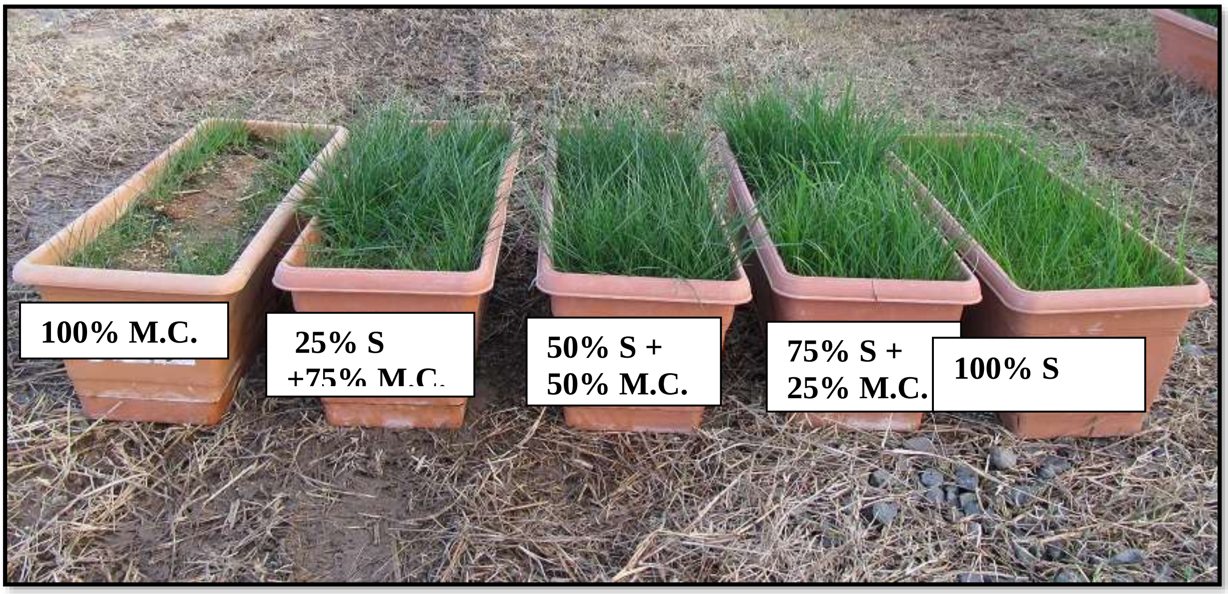

Figure 1: The effect of different doses of mushroom compost on the yield of perennial ryegrass plants.

Al, Cd, Co, Cr, Ni and Pb Content of Perennial Ryegrass (*Lolium perenne* L.) Grown with the Application of Waste Mushroom Compost

As seen in Table 4, it has been determined that there are significant differences in the heavy metal contents of grass plants grown by applying Waste Mushroom compost in different environments with soil. While the Al content of the grass plant in 100% soil condition was 777 mg kg^{-1}, it increased to 1232 mg kg^{-1} in 100% MC application. Similar trend, it was determined that this increase also occurred in the heavy metals Cd, Co, Cr, Ni and Pb. As shown in Table 4, it was determined that there was a significant decrease in Al, Co, Cr and Pb contents in grass plants grown under 50% soil + 50% mushroom mixture in 5 different environments.

Applying compost can affect heavy metal uptake in grass. Several studies have found that compost application generally does not lead to significant increases in heavy metal concentrations in grass or other crops. One study found that compost application "did not cause any phytoxicity to crops" and that yields were not markedly affected by the heavy metals supplied by the compost. Another study concluded that "the compost slightly increased heavy metal concentrations in the soil but did not cause any phytoxicity to crops (Zhang et al., 2000; Zając & Skrajna, 2024). This effect is due to the type and composition of the compost used significantly affecting its effectiveness in immobilizing heavy metals. Composts amended with materials such as biochar, bentonite, waste mushroom compost or other mineral additives have been shown to exhibit a significant and improved ability to bind heavy metals and reduce their bioavailability (Huang et al., 2016). Apart from these, the organic matter, pH and cation exchange capacity of the compost play an important role in retaining heavy metals. Another study that is consistent with our results was explained by Zając & Skrajna (2024) that application of waste mushroom compost such as MSC did not lead to high Al, Co, Cr or Pb levels in grass plants such as *Miscanthus sinensis*. The low heavy metal content of the heavy metal flour itself in growing grass plants with compost applications is, in a way, due to the low content of the compost used. If the waste mushroom compost used contains low metal content, we can think that it is unlikely to pose a risk of heavy metal pollution in lawns. However, it is important to note that specific heavy metal levels may vary depending on the source and composition of mushroom compost and further research may be needed to confirm these findings across different compost sources and grass types.

CONLUSUION

According to available evidence from this research, application of waste mushroom compost alone increases the uptake of heavy metals such as Al, Cd, Co, Cr, Ni and Pb by perennial ryegrass grown under it. It shows that a mixture of 50% soil and 50% waste mushroom compost can be an effective strategy to reduce heavy metal contents. The ability of S+MC to immobilize organic matter and nutrient content as well as heavy metals through adsorption and complexation processes contribute to this beneficial effect. Further research is needed to fully understand the mechanisms underlying the effects of S+MC on heavy metal availability and plant uptake, as well as to investigate the long-term implications of this approach for sustainable land management and phytoremediation.

ABSTRACT

Coastal dunes are among habitats with the worst conservation status on a global. Reporting theirs loss due to strategic importance of them is our duties protect the unique biodiversity heritage of the Albania. In this study we will try to figure up the costal vegetation. Highlighting its updated current conservation status at the EFD. The conservation status was evaluated through the following criteria: geographic range, surface area, structure, functions, pressures, threats, conservation measures and prospects. We have collected more than 100 releves in Albania shoreline, (mainly in Adriatic coast). Focused on the floristic study, tota plants identified 220 species and their endangerment status, based on red book as well as phytosociological study. The first group comprises of the *Cakilo-Xanthietum*, and *Eryngio-Sporoboletum.* The second group compose stable dunes with *Euphorbio paraliae-Agropyretum junceiformis, Medicagini marinae-Ammophiletum australis* and *Ephedra distachya* communities Results highlighted the dramatically bad conservation status of Albanian coastal dunes. Results showed a generalized threat and an alarming conservation status both on herbaceous and wooded communities, in particular in some relevant habitats, such as the embryo dunes. Plants associations are classified based on principles of Zurich–Montpellier school that made the bas of classification in Europe sites. Main pressures and threats were linked to residential, commercial and industrial activities, as well as alien species. Although some of the changes in distribution and trends are probably deriving from more accurate and updated data, the alarming conservation status of Albania coastal areas requires a better knowledge of pressures and threats for further management actions and monitoring plans. Finally, this scientific paper will be a powerful instrument for the future management of Adriatic costal habitats from a conservation perspective.

Key words: *Coastal dunes, EFD, embryo dunes, conservation status.*

INTRODUCTION

Coastal dunes are complex ecosystems occupying zones of transition between terrestrial and marine ecosystems. (Urban Silk 2016). This is a very dynamic environment, with distinct degrees of stabilization depending on the topography, natural disturbance and distance from the sea, and it harbors a mosaic of habitats (van der Maarel 2003). Plant communities on sand dunes have specific ecological requirements determining their position along the gradient from the sea inland (Carboni et al. 2009). Various ecological factors influence the distribution of plants along this gradient: sand abrasion, salt spray, burial by sand, erosion, accretion, tide level, wave attack, wind blasting and dehydration (Maun 2009; Miller et al. 2010). Zonation is very stable and a regular sequence of plant communities along the gradient can be observed worldwide (Doing 1985; Attorre et al. 2013). Vegetation of beaches and mobile dunes are considered azonal (Doing 1985), while more inland, stable dunes are covered by plant communities more adapted to local conditions (Buffa et al. 2012). Sand dune vegetation occurs all along the Mediterranean coasts and several authors have provided syntaxonomical schemes of this vegetation type. In the central and eastern part of the Mediterranean, overviews have been made for Italy (Géhu et al. 1984; Géhu & Biondi 1996; Brullo et al. 2001; Biondi 2007; Pirone 2014), Greece (Sýkora et al. 2003) and Turkey (Géhu et al. 1989), but not for Adriatic coast along the Balkan Peninsula. Research on psammophytic (sand dunes) vegetation started with Beck von Mannagetta (1901) and Morton (1915), who refer to the "Formation des Dünensandes". Horvatić (1934, 1939) was the first to study and provide a deeper insight into this vegetation type according to the Braun-Blanquet method, on the islands of Pag and Rab (Croatia), and he added new data in 1963 (Horvatić 1963). Extensive studies in Croatia were carried out by Trinajstić (1974, 1989a, 1995), Trinajstić & Jasprica (1998) and Alegro et al. (2003, 2004) Trinajstić & Jasprica (1998) and in Montenegro by Trinajstić (1989b) and Mijović et al. (2006, 2012). Vegetation research in Albania applying the Braun-Blanquet method only started in the late 1980s. One of the pioneering works was on the coastal vegetation of Albania (Mullaj 1989), while studies of halophytic and psammophytic vegetation have only recently emerged (Imeri et al. 2010; Fanelli et al. 2015). These differences in the degree of vegetation research along the Adriatic coast is evident from the distribution maps of the localities of sand dunes, on which the Adriatic coast must still be considered main spot in Europe (Géhu 1989; Trinajstić 1989a). The main reason of this research is: (a) to present the current state on the distribution of psammophytic vegetation along the Albania coast, (b) to determine the main vegetation types in real time (c) to describe these vegetation types from a floristic and taxonomic point of view (d) to emphasize the importance of dune coastal vegetation (e) to propose to government authorities the protection statues of these types of habitats (f) to contribute to save these areas from urbanization. About half of the population of the Albania, live in the coastal region. Economic activities in the coastal areas are constantly expanding. Permanently increasing tourism and pollution has already resulted in disruption of or highly negative impacts on fragile ecosystems, impacts on quality of life of resident populations and loss of habitats and species. Present and future trends concerning adverse global phenomena, climate change in particular, are expected to worsen the situation. Coastal area is considered as one of the most important areas in Albania based on the high biodiversity values and the number of habitat. Currently, (1. *Drini Bay Velipoje-Shengjin-Kune-Vain-Patok area, 2. Lalzi Bay, 3. Durresi Bay, 4. Segmenti kala e Turres-derdhja e lumit Shkumbin, 5. Derdhja e lumit Shkumbin-derdhja e lumit Seman Divjake-Karavasta area, 6. Derdhja e lumit Seman-derdhja e lumit Vjose, 7. Vlora Bay-Narta area.)* could be threatened by alteration of their functions which means degradation of their values. In the last years, we have witnessed a growing global awareness concerning habitat monitoring and conservation; habitats as a whole are probably more useful indicators of ecosystem functioning compared to individual species (Balmford et al. 2002; Cowling et al. 2004; Bunce et al. 2013; Gigante et al. 2016a). The protection of biodiversity requires a constant and rigorous technical-scientific commitment at national level, which should also be extended to the obligations deriving from community rules. In particular, the Habitats Directive (92/43/EEC) requires to implement surveillance on the conservation status of habitats and species of Community Interest, taking into account also the most important threat factors that influence their future prospects (Angelini et al. 2016; Gigante et al. 2016b). Monitoring and reporting are of strategic importance to determine the effectiveness of the implementation of the Community Directives on biodiversity. Moreover, they serve as a reference framework to identify priorities and critical issues for the next monitoring period (Genovesi et al. 2014).

METHODS

The study site is composed of beach-dune systems extending alongshore Adriatic Coast Albania.

This ideal natural laboratory (with about 284 km stretching), has been used for assessing beach-dune evolution and community composition. The coastal dune system has been softly managed by marram grass planting and branching, particularly to prevent the development of blowouts. We conducted a detailed bibliographic research on published studies regarding Albania costal dunes vegetation. Highlighting phytosociological relevés regarding plant communities of embryo dunes, mobile dunes, transition dunes, fixed dunes or wooded dunes). For each EU habitat we presented a brief description with the list of diagnostic species based on the European Manuals of the 92/43/EEC Habitats Directive (European Commission, 2007; Biondi et al., 2009). We also included the list of rare and threaten plants and their statues based on the IUCN Codes.

There are nine IUCN Red List categories:

1. Extinct (EX) – No known individuals remaining
2. Extinct in the wild (EW) – Known only to survive in captivity, or as a naturalized population outside its historic range
3. Critically endangered (CR) – Extremely high risk of extinction in the wild
4. Endangered (EN) – High risk of extinction in the wild
5. Vulnerable (VU) – High risk of endangerment in the wild
6. Near threatened (NT) – Likely to become endangered in the near future

7. Least concern (LC) – Lowest risk (does not qualify for a more at-risk category; widespread and abundant taxa are included in this category)
8. Data deficient (DD) – Not enough data to make an assessment of its risk of extinction
9. Not evaluated (NE) – Has not yet been evaluated against the criteria

The species extinction risk assessment is based on the Guidelines for IUCN Categories and Criteria Application version 4.0 (IUCN 2012a, 2012b).

We highlighted those phytosociological associations with their code and particular distribution pattern and finally, for each habitat we suggested major threats.

Fig.1 *Sampling sites (Sites are selected based on the previous experience)*

1. Drini Bay Velipoje Shengjin Kune-Vain-Patok areas,
2. Lalzi Bay,
3. Durresi Bay,
4. Segmenti Kala e Turres-derdhja e Lumit Shkumbin,
5. Derdhja e Lumit Shkumbin-derdhja e Lumit Seman, Divjaka-Karavasta Area.
6. Derdhja e Lumit Seman-derdhja e lumit Vjose.
7. Vlora Bay (Narta area)

These sampling points are the main costal habitats that express the dune vegetation in follow habitates:

- 1210 Annual vegetation of drift lines
- 2110 Embryonic shifting dunes
- 2120 Shifting dunes along the shoreline with Ammophila arenaria (‘white dunes’)
- 2130 * Fixed coastal dunes with herbaceous vegetation (“grey dunes’)
- 2250* Coastal dunes with Juniperus spp. (Juniperus oxycedrus subsp. macrocarpa)
- 2270* Wooded dunes with Pinus pinea and/or Pinus pinaster

All relevés follow the phytosociological method of ZurichMontpellier school (Braun-Blanquet, 1932, 1964). This analysis conducted with the support of Flora of Albania (Paparisto et al.,1984-2000) and Flora Europaea (Tutin et al., 1964-1980). The nomenclature followed is Paparisto et al.,1984-2000. Number, size, distribution pattern of the stations and transects depend on

the size and heterogeneity or diversity of habitats situated in the area of coastal areas, as well as on the bio-ecological characteristics of the species or group of species. The primary focus of this paper was to assess the conservation status of Annex I sand dune habitats in Albania at a representative sample of sand dune sites. The conservation assessment methodology was designed to complement the EU guidelines on assessing conservation status under Article 17 of the Habitats Directive (Evans and Arvela, 2011).

RESULTS

Results demonstrate plant communities on sand dunes along Adriatic that consists of six Habitat types. All releves (*shown on Tab 1*), represent a floristic situation in real time. Unfortunately, some plants of white dunes are disappeared and grey dunes are really in the emergency.

Tab. 1. *Coastal dune habitat and main costal Adriatic regions*.

Habitat types	**Regions**						
	Drini Bay Velipojë, Shëngjin, Kune –Vain, Patok areas	*Lalzi Bay*	*Durrësi Bay*	*Segmenti Kala e Turrës – Derdhja e Lumit Shkumbin*	*Derdhja e Lumit Shkumbin – Derdhja e Lumit Seman (Divjaka-Karavasta Area)*	*Derdhja e Lumit Seman - Derdhja e Lumit Vjosë*	*Vlora Bay – Narta Area*

**2130 Fixed coastal dunes with herbaceous vegetation (grey dunes)*	+	-	-	-	-	-	-
**2250, Dunes with Juniperus oxycedrus ssp. macrocarpa.*	+	-	-	-	++	+	+
**2270 Dunes with Pinus halepensis, pinaster, pinea.*	++	++	++	++	+++	+++	++

(Experiences for more than 20 years with such these habitats, based on the NATURA 200 code and specifics of Mediterranean terrain is established below table by authors).

- + Rare, ++ Abundant, +++ Frequent
- The code corresponds to the NATURA 2000 code.
- The sign'*' indicates priority habitat types.

The floristic inventory includes 220 plant species. Among the species characteristic for the class Cakiletea maritimae most common were *Xanthium orientale ssp. italicum* and *Cakile maritima*,

while among the common species of the Ammophiletea were *Elytrigia juncea, Echinophora spinosa, Eryngium maritimum, Euphorbia paralias* and *Medicago marina.*

There is an evident increase of some psammophytic species towards the south of studied area: *Glaucium flavum, Matthiola tricuspidata, Polygonum maritimum, Ammophila arenaria, Ephedra distachya, Achillea maritima* and *Sporobolus pungens*. Rare psammophytes in the studied area were *Ephedra distachya, Stachys maritima*, and *Ononis variegata*.

During the field trips in the Adriatic region, *(1. Drini Bay Velipoje-Shengjin-Kune-Vain-Patok area, 2. Lalzi Bay, 3. Durresi Bay, 4. Segmenti kala e Turres-derdhja e lumit Shkumbin, 5. Derdhja e lumit Shkumbin-derdhja e lumit Seman Divjake-Karavasta area, 6. Derdhja e lumit Seman-derdhja e lumit Vjose, 7. Vlora Bay-Narta area.).* These plants are studied in floristic and phytosociological point of view. Dominant families are Compositae and Graminae, followed by Leguminosae and Plantaginaceae.

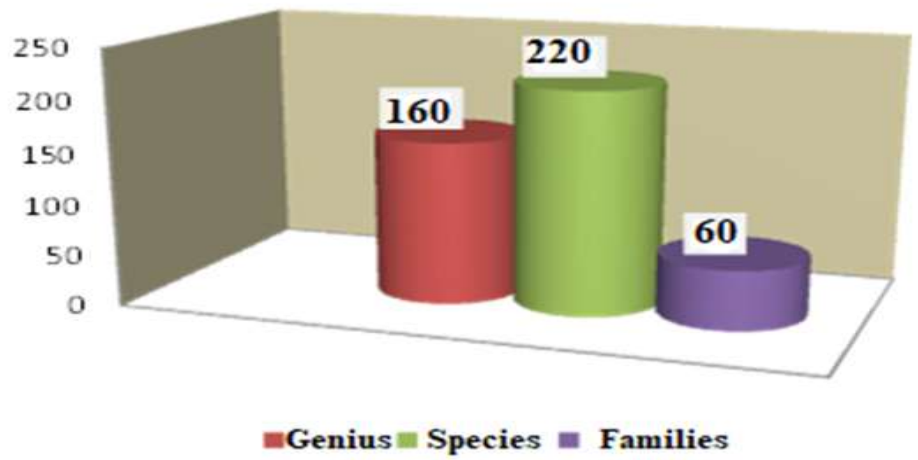

Fig 2. *Dominant families in coastal dunes habitates*.

The plants of sand beaches and dunes consist largely of specialist species. Sand dunes in *Drini Bay*, are very rich in plant species and breeding birds. The “aquatic” vegetation is important for many fish species, both for typical coastal fish and for many fish of the open sea that pass their first life stages in miseries of the coastal zone. Dunes are characterized by very specific plant species, especially dominated by the succulent species. The focus of the study was also the evaluation of rare and threaten plants in these sites in order to give the proper decision for the threaten and endangers plants. **Tab 3** shown the present situation about the threaten statues of the plants in different areas. Their statues according IUCN and the priority objectives for protection of the species. In all areas there are critically endangered species and habitats of global, regional or national importance. Costal habitats are distinguished for their endemic species or biodiversity.

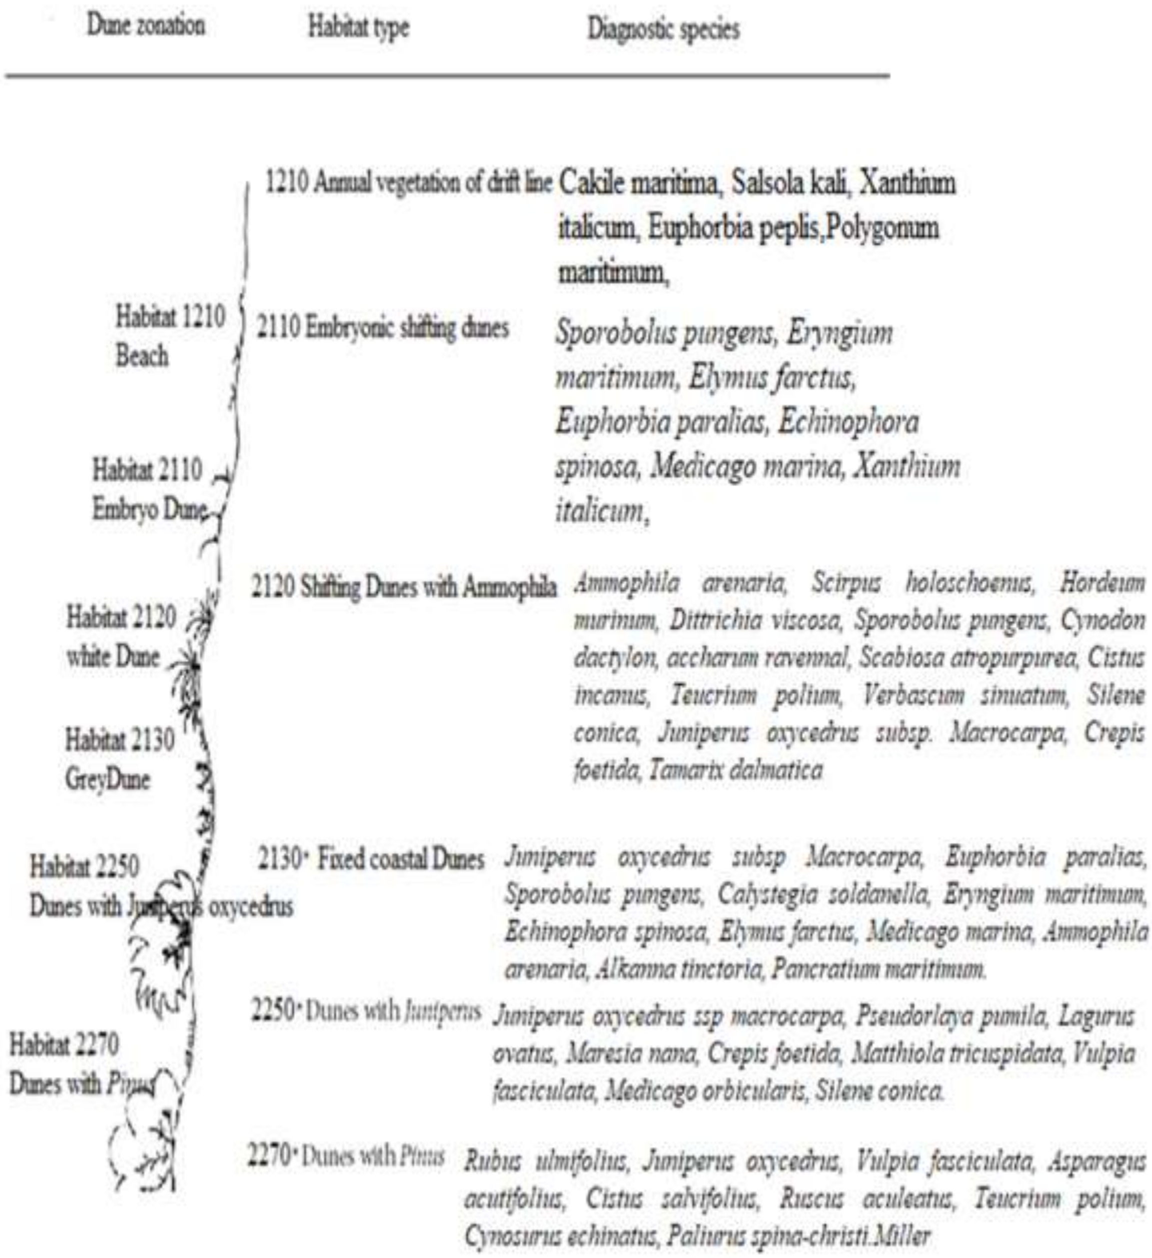

Fig 3. *Scheme of habitat types in Coastal dunes in Adriatic coast line with corresponding diagnostic plant species. (This scheme is worked in Paint program; we have all samples in national herbarium in the Botany chair at Agricultural University of Tirana, Albania.*

In Adriatic coast line there are 6 natural habitates:

1210 Annual vegetation of drift lines

1) Formations of annuals or representatives of annuals and perennials, occupying accumulations of drift material and gravel rich in nitrogenous organic matter (Cakiletea maritimae p.).

2) Plants: *Cakile maritima, Salsola kali, Atriplex spp, Polygonum spp., Euphorbia peplis, Mertensia maritima, Glaucium flavum, Matthiola sinuata, M. tricuspidata, Euphorbia paralias, Eryngium maritimum*.

3) Associations: - Cakilo-Xanthietum strumarii Beguinot 1941, Pign. 1953

2110 Embryonic shifting dunes

1) Formations of the coast representing the first stages of dune construction, constituted by ripples or raised sand surfaces of the upper beach or by a seaward fringe at the foot of the tall dunes.

2) Plants: - *Elymus farctus (Agropyron junceum), Sporobolus pungens, Euphorbia peplis, Medicago marina,Eryngium maritimum, Pancratium maritimum.*

3) Associations: -Cakilo-Xanthietum strumarii, Beguinot 1941, Pign 1953.

2120 Shifting dunes along the shoreline with Ammophila arenaria (white dunes)

1) Mobile dunes forming the seaward cordon or cordons of dune systems of the coasts

2) Plants: - *Ammophila arenaria, Eryngium maritimum, Euphorbia paralias, Calystegia soldanella, Otanthus maritimus, Medicago marina, Cyperus capitatus*.

3.) Associations: - Medicagini marinae-Ammophiletum australis Br.-Bl. 1921 corr. F. Prieto & T.E. Díaz 1991

2130 *Fixed coastal dunes with herbaceous vegetation (grey dunes)

1) Fixed dunes, stabilized and colonized by more or less closed perennial grasslands and abundant carpets of lichens and mosses.

2) Plants: - *Echinophora spinose, Alkanna tinctoria, Elymus farctus, Medicago orbicularis, Calystegia soldanella, Pseudorlaya pumila, Lagurus ovatus, Matthiola tricuspidat*a.

3). Associations: Pistacio lentisci-Juniperetum macrocarpae Caneva, De Marco e Mossa (1981)

2250 * Coastal dunes with Juniperus spp.

1) Juniper formations Mediterranean and thermo-Atlantic coastal dune slacks and slopes Juniperus communis formations of calcareous dunes.

2) Plants: *Juniperus oxycedrus ssp. macrocarpa, Euphorbia paralias L. Sporobolus pungens, Calystegia soldanella, Eryngium maritimum, Echinophora spinose, Elymus farctus, Medicago marina.*

3) Associations: - Juniperetum macrocarpae, Pistacio lentisci-Juniperetum macrocarpae

2270 * Wooded dunes with Pinus pinea and/or Pinus pinaster

1) Coastal dunes colonised by Mediterranean and Atlantic thermophilous pines, corresponding to the substitution facies or in some stations climax formations of evergreen oak of artificial origin Quercetalia ilicis.

2) Plants: *Pinus pinea, P. pinaster, P. halepensis, Juniperus macrocarpa, Phillyrea angustifolia, Rubus ulmifolius, Vulpia fasciculate, Asparagus acutifolius, Cistus salvifolius, Ruscus aculeatus, Teucrium polium, Cynosurus echinatus.*

3). Associations: -Pinea-pinaster.

Tab. 3. *IUCN categories and criteria. The species extinction risk assessment is based on the IUCN Red List Categories version 3.1 (IUCN 2001), on the Guidelines for the use of the IUCN Red List Categories and Criteria version 10 (IUCN 2013a), and on the Guidelines for IUCN Categories and Criteria Application version 4.0 (IUCN 2012a, 2012b). The risk categories are 9 and include:*

No.	Latin Species Name	Name in Albanian language	New speciesname	Existing National Threat Category and Criteria (2013)	Updated National Threat Category and Criteria (2019)	IUCN Current Threat Category and Criteria at Global, European and Mediterranean scale	Main reasons for National threat status being updated/revised
1	*Pinus pinea* L.	Pisha e butë		VU A2c	NT	LC	The main risk comes from woodcutting, but the pressure is not high
2	*Pancratium maritimum* L.	Zambak deti		EN A1b	EN A1b	LC	The threat category remains unchanged
3	*Aster albanicus subsp. paparistoi*	Aster shqiptar	*Galatella albanica* Degen	EN A1b	**VU B2**		According to Kosovo Red Book and in country assessments
4	*Matthiola tricuspidata* (L.) W. T. Aiton	Pllatkë trithimthore		EN A1b	EN A1b		The threat category remains unchanged
5	*Ephedra distachya* L.	Gjunjëz		EN A1b	**VU-AL-A3c**	LC	The species itself is present in sandy dunes of coastal area of Albania, but its habitat is exposed to risk, due to human intervention, which makes the species habitat vulnerable. One location in Durres (Golem beach) is already extinct.
6	*Quercus ilex* L.	Ilqe, lëqeshtë, hilqe, lëqeshtë, ylnjë, ylqer		EN A1b	NT	LC	The species has a wide range of distribution, mostly in the western hills of the country. The specimens are not endangered but still its habitat is under the anthropogenic pressure.
7	*Stachys maritima* Gouan	Sarushë bregdetare		VU A1b	VU A1b		The threat category remains unchanged
8	*Anacamptis morio subsp. caucasica* (K. Koch) H. Kretzschmar, Eccarius & H. Dietr. (=Orchis albanica)	Salepi shqiptar		EN A1b	EN A1b		The threat category remains unchanged
9	*Glaucium flavum* Crantz	Glauku i verdhë		EN A1b	EN A1b	LC	The threat category remains unchanged
10	*Ammophila arenaria* (L.) Link	Amofilë e ranishteve		EN A1b	EN A1b		The threat category remains unchanged

The importance of this area is illustrated by the fact that many of the threatened plant species in the Red Book of Albania occur in this area. In general, the natural ecosystem of Costal Adriatic can be seen as an essential part of Europe's natural heritage.

There are a lot of problems with costal environment and habitat loss is probably the most Important. A number of coastal plant species are now believed to have become extinct due to total destruction of their habitats, especially sand beaches.

Along the Albania, Adriatic coast there is a wide variety of psamophyllus plant community these areas are characterized by high species richness and by endemic and rare associations. Owner investigation was focused in Adriatic coast dunes and the time span of relevés concerns more than 10 years, it is also probable that in some areas the presence of coastal habitats could have been overestimated. In fact, some communities may have disappeared due to a more recent habitat loss. In addition, it is also possible that in other areas habitats were underestimated because of the lack of published phytosociological studies. The results of the meta-analysis showed that community patterns shift from annual beach communities to shrub-covered fixed dunes, probably associated with changes in the environmental characteristics. Dunes are among the most threatened habitats at national level, mainly due to anthropic activities. As it is highly probable that human development and recreational activities along coasts will continue to be intense, an appropriate management of well-preserved dune systems, paired with the restoration of the more damaged ones, are urgently needed. The information derived from this database could be used for the monitoring and surveillance of EU habitats and species, as required by Habitats Directive (EEC, 1992), as well as for the "Natura 2000" ecological network management (Boillotet al., 1997). An adequate implementation of the Habitats Directive will help to guarantee that coastal dunes retain their major features, promoting their conservation for the future generations.

Sintaxonomical review is presented in following list.

The floristic complex of the ***Llazi bay*** area dunes, *begin Eryngium maritimum, Cakile maritima, Echinophora spinosa, Euphorbia paralias* and *Ammophila arenaria*. They form almost the entire vegetation of the beaches and the shifting dunes. Perennial plants as a biological type dominate in floristic complexes, though in some cases (mainly on the beaches) the dominants are pioneer annual plants (*Cakile maritima, Salsola kali or Euphorbia peplis*). Analyzing the transversal profile of a dune (Uslu & Géhu 1990), starting from the shoreline, where the waves break, and continuing towards the inner part of the shore, one can observe a sequence of vegetation clusters which determine various habitats and various stages of growth of the dune's sandbar.
In accordance with the specified definition of psammophytic vegetation succession dynamics and stages of dune formation, the following parts of the dune complexes have been evidenced:
• The higher parts of the beaches with pioneer vegetation
• Embryonic dunes
• Shifting dunes
Pioneer vegetation on the higher parts of the beaches.
This association represents the first stages of development of littoral psammophytic vegetation in the higher beach places. Despite the poor floristic composition, the total abundance of the species is often very low. Pioneer plants are so called because they are the first plants capable of colonizing this type of hostile environment. The hostility is caused by strong thermal changes, poorness of water and finally, because of thevariable saline content. The most representative plants among them are Cakile maritima, Salsola kali, Inula crithmoides and Xanthium strumarium. These dune morphology is clearly expressed in *Drini Bay Velipoje-Shengjin-Kune-Vain-Patok* area, in this area **Embryonic dunes** gradually going away from the coast line and as the height of sandy dunes is increased, the physiognomy of vegetation is imparted by the species *Eryngium maritimum, Euphorbia paralias, Echinophora spinosa, Elymus farctus, Cyperus capitatus, Sporobolus pungens,* that pertain to a more evolved phase of psammophytic vegetation and from the beaches to the embryonic dunes. This type of vegetation represents a stable "potential" of

the sandy banks. The discussed vegetation, in most of the cases, is under human impact determined by the developing tourism, intensive usage and intensive erosion. An obvious result of human impact is the expansive distribution of *Xanthium strumarium subsp. italicum* in the highest beach places and the embryonic dunes. The species was introduced from America and is perfectly adapted in these areas.

Shifting dune vegetation is well expressed in *Segmenti Kala e Turrës – Derdhja e Lumit Shkumbin, Derdhja e Lumit Seman - Derdhja e Lumit Vjosë, Vlora Bay Narta-area,* the architecture of dune height is accompanied as well with the gradual change of the physiognomy of this vegetation. The highest dunes are colonized by the big tufts of Ammophila arenaria which grow especially on the crest of the dunes. This species is the real builder of the dunes. The presence of this species is an important factor in impeding the movement of sand quantities pushed away by the sea winds towards the continent. From this type of vegetation there are noticed two evaluative lines:

Retro dune or degradation of sandy dunes and the formation of depressions. The end of depressions is closer to the level of salted ground waters. The ground becomes wetter and different vegetation grows from that of dunes, dominated by *Erianthus ravennae, Scirpus holoschoenus, Schoenus nigricans* and *Plantago coronopus.*

Mediterranean pine forest: These forests occupy a considerable part of the Lalzi Bay area distributed mainly on sandy dunes. In generally, they represent relatively young forests, cultivated recently in order to stabilize the sandy dunes and protect the agricultural lands. The physiognomy of this formation is imparted by the species *Pinus halepensis* and *Pinus pinea*. The shrubby layer is represented by typical Mediterranean species. The most spread shrubs in this formation are *Myrtus communis, Juniperus oxycedrus subsp. macrocarpa, Erica manipuliflora* and *Pistacia lentiscus*. These forests constitute the last most evolved phase of the vegetation of sandy dunes.

On the other side monitoring along the coastline of Narta area from the delta of Vjosa river up to the Old Beach of Vlora. This region is known for some of the largest dunes of Albania, which altitude varies from 1-2 m to 4-5 m. The sandy belt along the coastline is completely bare of vegetation to a length sometimes extending up to 30 m. The lack of vegetation in this belt is a result of the active life of different animals, mainly crustacean species. After the first belt from the sea shoreline, the Phanerogamy vegetation appears in mudded belt, at the sandy belt area, which is already washed away by the considerable amounts of salt as a result of rainwaters.

Pioneer species, *Cakile maritima, Xanthium strumarium subsp. italicum, Salsola kali,* isolated at the first part of this belt, become more frequent when leaving the coastline. The vegetation of this sandy belt belongs to the pioneer association Cakilo-Xanthietum italici.

Gradually, going away from the coastline and as the altitude of sandy dunes is increasing; the physiognomy of vegetation is composed by species as *Ammophila arenaria subsp arundinaceae, Elymus farctus, Echinophora spinosa* etc. On sand dunes, these species are considered as important dune building plants. *Ammophila arenaria subsp. arundinacea* represents the characteristic specie of the association Ammophiletum. The degradation of sandy dunes and formation of depressions is accompanied by a different vegetation, dominated mainly by *Sporobolus punges*, characteristic specie of the association Sporoboletum. Ammophiletum association constitutes the last most evolved phase of the vegetation of sandy dunes or the borderline between dune vegetation and the Mediterranean pine forests. These forests occupy a considerable part of the Narta area, extending parallel with dune systems of this area. These forests are relatively of a young age, cultivated (30-40 years ago) recently in order to stabilize the sandy dunes and protect the agricultural lands.

The physiognomy of this formation is composed by the species *Pinus maritima, P. pinea, P. pinaster* (tall ligneous trees, the height of 10 year trees is about 5-7 m and the cover about 70-80% of total area). The shrub layer is represented by typical Mediterranean species such as *Pistacia lentiscus, Erica manipuliflora, Myrtus communis* etc, characteristic species of the Class Quercetea ilicis. The pine forests generally originated from plantations, cultivated many years ago for sandy
dune stabilisation and to protect arable land. However, it is now a feature of many
Mediterranean coastlines and currently they represent habitats with priority status, included in
Annex I to Directive 92/43/EEC. The forest is dominated by *Pinus halepensis* and *P. pinea* growing densely on sandy dunes. Generally, these forests are well preserved, with mature trees and very dense canopy cover. As a result of the high shade cast, there is an almost total
absence of shrubby and herbaceous under-storeys under mature trees. In clearings, shrubby and herbaceous understories exist, dominated by species such as Elm leaf blackberry (Rubus
ulmifolius), as well as Common myrtle (*Myrtus communis*), Heath (Erica manipuliflora),
Mastic tree (Pistacia lentiscus), Prickly juniper (Juniperus oxycedrus subsp. macrocarpa),
Rabit-tail (Lagurus ovata), etc. Plants: *Pinus pinea, P. halepensis, Rubus ulmifolius, Myrtus communis, Erica manipuliflora, Pistacia lentiscus, Juniperus oxycedrus subsp. macrocarpa, Lagurus ovata*, etc.

Recomandation and perspective job

1. We should highlight that the key dune habitat 2130 (Fixed coastal dunes with herbaceous vegetation) are threaten and should have a conservation status for all the criteria in both Biogeographical Regions.

2. Moreover, our results showed that both *Fixed coastal dunes with herbaceous vegetation* and *Dunes with Juniperus oxycedrus ssp. macrocarpa* Habitats are highly threatened.

3. The overall worrying state of conservation of the dune systems claims for a better knowledge of pressures and threats acting on these habitats and for further monitoring plans.

4. Without such a systematic approach, coastal dune habitats are going to face further degradation trends in both structure and functions, including also the disruption of spatial zonation of plant communities (Sarmati et al. 2019). This degradation process could finally

lead to a dramatic alteration of the ecosystem services they provide (Everard et al. 2010; Barbier et al. 2011; Drius et al. 2019). Additionally, degraded dune habitats are more susceptible to biological invasions (Del Vecchio et al. 2015; Gheza et al. 2018; Giulio et al. 2020).

5. In dynamic and vulnerable ecosystems such as coastal dunes, successful conservation outcomes in the long-term depend on sound evaluations of the effectiveness of current management measures, supported by regular and highly frequent on-ground monitoring, both inside and outside protected sites. We believe that our results provide bases and useful insights for dune habitats protection and management, in the context of the monitoring and reporting obligations set up by the Habitats Directive.

6. Therefore, we should clarify that for dune Habitats, some of the changes in distribution and trends might probably be related to the application of more accurate and updated data. However, even though the geographical distribution maps of these Habitats have been validated by long term experience in coastal field trips. Finally, it's worth noting that the information collected has been structured to ensure the archiving and traceability of both published and unpublished literature, placing a solid base of reliable and verified data at the local scale for the next reporting cycles (Gigante et al. 2019).

ABSTRACT

Irisin is a natural body hormone that can also be produced synthetically. Although the first research on irisin was on energy metabolism, recently its proliferative and anti-proliferative effects have been investigated in various types of cancer, depending on the type of cancer. In this study, the 48-h proliferation suppressive dose of irisin on the HeLa cervical cancer cell line was determined to be 50 nM. Additionally, when the same dose was applied to mouse healthy liver cell line AML12, 105.37 ± 5.87% viability was detected compared to the control group. As a result of qRT-PCR analyses performed upon application of this dose of irisin to the HeLa cell line, significant decreases in *PI3K*, *Akt*, *mTOR*, *HIF-1α*, *Mn-SOD*, *CAT*, and *GSR* gene expression levels were detected, whereas significant increases were detected in *GLUT1* and *p53* gene expression levels. As a result of flow cytometry analyses performed based on the same application, 71.84 ± 2.49% of ROS-affected and 51.23 ± 3.14% of total apoptotic and necrotic cell amounts were detected in the HeLa cell line compared to the control group. At the same time, depending on this application, apoptotic symptoms in the nuclear structures of HeLa cells were demonstrated by fluorescence microscope imaging. These data have shown that irisin can play an effective role in the fight against many types of cervical cancer, especially HeLa.

Keywords: Apoptosis, *GLUT1*, HeLa, *HIF-1α*, Irisin, ROS

INTRODUCTION

Irisin is a novel adipomyokine peptide that is secreted from skeletal muscle, and it was discovered in 2012 (Bostrom et al., 2012). Irisin is derived from its precursor, fibronectin type III domain-containing 5 (FNDC5), a transmembrane protein that is cleaved by specific proteases (Bostrom et al., 2012; Huh et al., 2012; Timmons et al., 2012). Although the discovery of irisin is still quite recent, initial studies have indicated that irisin, which is abundantly expressed in skeletal muscle, regulates fat metabolism by converting white adipose tissue into brown adipose tissue. (Robets et al., 2013; Hofmann et al., 2014). Building on the research on fat metabolism, subsequent studies have also investigated the benefits of irisin on glucose metabolism (Wang and Pan, 2016; Zhang et al., 2016). In addition to these data, the anti-cancer molecular mechanisms of irisin on various types of cancer have also been investigated.

As is well known, almost all types of cancer cells require extremely high amounts of energy compared to healthy cells in order to perform activities such as unlimited growth, angiogenesis, or inhibition of apoptosis. Cancer cells meet their increased energy needs by converting glucose to lactate in an oxygen-free environment (Gasinska et al., 2013). Sometimes, even when there is a sufficient amount of oxygen in the environment, cancer cells still prefer an anaerobic method by converting glucose to lactate. This phenomenon is called the Warburg effect (Liberti and Locasale, 2016). Generally, this situation occurs when cancer cells are under intense oxidative stress, and under normal conditions, glucose required for anabolic processes such as cancer cell proliferation is provided in this way. The needed glucose is provided by the glucose transporter family known as GLUT. The overexpression of membrane glucose transporters, including GLUT1, has been observed in many malignancies such as breast, colorectal, salivary gland, and stomach cancers (Józwiak and Lipinska, 2012). Despite the high amount of reactive oxygen species (ROS) in cancer cells, the overexpression of the GLUT1 gene to meet the high glucose demand can disrupt cellular homeostasis. This situation can lead to the suppression of cell proliferation and apoptosis. However, to suppress the accumulated ROS and excessive GLUT1 expression and restore homeostasis, the hypoxia-induced factor 1 alpha (HIF-1α) gene is effectively activated in cancer cells (Masson et al., 2012; Köhl et al., 2006). However, as a result of the suppression of glucose metabolism, the necessary energy must be compensated in some way, and this requirement is met by Phosphatidylinositol 3-kinase (PI3K), which supplies the needed ATP (Zhang et al., 2020). Epidermal growth factor (EGF) and insulin-like growth factor-1 (IGF-1) activate PI3K. Activated PI3K then activates protein kinase B (Akt) in the cell membrane (King et al., 2015). Additionally, the mammalian target of rapamycin (mTOR) is activated by PI3K/Akt and subsequently increases the expression of HIF-1α. Increased HIF-1α expression induces VEGF expression, promoting vascular expansion (Park et al., 2014). The increase in VEGF expression leads to the opening of new glucose pathways. Thus, with the facilitated glucose flow, ROS is suppressed, and the increased Akt/mTOR/HIF-1α pathway expression returns to its previous level, restoring homeostasis (Lin et al., 2021).

According to a study, irisin activates the PI3K/Akt pathway in liver cancer (HepG2, SMMC7721) cell lines, particularly at a dose of 2.5 nM, increasing cell viability, migration, and invasion, and reducing the cytotoxic effect of doxorubicin (Dox) (Shi et al., 2017). Another study reported that irisin has no proliferative and adhesive effects on tumor development in endometrial (KLE, RL95-2), colon (HT29, MCA38), thyroid (SW579, BHP7), and esophageal (OE13, OE33) cancer types (Moon and Mantzoros, 2014). In contrast, irisin has been reported to reduce cell count and migration, suppress Nf-κβ expression levels, and promote apoptosis in breast (MCF-7, MDA-MB-231) cancers (Gannon et al., 2015). Additionally, irisin has shown antiproliferative effects in prostate (LNCaP, DU-145, and PC3) cancer cell lines, especially reducing the lifespan of the LNCaP cell line (Tekin et al., 2015). Furthermore, doses of 20-50 nM of irisin have been shown to inhibit proliferation, growth, migration, and invasion in A549 (NSCLC) and NCI-

H446 (SCLC) lung cancer cell lines (Shao et al., 2017), osteosarcoma (U2OS, MG-63) cell lines (Kong et al., 2017), and pancreatic cancer (MIA PaCa-2, Panc03.27) cell lines (Liu et al., 2018).

Despite the proliferative/anti-proliferative effects of irisin on these mentioned cancer cell lines, its effects on cervical cancer cells are not frequently found in the literature. According to World Health Organization data, cervical cancer is the fourth most common cancer in women globally, with approximately 660,000 new cases and around 350,000 deaths in 2022. Cervical cancer is the most well-documented cancer linked to a sexually transmitted infection with human papillomavirus (HPV) (Burd, 2003). HeLa is one of the oldest defined (1951) cell lines related to HPV-associated cervical cancer (Jones, 1997).

Due to the role of irisin in glucose metabolism (Wang and Pan, 2016; Zhang et al., 2016) and the importance of the PI3K/Akt/mTOR/HIF-1α pathway-GLUT1 balance for cell survival in almost all cancer types, including the HeLa cell line (Arsham et al., 2002), this study investigated the proliferative/apoptotic effects of irisin on the HeLa cell line.

MATERIAL AND METHOD

Healthy mouse (AML12, ATCC® CRL-2254) cell line and human cervical cancer (HeLa, ATCC® CCL-2) cell line were obtained from the American Type Culture Collection (Rockville, MD, USA). The cells were seeded into 75 cm² flasks (NEST, China) with 10 mL of medium and incubated at 37°C with 5% CO_2 in a Hera Cell CO_2 incubator. A culture medium consisting of DMEM/EMEM/Ham's F-12 (1:1:1 ratio) (Wiesent Multicell, Canada), 5% fetal bovine serum (FBS, Capricorn, Germany), and 1% L-Glutamine (Thermo-Fisher, USA) was used for cell passaging. To protect the cells from bacterial contamination, the medium was supplemented with 100 IU/mL penicillin-streptomycin (Pen-Strep; Thermo-Fisher) antibiotic and 100× antibiotic-antimycotic (Gibco, USA). Cell passaging was carried out approximately every 48 hours, ensuring the cells reached 97% confluency before passaging.

MTT assays were conducted to assess the effective cytotoxic dose of Irisin on AML12 and HeLa cell lines. Cells were plated separately into transparent 96-well plates with a volume of 180 µL per well and a density of 5×10^3 cells per well.1.56 nM, 3.12 nM, 6.25 nM, 12.5 nM, 25 nM, 50 nM, 100 nM, 200 nM of irisin (Cayman Chemical, 11451) applied to both cell lines for 48-h. Cells without treatment served as controls for comparison with the treated groups. At the end of the irisin application period, 20 µL of MTT solution (Biomatik; A3338-5GM, Canada) was added to each well and incubated for 3 hours. After 3 hours, the liquid from each well was removed, and 100 µL of dimethyl sulfoxide (DMSO) was added. Cell viability was determined by measuring the absorbance at 570 nm using a spectrophotometer (Thermo Scientific Multiskan GO, USA). Untreated control cells with irisin were considered 100% viable. Changes in cell viability due to the application of irisin in doses ranging from 1.56 nM to 200 nM on AML12 and HeLa cells were calculated using the formula below:

Cell viability (%) = (absorbance value of the releated dose of the irisin applied to the wells / absorbance value of the control wells) × 100.

HeLa cell line was seeded into 25 cm² culture flasks at a density of 1×10^5 cells per flask, with 3 replicates for irisin treatment and 3 replicates as controls. After the treatment period, total RNA was isolated from each flask using the Column Pure RNA Miniprep kit (ABM Good, Canada) according to the manufacturer's protocol. RNA quantities from each flask were equalized, and cDNA synthesis was performed using the OneScript Plus cDNA Synthesis kit (ABM Good) according to the manufacturer's instructions. The cDNA samples were stored at -20°C until further RT-PCR analysis.

Expression levels of *PI3K*, *Akt*, *mTOR*, *VEGF*, *HIF-1α*, *Mn-SOD*, *GSR*, *CAT*, *GLUT1*, *p53* genes were analyzed in HeLa cell line for irisin treatment, compared to the control groups. Quantification was performed using a qRT-PCR device (QuantStudio 6 Flex, Applied Biosystems). Changes in gene expression were calculated using the $2^{-\Delta\Delta CT}$ formula and normalized to the internal control glyceraldehyde 3-phosphate dehydrogenase (GAPDH). Gene expression levels were analyzed using SPSS Paired Samples T Test (IBM SPSS Statistics 22). Results are presented as the mean and standard error of the mean (mean _ SD). * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$. The PCR conditions and primer sequences used are provided in the Table 1.

Six-well plates were seeded with 1×10^5 HeLa cells, with three replicates for the control and three replicates for the irisin treatment. Following irisin treatment, the Reactive Oxygen Species (ROS) Fluorometric Assay Kit (Elabscience, E-BC-K138-F, USA) was used to measure and compare the levels of ROS in HeLa cells to control cells. The manufacturer's instructions were followed, and flow cytometry (Applied Biosystems, Attune acoustic focusing cytometer, USA) was employed. Furthermore, the apoptotic cell population was assessed utilizing the Annexin V-FITC/PI Apoptosis Kit (Elabscience, E-CK-A211) in accordance with the flow cytometer's manufacturer's recommendations. Changes in ROS-positive and apoptotic cell numbers in HeLa cells, relative to control groups, following irisin treatment were analyzed using SPSS Paired Samples T Test (IBM SPSS Statistics 22). Results are presented as the mean and standard error of the mean (mean _ SD). * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$.

HeLa cells were seeded into 6-well transparent plates (NEST) as a 1×10^5 cells per well. Hoechst 34580 dye (Cayman Chemical, USA) was used for screening alterations in nuclear structures brought on by apoptosis. 1×10^5 cells per well of six-well plates were used to seed the treatment and control cell groups. All of the wells' media was taken out after the treatment time. The cells were then covered with 500 µL of a solution that included 25 mg of Hoechst 34580 dissolved in 10 mL of 1× PBS in each well. For twenty minutes, the plate was incubated at room temperature in the dark. At the conclusion of the incubation time, all liquid was removed from the wells and the cells were twice rinsed with 1× PBS to prevent false positive findings. Images were taken by a fluorescence microscope with a DAPI filter under a 20× objective.

RESULTS AND DISCUSSION

In this study, the possible cytotoxic effects of irisin hormone, which is a natural hormone in both human and mouse bodies and has 100% homology (Bostrom et al., 2012), on AML12, a mouse healthy liver cell line, and HeLa, a human cervical cancer cell line, were investigated. According to the MTT analysis, it was determined that when 1.56 nM-100 nM irisin was applied to the HeLa cell line for 48-h, there was a regular decrease in the amount of cell viability as the irisin concentration increased. On the other hand, compared to the control group in the AML12 cell line, 99.57 ± 2.03% cell viability was detected due to the application of 3.12 nM irisin, whereas an increase in cell viability was detected compared to the control group for all other application doses of irisin (Figure 1).

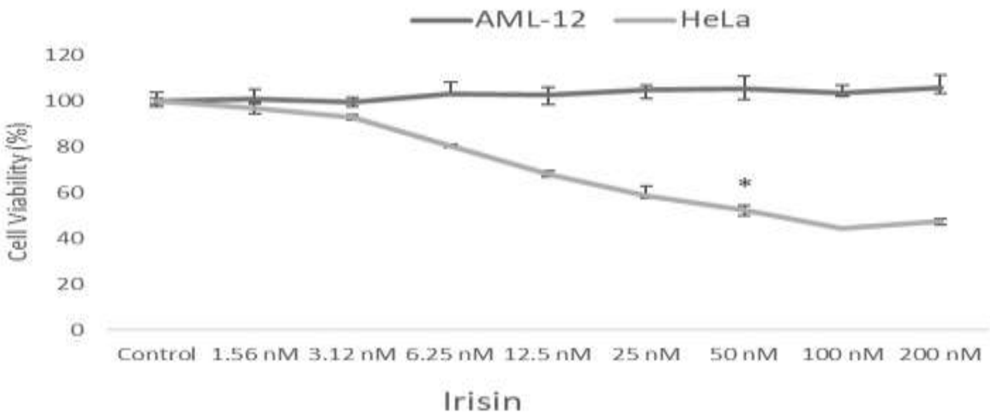

Figure 1. Changes in cell viability due to the application of 3 repeats of irisin to AML12 and HeLa cell lines at a dose range of 1.56 nM - 200 nM for 48-h.

Since 52.21 ± 5.87% viability was detected in the HeLa cell line due to the application of 50 nM irisin and no significant cytotoxic effect was observed for all doses of irisin in the AML12 cell line, it was decided to apply 50 nM irisin to the HeLa cell line for 48-h in the next steps of the study.

It was observed that the expression level of *PI3K* was 0.44 ± 0.03-fold, the expression level of *Akt* was 0.49 ± 0.1-fold, the expression level of *mTOR* was 0.26 ± 0.11-fold, the expression level of *VEGF* was 0.38 ± 0.19-fold, the expression level of *HIF-1α* was 0.12 ± 0.01-fold, the expression level of *Mn-SOD* was 0.23 ± 0.14-fold, the expression level of *GSR* was 0.21 ± 0.03-fold, the expression level of *CAT* was 0.43 ± 0.18-fold, the expression level of *GLUT1* was 6.72 ± 2.25-fold, and the expression level of *p53* was 4.89 ± 1.67-fold changed compared to the control group upon the application of 50 nM irisin to the HeLa cell line (Figure 2).

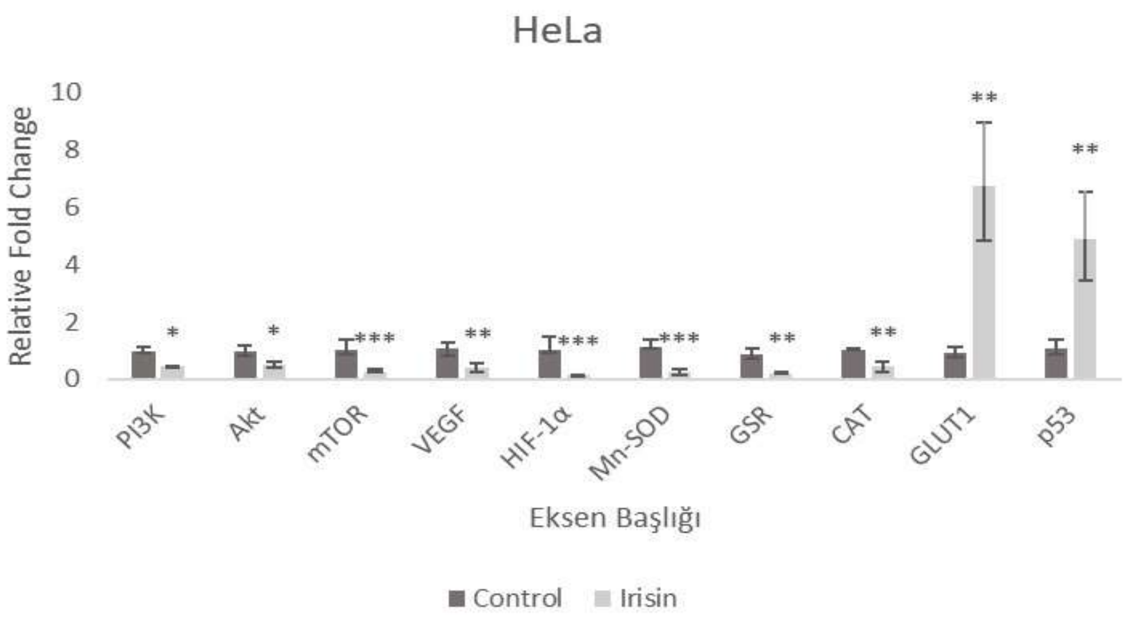

Figure 2. Changes in the expression levels of cell division, antioxidant, hypoxia, and apoptotic genes compared to the control group upon the application of 50 nM irisin for 48-h to the HeLa cell line (Mean= ±SD, *p<0.05, **p<0.01, ***p<0.005).

As seen in Figure 2, despite significant decreases in the expression levels of the PI3K/Akt/mTOR/HIF-1α hypoxia regulatory pathway genes (Lin et al., 2021) due to the application of irisin compared to the control group, the significant increase in GLUT1 expression levels indicates that the energy provided by glucose metabolism is insufficient for HeLa cells. This condition (hypoxia) results in ROS, which cannot be balanced by the antioxidant genes Mn-SOD, GSR, and CAT, ultimately leading to significant increases in the expression levels of the p53 tumor suppressor gene and causing cells to undergo apoptosis (Masson et al., 2012; Köhl et al., 2006).

Additionally, according to the flow cytometry analyses, 71.84 ± 2.49% of cells were affected by ROS and 51.23 ± 3.14% of the total apoptotic and necrotic cells were detected due to the application of irisin (Figure 3).

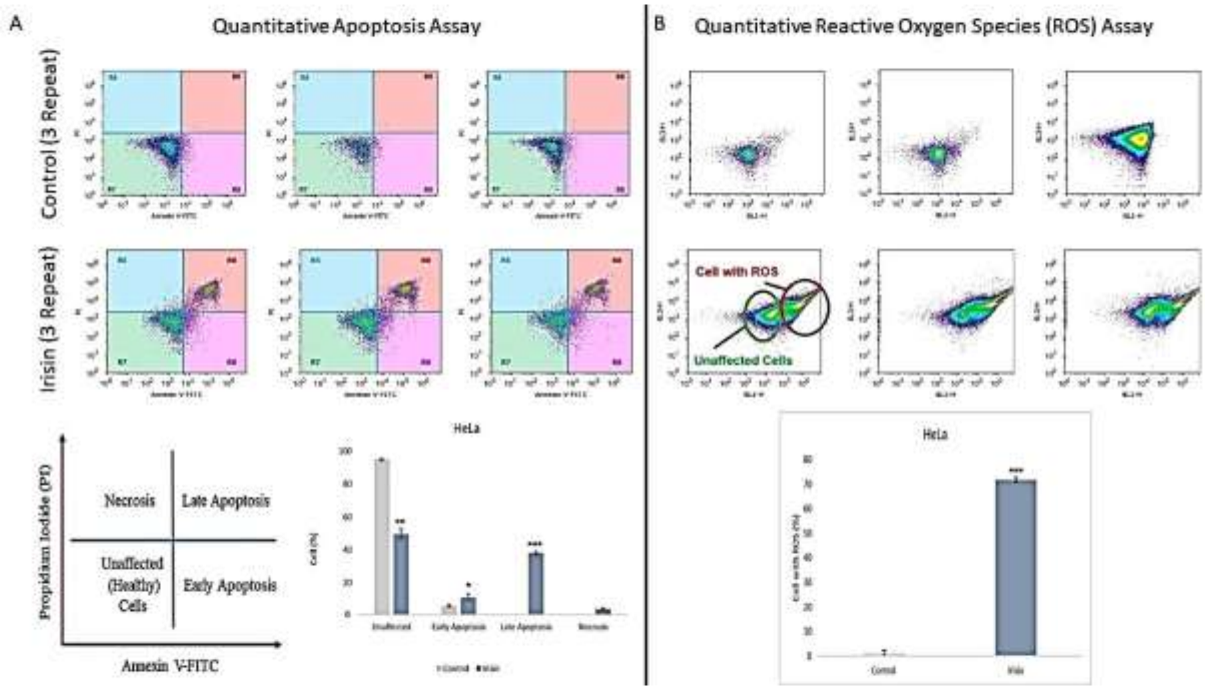

Figure 3. Flow cytometry analyses showing a) the amount of apoptotic cells and b) the amount of ROS-affected cells in the HeLa cell line following the application of 50 nM irisin for 48-h in triplicate (Mean = ±SD, *p<0.05, **p<0.01, ***p<0.005).

Similar to the gene expression analyses, this indicates that irisin suppresses glucose metabolism, leading HeLa cells to undergo apoptosis as a result of ROS impact under hypoxic conditions.

Finally, the changes in the nuclear structures of cells due to the application of 50 nM irisin to the HeLa cell line were compared with the control group and shown under a fluorescence microscope using the Hoechst 34580 staining method (Figure 4).

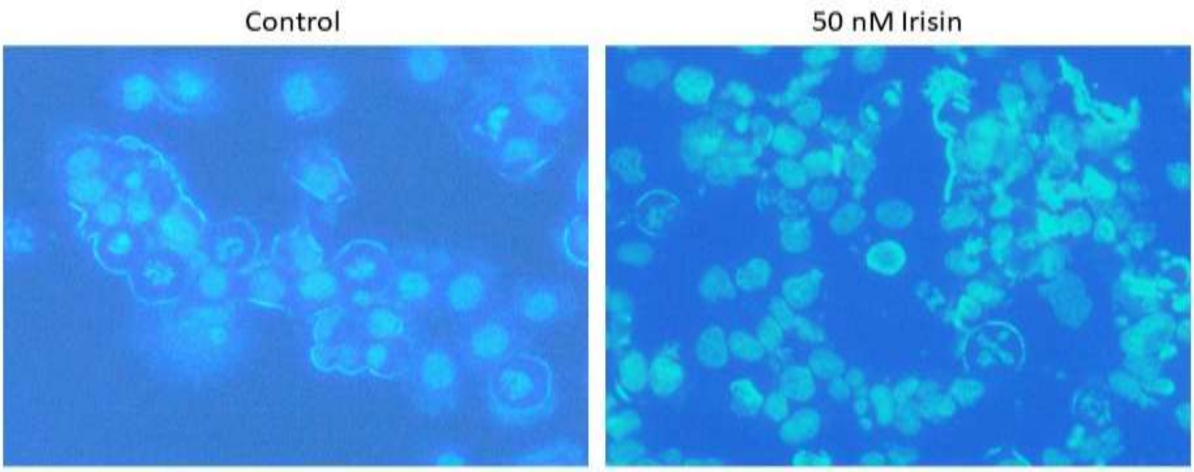

Figure 4. Comparison of the changes in the nuclear structures of cells due to the application of 50 nM irisin to the HeLa cell line with the control group cell line (20× objective).

The dye Hoechst 34580 has a remarkably strong affinity for nucleolar DNA. Since the nuclei in resting cells normally do not condense, Hoechst 34580 binds to DNA poorly and does not cause an excessive brightening. Conversely, in cells that are dividing or going through apoptosis because of DNA damage, the condensation of the nuclear structures diminishes, which makes it possible for Hoechst34580 to bind tightly to the DNA and pass through the weakened links, producing bright fluorescence (Dasari et al., 2013). As seen in Figure 4, the application of 50 nM irisin resulted in the occurrence of bright spots in the nuclear structures of HeLa cells, indicating DNA damage and apoptosis.

CONCLUSIONS

In this study, it was shown that oxidative stress resulting from the suppression of glucose metabolism by irisin leads HeLa cells to undergo apoptosis, while no cytotoxic effects were observed in healthy AML12 cell lines within the 1.56 nM-200 nM dose range, and it even contributed to cell proliferation. Therefore, it is thought that externally administered irisin could have positive effects in combating cervical cancer, particularly HeLa cells. Additionally, since irisin produced by the human body shows complete homology with irisin produced by mice, it is highly likely that this hormone will shed light on successful and rapid results in phase II studies of cervical cancer and other cancers without the need for any post-modification.

ABSTRACT

Amziggar is located in Tabelot municipality west edge of Aïr massif, arid region. The geological formations are constitued by the basement. The water resources is represented by the alluviums aquifers which often dry up before the return of rainy season, with the development of gold-mining activities and its concomitant attraction of local population see national and international have highly exert pressure on these weak groundwater resources. The objective of this study is to determine the fractured and/ or altered areas favorable for drilling hydraulic borholes. The methodological approach, which based on the combined methods of Remote sensing and GIS and field work are allowed to cartograhy and mapping the fractures network. The fracture map produced shows that the main fractures are oriented N0°-N10°, N90°-N100°, N130°-N150°, and N40°-N50° directions.This map will be a precious tool in future groundwater research for Tabelot municipality.
Keywords: DEM, GIS, fractured aquifers, Remote sensing, Arid region, Agadez

INTRODUCTION

In fractured zones, fracking and weathering are the two main conditions of aquifer existence (Engalenc, 1978). In West Africa, several studies have shown great interest in the study of fracking in the identification of discontinuous aquifers including in Ivory Coast (Sokeng et *al*., 2014; Koudou et *al*., 2010; Assoma et *al*., 2013; Kouakou et *al*., 2014), in Burkina Faso (Nakolendousse, 1991; Savadogo, 1984; Faye et *al*., 2023) and in Niger (Corgne et *al*., 2010; Alhassane et *al*., 2018; Babaye et *al*., 2021; Alhassane et *al*., 2023) . These studies have provided very satisfactory results in the determination of discontinue aquifers of basement, mainly the areas where drilling is being carried out.
The area of Amziggar, in the massif of Aïr, is an arid area located in the basement area by excellence and has great difficulty in supplying drinking water. Water resources are represented by alluvial aquifers that dry up before the return of rains(Alhassane et *al*., 2018;

Alhassane et *al*., 2019). With the development of semi-mechanized gold mining activities, this water resources available are heavily stressed for water supply to the populations and for gold mining activities. Moreover, this is added an increase in the population due to the activities of gold comes from various horizons of the country or other nationalities. The area of Amzzigar has become a hub in the economy of Agadez region and for the municipality of Tabelot in particular.

Several tantative of implantation of waters supply was realized by the privates and the the holders of licences of gold mining in the area. However, a significant failure rate is reported from several drilled boreholes. Also, other positive boreholes dry in less than one year of activities. Thus, it is necessary to carry out a study in order to determine areas favorable for drilling borehols. This is achieved by the determination of fractured and/or altered areas. It is in this context that the present study is part of which aims to determine the fractured zones and the favorable areas for wells hydraulic works in Amziggar area. It will be used the methods of sapatial analyses including the Geographic Information Systems (GIS) and Remote sensing.

The Digital Elevation Model (DEM) offers various advantages in the mapping of fractured areas as well as the characterization of the fractured and altered reservoirs of the basement (Cardona et *al*., 2004; Durand, 2005; Ta et *al*., 2008; Alhassane et *al*., 2018).

MATERIAL AND METHODS

Location of study area

The area of Amziggar is the western part of the rural municipality of Tabelot, located at 200 km northwest of the head town of the Department of Tchirozerine and 160 km north at the chief town of Agadez Region. This area belongs to the western flank of Bagzam Mount and its space is dominated by small mountain massifs more or less raked off the mount of "Amziggar" from which the locality gets its name. This municipality is located between 8°51’40’E and 8°58’10’E of east longitude and 17°32’20’’ N and 17°36’40’' N of north latitude (Fig.1).

The climate is semi-arid, of Sahelo-Saharan type with high thermal amplitudes. Four seasons are distinguished in the year: (i) The cold season that goes from november to march. This is the season of harmattan, a dry wind that blows continuously bringing dry mists (Morel, 1983) (Morel and Giazzi, 2001). It is characterized by a drop in temperatures. (ii) The warm season that extends from april to june. This is the season when the intertropical front (ITF) gradually rises northward and the monsoon (humid air) slips under the harmattan. (iii) The rainy season lasts from july to september; and the intermediate season is rather short but difficult for farmers to overcome. Annual averages of low rainfall are always below 200 mm (Morel, 1983). The rains are irregular and poorly distributed in time and space.

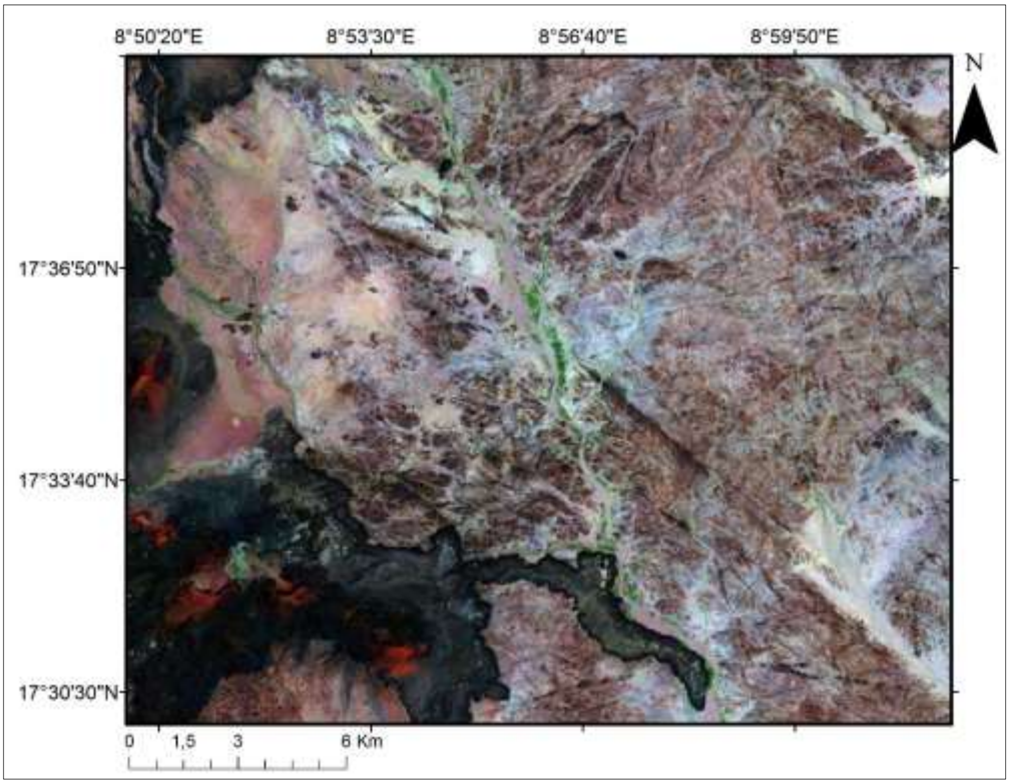

Figure 1. Location map of study area

Geological and hyrogeological context

The Aïr massif is a south-eastern appendix of the Tuareg shield (fig.2). It consists of three main domains that are from West to East: (i) the Assodé domain, formed by two N-S accidents: the Arlit fault in the West and the "Raghane" accident in the East; (ii) the Barghot domain; and (iii) the Aouzegueur domain (Liégeois et *al*., 1994; Liégeois et *al*., 2005; Liégeois et *al*., 2013). At the end of the phase of convergence between the West African craton and the Saharan meta-craton, around 670 Ma, the domains of Aouzegueur and Barghot are charred and attached to the East-Saharan craton (Black et *al*., 1985; Black et *al*., 1994) while the Assodé estate moved by dextrous sliding along the "Raghane" accident, northward, to the upper Pan-African.

The geological formations of Aïr Massif include (Black et *al*., 1979; Black et *al*., 1985) of eburnian gneiss containing amphibolites, quartzites, diopside marbles, granitoid of Precambrian anatexia related to pan-African tectonics and sub-volcanic and hyperalkaline volcanic complexes ("younger granites") (Moreau et *al*., 1994; Pouclet et *al*., 1994; Pouclet and Durand, 1985; Pouclet et *al*., 2006) with annular structures intersecting the whole, and which were set up in the Ordovician and Silurian (Black et *al*., 1985) (Pouclet et *al*., 1994) (. According to Joseph, (1991) four accident families affects the massif according to the directions NW-SE, N80°, N45° and N120°-N150°.

The aquifers of the alterites are located in the altered zones of the basement, they are mainly captured by cemented wells with large diameter and their average depth is about 22 m. The waters are of an average salinity, for most of the works. Alluvial aquifers are located on the edges, and at the bottom of the koris which generally cut the young massifs to the foothills from which the springs and gueltas are found (Joseph et *al*., 1990; Joseph, 1991; Gallaire, 1995). These aquifers are captured by shallow wells (6 to 18 m). The waters of these aquifers have low salinity.

The site is located in the massif of Aïr, it is mainly based on the crystalline basement, where the geological framework is represented by magamatic and crystallophyllic formations (Fig.2). Thus, the resources of water in the sub-region are confined to alluvial streams (valleys) representing shallow alluvial aquifers captured by cemented wells. The second reservoir is formed by the fractured, cracked and or altered formations of the basement.

As for the catchment works, they are constituted mainly by cemented wells of shallow depth (22 m) capturing the alluvial layer dependent on rainfall. The water in these aquifers is poorly mineralized. They are used for the supply of drinking water to populations, abreveument of the livestock and in market activities. They are also represented in recent years by drilling to capture the discontinuous aquifers of the base with more or less important flows around 6 m^3/h. In some places, the water of the aquifers of the base is highly mineralized and unsuitable for any activity.

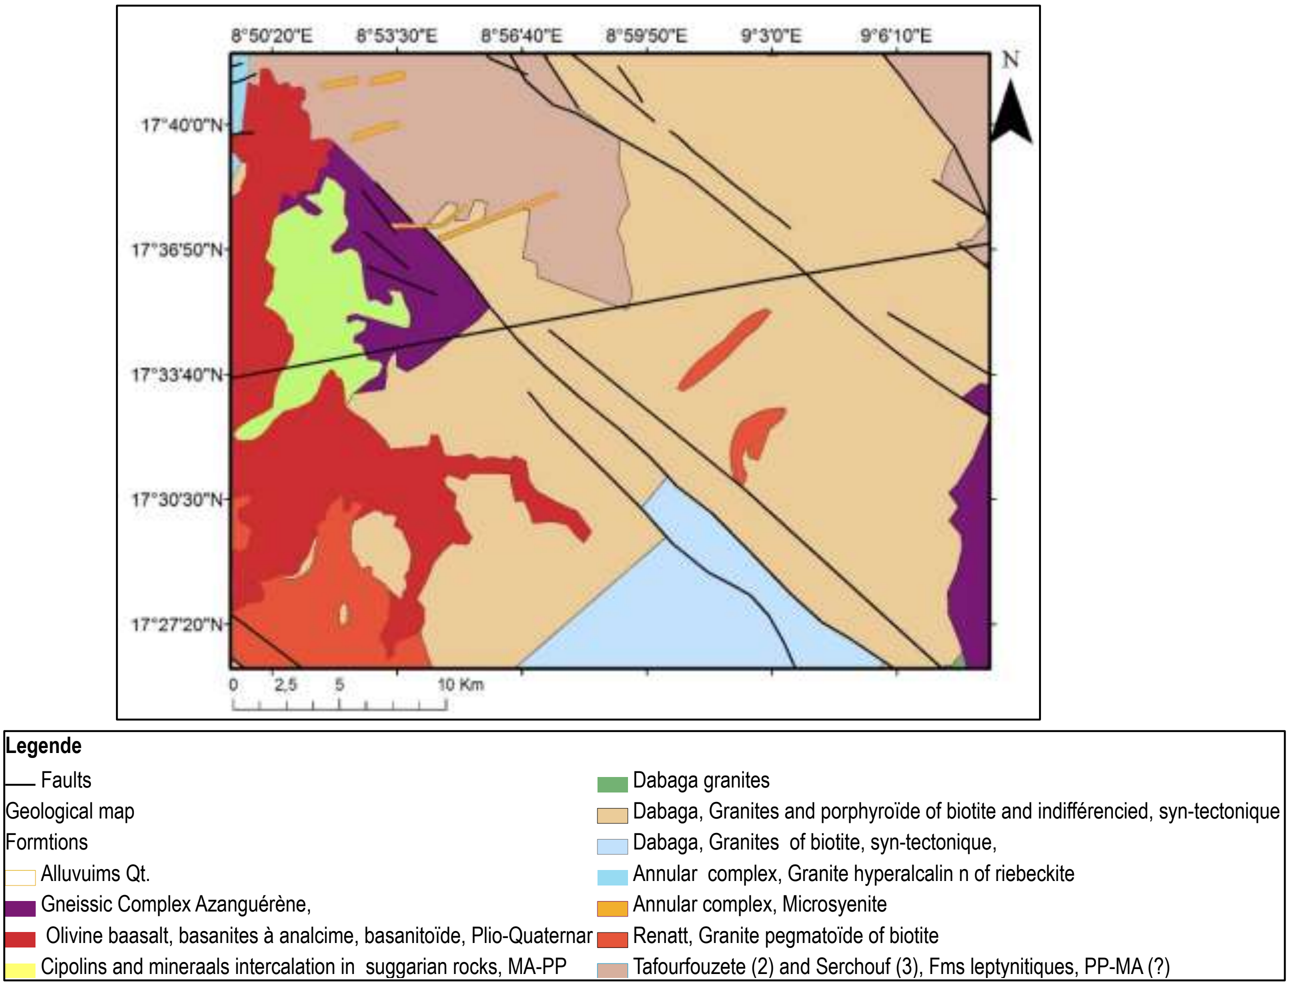

Figure 2. Geological map of the study area

METHODOLOGY

The cartographic database used for this study mainly includes a Digital Elevation ModelModel (DEM, resolution 30 m, scenes: 17-008 and 17-009, SRTM 30 M, NASA, USGS/2011). A topographic map of the Elmeki sector (Marchaud et *al*., 1961) (sheet Elmeki NE-32-IV) at 1/200 000e and a geological map of the Air (Black et *al*., 1979) were also used at 1/500 000e .

The DEM, which was image-to-image corrected, was performed from four calibration points from the area corrected ETM^+ bands. The degree 1 polynomial transformation and a re-sampling by the cubic convolution method were used for these four calibration points. The average RMS (Error Refractive Mean) for the DEM image is 0.218 m and compared to half pixel (15m), these errors are smaller than this one, so correction is acceptable (Corgne et *al.*, 2010; Koita et *al*., 2010).

After the pretreatment phase, the Digital Elevation Model (DEM) was subjected to various treatments including the technique of the stompage. This classic mapping technique, is to represent the effect of the relief by illuminating the DEM in a defined direction and thus creating shadows forming a monochrome image (Donnay, 2000). In this study, the DEM was estomping in four directions (N045°, N090°, N135° and N180°) to accentuate the structural directions perpendicular to them (NW-SE, N-S, NE-SW and E-W). This will allow the lineaments to be identified and plotted manually (Babaye, 2012; Sokeng et *al*., 2014; Alhassane et *al*., 2018; Babaye, et *al*., 2021) (Fig.3).

The lineaments highlighted from the DEM estompage were confronted and superimposed on the accidents represented on the geological map (Black et *al*., 1979) to gave a structural significant of lineaments for the validation data. However, on the geological map the density of faults is very low and it has been supplemented by field work. Subsequently, a field survey with outcrops and hydrogeological observations was carried out: (i) Type of aquifer and depth of the captured water table, (ii) identification of flood and erosive zones; (iii) location of possible pollution hotspots (cemeteries-livestock run and pass area); and (iv) information on the hydrographic network.

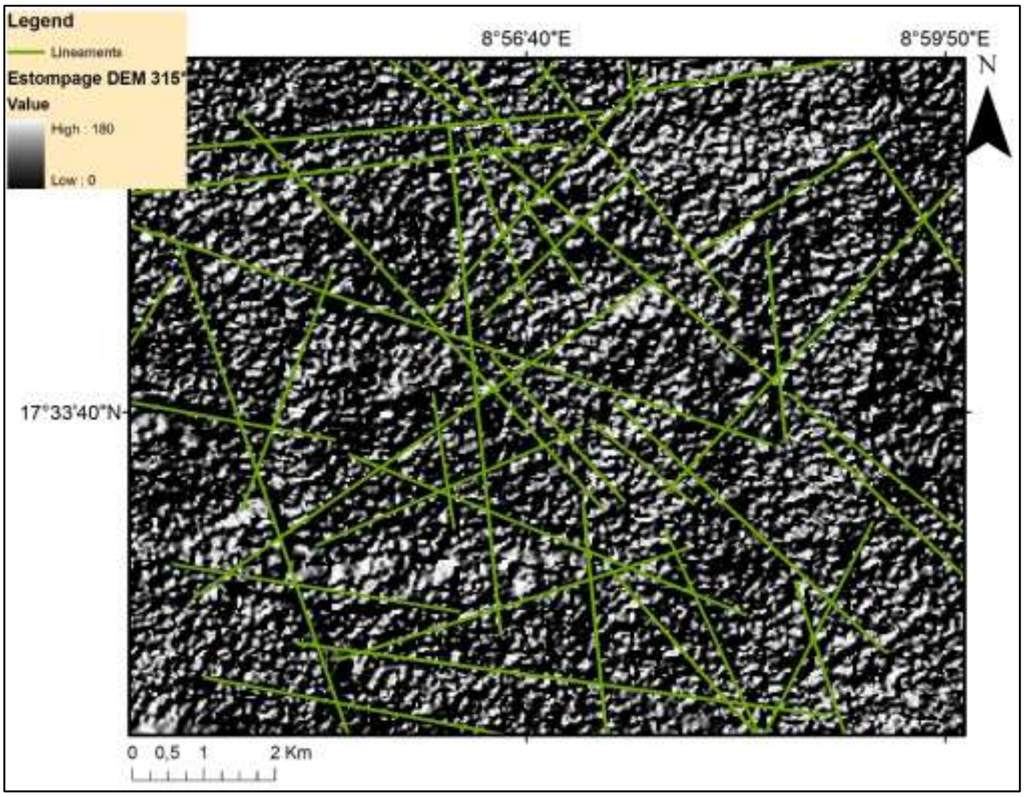

Figure 3. Estompage of DEM in 315 °

RESULTS AND DISCUSSION

Directional distribution of fractures

The four main fracture directions in number with the highest percentages, (Table 1), are N0°-N10°, N90°-N100°, and N160°-N180°, with respective percentages: 16%, 11%, and 9%. Then comes the directions N140°-N150°, N100°-N110°, and N130°-N150°, N150°-N160°, N120-N130°which have only percentages of 7% to 5%.

With regard to the cumulative lengths of fractures (Table 1), four main directions are distinguished: N130°-N140°, N40°-N50°, N140°-N150°, N160°-N170°, with the respective percentages being: 13%, 10%, 10% and 8%. Finally, the lowest percentages are found in N100°-N110°, N170°-N180° and N130°-N140°, with 7% and 6%, respectively.

Table 1: Percentages of fracture directions, in number and cumulative lengths, from the DEM estompage.

Supports	Directions	% number of fractures	Directions	% cumulatives lengt of fractures
MNT (Estompage)	N0°-N10°	16%	N130°-N140°	13%
	N90°-N100°	11%	N40°-N50°	10%
	N160°-N170°	9%	N140°-N150°	10%
	N170°-N180°	9%	N160°-N170°	8%
	N140°-N150°	7%	N100°-N110°	7%
	N100°-N110°	7%	N170°-N180°	6%
	N130°-N150°	5%	N130°-N140°	6%
	N150°-N160°	5%	Others	< 5%
	N120°-N130°	5%		
	Others	< 5%		

Synthesis of fractured mapping

The summary of the results of the statistical processing of fracking data (fig. 4) shows that the following directions: N0°-N10°, N90°-N100° and N160°-N180° are dominant followed by those that are secondary, oriented: N140°-N150°and N100°-N110°.

The cumulative fracture lengths (Fig.5b) are more important in the directions N130°-N140°, N140°-N150°, and N40°-N50°, corresponding to those of the mega fractures. Next are directions N160°-170° and N100°-N110°, with little significant cumulative length for secondary fractures.

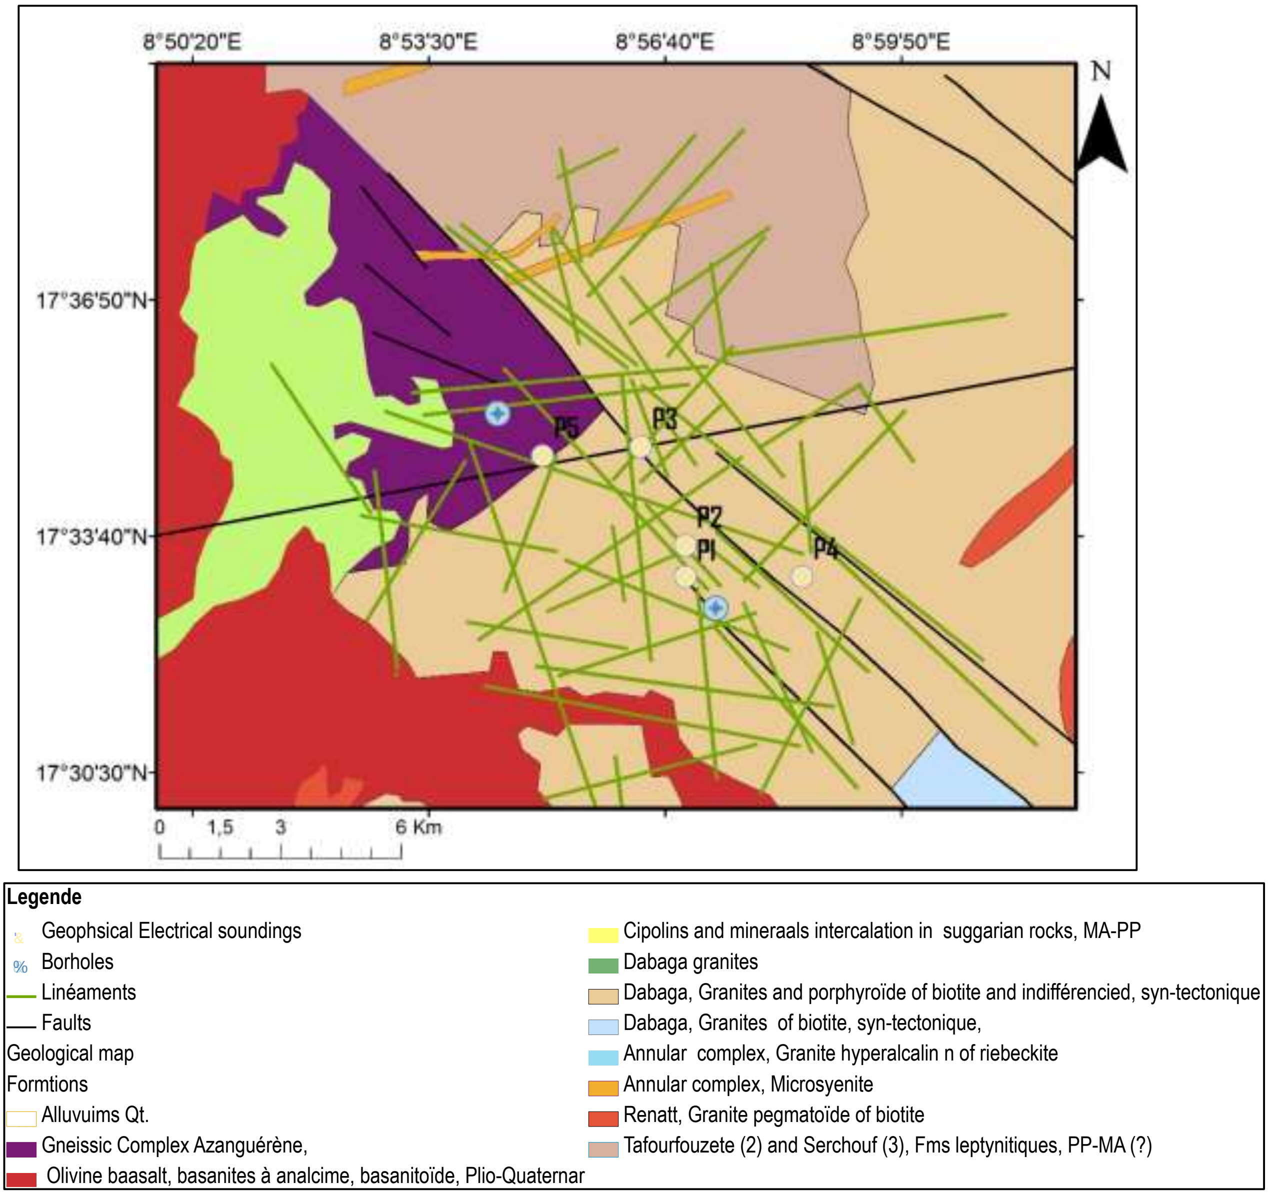

Figure 4. Fracturation Map of study area

DISCUSSION

In the fracking network mapping, the DEM blurring has made it possible to highlight the usefulness of this tool in the characterization of fracturation in the basement zones. Various work has used the DEM in identifying discontinuous aquifers of the basement (Durand, 2005; Corgne et *al.*, 2010; Otchoumou et *al.*, 2012; Sokeng et *al.*, 2014; Alhassane et *al.*, 2018; Babaye et *al.*, 2021).

The direction N0°-N10° is the most abundant and represents the shear of "Raghane" crossing the Aïr on the north-south direction wide from 5 to 10 km over more than 400 km (Liégeois et *al.*, 1994). In the area of Timia, central Aïr, this direction is also well represented and it is the most important (Alhassane et *al.*, 2018) .

Accidents N90°-N100° and N160°-N180° are the most numerous after class N0°-N10° in the Amziggar area. The former are observed throughout the study area and control the direction of most watercourses in the orientation zone (N70°-N80°, N90°-N100°). In Timia area, most courses are in this direction (Alhassane et *al*., 2018). According to (Joseph, 1991), the accidents N70°-N80° affecting not only the base but also the sedimentary formations of the western edge of the massif of the Aïr, can provide a possible hydraulic transfer.
Accidents N160°-N180° are the majority of directions for quartz and quartzite veins in the Central Aïr (Alhassane et *al*., 2018). the presence of N160°-N170° accidents is evidenced in the Téfidet trough (Ahmed et *al*., 2017).
The N130°-N140° directional fractures represent the largest class in length accumulated in the Amziggar sector, constituting mega-lineaments observable over great distances (Black et *al*., 1979). Also, they were observed mainly on the relics of the Pan-African base flush on the eastern, western and central edges of the Timia area (Alhassane et *al*., 2018). These fracture bundles played a significant role in the structuring of the Tefidet trough (Black et *al*., 1979; Ahmed et *al*., 2017). The N140°-N150° direction fractures give the same percentage as the N130°-N140°(10%) in length cumulative. Thus, they are of the same family of accidents. In the case of N40-N50 accidents, it is carried by numerous rhyolitic and gabbro dykes (Black et *al*., 1979). Finally, accidents N160°-N170°, this family is observed in the Téfidet trough (Ahmed et *al*., 2017).
Various works carried out in the West African base based on satellite images analysis, in Niger (Alhassane et *al*., 2018; Babaye et *al*., 2021), in Côte d'Ivoire (Lasm, 2000; Kouassi et *al*., 2012; Kouamé et *al*., 2014; Koudou et *al*., 2014) and in Burkina Faso (Nakolendousse; 1991; Koussoubé, 2003; Faye et al., 2023) have improved knowledge of the fractured aquifers of the base.

CONCLUSIONS

The analysis and exploitation of the Digital Model elevation (DEM) has made possible to identify and map the fracture network in the Amziggar sector. They are mainly oriented towards N0°-N10°, N90°-N100° and N160°-N180° in number of fractures and N130°-N140°, N140°-N150°and N40°-N50° in length cumulated. These fractures are not enough to constitute an aquifer. However, these structures in conjunction with other additional hydrogeological information may help to identify areas favourable for the establishment of drilling in the Amziggar area. Geophysical studies will confirm these structures in evidence as well as their water saturation.

ABSTRACT

Soil is a key component of the planet and plays a crucial role in achieving the United Nations Sustainable Development Goals and addressing the challenge of land degradation neutrality. Salinity and sodicity are among the most significant challenges faced by irrigated agriculture worldwide Due to the scarcity of fresh water, highly saline groundwater has become the primary source of irrigation. Saline water is used to irrigate cultivated lands in various parts of the world, especially in arid and semi-arid regions that cover 41% of the Earth's surface (UNDP 1997), despite the poor quantity and quality of this resource. Salts are naturally present in soil and groundwater. However, when the levels of soluble salts in the soil or water exceed natural concentrations, it can lead to salinity, posing significant risks to health and reducing plant productivity. Globally, approximately 0.9 × 10^9 hectares are affected by varying levels of salinity and sodicity, and this soil degradation is progressively worsening over time. The widespread presence of saline soils and waters, along with their current and future intensive use in agriculture, necessitates immediate attention and concerted efforts to improve their productivity, which is generally very low under routine management conditions.

To address this issue, gaining a deeper understanding of how salinity and sodicity affect the hydraulic properties of soils, along with their interactions with other soil characteristics, is essential. An energy-based approach to monitoring salinity and sodicity is crucial for comprehending water movement through the soil. This method considers soil texture and the gradients of salinity and sodicity within the soil profile. It serves as a vital tool for understanding how varying levels of salinity and sodicity impact soil hydraulic properties. Consequently, soil hydraulic conductivity is a key factor for the restoration of desert lands and the planning of irrigation projects. This understanding is crucial for assessing soil degradation, restoring affected soils, and effectively planning their conservation and optimal use of land resources.

The goal of this study is to establish a diagnostic protocol for analyzing water transfer in soil, focusing on soil texture and gradients of salinity and sodicity in irrigation water. To achieve this, experiments will be performed using soil samples in Plexiglas columns under controlled conditions, where different salinity and sodicity gradients will be applied to various soil textures to simulate water movement. Control columns will receive irrigation with distilled water.

Preliminary results indicate that soil salinity and sodicity levels can be managed by adjusting irrigation water quality and considering soil texture, provided there is effective drainage. This strategy helps prevent physical soil degradation caused by sodicity. Therefore, it is important to select salt-tolerant crops for clayey soils with high sodicity and to implement early diagnostic measures to address the effects of salinity and sodicity, in order to maintain soil physical quality. has more than 40 % of Turkish sunflower production. Based on the study results, some candidate hybrids had higher drought tolerant indices such as total chlorophyll content, hairiness, dry root weight at stem than control hybrids in the study.

INTRODUCTION

Soil and water salinity is one of the economically costly challenges for achieving sustainable development globally. Salinity poses a significant environmental issue, particularly in arid and semi-arid regions where precipitation is insufficient to leach salts from the root zone. Over 75 countries worldwide face salinity issues.

Recent trends and future demographic projections indicate that increasing food and fiber production will require effective use of salt-affected lands and saline water resources. Currently, at least 20% of irrigated lands globally are saline and/or irrigated with water containing high salt levels. Several major irrigated areas have experienced issues with salinity and sodicity, which have diminished their agricultural productivity and sustainability.

It is estimated that salinization of irrigated lands results in an annual global revenue loss of about $12 billion, impacting national economies in countries affected by saline land degradation and saline water resources.

Typically, the most severe impacts of salinity occur in areas where farming communities are relatively poor and face economic challenges. In extreme cases, salinization leads to the displacement of affected communities, with men seeking non-agricultural income opportunities elsewhere.

According to Gergely (2010), there are two processes of salinization: primary and secondary.

Primary salinization involves the accumulation of salts through natural processes due to high salt content in the parent material or groundwater. Secondary salinization is caused by human activities, such as inappropriate irrigation practices and inadequate drainage.

Saline soils account for approximately 40% of the global area affected by salt These soils are non-sodic and contain sufficient soluble salts to adversely affect the growth of most crops.
Sodic soils represent approximately 60% of the global area affected by salt. These are non-saline soils containing sufficient exchangeable Na^+ to impair agricultural production and soil structure under most soil and plant conditions.

Saline water is used to irrigate cultivated lands in various parts of the world, particularly in arid and semi-arid regions, which account for 41% of the Earth's surface (UNDP 1997), often with poor water quantity and quality. In these areas, limited precipitation (≤ 400 mm/year) is insufficient to leach salts from the root zone, leading to the accumulation of irrigation water salts in the soil and affecting its properties.

Saline water is not beneficial for irrigated agriculture, but it can still be a primary source of irrigation water in extensive arid regions, especially in developing countries where extreme freshwater scarcity and rapid population growth demand more water.
It impacts various physical and chemical properties of the soil, there by influencing its suitability as a growing environment for plants
The increase in soil salinity and/or sodicity affects soil structure, in turn, have significant impacts on soil hydraulic properties such as water retention capacity and hydraulic conductivity.
Soil hydraulic properties are among the most important and fundamental soil variables due to their effects on agricultural production, ecological and environmental protection, engineering, and construction. Hydraulic conductivity can be used to establish soil-water relationships.
Saturated hydraulic conductivity determines the soil's ability to transmit water and affects all soil-plant-water relationships and processes. It primarily depends on soil structure and texture. The hydraulic conductivity of soil can be altered by the composition or concentration of salts in the aqueous solution.
To address this challenge, it is crucial to gain a better understanding of the impacts of salinity and sodicity on soil hydraulic properties, as well as their interactions with other soil characteristics.

MATERIAL AND METHOD

In this study, we examined the saturated hydraulic conductivity of the soil using disturbed samples arranged in soil columns. The soil column is a classic laboratory tool widely used to study solute transport. We conducted several experiments with it, using different saline concentrations and soil textures. Soil texture is one of the most important characteristics of soil and is considered key to its fertility. It is related to many other soil properties and controls its physical, chemical, hydrological, and mechanical behavior. four soils with different textures were investigated in these experiments. The samples taken are first characterized in terms of their physicochemical properties. The disturbed soil samples were air-dried and passed through a 2 mm sieve. A portion of the sample was used for particle size analysis. Subsequently, soil texture classes were determined according to the USDA soil classification system (USDA, 1987).

To control both salinity and sodicity parameters, saline solutions were prepared using two salts: sodium chloride (NaCl) and calcium chloride ($CaCl_2$). The choice to combine these two salts is deliberate. On one hand, it allows for the expression of both beneficial and detrimental effects respectively attributed to Ca^{2+} and Na^{+} ions in the environment. On the other hand, it reflects the real-world scenario where a single salt, particularly NaCl, is rarely found in isolation, as salts generally occur in various forms or even complex combinations. We obtained four chosen values for Salinity concentration (0, 250, 450, and 775 méq/L) and four additional values for SAR (0 / 22,37 / 39,36 and 42,43), in accordance with the relationship between SAR and salinity concentration: The Sodium Adsorption Ratio (SAR) is a useful index for assessing soil sodicity or the relative sodium status of soil solutions. It is calculated as follows (Gregorich and Carter, 2007):

$$x = \frac{(\mathrm{Na+})}{\sqrt{(\mathrm{Ca2+}) + (\ \mathrm{Mg2+})/_{2}}}$$

We note that the range of sodicity (SAR) we have chosen includes a value considered average in the arid and semi-arid regions of Algeria, which is 15. In this context, the SAR value of 42,43 is intended to represent extremely severe aridity conditions in these regions.

Hydraulic Conductivity Measurement Setup

The setup for measuring saturated hydraulic conductivity (CHs) is based on the design described by Aubert (1978). It consists of four graduated columns connected to a tube, which is linked via a valve to a Woolff flask. This flask is fed from another Woolff flask using a valve. The upper Woolff flask provides water to the lower flask, which maintains a constant head on the sample columns. The lower flask supplies the columns through the tube. After equilibrium is reached between the solution and the sample, the volumes of the collected solutions are measured after one hour of percolation. During each irrigation, we make sure to keep a consistent stagnant water depth of 3 cm at the top of each soil column. Before measuring the CHs, we allowed the saline solution to percolate through the sample until the electrical conductivity (EC) of the collected drainage solution matched that of the saline solution. The equilibration time varies depending on the clay content and the relative levels of salinity and sodicity involved. The electrical conductivity (EC) is measured using a conductometer on a saturated paste extract. Distilled water, with zero salinity and sodicity, is used as the control solution. All CHs measurements are repeated three times.

RESULTS AND DISCUSSION

The soil infiltration process is indicated by changes in the infiltration rate, which reflect the soil's infiltration capacity. Variations in infiltration rates under four different salinity levels over time are presented in figure 1, 2 and 3. The graphs show an inverse correlation between the increasing salinity of the irrigation water and the hydraulic conductivity of the four textures, indicating a systematic reduction in the latter as salinity increases.
The results of saturated hydraulic conductivity as a function of salinity and sodicity and soil texture are presented in Figures 1, 2, and 3

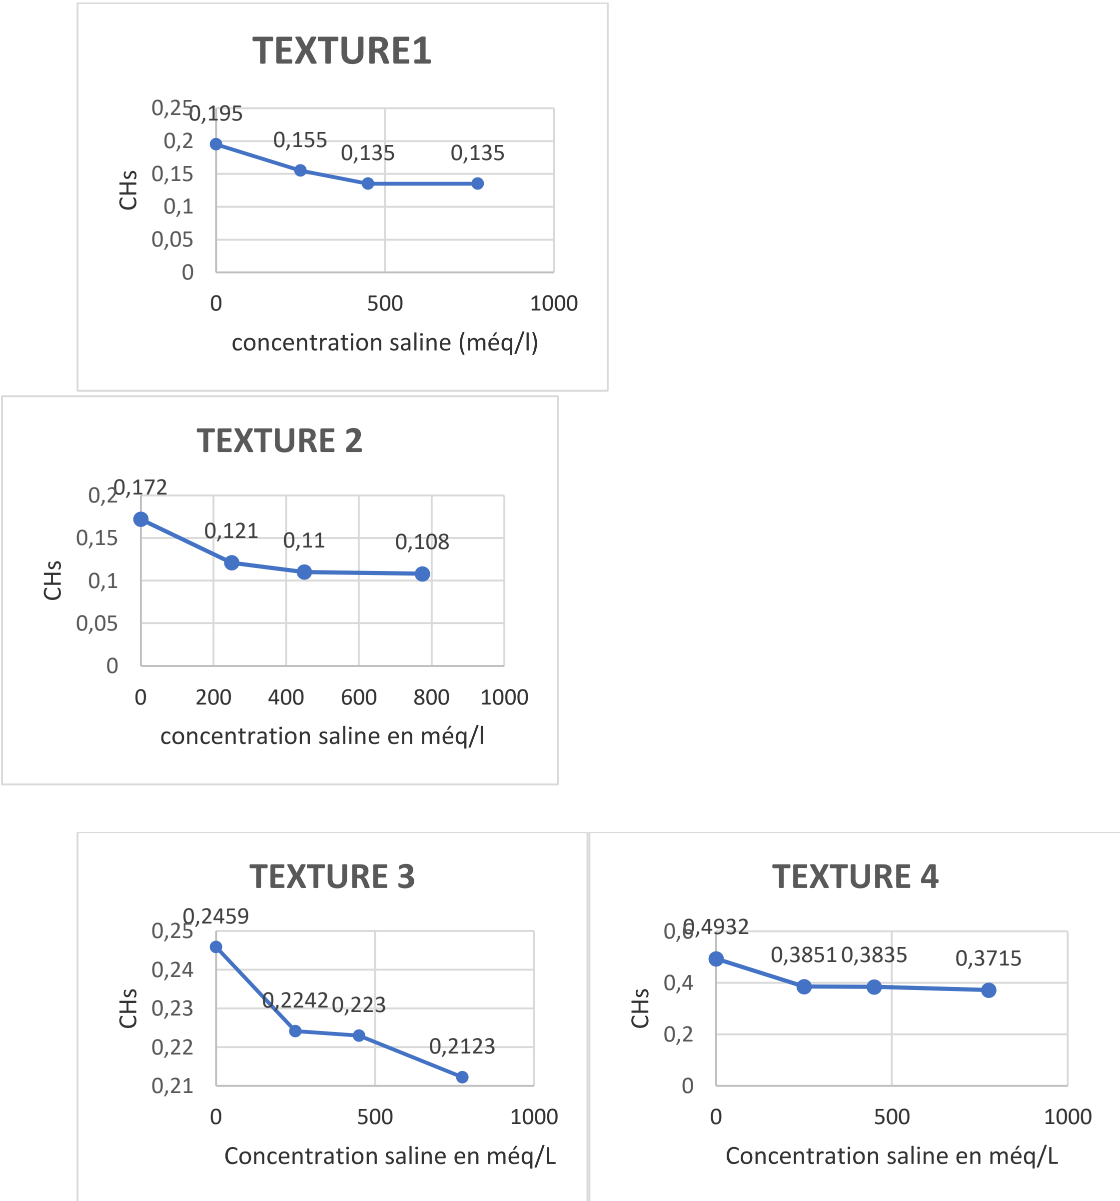

Figure 1: Soil hydraulic conductivity (Cm/min) affected by soil texture and salinity

Increased salinity in irrigation water results in higher concentrations of dissolved salts, which can alter soil physical properties. Elevated salinity can lead to the dispersion of soil particles, particularly in clay-rich soils (texture 2). This dispersion reduces soil aggregation and pore connectivity, thereby diminishing the soil's hydraulic conductivity.

Overall, the relationship between irrigation water salinity and hydraulic conductivity is characterized by a negative correlation, where higher salinity levels correspond to reduced hydraulic conductivity due to the detrimental impact of salts on soil structure and pore dynamics.

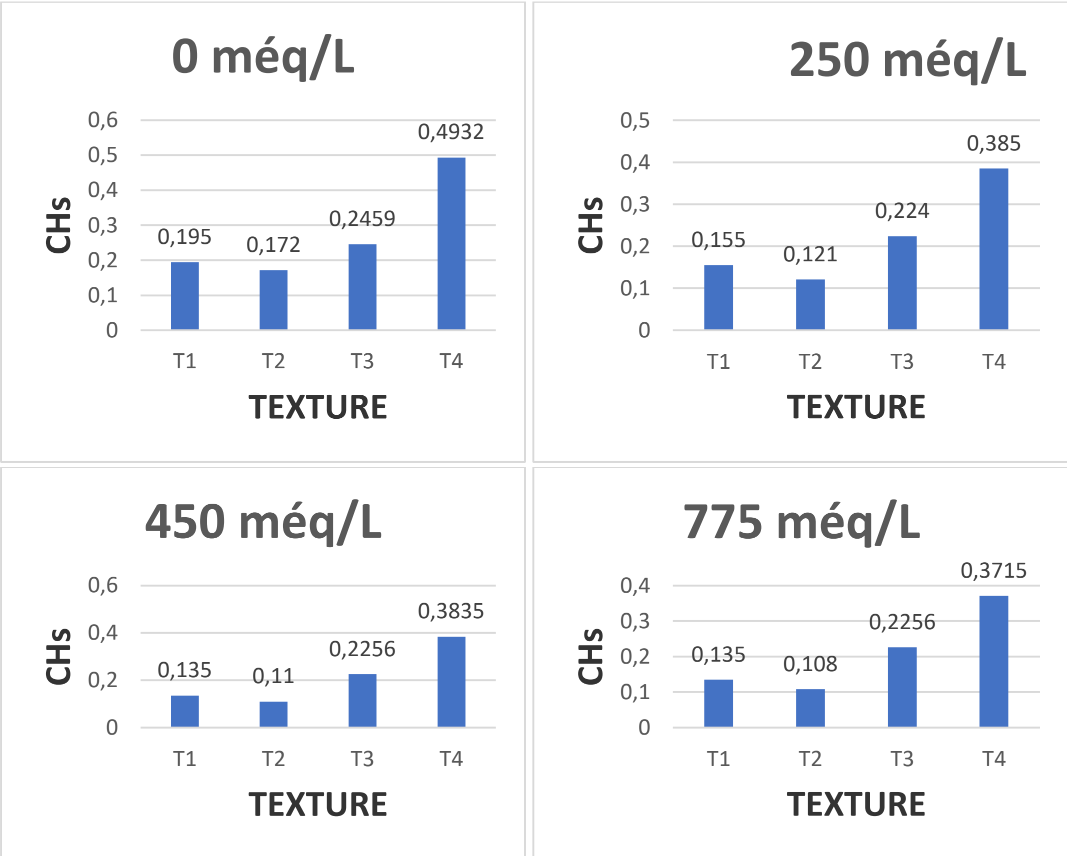

Figure 3: Soil hydraulic conductivity (Cm/min) affected by soil texture

The results indicate that the clay content percentage plays a crucial role in water movement through the soil. Soils with higher clay content tend to exhibit lower infiltration rates compared to soils with lower clay content.

This is likely due to the fact that clay particles, being fine and cohesive, reduce the soil's permeability and increase its capacity to retain water, thereby limiting the infiltration rate.

The impact of the salt content in irrigation water on water infiltration characteristics varies depending on the different soil textures.

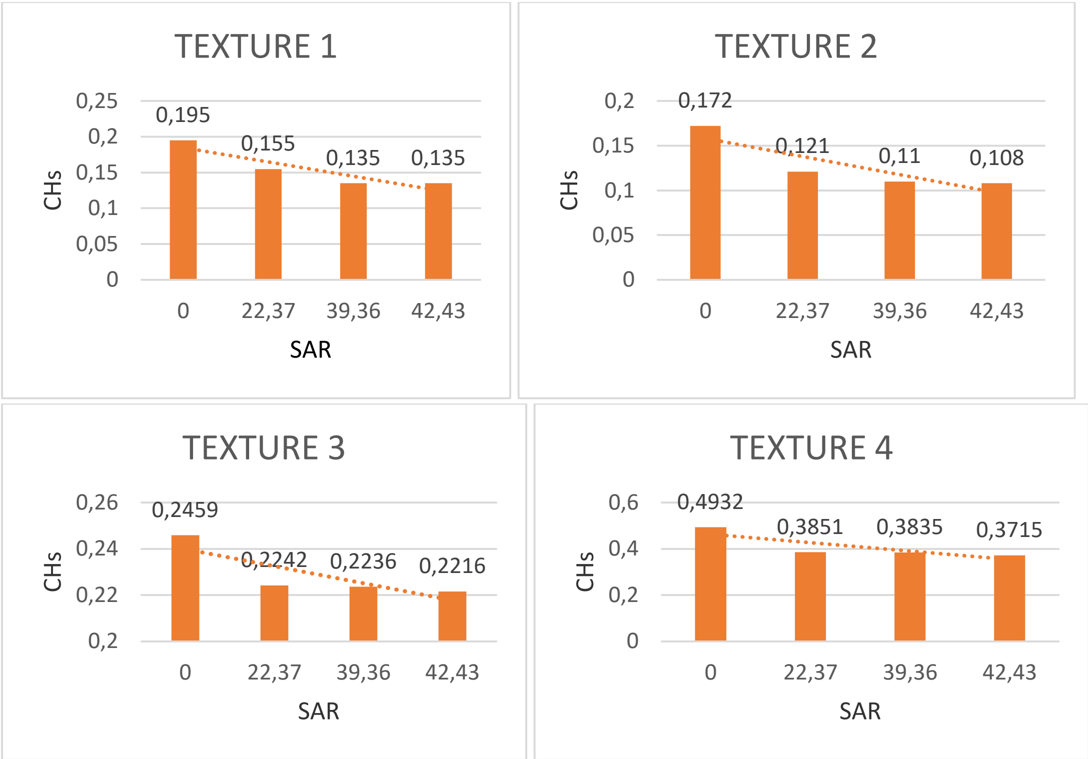

Figure 2: Soil hydraulic conductivity (Cm/min) affected by soil texture and sodicity

first general observation from these histograms is that sodicity tend to decrease the values of saturated hydraulic conductivity. The soil infiltration rate, decreased with increasing salt concentration in the irrigation water. The rise in sodium ions caused clay swelling upon wetting, which destroyed the soil structure by inducing swelling, settling, and dispersion of the clay. This led to the collapse of macropores and blockages, there by impeding water movement through the soil matrix.

CONCLUSIONS

This study was designed to provide detailed information on the effect of a wide range of saline and sodic solutions on the saturated hydraulic conductivity of several well-characterized soils.

Irrigation with water having a high SAR leads to an increase in the exchangeable sodium percentage (ESP) in the soil, which negatively impacts its physical properties, such as hydraulic conductivity (HC), due to clay dispersion caused by Na+ ions. Changes in soil sodium content can also lead to alterations in the physical and chemical properties of the soil, affecting the composition of cation exchange complexes and mineral composition. This, in turn, influences how soil particles interact and bond with each other within aggregates.

However, the effects of sodium and salt concentrations on soil hydraulic properties were also influenced by other soil properties, such as soil texture.

Saturated hydraulic conductivity is a key determinant of a soil's ability to transmit water and plays a critical role in the interactions and processes among soil, plants, and water. This property is mainly influenced by the soil's structure and texture. Furthermore, the hydraulic conductivity of the soil can be affected by the concentration and composition of salts in the aqueous solution, which can modify the soil's hydrodynamic behavior.
Studying the effects of soil salinity on hydraulic conductivity will provide valuable insights for developing irrigation systems and implementing salt leaching methods.

APPLICATION OF EMULSION BASED ENCAPSULATION METHODS IN FOOD TECHNOLOGY: A REVIEW

Jasmine Tahmaz

Faculty of Agriculture and Food Sciences, University of Sarajevo, Sarajevo, Bosnia and Herzegovina

ABSTRACT

Encapsulation is a method of entrapping and protecting sensitive active compounds into the structure of an encapsulation carrier (coating material). Capsules of different dimensions (macro, micro, and nano) are obtained as encapsulation products. Each capsule consists of two main materials: 1) active compound and 2) carrier (coating material). The main aim of encapsulation is to protect active compounds from degradation influenced by different external factors. Encapsulation is a technique that can increase the stability and improve the usability of many active and biologically valuable natural ingredients. In recent times it is increasingly used in food technology. Emulsification is one of the most important encapsulation methods suitable for use in food technology. It can be used alone or in combination with other encapsulation methods. Formation of emulsion can be used for the encapsulation of hydrosoluble and liposoluble liquid substances. The size of droplets within such emulsions ranges from 0.1-5000 μm. The main advantages of this encapsulation method are good protection of the encapsulated substance from high temperatures and oxidation during heat treatment and drying, the possibility of encapsulating liposoluble and hydrosoluble substances, and controlled release of the active substance. Emulsion-based techniques are widespread encapsulation methods suitable for the food industry. A wide range of active substances can be encapsulated, such as probiotic bacteria, proteins, amino acids, essential oils, flavonoids, vitamin E, lutein, beta carotene, fish oil, omega 3 fatty acids, aspartame and other sweeteners, xylitol and menthol in chewing gum (prolonged cooling effect), curcumin, catechin, vitamin C, vitamin B12 (for the enrichment of dairy products), vitamin B1 and herbal extracts. Obtained capsules can be applied in the production of functional milk and dairy products, salad sauces and dressings, fruit juices, dried soup mixtures, functional meat products, the oil industry, and confectionery.

Keywords: Encapsulation, Emulsions, Food technology, Stability, Enrichment

INTRODUCTION

Encapsulation is a technique by which a material or mixture of materials is packed into the structure of another material. The beginnings of encapsulation use in industry date back to around 1950th years (Madene et al., 2006). Firstly it was commonly used in the pharmaceutical industry and in in recent time in food industry, too. For the needs of the food products, the most common encapsulated active compounds are: vitamins, minerals, dyes, enzymes, probiotics and flavors.

The importance of encapsulation lay in fact that it is a technique that can improve the stability, usability and availability of many biologically valuable natural ingredients. The goal of encapsulation is the formation of stable capsules from natural or synthetic polymer materials within which the active substance is encapsulated (Pegg and Shahidi, 1999).

Each capsule consists of two basic compounds: 1) coating material (carrier, sheath, wall material, shell or encapsulation matrix) and 2) active substance (encapsulant, inner phase or capsule core).

The active substance is the material that is encapsulated inside the capsule. The coating is the material which coats and protect active compound in its structure. The role of the carrier is to create a boundary layer between the active substance and the environment. The choice of carrier depends on the size and shape of the capsule, the cost of encapsulation, encapsulation method, and the mechanism of release of the active substance. Edible and harmless biopolymer substances, which do not react with the active substance, are used as carriers.

The most common reasons for applying encapsulation are:

1. Protection of the active substance from external influences, i.e. from degradation under the influence of external factors (heat, oxidation, moisture, air, light, chemical ingredients with which it can react).

2. Enrichment of food products with biologically valuable active ingredients (vitamins, minerals, omega fatty acids), which are often sensitive and easily decomposed.

3. Modification of the physical characteristics and structure of the original material, which makes it possible to achieve easier handling, improvement of the texture of the product into which they are dosed, and better rheological properties. E.g. liquid substances can be inserted into solid materials by encapsulation. It is possible to prevent the formation of lumps, reduce hygroscopicity, improve flowability, and modify the consistency of the medium to which the capsules are added.

4. Controlled release of the active substance (gradual, slow or at the exact desired moment). The release of the active substance in the product is slower if the substance is encapsulated. E.g. by encapsulating the sweetener, a gradual release of the sweet taste is achieved.

5. Uniform distribution of the active substance when added to different food products.

6. Encapsulation can dilute the concentration of the active substance, which is significant when it is necessary to uniformly mix very low concentrations of the active substance in a larger amount of product.

7. Masking of unwanted taste, smell and aroma (e.g. encapsulated fish oil, bitter substances, etc.)

8. Prevention of unwanted reactions of the active component with the ingredients inside the product.

ENCAPSULAION METHODS AND CAPSULE TYPES

Encapsulation methods can be devided into two main groups: mechanical and chemical. In food technology, the most common encapsulation methods are: spray drying, emulsion based methods, centrifugal separation, coacervation, liposomal capsules and fluidization (fluid bed coating).

Capsule types

The basic types of capsules are illustrated in Figure 1. Considering the structure and the way the carrier is arranged around the active substance, there are three basic types of capsules (Zuidam and Shimoni 2010):

1. Aggregate, matrix or microsphere type – the aggregate structure of the capsule. These are capsules that have several separate cores of the active substance or, more often, a larger number of central particles (molecules or groups of molecules of the active substance that make up the particle) embedded within a continuously distributed matrix or carrier. This is the most common type of capsule and is obtained by applying the largest number of encapsulation techniques. Encapsulant molecules can also be found on the surface layers of the capsule. Therefore, this is the least efficient way of encapsulation.

2. Type of central accumulation. It is the simplest and most obvious form of capsule structure. The core with the encapsulated content is spherical in shape, surrounded by a shell or membrane of uniform thickness like a hen's egg and shell. The thickness of the coating and the proportion of the active substance can be different (Pegg and Shahidi, 1999).

3. Type of multilayer casing. The sheath is wrapped around the core in the form of two or more concentric layers of different materials. Such capsules are designed to allow controlled release of the active substance (Pegg and Shahidi, 1999).

Capsules are not always spherical or other regular shape. The active substance can be evenly or unevenly distributed inside the capsule (Bakry et al. 2014). Also, there are cases where already formed smaller capsules are encapsulated inside larger capsules (capsule within a capsule). The reason for this kind of encapsulation is when one wants to achieve the intended controlled release of the active substance. Therefore, these three basic types of capsules can differ in shape, structure and size. In addition, depending on the encapsulation carrier and the method of formation, capsules can have a different internal structure (Rodriguez et al. 2016).

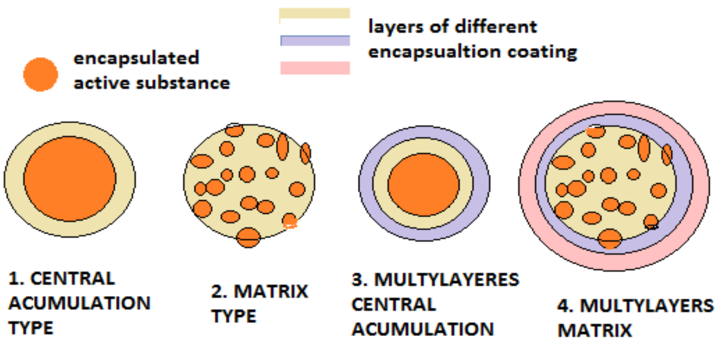

Figure 1 Types of capsules

A matrix-type capsule (with multiple separate encapsulated regions) is often referred to as a microsphere. Liposome capsules are capsules of the central accumulation type where the encapsulation carrier completely covers the encapsulated substance. In the case of liposomal capsules, the carrier (coating) is formed from a double layer of phospholipid molecules that cover the active substance in the form of a film. The phospholipid bilayer in the liposomal capsule is formed by connecting the non-polar ends of phospholipid molecules to each other, forming a spherical particle (liposome), while the polar groups remain oriented towards the surface and inside the particle. A cyclodextrin capsule is a chemical complex in which the active substance is encapsulated in the empty inner part of the ring of the cyclodextrin molecule. In this way, the active substance forms a chemical complex with the cyclodextrin molecule, which is why this method of encapsulation is called molecular inclusion. Capsules in emulsion actually represent particles of an active substance coated on all sides with particles of a surface-active substance (emulsifier or stabilizer). In this way, a hydrophobic active substance is stabilized in a hydrophilic environment or vice versa (Rodriguez et al. 2016).

Micelles are complex particles formed by aggregation or self-association of the same or similar molecules (most often proteins such as casein). Aggregation and self-association of molecules in the micellar structure is achieved by hydrophobic and/or electrostatic interactions. The main feature of the micelle is the hydrophilic character on the surface and the hydrophobic interior. Under the influence of physical factors, micelles can dissociate into their constituent parts and reassociate again, i.e. to associate. Precisely because of this, the encapsulation of smaller molecules within the micellar structure is possible. Casein micelles are the most common coating material in the formation of micellar type capsules. Different active compounds with particle size smaller then micelle could be encapsulated inside micellar structure of casein or other proteins. The structure of casein micelle allows encapsulation of small molecules of active compounds and formation of matrix type capsules. Casein micelle is the spherical particle with common size 100-200 nm and consisted of smaller spherical particles (submicelles) bound together in micellar structure. Submicelles are bounded together in the micellar structure through pretty strong colloidal calcium phosphate bridges. Beta carotene can be encapsulated inside the micellar casen capsules. Such kind of encapsulation can be improved by high hydrostatic pressure induced dissociation and reassociation of casein micelle. Dissociation of micelle helps incorporation/encapsulation of beta carotene inside micellar structure, Reassociation of casein micelle with encapsulated beta carotene occurs when pressure decreased (Tahmaz 2014).

EMULSIONS AND THEIR PREPARATIONS

Emulsification is one of the most common methods in encapsulation (immediately after spray drying), whether it is applied alone or as part of other encapsulation methods.

An emulsion is a stable mixture of two liquids between which high surface tension occurs and which therefore cannot mix. A large surface tension in between occurs as a result of the difference in polarity. Polar and non-polar liquids do not mix together. Typical examples of polar liquids are water, salt and electrolyte solutions, polar organic liquids (alcohols, acids, etc.). Emulsion is obtained by vigorous mixing of polar and non-polar liquid. Vigorous mixing breaks up the layers and breaks up their droplets. In this way, the total contact surface between the particles of polar and non-polar liquid increase, and their merging into a mixture occurs. The emulsion created by vigorous mixing is unstable, because the particles of polar and non-polar liquids do not show affinity towards each other. Although they are mixed, there is still a high surface tension between them, which is why they repel each other and delamination occurs very quickly. On the other hand, mutual attractive forces between polar and non-polar liquid molecules are activated. As a result of these attractive forces, polar particles are regrouped on the one side, and non-polar on the other and emulsion separate to two phases. In other words, vigorous mixing without the presence of a surface-active substance will result in formation of unstable emulsion. Such emulsion is not thermodynamically stable, but is only kinetically stable for a short time.

Every stable emulsion consists of three basic parts: a polar (hydrophilic, lipophobic) liquid, a non-polar (hydrophobic, lipophilic) liquid and a surfactant. In order to obtain a thermodynamically stable emulsion, it is necessary to reduce the surface tension between polar and non-polar liquids so that they remain mixed. Emulsifiers are surface-active substances, whose molecular structure is such that they have polar (charged) and non-polar (non-charged) parts in the same molecule. Polar moieties are mostly functional groups with oxygen such as OH- group or some other groups that have free electrons. Nonpolar groups are nonpolar ends (radicals) of organic molecules (eg fatty acid radicals). Typical examples of emulsifiers are lecithin, phospholipids, fatty acid monoesters, milk proteins, other proteins, etc. When an emulsifier is added to an unstable emulsion, the polar end of the emulsifier connects to the polar liquid, while the nonpolar end connects to the nonpolar liquid.

In the food industry, the emulsification process is often used to obtain stable food products. A large number of food products are typical emulsions. Typical examples of natural food emulsions are milk, butter and egg yolks. In milk, the milk fat is emulsified in the aqueous phase with lecithin and milk proteins as emulsifiers. Typical food emulsions obtained by artificial emulsification (in the production process) are mayonnaise, margarine, cream, sour cream, cake mixes, baby food, etc.

Emulsions can be divided into different types depending of amount and nature of each phase (Figure 2):

1. Single emulsions:
   a. Oil-in-water emulsions - known as o/w emulsions (eng. oil/water)
   b. Water-in-oil emulsions - known as w/o emulsions (eng. water/oil)
2. Double emulsions:
   a. Oil in water and all in oil - o/w/o (oil/water/oil)
   b. Water in oil and all in water - w/o/w (water/oil/water).
3. Multiple emulsions (eg. o/w/o/w or w/o/w/o)

Oil-in-water (o/w) emulsions have more intense properties of the water polar phase. They can be mixed with water or other polar liquid, show higher values of electrical conductivity (due to higher water content and higher polarity). Components that are soluble in water can be mixed in them. Emulsifiers soluble in water are added to this type of emulsion to stabilize them. A typical example of such emulsions is milk and cream. In water-in-oil (w/o) emulsions, the dominant phase is oil (non-polar phase). These emulsions are soluble in oils, have low electrical conductivity (due to the low content of polar components). Typical examples of w/o emulsions are butter and margarine.

Some products show properties of both types of emulsions (w/o and o/w) at the same time. The characteristic of these emulsions is that they can be mixed with both oil and water phase, which means that liposoluble and hydrosoluble active components can be added to them. They are considered stable emulsions, because they show good affinity towards polar and non-polar substances. Examples of such emulsions are mayonnaise, cake and pancake mixes and many other food products. Although it contains greater amount of oil phase mayonnaise is defined oil in water emulsion. These are mixed emulsions, which are very stable, because they contain a relatively high proportion of emulsifiers and/or an equal proportion of polar and non-polar phases. This is exactly why they have the properties of o/w and w/o emulsions.

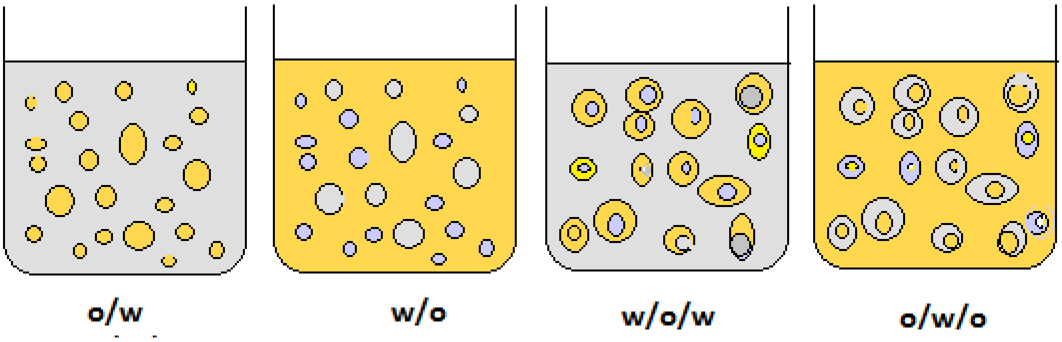

Figure 2 Illustrations of emulsion types

Multiple emulsions (Figure 2) can be double (w/o/w and o/w/o) or even triple (w/o/w/o and o/w/o/w). These emulsions are obtained by the process of double or multiple emulsifying. They can be considered as an emulsion dissolved in an emulsion. Preparation of double or triple emulsions includes the following steps. The first step is preparation of stable primary w/o or o/w type emulsion. The primary emulsion is dosed into another liquid, in which it could not be mixed into stable mixture without emulsifying. But, in the presence of emulsifier or other surface-active substance, mixing occurs and a multiple emulsion is formed in which the droplets of the original emulsion are dispersed and stabilized. For example, in the case of a w/o/w emulsion, a stable water-in-oil emulsion is first formed. Water in oil emulsion mostly shows properties of oil phase and it cannot be mixed with water phase in stable mixture without emulsifying. Because of that primary water in oil emulsion is added to the polar water phase with vigorous mixing in the presence of emulsifier. Vigorous mixing help to primary emulsion to be mixed en dispersed in water phase, while presence of an emulsifier ménages to stabilize double emulsion. In an o/w/o emulsion, an oil-in-water type emulsion is firstly formed, which is then added to the non-polar fat phase with which it is mixed and stabilized in the presence of a suitable emulsifier. These procedures of additional emulsification can be repeated several times according to the same principle, so that quadruple emulsions and other more complex emulsions can be obtained.

The key factor for emulsion stability is homogenization, i.e. the better dispersion of particles of the dispersing phase within the dispersing agent (continuous phase). Therefore, it is necessary that the particles of the dispersed phase be as small as possible. Thus, a larger specific surface area of the continuous phase particles and a larger contact surface between the dispersed phase and the dispersing agent are achieved. The smaller the particles, the more stable the emulsion. Emulsion homogenization can be done with different devices:

1. High speed vertical mixers – the mixing speed is not high and they usually give weak emulsions whose particle sizes are around 10 µm

2. Homogenizers – devices that operate on the principle of passing liquid material through small holes under high pressure

3. ultrasonic mixers/homogenizers – for homogenization, that use ultrasonic energy, pulverize dispersed phase particles to very small dimensions (nanoparticles), produce very stable emulsions (nanoemulsions)

4. colloid mills – which have fast rotation, where they grind particles to colloidal dimensions

5. membrane homogenizers where the particles of the dispersed phase are passed through the microporous membrane and

6. microfluidizers.

With the membrane process, it is possible to obtain fine and stable emulsions. This is why the encapsulation process itself is very successful, because very small and stable capsules are formed in such emulsions. Emulsifying using a membrane homogenizer has proven to be a very successful method for encapsulation. It is a process that involves passing the pre-emulsion through a microporous membrane. Depending on the size and character of the pores (hydrophilic or hydrophobic pores), it is possible to encapsulate hydrophobic and hydrophilic active substances. Hydrophilic active substance is encapsulated in w/o, and hydrophobic in o/w emulsion.

ENCAPSULATION BY EMULSIFICATION

After spray drying, emulsions and emulsifying processes are the second most common encapsulation technique used in industry. The commercial possibilities of using double emulsions are reflected in the production of low-calorie foods (sauces, mayonnaise, whipped cream, etc.) and for the encapsulation of nutritionally valuable ingredients, flavors and additives (Muschiolik and Dickenson 2017). Some examples of encapsulation using the double emulsification technique are given in Table 1. Emulsifying can be used as primary and main encapsulation method or it can be combined with other encapsulation methods like spray drying, freeze drying, high hydrostatic pressure to obtain more stable particles.

Emulsification can be used to encapsulate water-soluble and lipid-soluble liquid substances. The size of the droplets inside such emulsions ranges from 0.1-5000 μm. The stability of the encapsulated substance can be improved by forming a multilayer shell (Prichapan and Klinkesorn 2014). Encapsulation proceeds by first dissolving the encapsulation carrier in an organic solvent (non-polar - organic phase), and the active substance is added to that solution. An aqueous solution containing an emulsifier is added to the organic phase. By mixing these solutions, an emulsion is formed. The organic solvent is removed by evaporation, while the carrier polymer molecules form a shell around the active substance. The obtained emulsion can be spry or freeze dried (Silva et al 2014). Encapsulation in different emulsion types and images of obtained capsules are illustrated in Figure 3,

Encapsulation by emulsification can be carried out in single or double emulsions. During emulsion base encapsulation, two basic processes are crucial: 1) the emulsification of the active substance in the carrier solution and 2) the precipitation of the obtained capsules (Figure 3).

Encapsulation efficiency is increased with the addition of cross-linking agents. The formation of cross-links can be assisted physically (precipitation of proteins by heating) or chemically (precipitation after the addition of cations - usually Ca2+ ions or by lowering the pH value). The encapsulation carrier is dissolved in an aqueous medium containing a cross-linking agent (CaCl2). The resulting solution is mixed with oil or another hydrophobic medium in which the active substance is dissolved. Smaller particles of the active substance remain encapsulated within the cross-linked structure of the encapsulation carrier (Mannyana et al., 2010).

Coaxial mrofluidizer can be used as a device, which is able to form very small microdroplets in emulsions for encapsulation. Using this device, microcapsules of the central accumulation type are obtained in single, double and triple emulsion. The advantage of using a coaxial encapsulator is its possibility to form capsules of uniform and regular spherical shape and size with a thin shell with uniform thickness (Li et al. 2018). This method is very similar to encapsulation by co-extrusion, because the active substance is coated when leaving the microfluidizer in the same way as in co-extrusion.

Pickering emulsion is emulsion stabilized by fine solid particle, which absorb irreversibly on emulsion droplets. It is very applicable for encapsulation in functional food products (Cheon et al., 2023).

Capsules of different types can be formed by encapsulation in an emulsion (FIGURE 68), which depends on the emulsification method, the type of emulsifier, stabilizer and biopolymer, the aggregate state of fat droplets and the water phase. In an ordinary single emulsion, the active substance is stabilized only by a layer of emulsifier molecules. In the case of double emulsions, a single emulsion is first formed, which is then dissolved in an aqueous or fat phase different from the dispersing agent of the primary emulsion. If the aqueous phase contains a biopolymer that causes gelation (gelatin, pectin, starch, alginate), then an emulsion in the gel state is obtained. In such an emulsion, the fat droplet with the active component is coated with emulsifier molecules, and around it is a gelled water phase. Gelation further stabilizes the emulsion. Encapsulation in an emulsion can be achieved by coating the active component with solid colloidal stabilizer particles. If the oil phase has a high melting point, then by emulsification it is possible to obtain capsules of the SLP type, i.e. solid lipid particles coated with emulsifier molecules. For the formation of such emulsions, heating is necessary in order to melt the fatty phase. The dissolved fat phase is emulsified in an aqueous solvent, the small droplets are coated with emulsifier molecules, and after cooling, the encapsulated fat droplets return to a solid aggregate state (Mao and Miao 2015).

Encapsulation in single emulsions

If the active substance is lipophilic (eg. beta carotene), it can be encapsulated in o/w emulsions. Encapsulation occurs when a hydrophilic shell of surfactant and carrier is formed around the beta-carotene particle. The hydrophilic coating enables the solubility of beta-carotene in the aqueous environment (Ax 2003; Ribeiro et al. 2010). If the active substance is hydrophilic, then the encapsulation is carried out in a w/o emulsion, and the surface of such a capsule is lipophilic (Manyanna et al. 2010). Shematic representation of formation of capsules in single emulsion is showed in Figure 3.

Peng et al. (2023) investigated influence of emulsion particle size on encapsulation efficiency of encapsulated sweet orange essential oil into maltodextrin and modified starch capsules. Emulsion was prepared by mixing of dispersed phase containing orange oil with continuous phase containing coating material dissolved in water. After completed homogenization emulsion was divided into three phase with large, small and nano sized capsules. The results showed that encapsulation efficiency increased when capsule size decreased.

Fitri et al. (2022) reported very high values of encapsulation efficiency (96.6-99.88%) of beta carotene encapsulated in nanocellulose by preparing of o/w single emulsion. Zeta potential of obtained particles ranged between -8.69 and -19.73 mV.

Tessaro et al. (2022) encapsulated polyphenol rich pitanga leaf extract in soybean oil using single w/o emulsion. The obtained particles had sizes between 250 and 4250 µm and improved stability of antioxidative compounds. Extract firstly was dissolved in aqueous phase. Water in oil (w/o) emulsion was prepared by dropwise addition of aqueous extract into soybean oil containing lipophilic emulsifier PGPR under continuous high speed ultrasound homogenization (15000 rpm for 5 minutes). Emulsion droplet size ranged between 0.25 and 4250 µm depending of emulsifier and extract concentration. Emulsion wit 20% of extract concentration had the smallest particles and the highest physical stability.

Table 11. Application of double emulsion encapsulated active compounds in different food industrie (Muschiolik and Dickenson 2017)

Emulsion type	Active compound	Application in foods
w/o/w and o/w/o	Flavours encapsulated in gelatinizing polysaccharides	Addition in preparation of low calorie salad dressings, margarine and similar spreads
w/o/w	Vitamins encapsulated in 40% sucrose solution	Enrichment of confectionery products
w/o/w	Polyunsaturated seed oils	In different products that commonly contain milk fat, replacement of milk fat with encapsulated oils
w/o/w	w/o emulsin droplets	Replacement of oil or fat in low-calorie products (e.g. meat dough for the production of sausages and pate), drops have a lower oil content than oil alone, but give the perception of taste, aroma and texture as oil alone, improved sensory properties of low-calorie products
w/o/w	Na-ascorbate	Enrichment of milk before UHT sterilisation. Improved stability of ascorbate under thermal ttreatment
w/o/w	$CaCl_2$	Fortification of soy milk with Ca without of changes in consistency of soy milk. Encapsulated Ca does not change the consistency of milk, unlike non-encapsulated, which can lead to curdling
w/o/w	Natural colors	Application in confectionery industry and ice cream production – coloring of different products. Natural colors (beta carotene, anhocyanins) are

		mostly antioxidative compounds, very sensitive for oxidation and high temperature. Becaus eof that these colors are more stable in encapsulated form
o/w/o	Fish oil	Fortification of margarine and other spreads
w/o/w	Polyunsaturated oils	Replacement of pig fat with encapsulated oils in frakfurter sausages.
w/o/w	Sunflower oil	Fortification of milk
w/o/w	Vitamin B_{12}	Application in technology of functional dairy products
w/o/w	Aspatrame and other sweetners	Application in production of chewing gums. Encapsulated sweetners are released slowly then non encapsulated, and becaus eof that sweet taste is released gradualy.
w/o/w	xylitol and menthol	In the production of chewing gum - encapsulation achieves a prolonged cooling effect and keeps the menthol aroma longer
w/o/w	$MgCl_2$	As a coagulant in the production of soy milk cheese - encapsulation masks the bitter taste
w/o/w	Curcumin and catehine	Fortification and colouring of different drinks, juices and beverages
w/o/w	Grape seeds extract and saffron extract	Enrichment of different food products
w/o/w	NaCl	Application in production of low salt products. Increased perception of salty taste in products with reduced NaCl content, destabilization of the double emulsion with encapsulated NaCl occurs in the mouth, NaCl is gradually released.
w/o/w	Probiotics	Fortification of different foods
w/o/w and o/w/o	Flavours encapsulated in gelatinizing polysaccharides	Addition in preparation of low calorie salad dressings, margarine and similar spreads

Encapsulation in double emulsions

Encapsulation using the double emulsification technique is more often used, because smaller capsules can be obtained in comparison to single emulsion. The formation of capsules in double emulsions is illustrated in Figure 3. W/o/w emulsions are more often used for encapsulation needs in food technology in comparison to o/w/o emulsions. Some examples of application of double emulsion in encapsulation for purpose of food products are shown in Table 1.

In the case of lipophilic active substance, encapsulation can be achieved in an o/w/o emulsion, and in that case the encapsulation carrier is dissolved together with the emulsifier in the aqueous phase. The two phases are vigorously mixed to form a primary emulsion, which is allowed to stand for a period of time before a new amount of the aqueous phase will be added. By adding an aqueous phase, a double (secondary) emulsion of the o/w/o type is formed in which biopolymer particles with an encapsulated substance are deposited. The re-dosed aqueous phase destabilizes the primary emulsion (o/w), causing the capsules to separate. During this process, interactions occur between molecules of the encapsulation carrier, which leads to the formation of cross-links. This process contributes to the encapsulation, and the finer particles of the active substance stabilized in the oil remain encapsulated between the cross-linked carrier molecules (Manyanna et al 2010). Double o/w/o emulsions are mainly used for encapsulating different oils. Especially it is interesting to encapsulate fish oil in double o/w/o emulsion with purpose to mask its smell. Encapsulating fish oil masks its unpleasant odor and aroma, so that it can be added to different food products. In this emulsion type, fish oil is dispersed in water phase, while the secondary oil phase differs from the primary one (o1/w/o2). The most common emulsifier in the primary emulsion (o1/w) is gluten, while in the secondary emulsion it is Na-caseinate. In this type of emulsion, gluten and Na-caseinate are not only surfactants, but also encapsulation carriers. The encapsulation of fish oil via a double o1/w/o2 emulsion takes place in the following order. In the first step, fish oil is dispersed in an aqueous phase containing Na-caseinate, forming a primary emulsion. The primary emulsion is mixed with a second oil phase consisting of equal parts of olive oil and polyglycerol-polyricinoleate (surfactant) to form a secondary emulsion. Capsules are isolated/separated by spray drying. Before drying, the double emulsion is mixed with an aqueous phase with disolved Na-caseinate and lactose monohydrate dissolved (Muschiolik and Dickenson 2017).

Double w/o/w emulsions are used for encapsulation of hydrophilic active substances such as anthocyanins, phytosterols, betalains, natural colors, probiotics, B group vitamins, vitamin C, mineral salts (NaCl, CaCl2, MgCl2) and sweeteners. Lecithin is the most often used as an emulsifier, while gelatin, Na-caseinate and whey protein isolates are used as carriers coating materials). In this type of emulsion, the secondary emulsion water phase can be the same as in the primary (w/o/w), or it can be different (w1/o/w2). The primary emulsion usually contains lecithin, which stabilizes the hydrophobic active substance, while the second aqueous phase w2 represents a solution of a surface-active encapsulation carrier. Encapsulation occurs only after the addition of the second aqueous phase (w2) with another biopolymer, whereby biopolymer 2 simultaneously stabilizes the new secondary emulsion and forms a shell around the droplets of the primary emulsion containing the particles of the active substance. The first water phase often contains NaCl, CaCl2 or glucose in its composition. These components help form the coating on the surface of the capsule. NaCl and glucose increase the osmotic pressure, which leads to the precipitation of biopolymers, while Ca2+ ions cause aggregation by forming cross-links between carrier molecules and thus help the precipitation of capsules (Muschiolik and Dickenson 2017).

The encapsulation of fish oil in a two-layer (secondary) emulsion is carried out to prevent oxidation of omega 3 fatty acids and to mask the unpleasant smell of fish oil. The primary emulsion is formed by homogenizing fish oil and the aqueous phase with lecithin at pH 3. First, a negatively charged layer (lecithin) is formed on the surface, and the secondary emulsion can be obtained by adding a cationic stabilizer (chitosan). The anionic layer of lecithin binds chitosan cations and a positively charged particle coated with a lecithin-chitosan layer is formed (McClements et al. 2007).

Dang et al. (2024) encapsulated acerola juice (rich in vitamin C) with maltodextrin and gum arabica as coating materials by preparing of double w/o/w emulsion. Firstly the primary w/o emulsion was prepared by mixing of acerola juice with oil in proportion 40:60 and with addition of lipophilic emulsifier PGPR. The mixture of juice, oil and emulsifier was virgously stirred by mixer speed of 700 rpm. When primary w/o emulsion was prepared and stabilized, the secondary water plus emulsion was finished maltodextrin and gum Arabica dissolved in water phase was added. Water phase with dissolved wall material and emulsifier (Tween 20) was added slowly drop by drop into primary emulsion with continuous high speed mixing (900 rpm). Encapsulation yield of vitamin C ranged between 20.83 and 28.36%.

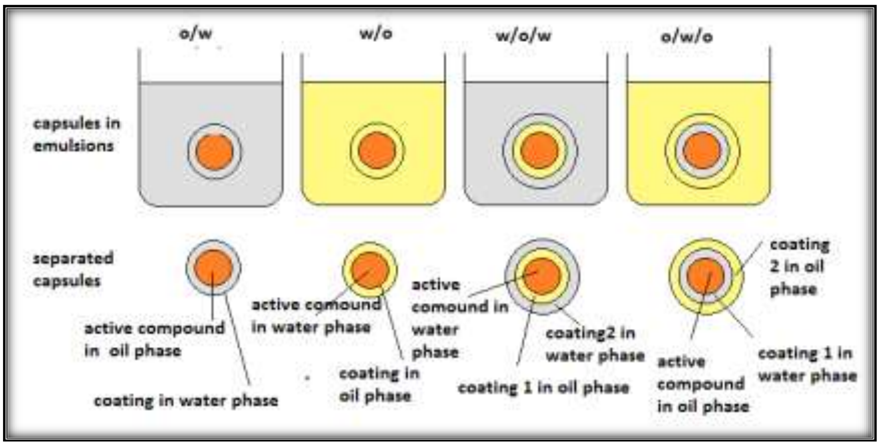

Figure 3 Illustration of capsules formed in emulsions

Encapsulation In multilayered emulsions

The formation of a multilayer shell around the active substance in the emulsion significantly increases the stability of the encapsulated active substance. Multyleyerd emulsions are known as m-o/w (multilayered o/w emulsions) or m-w/o (multy layered o/w emulsions).

Capsules with a multilayer shell produced most often in oil-in-water (o/w) emulsion are known as m-o/w emulsions. In that emulsions, the active substance is usually hydrophobic (but can also be hydrophilic), dissolved in oil and encapsulated in a hydrophobic phase. These are central accumulation type capsules in which the droplet of the hydrophobic phase (oil) is encapsulated by being coated with a three-layer shell. Three-layer coating is achieved by triple homogenization by forming a primary, secondary and finally tertiary emulsion. In the primary emulsion, the particles of the hydrophobic phase are coated only with emulsifier particles (water-soluble ionized emulsifier with a polar end). The secondary emulsion is created by homogenizing the primary emulsion after adding a surface-active biopolymer solution (hydrocolloid 1). In the secondary emulsion, a second shell of hydrocolloid molecules 1 is formed around the emulsified particles of the fat phase. The third shell will be formed in the tertiary emulsion, i.e. by the third homogenization after the addition of the second biopolymer (hydrocolloid 2) to the secondary emulsion. With this procedure, it is possible to control the amount of encapsulated active component (it depends on the size of the droplets of the fatty phase in the primary emulsion), the thickness of the shell and the size of the capsule. In secondary and tertiary homogenization, shell porosity, shell thickness, sign and strength of capsule charge are controlled (McClements et al 2007).

The stacking of layers around the droplet of the hydrophobic phase with the active substance takes place according to the principle of electrostatic attraction. At the beginning, there are only fat droplets dissolved in the aqueous phase and emulsifier particles that coat around the particles of the fat phase. The non-polar ends of the emulsifier molecule bind to the fat droplet, and the polar ends are directed towards the aqueous phase. In this way, a barrier to the water phase is created. The fat droplet becomes encapsulated in the aqueous phase, because there is a polar outer layer of emulsifier molecules on its surface. When biopolymer particles oppositely charged to the emulsifier molecules are added to the primary emulsion, they will be attracted to the coated fat particles due to electrostatic attraction of opposite charges. The third layer is formed after the particles of biopolymer 2 are added to the secondary emulsion, the molecules of which are charged opposite to the molecules of the first biopolymer, and the process is repeated in the same way. According to the principle of electrostatic attraction, the number of layers can continue to increase.

An excess of biopolymer molecules remains in the emulsion, which failed to bind to the surface of the capsule. To finish the coating and obtain the finish surface capsule layer, it is necessary to bind the excess particles to the capsule. The finish surface layer should be the thickest. This can be achieved by adjusting the pH value, commonly by adding Ca^{2+} ions, etc. By changing the pH value, there is a change in the sign of the charge of the capsule and the capsule is again able to adsorb a new amount of biopolymer of the opposite charge. Also, there can be a change in the charge of the dissolved biopolymer, and then its particles can again bind to the oppositely charged capsule. At the end of coating, excess electrolyte is removed from the surface of the capsules (McClements et al 2007), and after that they can be spray dried.

The main advantages of encapsulation through a multilayer emulsion are reflected in the improved physical and chemical stability of the active substance and the possibility of targeted release through the gradual destruction of the structure of the multilayer shell. Natural biopolymers such as proteins, polysaccharides and phospholipids are used as coating layers. The basic prerequisite for encapsulation is that their molecules possess polar parts, ie charged functional groups. Some examples of such encapsulation carriers are casein micelles, lecithin and other phospholipids, polysaccharides (OH-groups - anions), chitosan (cations) and the like. It is considered an ideal method for the encapsulation of hydrophobic liposoluble active substances (eg different oils or some other liposoluble components) (Tahmaz 2015).

With the described procedure, it is possible to encapsulate hydrophilic substances, with the fact that the hydrophilic substance cannot be encapsulated as an integral part of the fat droplet, but as an integral part of one of the coating layers (McClements et al. 2007).

The disadvantage of using this method is that it requires great precision in order to obtain the desired thickness of the coating, but also to avoid the aggregation of the capsules.

Limonen could be encapsulated by forming a three-layer in triple emulsion. Limonene is encapsulated in a three-layer emulsion to prevent it from straightening during spray drying. The primary emulsion is formed by homogenizing the aqueous phase and oil with dissolved limonene. A hydrophilic emulsifier (proteins from lupine seeds - Lupinus album) is dissolved in the aqueous phase, the molecules of which are negatively charged. Because of that, a thin negatively charged layer of lupine protein isolate is created around the droplet of oil with dissolved limonene. The next layer from a secondary emulsion is formed when positively charged biopolymers (chitosan) are added to the primary emulsion. Chitosan binds to the free negatively charged ends of the lupine protein, causing the coated oil droplet in the secondary emulsion to become positively charged. The third layer is formed when negatively charged polysaccharides (xanthan gum, pectin and Na-alginate) are added to the secondary emulsion. Thus, in the end, the coated droplet becomes negatively charged (Burgos-Diaz et al 2018).

Ribeiro et al. (2021) used self-aggregated and cross-linked chitosan nanoparticles and maltodextrin for encapsulation of roasted coffee oil rich in phenolic compounds. Emulsion was prepared by mixing of roasted coffee oil with water suspension of cross linked and self-aggregated chitosan nanoparticles. To obtain stable capsules maltodextrin was added in prepared emulsion of coffee oil in chitosan water phase. The mixture was homogenized by high speed of ultrasonic mixer (12000 rpm for 5 minutes). Obtained emulsions were dried by freeze drying and spray drying. Particle size of dried microcapsules ranged between 10.73 and 276.21 μm. Freeze dried emulsions had significantly larger particles and higher oil retention in comparison to spray dried. Oil retention ranged 76.29 – 96.46% in freeze dried and 19.10 – 25.47 in spray dried capsules. Total phenolic content and antioxidative activity also were higher in freeze dried then in spray dried emulsions.

Application in food technology

There are many examples of application of active compounds encapsulated by emulsion based methods in enrichment of different food products. Emulsion based encapsulation techniques are very applicable for food industry. Obtained capsules can be used in original liquid emulsion form or could be additionally preserved by spray drying or freeze drying. Encapsulation of active substances in an emulsion is a very suitable encapsulation method for the food industry, and especially for products that by their very nature are emulsions. Such emulsion based products are e.g. mayonnaise, sauces, sausages, meat pates, cheese and vegetable spreads, dairy products, yogurt, cream, milk, chocolate, etc. Many of these products can be enriched with active substances encapsulated in the original liquid emulsion without drying. For other non-emulsion food products it is recommended to be enriched with previously dried emulsion based encapsulated substances.

Table 2. Examples of food products prepared with encapsulated active compounds obtained by emulsion based methods

Food type	Food product	Active compound	Coating material & emulsion method	Achieved effects
Confectionery products	Jelly and gummies	Chlorophyll from alpha-alpha	Agar and gelatin	Coloring jelly and gummy candies with green pigment chlorophyll, greater stability of encapsulated chlorophyll when heated during production (Raei et al., 2017)
	Chewing gums	Aspartame	w/o/w emulsion	Gradual/prolonged release of sweet taste
	Chocolate	Antioxidant rich moringa leaf extract	Soybean and coconut oil & w/o single emulsion	Enrichment of chocolate with antioxidants, improved stability of antioxidants from moringa leaves (Kaltsa et al., 2021)
Dairy products	Functional ice cream	*L. casei and L. lactis*	Alginate and modified starch	Improved stability of probiotic bacteria and acceptable sensory properties (Hamayouni et al., 2008)
	Cheddar cheese	Bixin	Multi-layered coating: kappa carrageenan, casein and wax & Multiple o/w/o/w	Improved stability of bixin color (Ravanfar et al., 2018)
	Melted cheese in slices	Fish oil	Milk proteins	Masked undesirable odor and taste of fish oil, acceptable sensory properties, improved oxidative stability of fish oil (Tolve et al., 2016)
	White brine cheese	*L. acidophilus. B. bifidum*	Carrageenan, Na alginate	Improved stability of probiotics (Tolve et al., 2016)
	Milk	*L. breve*	Gelatin and starch	Improved stability of probiotics in digestive tract (Tolve et al., 2016)
	Milk	Fe	Fatty acids, phospholipids	Masked metal taste, enrichment with Fe (Tolve et al., 2016)
	Yogurt	*L. acidophilus B. lactis*	Alginate and modified starch	Improved probiotic stability after 7 weeks of cold storage (4 C), mostly unchanged sensory properties, only smoothness was significantly lower in comparison to control (Tolve et al., 2016)
	Yogurt like functional beverage	Vitamin E	Yogurt based emulsion	Improved stability of vitamin E during pasteurization at 65°C, good sensory properties, increased antioxidant activity, good survival of lactic acid bacteria (Raikos et al., 2021)
Tofu	Tofu	$MgCl_2$	Alginate	Improved hardness with masked bitter taste (Tolve et al., 2016)
Ready to eat food	Mayonnaise	*L. acidophylus*	Ca-alginate and resistant starch	Better survival of probiotics, improved sensory properties (Mohammadi et al., 2013)
	Mayonnaise	*L. acidophilus, L. casei*	Ca-alginate, resistant starch	Better probiotic stability, lower

				acidity and better sensory properties (Bigdelian and Razavi, 2014)
	Mayonnaise	Walnut oil	Pectin and maltodextrin	Improved shelf life, lower peroxide number and lighter color (Akhtar et al., 2022)
	Mayonnaise	*L. casei, B. bifidum*	Resistant starch and Ca-alginate	Enhanced survival of probiotics (Fahimdanesh et al., 2012)
	Yogurt sauce	*L. paracasei*	Resistant starch and Na-alginate	Increased survival of probiotics without negative effects on color, consistency, taste and acidity (Porjavid et al., 2022)
	Soy sauce	*Z. rouxii, T. halophylus*	Alginate & w/o/w	Enhanced soy sauce aroma development during moromi fermentation (Dewanthi et al., 2018)
	Instant soup mixture	Fish oil	Skimmed milk powder & Emulsification and spray drying	Improved oxidative stability of omega 3 fatty acids, acceptable sensory properties, masking fish oiltaste (Fakir et al., 2018)
	Beef burger	*Thymus vulgaris* essential oil	Chitosan & o/w emulsion and ionic gelation	Improved antimicrobial stability and sensory properties, inhibition of discoloration (Ghandari et al., 2016)
	Beef burger	Safflower oil enriched with acai extract	Amorphophallus konjac and Na-alginate & Hydrogel emulsion technique	Extended shelf life of beef burger (Hanula et al., 2022)
	Meatballs	Cod liver oil	Na alginate and lupin protein isolate & o/w emulsion	High encapsulation efficiency 95,62%, improved heat stability of meatballs during heat treatment at 70-100C. scceptable sensory properties (Elsebaie et al., 2022)
	Fish burger	Lemon essential oil	Chitosan and modified starch	Reduced oxidation during cold storage and increased shelf life (Hasani et al., 2020)
Oils and fats	Margarine like reduced fat spreads	Beta carotene	Palm originated nanofibrilated cellulose & Pickering o/w emulsion	Enrichment of low fat margarine with beta carotene (Bernice et al., 2024)
	Margarine	Anthocyanins from rossele and red cabbage	Maltodextrin & Microwave melting of maltodextrin and encapsulation in o/w emulsion	Enrichment of margarine with anthocyanins, higher antioxidative activity of margarine, improved stability of anthocyanins against oxidation (Zaidel et al., 2014)

Bernice et al. (2024) used o/w Pickering emulsion method to produce nanofibrilated cellulose nanocapsules with beta carotene, which were used as fat replacements in formulation of low fat margarine like spreads. Obtained capsules had particle size between 64.67 and 94.73 nm, zeta potential from -32 and -38 mV and very high encapsulation efficiency 86..87 – 89.90 %. Pretty high negative values of zeta potential indicate to good particle stability against aggregation. All values (particle size, zeta potential and encapsulation efficiency) increased with increasing concentration of coating material (nanocellulosose). Obtained maragrine like spread had increased viscosity (1.83 (control without cellulose) – 10545 mPas) with increased concentration of coating material.

Low fat spreads and other low fat products are insufficient in liposoluble vitamins and provitamins content, and because of that it is desirable to be enriched with encapsulated liposoluble vitamins. Encapsulation of beta carotene improved its solubility in water and hydrophilic solutions (Tahmaz 2014).

Some examples of possible applications of emulsion based encapsulated active compounds in food technology are given in Table 2.

Kultsa et al. (2021) encapsulated antioxidants rich moringa leaf extract into single w/o emulsion containing soybean and coconut oil, and emulsifiers/surfactants Span 80 and Tween 80. In first step, oils were mixed with surfactants using pretty low speed (600 rpm) until obtain stable homogeny mixture. Then, extract started to be slowly added drop-by-drop under higher speed stirring (1000 rpm). Obtained emulsion with encapsulated extract was added to chocolate to enrich its antioxidative properties. Emulsion particle size ranged between 15.1 and 82.60 nm, and increased by increasing content of oil in emulsion.

Fish burgers produced with the addition of nanocapsules of lemon essential oil encapsulated in chitosan/starch mixture (o/w emulsion) had extended shelf life and better quality during 18 days of cold storage. Nanocapsules with essential oil improved antioxidative properties and inhibited lipid oxidation of fish burger during storage. Fish burger with encapsulated lemon oil had better overall acceptability in comparison to control.

Encapsulated probiotic bacteria L. acidophilus added to mayonnaise sauce had survived longer in comparison to free bacteria. The L. acidophilus cells are very sensitive under different factors during processing, and because of that encapsulation could serve as a promising method to protect probiotics and to improve the probiotic activity of the yogurt sauce. Besides the improved probiotic activity, yogurt sauce with encapsulated probiotics had better sensory properties (Mohammadi et al., 2013). Encapsulated bacteria L. acidophilus and L. casei reduce the overall acidity of the mayonnaise-based sauce without significant changes in consistency and rheological properties. After 90 days of refrigerator storage, encapsulated probiotic cells in sauce can remain preserved in an amount corresponding to the probiotic therapeutic minimum (Bigdelian and Razavi 2014).

Raikos et al.(2021) used emulsion method to formulated functional yogurt based drink with encapsulated vitamin E. Vitamin E was dissolved in corn oil, which represent oil phase. Yogurt base beverage was formulated by mixing of water, goat milk powder and freeze dried lactic bacteria yogurt culture. Obtained yogurt based mixture represented water phase in emulsion. Both mixtures were mixed together, by adding of oil phase slowly into water phase and stirred using high speed mixer. Obtained emulsion was fermented at 43°C. Encapsulated vitamin E had better stability in comparison control. Yogurts with encapsulated vitamin E had better survival of lactic bacteria from culture during pasteurization and storage.

CONCLUSION

Emulsions are used in almost every encapsulation technique, tha are based on dispersing of active substance in the solution of coating material. Encapsulation methods based on emulsions can be used alone or be combined with other encapsulation techniques like spray drying, freeze drying, microwave heating, high hydrostatic pressure.The most relevant characteristics of capsules obtained by emulsion based methods are:

- Capsule type:
  - central accumulation type (multi-layer coating in emulsion); and
  - matrix (encapsulation in single or double emulsion)
- Capsule size: micro or nanocapsules depending on the particle size
  - Encapsulation carriers: biopolymers, emulsifiers and other surfactants, e.g. proteins (gelatin, casein, whey proteins), chitosan, lecithin, etc.
- Advantages: good protection of the encapsulated substance from high temperatures and oxidation during heat treatment and drying, the possibility of encapsulating liposoluble and hydrosoluble substances, controlled release of the active substance.
- Disadvantages: poor encapsulation efficiency for hydrophilic active substances in the case of single-layer emulsion.
- Application possibilities: A widespread encapsulation method in industrial application, a wide range of active substances can be encapsulated, such as probiotic bacteria, proteins, amino acids, essential oils, fish oil, flavonoids, vitamin E, lutein, beta carotene, fish oil, omega 3 fatty acids, aspartame and other sweeteners, xylitol and menthol in chewing gum (prolonged cooling effect), $MgCl_2$ used in the production of tofu to mask its bitter taste, curcumin, catechin, vitamin C, vitamin B_{12} (for enrichment dairy products), vitamin B1, stevia, saffron, grape seed extracts, dyes, vitamins and minerals. The highest potential has in emulsion based or emulsion containing food products such as dairy products, sauces and dressings, mayonnaise, minced meat ready to eat products, margarine and low fat spreads.

PHYSICAL PROPERTIES AND FLOWABILITY PROPERTIES OF COMMERCIAL TOMATO CREAM AND TARHANA SOUP POWDERS

Jasmine Tahmaz

Faculty of Agriculture and Food Sciences, University of Sarajevo, Sarajevo, Bosnia and Herzegovina

ABSTRACT

This study aimed to investigate the physical properties of commercial tomatosoup powders and tomato soups with tarhana noodles. Three samples of tomatocream soup without noodles and three samples of tomato soup with tarhananoodles were analyzed for different physical properties (density, viscosity, granulation, bulk density, tapped density, angle of repose, adhesiveness, foam capacity, hygroscopicity, rehydration ratio). Flowability was assessed from the valuesof the angle of repose, Hausner ratio andCarr index. Thermophysical propertieswere estimated from moisture content. Resultsshowed that tomato soup powders with tarhana noodles had thinner consistency, lowerviscosity, higher bulk and tapped densities, lower adhesiveness and lower repose angle than cream soups. Considering values of the Hausner ratio andangle of repose, it can be concluded that tomato soups with tarhana noodles hadbetter flowability and lower cohesiveness in comparison to tomato cream soupswithout noodles. Values of the angle of repose indicated that tarhana soup powdershad moderate/fair flowability, while tomato cream soup powder had very poorflowability. Samples with higher noodle content had lower angles of repose, higher flowability, higher density, and lower dispersibility. Kinematic viscosity ranged between 15.73 and 176.80 mm^2/s. Thermophysicalproperties increased by increasing of water content.

Keywords: *tomato cream soup, tarhana soup, powders, physical properties, flowability*

INTRODUCTION

Soups are widely used liquid foods madeby cooking basic and additional ingredients usually served as warm appetizers at the beginning of lunch. Industrial soups are the most commonly preserved by dehydration (drying and powdering). Soups are classified as clear and cream soups. Dehydrated soups are instant products, which could bereconstituted in warm water or boiled for 5 to 10 minutes. Commercial soups reached their popularity after the invention of the canning process in the 19th century. The main advantage of dried soup production is its long shelf life and the possibility to be stored at room temperature (Fernandez-Lopez et al. 2020). Tomato soup is prepared from mashed tomato or tomato powder with the addition of different additional ingredients, such as spices (onion, pepper, paprika, garlic, parsley), mozzarella or other cheeses, milk powder, whey, different starch, noodles. İt can be produced as cream or clear (thin soup) with or without noodles. Also, one of the very popular modern trends is the industrial production of traditional dishes, such as traditional soups and tarhana. In traditional Turkish cuisine, there are many variations of tarhana soups, made from different ingredients, depending on the region. Tarhana soup is a thick or clear soup that contains tarhana noodles, as the main ingredient. Traditionally these noodles have irregular spherical round shapes and are produced from fermentedtarhana dough. Turkish tarhana noodles are commonly prepared by mixing yogurt, cereals, and/or legume flour and different cooked vegetables such as paprika, tomato, onion and seasoned with spices like mint and paprika (Trakci et al.2004, Tahmaz et al. 2023). In Bosnia and Herzegovinian cuisine tahana soup camefrom the Ottoman Empire, and become one of the most popular dishes today. Tarhana noodles, traditional to Bosnia and Herzegovina, are prepared from ashard dense fermented dough, made from white wheat flour, eggs, and mashed tomatoes or tomato juice with or without yogurt. Prepared dough ferments at room temperature for 3–4 days, resulting in sour tarhana dough. After fermentation dough is kneaded and passed through kitchen colander holes and driedat room temperature. Bosnian tarhana soup is prepared by cooking of tarhana noodles in meat broth with an addition of salt, butter, chopped/diced tomato, and spices (black paper, dried paprika powder celery, and parsley) (Lakišić1999). Because of fermentation, traditional tarhana noodles have a pleasantsour taste and aroma specific to fermented dough. In industrial conditions, tarhana soup is commonly made from ordinary non-fermented pasta formed in a spherical-like shape similar size to traditional pasta, but without thefermentation. For that reason, the taste and aroma of industrial tarhana soups are not like traditional (Tahmaz et al. 2023). Fresh tomato fruits have the following proximate composition: moisture 94%, total solids 6%, total soluble solids 5.2%, total carbohydrates 3.41%, reducedsugars 2.96%, proteins 0.30%, fats 0.70% and ash 0.55%, fresh tomatoes also contain some nutritionally valuable bioactive compounds such as vitamin C 26.6mg%, total carotenoids 37.7 mg%, lycopene 31.82 mg% and total flavonoids 18mg/g. Lycopene is a very strong antioxidant and red pigment in tomatoes (Ramadan et al. 2021; Ali et al. 2020). Tomatoes also contain pectin, which is the mostimportant ingredient for the physical properties of tomato products. Pectins are goodfood stabilizers and emulsifiers and are widely used in the food industry as athickener (Sharma et al. 1998). Over 80% of the world-produced tomatoes are consumed in the form of processed products (Gould, 1992).

MATERIALS and METHODS

Material

Research was done on six samples of commercial dehydrated/powdered tomato soups (Figure 1), from three different producers:

- TC-1 (Vispak, Visoko Bosnia and Herzegovina) - tomato cream soup, ingredients: Dehydrated tomatoes 30%, wheat flour, maize starch, salt, hydrogenated vegetable fat, sugar, skimmed milk powder, dehydrated vegetables, spices., fat in powder: 6.6%, reconstitution data: 60g of powder in 1000 ml of water

- TC-2 (Podravka, Koprivnica Croatia) - tomato cream soup with mozzarella, ingredients: Dried tomatoes 34%, potato starch, sugar, wheat flour, salt, palm oil, corn flour, skim milk powder, mozzarella cheese powder 2.1 %, whey powder, dried celery and onion,, fat in powder 8.62%, reconstitution: 80g of powder in 750 ml of water

- TC-3 (Maggi Nestle Adriatic, Surčin, Serbia) - tomato cream soup with basil, ingredients: corn starch, dried vegetables 26 % (tomato powder 25%, beetroot powder, wheat flour, sugar, salt 10.3%, spices 3.3 %, palm oil, sunflower oil,, fat in powder: 4.5%, reconstitution: 56 g of powder in 750 ml of water.

- TT-1 (Vispak, Visoko, Bosnia and Herzegovina) - tarhana dehydrated soup, ingredients: noodles 55% (wheat flour and tomato paste), concentrate 45%

(dehydrated tomato min. 25%, potato starch, salt, hydrogenated vegetable fat, parsley, spices, flavor),fat in powder 6.66%, reconstitution instruction: 60 g of powder in 1000 ml of water

- TT-2 (Podravka, Koprivnica Croatia) - tarhana dehydrated soup with noodles and tomato ingredients: noodles 43%, salt, dried tomatoes 7.7%, wheat flour, palm oil, dried beef meat extract, red pepper, fat in powder 7.14%, reconstitution instruction: 70g of powder in 1000 ml of water

- TT-3 (Maggi Nestle Adriatic, Surčin, Serbia) - tarhana soup, ingredients: noodles 40%, tomato powder 22%, dried onion 1.7%, parsley 0.3%, other dried vegetable 2.1% (beetroot, carrot), garlic powder 0.2%, salt 11.8%, corn starch, sugar, palm oil, spices (parsley leaves, red pepper powder), fat in powder: 2.7%, reconstitution instruction: 60g of powder in 1000 ml of water.

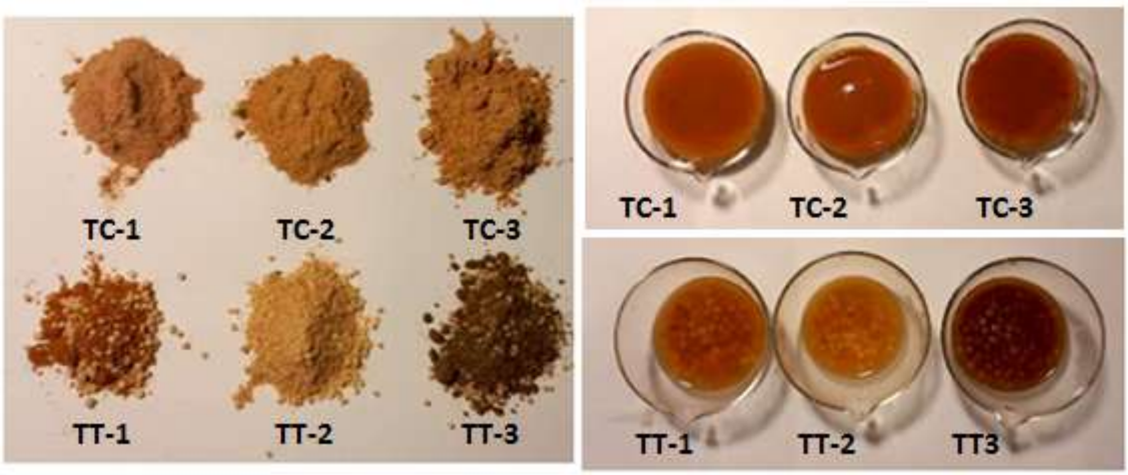

Figure 1 Image of soup powders and prepared liquid soups

Methods

Chemial analysis

Moisture content was determined by drying at 105 °C to constant weight (AOAC 1995). pH value was measured by pH meter (Mettler Toledo).

Physical analaysis of soup powders

The following characteristics were analysed on soup powders: amount and size of noodles, granulation, bulk density, tapped density, hygroscopicity, wettability, dispersibility, foam capacity and rehydration ratio.

The **amount and size of tarhana noodles** were analyzed in tarhana soup samples by sieving (Prufsieb ISO 3310–1). The size of the noodle pieces was measured by a digital caliper. 20 measurements were done on each sample, and the mean value was calculated.

For **granulation** determination, the whole amount of packed sample was sieved through sieves (PrufsiebISO 3310-1) and 5 fractions were obtained (≥ 2.5 mm, ≥ 1 mm, ≥ 0,5 mm, ≥ 0,25mm and < 0,25 mm). Determination of wettability[s] was described by Fernandes et al. (2013) with some modifications. 0.5 g of soup powder was put over the surface of 200 ml of distilled water (20 ◦C) without agitation and time was recorded after all powder had been wetted.

For **dispersibility** determination, 5 g of powder was put in a 50 ml measuring cylinder and distilled water (20 ◦C) was added to 50 ml. The mixture was vigorously stirred and left to stay for 3 h without agitation. Dispersibility [%] was calculated as a percentage of liquid phase volume in total volume (50 ml) (Alawode et al. 2017, Asma et al. 2006, El-Gindy 2018).

For **hygroscopicity** determination, 1-2 g of powder was weighted into open glass containers. Samples and saturated NaCl solution (40 g of NaCl in 100 ml of water) were left in a closed desiccator for 7 days. Hygroscopicity is calculated according to the formula (Fernandes et al. 2013):

$$\boldsymbol{Higroscopicity}\ (\%) = \frac{\boldsymbol{m_2 - m_1 - m}}{\boldsymbol{m}}\mathbf{100}$$

Where m2 is mass of container with sample after 7 days, m1 is mass of empty container and m is initial mass of sample (1-2 g).

For determination of **rehydration ratio** 5 g of powder was mixed with 50 ml of distilled water and put to boil for 2 minutes in a covered container. After boiling, the sample was filtered through weighted medical gauze and the gauze with the sample was air dried for 4 hours at room temperature (Kour et al. 2024). Rehydration ratio was calculated according to the formula:

$$\boldsymbol{Rehydration\,ratio} = \frac{\boldsymbol{m_2 - m_1}}{\boldsymbol{m}}$$

Where m_2 is the mass of rehydrated sample on the gauze, m_1 is the mass of gauze and m is initial sample mass.

Reconstitution index was calculated as weight ratio of prepared ready to eat liquid soup and soup powder used for preparation. Liquid soups were prepared according to producer instructions.

For **foam capacity** determination 2 g of the sample and 50 ml of distilled water (30 C) are put in a 100 ml measuring cylinder. The initial volume (before shaking) of the sample with water was recorded. Then the sample was mixed with water and the mixture was vigorously shaken for 3-5 minutes and the foam volume was measured. The foam capacity was calculated according to the formula (Imtiaz et al. 2007):

$$\boldsymbol{Foam\ capacity}\ (\%) = \frac{\boldsymbol{V_{foam}}}{\boldsymbol{V_{initial}}}\mathbf{100}$$

Bulk density was determined as ratio of weight and volume of powder in measuring cylinder. Sample powders were poured gently into a 50 ml graduated and tarred measuring cylinders. Bulk density was calculated as ratio of sample weight and volume (Fernandes et al. 2013).

Tapped density was determined after bulk density determination. In the same measuring cylinder soup powders were tapped 100 times (or to constant volume) by beating on a plain surface. The new tapped volume was recorded, and tapped density was calculated as ratio of sample weight and tapped volume (Fernandes et al. 2013, Imtiaz et al. 2007).

Table 12 Referent values of Carr index, Hausner ratio and angle of repose for flowability estimation

Carr index	Hausner ratio	Angle of repose (degrees)	Flowability
≤10	≤1.11	≤30	Excellent, easy flow
11-15	1.12-1.18	31-35	Good
16 -20	1.19-1.25	36-40	Fair
21-25	1.26-1.34	41-45	Passable
26-31	1.35-1.45	46-55	Poor
26-31	1.35-1.45	46-55	Poor
32-37	1.46-1.59	56-65	Very poor, limited
>38	>1.60	>66	Extremely poor
Carr index	Hausner ratio	Angle of repose (degrees)	Flowability

Szulz and Lenart (2016, Jan et al. (2015)

Flowability and cohesiveness

Angle of repose, Carr index and Hausner ratio were used as indicators of flowability and cohesiveness of soup powders. For determination of angle of repose, 50 ml of dehydrated soup sample powder was carefully sloped through a funnel (D = 1 cm) on a plain surface base. The height (h) and diameter (d) of the powder heap were measured. Angle of repose α was calculated as:

$$\mathbf{tg\ \alpha} = \frac{\boldsymbol{2h}}{\boldsymbol{D}}$$

Dynamic angle of repose was calculated as 70% of angle of repose.

The Hausner ratio and Carr index were calculated from bulk (ρB) and tapped (ρT) densities using following formulas (Szulz and Lenart 2016):

$$\boldsymbol{Hausner\ ratio} = \frac{\boldsymbol{\rho}}{\boldsymbol{\rho_B}}$$

$$\boldsymbol{Carr\ index}\ (\%) = \frac{\boldsymbol{\rho_T} - \boldsymbol{\rho_B}}{\boldsymbol{\rho_T}}\mathbf{100}$$

Carr index and Hausner ratio were compared to referent values (Szulz and Lenart 2016, Jan et al. 2015; Sahni and Shere 2017), and flowability was described in comparison to Table 1.

Physical analysis of reconstituted soups

Liquid soup samples were cooked according to producer instructions. Density of liquid samples was calculated as ratio of measured weight and volume of liquid soup in measuring cylinder. Determination of density was done at 5, 25, 55 and 100 C.

Measurement of kinematic viscosity was performed at 55°C by capillary viscometer Micro Ostwald 516 30/III and calculated as product of viscometer constant and time (s) needed

to soup sample pass through capillary. Dynamic viscosity (apparent viscosity) was calculated as product of kinematic viscosity and density at 55C. Apparent fluidity was calculated as reciprocal value of dynamic viscosity (Hlavač et al. 2019; Sing and Heldman 2003).
Determination of adhesiveness was done by method described by Sihshobhon et al. (2013) with some modifications. 100 g of prepared soup samples was placed into laboratory glass, and wooden stick (15x1.7x0.1 cm) was immersed into samples, taking care that 10 cm of stick should be immersed. Adhesiveness was calculated by formula:

$$\boldsymbol{Adhesiveness}\ (\%) = \frac{\boldsymbol{m_2 - m_1 - m}}{\boldsymbol{m}}\boldsymbol{100}$$

Where are: m_2 is weight of wooden stick with sample, m_1- initial weight of wooden stick without sample and m – weight of sample in glass.
Thermophysical properties were estimated by different mathematical models from moisture or total solids content in liquid samples.
Freezing point was calculated by Guegov`s model applicable for food with solids between 3.50 and 27% (Guegov 1980):

$$\boldsymbol{Freezing\ point}\ (°\boldsymbol{C}) = \boldsymbol{0.36 - 0.175}\ \%\boldsymbol{solids}$$

Specific heat capacity (cp) was calculated by model established by Dickerson for liquid or semiliquid food (>50% of water) (Delgado et al. 2006):

$$\boldsymbol{c_p(J/kgK) = 1674.7 + 25.12}\ \%\boldsymbol{water}$$

Bowman`s model was used for prediction of thermal conductivity coefficient:

$$\lambda(\boldsymbol{W/mK}) = \boldsymbol{0.056 + 0.567}\ \%\boldsymbol{water}$$

Thermal diffusion coefficient was calculated from general definition equation, which assumed density, thermal conductivity and specific heat capacity (Singh and Heldman 2003):

$$\boldsymbol{\alpha}\ (\frac{\boldsymbol{m^2}}{\boldsymbol{s}}) = \frac{\boldsymbol{\lambda}}{\boldsymbol{\rho\ c}}$$

where α is thermal diffusion coefficient [m2/s], λ is thermal conductivity calculated by Browman`s model [W/(mK)], ρ is measured density at 25C [kg/m3] and Cp is calculated specific heat capacity [J/(kgK)].
Statistical analysis: was performed by one-way ANOVA and Tukey test ($p \leq 0.05$) using SPSS version 20.0 (SPSS Inc., Chicago, IL, USA). All analysis was done in triplicate and results were shown as mean ± standard deviation (SD).

RESULTS and DISCUSSION

Chemical anlysis

Results of chemical analysis are given in Table 2. In soup powders moisture content ranged between 5.56 and 8.89% without significant differences between samples. Tarhana soups had slightly lower moisture content in comparison to cream soup powders, but differences were not significant ($p \leq 0.05$). All samples had moisture content lower than 10%, which is recommended for dry food. Obtained results were in agreement to literature data for similar soup samples (Bhargavavanadha et al. 2021; Goncu and Celik 2020, Cagindi et al. 2016, Ansari et al. 2021; Tahmaz et al. 2023, Celik et a. 2010, Verma and Mogra 2017, Gandhi, et al. 2017, Kambabzi et a. 2020). Reported moisture content commonly ranged between 5.30 and 10. 95% in dry tarhana soups (Tahmaz et al. 2023, Goncu and Celik 2010, Celik et al. 2010, Dagtekin and Misir 2023, Cagindi et al., 2016), while between 5.14 and 9.04% in tomato cream soup powders (Bhargavanandha et.al. 2021, Verma and Mogra 2017, Gandhi et al. 2017). Literature data also reported that industrial tarhana soup has lower moisture content in comparison to homemade and experimentally produced (Tahmaz et al 2023, Celik et al., 2010). Moisture content in prepared liquid soup ranged between 87.85 and 94.52%. According to Gawad et al. (2022) moisture content in liquid cream soup was 87.5%, which is similar to sample TC-2 (tomato cream soup with mozzarella).

pH varied between 4.25 and 5.20 (Table 2). Tarhana soup TT-1 had significantly the highest pH value in comparison to other samples. Obtained results are in agreement to literature data (Hassan and Gadallah 2018, Ertop et al. 2019, Celik et al., 2010, Koc and Ozgire, 2019, Goncu and Celik 2020, Cagidri et al. 2016, Tahmaz et al. 2023). Reported pH values ranged between 3.20 and 5.70 for tomato cream soup (Jamshidvand et al. 2023, Sharma et al. 2023, Bhargavanandha et al. 2021, Gawad et al. 2022) and between 3.6 and 6.0 for tarhana soups (Hassan and Gadallah, 2018, Ertop et al. 2019, Celik et al. 2010, Koc and Ozgira 2019, Goncu and Celik 2020, Cagidri wt al. 2016, Tahmaz et al. 2023, Gohari 2022) depending on formulation.

Table 2 Results of chemical properties

Samples	Moisture in soup powders (%)	Moisture in liquid ready to eat soups (%)	pH
TC-1	6.76±0.33	94.52±0.42	4.65±0.07[ab]
TC-2	8.89±0.54	87.85±8.41	4.90±0.14[ab]
TC-3	6.42±0.84	93.36±0.25	4.40±0.14[ab]
TT-1	6.42±1.86	91.06±0.27	5.20±0.28[a]
TT-2	5.56±0.37	92.83±2.10	4.90±0.14[ab]
TT-3	7.77±2.09	94.06±1.12	4,25±0.35[b]

*Different small letters in columns represent statistically significant differences ($p \leq 0.05$) between samples

Table 3 Amount and size of noodles

Samples	Amount of noodles (%)	Noodle size (mm)
TT-1	55.32±0.18[a]	2.45±0.84[a]
TT-2	49.77±2.05[a]	2.01±0.51[ab]
TT-3	43.23±1.44[b]	1.74±0.44[b]

*Different small letters in columns represent statistically significant differences ($p \leq 0.05$) between samples

Physical anlysis

Amount of noodles in tarhana soups ranged between 43.23 and 55.32% (Table 2, Figure 2). TT-3 sample had significantly lower amount of noodles in comparison to other samples. Tahmaz et al. (2023) reported 55.99% of noodles in tarhana soup from the same producer like TT-1, which is very close to results for TT-1.

Average tarhana noodle size ranged between 1.74 and 2.46 mm (Table 3). TT-1 sample had the largest noodles, while TT-3 had the lowest. Noodles had cylindrical shape (unlike traditional tarhana), which was obtained by cutting of cylindrical extruded noodle dough (Figure 3). Traditional tarhana noodles commonly have rough irregular spherical/rounded shape with different sizes. All pieces of traditional tarhana have smooth rounded edges and sides without sharp parts. Industrial noodles from analyzed samples were not real tarhana noodles produced from fermented dough. As a metter of fact, these noodles were tarhana-like noodles produced from ordinary nonfermented dough. It can be seen (Figure 3) that TT-1 sample had the largest noodles with porous surface, while other samples had smooth compact surfaces without any ruptures. TT-2 and TT-3 had smaller and more uniform noodles in comparison to TT-1.

Figure 2 Image of powder and noodle fraction in tarhana soup samples

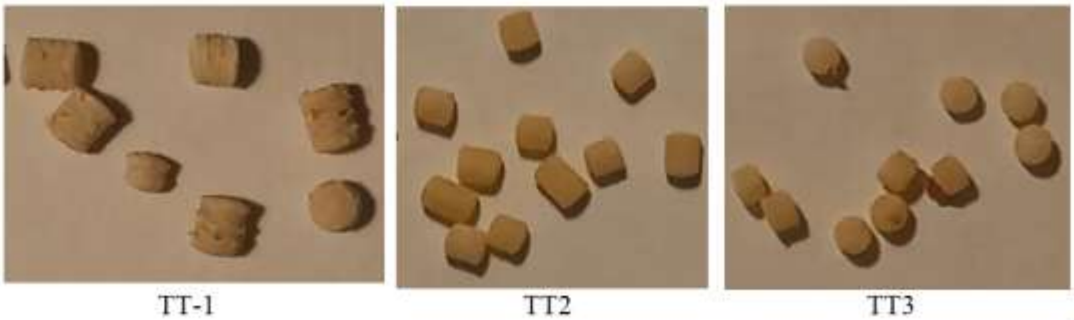

Figure 3 Shapes of the noodles

The results of the granulation analysis are given in Table 4. Cream soup samples had significantly the largest amount of very small particles (< 0.25 mm), while tarhana soups had significantly the largest amount of large particles (>1 mm). Tomato cream soups had extremely highest amount of total small particles (76-91,33%), while tarhana soup samples had more or less similar amounts of the total large (41.98-47,12%) and the total small particles (40.81-55.35%). All samples contained the lowest amount of medium particles. Particles larger than 2.5 mm were pretty low presented in all samples, and noodle sizes were mostly between 1 and 2.5 mm. Large particles (>1 mm) consisted of tarhana noodles in tarhana soup samples, while very large particle fraction (>2mm) mostly consisted of powder lumps and small amounts of dried vegetables (Figure 2). The highest amount of powder lumps was noticed in the TT-3 sample. Considering cream soups the highest amount of powder lumps was noticed in sample TC-2, which has the highest level of large particles (13.99%) in comparison to other cream soups (3.26-3.70%). Very large particle fraction (>2.5 mm) in all samples was the least represented fraction, which mostly contained powder lumps or some pieces of stuck or oversized noodles. Medium and small particle fractions mostly contained salt crystals and small pieces of dried green vegetables and spices.

Table 4 Results of granulation analysis (%)

Samples	Very large ≥ 2.5 mm	Large ≥1 mm	Medium ≥ 0.50 mm	Small ≥ 0.25 mm	Very small < 0.25 mm
TC-1	0.40±0.14^{c}	2.86±0.63^{b}	5.41±0.59^{cd}	2.71±0.9^{a}	88.63±0.29^{a}
TC-2	6.71±1.15^{a}	6.88±1.40^{b}	10.34±0.35^{ab}	6.28±3.27^{b}	69.73±0.48^{b}
TC-3	1.28±0.08^{bc}	2.42±0.39^{b}	8.23±0.66^{bc}	3.15±1-65^{b}	87.97±5.78^{a}
TT-1	9.07±1.92^{a}	38.80±4.11^{a}	11.33±1.23^{a}	17.09±3.21^{a}	23.72±4.06^{e}
TT-2	0.75±0.35^{bc}	46.37±1.16^{a}	5.81±0.30^{cd}	3.78±1.25^{b}	43.18±2.63^{d}
TT-3	5.35±1.88^{ab}	36.63±4.16^{a}	4.58±0.83^{d}	3.81±1.71^{b}	51.54±6.19^{c}
Samples	**Large ≥1 mm**		**Medium ≥ 0.50 mm**	**Small ≥ 0.25 mm**	
TC-1	3.26±0.77^{b}	5.41±0.59^{cd}	91.33±0-18^{a}	3.26±0.77^{b}	5.41±0.59^{cd}
TC-2	13.59±2.55^{b}	10.34±0.35^{ab}	76.00±2.79^{a}	13.59±2.55^{b}	10.34±0.35^{ab}
TC-3	3.70±0.47^{b}	8.23±0.66^{bc}	91.12±4.13^{a}	3.70±0.47^{b}	8.23±0.66^{bc}
TT-1	47.86±6.02^{a}	11.33±1.23^{a}	40.81±7.27^{b}	47.86±6.02^{a}	11.33±1.23^{a}
TT-2	47.12±1.51^{a}	5.81±0.30^{cd}	46.96±1.38^{b}	47.12±1.51^{a}	5.81±0.30^{cd}
TT-3	41.98±6.04^{a}	4.58±0.83^{d}	55.35±7.90^{b}	41.98±6.04^{a}	4.58±0.83^{d}

*Different small letters in columns represent statistically significant differences ($p \leq 0.05$) between samples

The smallest fraction (<0.25 mm) in all samples contained only powder (mostly tomato powder and starch). İt can be seen that samples differed significantly in each fraction. Sample TC-1 had the highest amount of very small particles, while TT-1 had the highest amount of very large particles. The sample with the highest amount of tarhana noodles had the highest amount of very large particle fractions. When comparing tarhana soup samples, it can be seen that the sample with the lowest noodle content (TT-3) had the lowest amount of total large particles (41.98%) and a higher amount of very large particle fraction in comparison to other tarhana samples. This can be explained by observing the highest content of powder lumps in TT-3 samples (Figure 2). Because of the higher presence of powder lumps (Figures 1 and 2), TT-1 and TT-3 had higher amounts of very large particles larger than 2.5 mm. Samples with the highest amount of very large particles (>2.5 mm) were TC-2, TT-1 and TT-3. These three samples also had the highest moisture content (Table 1). The presence of high amount of lumps in these samples could be explained by high moisture content. A high lever of moisture probably caused the sticking of powder particles and the formation of the lumps. The medium fraction was the most dominant in TC-2 and TT-1.

In comparison to other cream soup samples, tomato soup with mozzarella (TC-2) also had the largest amount of small particles (between 0.25 and 0.5 mm), but also the smallest amount of very small particles below 0,25 mm. This could be explained by the presence of mozzarella powder, which could be assumed to have larger particles than starch and other powders. This sample had the highest sum of medium and small particles (16.62%). According to the producer specification (Angelstarch 2024), tomato cream soup should contain a minimum of 65% of fine particles with a size below 0.25 mm. Results obtained for cream soups (Table 4) are in agreement with the literature (AngelStarch 2024).

Bulk density (Table 5) ranged between 464.6 and 775.4 kg/m^3. Tarhana soups had significantly ($p \leq 0.05$) higher values (641-755.4 kg/m^3) of bulk density in comparison to tomato cream soups (464.6-524 kg/m^3). Because of the noodle's compact structure, the presence of tarhana noodles significantly ($p \leq 0.05$) increased bulk density. The sample with the lowest moisture content (TT-2) had the highest bulk density. On the other hand, samples with the lowest bulk density (TC-1 and TC-3) had the highest amount of small powder particles. According to literature data, bulk density varied in ranges 450-790 kg/m^3 for tomato cream soups (Verma and Mogra 2017, Bharagavanandha et al 2021; Kour et al. 2024), and 621 – 948 kg/m^3 for tarhana soups (Koc and Ozcira 2019; Tahmaz et al. 2023). The obtained results were in agreement to literature data, which mostly reported that tarhana soups (and other soups with noodles) had higher bulk density in comparison to tomato and other cream soups.

Table 5 Results of bulk density, tapped density and hygroscopicity of analysed soup powders

Samples	Bulk density (kg/m^3)	Tapped density (kg/m^3)	Hygroscopicity (%)
TC-1	464-60±19.18^c	748.60±1.13^c	25.44±8.76
TC-2	524.30±17.39^c	809.78±4.60^b	25.59±3.08
TC-3	472.50±7.50^c	801.23±31.91^{bc}	21.16±6.35
TT-1	652.80±40.73^b	858.22±12.73^b	20.79±2.16
TT-2	755.40±7.92^a	981.21±7.99^a	21.25±0.66
TT-3	641.00±13.01^b	840.15±10.87^b	21.10±1-55

*Different small letters in columns represent statistically significant differences ($p \leq 0.05$) between samples

Tapped density (Table 5) varied in the range 748.60-981.21 kg/m^3. Tarhana soup powders had higher tapped density. Soups with tarhana noodles had higher tapped density. Samples with the highest and the lowest bulk densities had also the highest and lowest tapped densities. Similar results were obtained by other authors, for example, 866-975 kg/m^3 in tarhana soup powders (Koc and Ozcira 2019, Tahmaz et al. 2023).

Hygroscopicity (Table 5) ranged between 20.79 and 25.44% without significant differences between samples. Tomato cream soups had slightly higher hygroscopicity than tarhana soup. Samples with the highest hygroscopicity (TC-1 and TC-2) also had the lowest values of bulk density, low amount of large particles and high amount of small particles (Table). A higher amount of noodles did not have a significant influence on hygroscopicity decreasing, although TT-1 sample had the largest noodles content and the lowest hygroscopicity in comparison to other tarhana soup samples. According to previous research (Koc and Ozcira 2019; Elrih and Ismael 2020), the hygroscopicity of dried soups ranged between 0.6 and 10%, depending on the sample type and determination method. Lower values obtained in previous research can be explained by some differences in determination methodology and in shorter testing time. Koc and Ozcira (2019) reported that tarhana soup samples had hygroscopicity of 3.1 - 10%.

Powder flowability assessment

Hausner ratio, Carr index and angle of repose were used as indicators of the flowability and cohesiveness of soup powders (Table 6). Higher values indicate lower powder flowability. Powders with low flowability are more cohesive and more compressible. Hausner ratio and Carr index had values of 1.30 - 1.70 and 23.01 - 41.00. These values indicate pretty poor flowability properties. There were no significant differences between cream soup samples and between tarhana soup samples. The lowest flowability had TC-3 sample (tomato cream soup with mozzarella), which indicated very high cohesiveness and extremely poor flowability. This sample had a high amount of moisture content, the highest amount of small particles, a low amount of large particles, low bulk density but high tapped density, the highest angle of repose and the lowest wettability time. This sample also contained the visible amount of powder lumps in the large particle fraction. Samples TC-2 and TC-3 contained powder lumps larger than 2.5 mm. Both indicators were higher in tomato cream soup powders than in tarhana soups. The lowest value was noticed in the TT-2 sample. This sample had the lowest moisture content, the highest tapped density, the lowest angle of repose, the highest amount of large particles between 1 and 2 mm, the lowest viscosity, and the highest fluidity, low rehydration ratio, and adhesiveness. Between tarhana soup powders TT-2 had the highest bulk and tapped density and the smallest noodle size. All tarhana soup samples had very similar values of the Hausner ratio and Carr index. If observing only tarhana soups, the lowest flowability was in TT-1, although this sample contained the highest noodle content. Considering the values of the Hausner ratio and Carr index, the flowability of tarhana soup powders can be assessed as passable with normal (medium) cohesiveness. On the other hand, the flowability of tomato cream soups was recognized as much weaker and estimated as poor to extremely poor with high cohesiveness. Samples with higher noodles content did not show especially more intense flowability, considering that values of Carr index and Hausner ratio between tarhana soup powders were very similar.

Table 6 Hausner ratio, Carr index and flowability assessment of soup powders

Samples	Hausner ratio	Carr index	Flowability
TC-1	1.61 ± 0.07^{a}	37.94 ± 2.47^{a}	Extremely poor
TC-2	1.55 ± 0.04^{ab}	35.26 ± 1.78^{ab}	Very poor
TC-3	1.70 ± 0.04^{a}	41.00 ± 1.41^{a}	Extremely poor
TT-1	1.32 ± 0.10^{bc}	23.89 ± 5.85^{bc}	Slightly fair to passable
TT-2	1.30 ± 0.02^{c}	23.01 ± 1.40^{c}	Slightly fair to passable
TT-3	1.31 ± 0.04^{bc}	23.69 ± 2.54^{bc}	Slightly fair to passable

*Different small letters in columns represent statistically significant differences ($p \leq 0.05$) between samples

Values for the Hausner ratio and Carr index were in agreement with the literature data (Koc and Ozcira 2019, Kumari et al. 2023, Bhargavanandha et al. 2021, Tahmaz et al. 2023). Reported values were in ranges 1.02-1.57 for the Hausner ratio and 23.67-34 for the Carr index. According to Tahmaz et al. (2023), commercial tarhana soup powder had a lower value of Hausner ratio in comparison to cream soups (1.39 vs. 1.57). Bhargavanadha et al. (2023) reported lower values (1.28-1.33) for tomato powder and tomato cream soups probably because of different compositions, which are mostly reflected in the lower starch content in the formulation. Instead of starch, the mentioned authors used gum Arabica in different concentrations. Koc and Ozcira (2019) also obtained lower values (Hausner ratio 1.02-1.05 and Carr index 2.02-4.8) in the estimation of flowability and cohesiveness of tarhana noodles, which indicated better flowability and lower cohesiveness. Since analyzed tarhana soup samples contained powdered fraction (consisting of starch and tomato powder) together with noodles, obtained results were expected Because of that the flowability of soup mixtures was lower in comparison to tarhana noodles reported by Koc and Ozcira (2019). The most similar values to the obtained results were reported by Kumari et al. (2023) for cream soups and Tahmaz et al. (2023) for commercial tarhana soup mixture and cream soups. According to Kumari et al. (2023), cream soup powders had a Carr index of 26.36-34 and a Hausner ratio of 1.35-1.52, which indicated poor to very poor flowability. Tahmaz et al. (2023) also reported that tarhana soup mixtures had higher flowability (Hausner ratio 1.39) and lower cohesiveness in comparison to cream soups (Hausner ratio 1.56-1.57). According to those values flowability of tarhana soup powder was estimated as poor, while the flowability of cream soup powder was estimated as very poor.

The angle of repose ranged between 36.16 and 43.10 degrees (Table 7). Tomato cream soups had a higher angle of repose. The presence of tarhana noodles helped the powder to be loose and have a lower angle. The highest value was noticed in TC-3 and the lowest in TT-2 soup. Considering tarhana soup samples, it is obvious that samples with the lowest angle of repose had the highest noodles content, the highest amount of large particles, and the highest tapped density. On the other hand, tomato cream soup TC-3 had the highest angle of repose, the lowest bulk density and hygroscopicity. Between tarhana soup samples, the highest angle of repose was in TT-3 and the lowest was in TT-2. TT-3 had visible powder lumps in the large particle fraction (Figure), the highest moisture content, the lowest bulk density, tapped density and hygroscopicity, the highest amount of small particles and the lowest amount of noodles. All these characteristics caused the highest cohesiveness and the lowest flowability in comparison to other tarhana soup powders. Lower bulk density could be explained by less heavy powder particles, which easily stand on the top of the heap. Higher moisture content makes powder more sticky, which can contribute to the formation of a higher pile and increase the angle of repose. All these facts could contribute to higher cohesiveness and lower flowability. In the tarhana soup powders, the noodles are the heaviest fraction with the highest specific gravity/density. This fraction shows a higher tendency to be loose and scatter. Because of that, tarhana soup powders with higher noodle content had a lower angle of repose and better flowability. The angle of repose values indicated that the flowability of tomato cream soup powder can be assessed as fair to passable (with needed hang-up), while tarhana soup powders are fair without the need to be aided or agitated.

Table 7 Angle of repose and flowability assesment of soup powders

Samples	Angle of repose (degrees)	Dynamic angle of repose (degrees)	Flowability
TC-1	39.44±2-55^{abc}	27.01±1.79^{abc}	Fair, aid not needed
TC-2	42.09±1.47^{ab}	29.40±1.03^{ab}	Passable, may hang up
TC-3	43.10±1.65^{a}	30.17±1.16^{a}	Passable, may hang up
TT-1	37.08±0.14^{bc}	25.90±0.10^{bc}	Fair, aid not needed
TT-2	36.16±0.57^{c}	25.31±0.40^{c}	Fair, aid not needed
TT-3	39.16±1.24^{abc}	27.41±0.87^{abc}	Fair, aid not needed

*Different small letters in columns represent statistically significant differences ($p \leq 0.05$) between samples

The obtained values are in agreement with literature data for tomato soups and similar powders. Reported values for tomato cream soup ranged between 34 and 47 degrees (Bhargavananha et al. 2021), while for vegetable cream soup from 34.17 to 57 degrees (Tahmaz et al. 2023, Elrih and Ismael 2020, Kamble et al. 2019; Yadav et al. 2022). Tahmaz et al. (2023) reported that tarhana soup had a lower angle of repose in comparison to traditional cream soups, which is in agreement with the results obtained in this study (Table 7).

Physical properties related to soup powders ability to be dissolved

Dispersibility, wettability, foam capacity, rehydration ratio and reconstitution index are the most relevant physical properties related to soup powders ability to be dissolved and reconstituted. The highest values of dispersibility, rehydration ratio and the lower values of wettability time indicate better reconstitution. Results are presented in Table 8.

Wettability time (Table 8) varied in very huge range between 6.28 and 476.29 sec. The amount and the nature of powder fraction have a crucial influence on wettability time, while noodles represent the heavy fraction which fails very easily and fast. Because of that, samples with tarhana noodles (except TT-1) had a shorter wettability time in comparison to cream soups. Significantly the highest wettability time was noticed in TT-1. Such a long wettability time can be related to the combination of different factors (pretty high-fat content, the highest amount of medium particles with non-heavy pieces). A higher amount of low heavy (less heavy) compounds (fat and dried spices in medium fraction) probably could cause a long wettability time. This sample hadn't only the longest wettability time, it also had the lowest dispersibility and rehydration ratio. Besides that, the two samples with the longest wettability time (TT-1 and TC-2) had the lowest fat content and potato starch in their composition, unlike other samples. TC-3 and TT-3 samples had the lowest wettability time and a high amount of small particles. The obtained results were in agreement to the literature. Wettability time in soup powders commonly ranged between 1.16 and 585.8 s, depending on the soup type. It is not uncommon that tarhana soup powder has a long wettability time. According to Tahmaz et al. (2023), the Commercial tarhana soup sample (the same sample as TT-1) also had an extremely high wettability time (585.62

s) in comparison to other samples. Koc and Ozcira (2019) also reported medium to long wettability time for tarhana soups which varied in the range of 16.25 -385.5 s. The reported wettability for different tomato cream soup powders was 48-55 s (Bhargavanandha et al. (2021) and 47.23-96.26 s (Verma and Mogra (2017). Lower values (116 – 220 s) were reported for vegetable cream soups (Elrih and Ismael 2020; Bader et al. 2022, Ocieczek and Palich 2007).

Table 8 Results of physical properties related to powder ability to be dissolved in water (wettability, dispersibility, foam capacity, rehydration ratio and reconstruction index)

Samples	Wettability (s)	Dispersibility (%)	Foam capacity (%)	Rehydration ratio	Reconstitution index
TC-1	39.80±7.79^{bc}	65.50±3.54^{bc}	15.78±4.56^{a}	3.81±1.42	17.66
TC-2	56.63±6.33^{b}	82.50±3.54^{a}	15.71±1.27^{a}	5.52±1.53	10.37
TC-3	6.28±2.06^{c}	70.00±2.83^{abc}	14.02±0.79^{a}	4.34±1.16	14.39
TT-1	476.29±28.20^{a}	59.00±1.41^{c}	4.86±1.44^{b}	2.82±1.02	17.66
TT-2	14.52±1.30^{c}	75.00±1.41^{ab}	7.11±2.20^{ab}	2.89±0.65	15.28
TT-3	6.90±0.54^{c}	76.00±5.66^{ab}	4.83±1.34^{b}	3.07±1.19	17.66

*Different small letters in columns represent statistically significant differences ($p \leq 0.05$) between samples

All soup samples showed good dispersibility, with values of 59 - 82.50% (Table 8). Dispersibility of tarhana soups ranged between 59 and 76%, while in tomato cream soups 65.5 and 82.5%. Tomato cream soups had slightly higher dispersibility values than tarhana soups. Tomato soup with mozzarella (TC-2) had the highest dispersibility. Between cream soup samples, this sample had the highest amount of medium particles, the highest amount of large particles and the lowest amount of small particles, a high angle of repose, and pretty low bulk density in comparison to other samples. Low bulk density probably helps the sample to disperse better. Sample TT-1 with the lowest amount of small particles, the highest amount of noodles, the longest wettability time and the lowest hygroscopicity had the lowest dispersibility. The obtained results were in agreement with the literature. According to Koc and Ozgira (2019) dispersibility of tarhana soup ranged between 31.45 and 84.56%, Tahmaz et al. (2023) reported dispersibility of 59%, in commercial tarhana soup, which was very close to the result obtained for TT-1 sample. Other literature data give results of dispersibility in vegetable cream soups, which ranged between 57 and 82% (Elrih and Ismael 2020; Mohajan et al. 2017, SSepuya et al. 2018, Tahmaz et al. 2023).

Tomato cream soups had significantly higher foam capacity (Table 8) in comparison to tarhana soups. All samples had pretty low foam capacity. The highest foam capacity was noticed in TC-1 and TC-2. TC-1 sample had the highest amount of very small fine particles (<0.25 mm), which have crucial importance in foam stabilization, while TC-2 had the highest dispersibility. The lowest amount of foam capacity was obtained in the TT-1 sample, which had the longest wettability time and the lowest dispersibility. Foam capacity had values of 4.53-15.78%. These values were in agreement with literature data (2.13-15%), reported for vegetable cream soups (Singh and Kaur 2020, Kambabazi et al. 2022, Abd-Elhak and Salem 2017). Gohari 2022 reported an extremely high value of foam capacity for tarhana soup (43%), which could be explained by differences in tarhana soup preparation. The tarhana prepared in the mentioned research (Gohari 2022) was real tarhana prepared from fermented dough, and because of that had higher foam capacity and more stable foam. Tarhana soup samples analyzed in this study are commercial soup samples that are prepared from ordinary nonfermented noodles. It is well known that fermented products have ability to form foam.

Rehydration ratio showed values between 2.82 and 5.52 (Table 8), without significant differences between samples. The highest values were noticed in samples with the highest viscosity values. Tomato cream soups had a higher rehydration ratio in comparison to tarhana soups. Tarhana soups with higher amounts of noodles had lower rehydration ratios. According to the literature data rehydration ratio for different soups had values 2.5-6.5 (Ansari et al. 2021, Bhargavanandha et al. 2021, Abdel Haleem and Omran 2014; Bader et al. 2022), which is very similar to the obtained results. Bhargavananha et al. (2021) reported that tomato cream soup had rehydration ratio values of 3.18-3.65, which is very close to the results obtained in this study (except TC-2 and TC-3). Cream soup samples TC-2 and TC-3 had slightly higher rehydration ratio values than reported by Bragavanandha et al. (2021). These low differences could be explained by differences in tomato soup composition, viscosity and other properties. Bhargavanandha et al. (2021) reported lower viscosity values for tomato cream soups (10-49.1 mPas), while the viscosity of TC-2 and TC-3 samples had much higher values (131-176 mPas). Samples with lower viscosity (15.66-30.28 mPas) had a rehydration ratio more similar to those reported by Bhargavanadha et al. (2021). Samples with higher viscosity commonly had higher total solids content, and because of that probably had a higher rehydration ratio. Samples with a higher reconstitution index had a lower rehydration ratio.

The reconsttution index of commercial soup samples was calculated from instructions for preparation. Values ranged between 10.37 and 17.66. Higher values mean higher water content. Because of that samples with higher moisture content in the liquid soup had a higher reconstitution ratio. Tomato cream soup with mozzarella (TC-2) had the lowest reconstitution index. This sample had the highest values for total solids content, dynamic viscosity, adhesiveness and density. Higher total solids increase the values of reconstitution ratio, viscosity, and density. On the other hand, higher viscosity values increase the adhesiveness and rehydration ratio. According to Ansari et al. (2021), the reconstitution ratio in the cream soup had values between 14.26 and 16.33. Jamshidvand et al. (2023) reported a reconstitution ratio of 10.88 in tomato cream soups. Analyzed samples had values of reconstitution ratio very similar to those reported by Ansari et al. (2021) and Jamshidvand et al. (2023).

Physical properties of liquid soup samples

Results of the physical properties of reconstituted ready-to-eat soups are given in Table 9.

Kinematic viscosity had values of 15.73-176.80 mm2/s, while dynamic viscosity was 15.66 – 176.18 mPas, Tarhana soup samples had significantly lower viscosity in comparison to cream soups. The highest viscosity was in tomato cream soup with mozzarella (TC-2). This sample had the highest content of dry matter, the highest dispersibility, adhesiveness, rehydration ratio, and the highest amount of powder used for preparation. Similar values were reported by other authors. Apparent viscosity commonly ranged between 5 and 298 mPas for similar soup samples depending on temperature and sample type. Reported values for tomato cream soups were 15-298 mPas (Chawan et al., 2015, Verma and Mogra, 2017, US FDA, 2008; Skotnicka and Palich 2019, Jamshivand et al. 2023), and for tarhana soups 5-280 mPas (Tahmaz et al. 2023, Ertop et al. 2019, Hassan and Gadallah 2018). Values for apparent viscosity (Table) varied in ranges 25.0-176.18 mPas (cream soups) and 15.66-30.208 mPas (tarhana soups). Tarhana soups were more unique in consistency in comparison to tomato cream soups. The consistency of tarhana soups was thin with dissolved noodles, and because of that these samples had significantly lower viscosity in comparison to cream soups. Commercial tarhana soups had a consistency more similar to clear soups with noodles. Considering the literature data viscosity of commercial tarhana soup at 50°C was 32.33 mPas (Tahmaz et al. 2023) which is very similar to the value obtained for TT-3. Lower values for other tarhana soup samples (TT-1 and TT-2) are probably obtained because of higher measuring temperatures and different methods of determination. It should be mentioned that kinematic viscosity was measured by a capillary viscometer and dynamic (apparent viscosity) was calculated from values of kinematic viscosity and density at 55°C. In other studies (Hassan and Gadallah 2018; Ertop et al. 2019) higher viscosity values were reported for experimental tarhana soups (with fermented tarhana dough and the addition of different ingredients or processes to traditional recipes). Because of that fermented tarhana noodles have different physical and functional properties which consequently have an impact on final soup consistency and viscosity. Viscosity values of tomato cream soup samples varied in a bigger range than commercial tarhana soups, and the obtained results were in agreement with the literature. Chawan et al. (2018) reported that the viscosity of commercial tomato soups at 45°C ranged between 60 and 180 mPas, while Skotniska and Ocieczek (2019) reported values of 102-298 mPas for tomato soups. The viscosity of commercial tomato soup is about 40 mPas (USDA, 2008) According to producer specifications reported by Angelstarch (2024) viscosity values can range between 70 and 150 mPas. The obtained results are the most similar to data reported by the US FDA (2008), Chawan et al. (2015), and AngelStarch (2024).

Table 9 Results of physical properties of reconstituted ready to eat soup samples

Samples	Kinematic viscosity at 55°C (mm^2/s)	Apparent viscosity at 55°C (mPas)	Apparent fluidity $(Pas)^{-1}$	Adhesiveness (%)
TC-1	25.26±4-36^{c}	25.06±4.29^{c}	40.50±6-93^{ab}	0.27±0.08^{c}
TC-2	176.80±19.52^{a}	176.18±17.78^{a}	5.71±0.57^{c}	1.31±0.01^{a}
TC-3	132.09±5.94^{b}	131.07±6.42^{b}	7.64±0.37^{c}	0.63±0.13^{b}
TT-1	17.11±4.09^{c}	16.59±3.96^{c}	62.04±14.81^{a}	0.11±0.02^{c}
TT-2	15.73±0.01^{c}	15.66±0.10^{c}	63.86±0.41^{a}	0.13±0.02^{c}
TT-3	32,03±3.82^{c}	30.28±5.40^{c}	33.56±5.98^{b}	0.09±0-00^{c}

*Different small letters in columns represent statistically significant differences ($p \leq 0.05$) between samples

Adhesiveness (Table 9) of soup samples was measured at 5°C on liquid samples prepared according to producer, after 24h of cold storage. All soup samples showed expected very low adhesiveness, considering their liquid-thin consistency. Because of that adhesiveness was measured at a temperature of 5C, at which the samples had the highest density and viscosity with the thickest consistency. Adhesiveness ranged between 0.11 and 1.31%. Tomato cream soups had significantly higher consistency in comparison to tarhana soups. Sample TC-2 with the highest viscosity and density had the highest adhesiveness. This sample also had the highest amount concentration, rehydration ratio and reconstitution index. All these properties are closely related to each other, which also affects adhesiveness. Especially high solid concentration and high viscosity are the most relevant properties that could increase adhesiveness.

Table 10 Density of reconstituted ready to eat soups at different temperatures (kg/m^3)

Samples	100 °C	55 °C	25 °C	5 °C
TC-1	976.89±1.13^{C}	992.39±1.70^{B}	998.97±1.77^{B}	1008.83±2.68^{bA}
TC-2	957.89±37.67^{B}	997.01±9.47^{B}	1004.74±17.54^{B}	1340.00±38.18^{aA}
TC-3	951.60±26.86^{B}	992.16±4-02^{AB}	1007.23±1.74^{AB}	1050.09±36.65^{bA}
TT-1	985.33±1.43^{D}	969.65±0.21^{C}	1005.24±2.21^{B}	1012.93±1.51^{bA}
TT-2	918.61±101.40	995.85 at ±5.87	1015.50±0.71	1137.05±43.46^{ab}
TT-3	852.95±69.67	942.05±56.20	1010.74±1.32	1111.69±114.29^{b}

*Different small letters in columns represent statistically significant differences (p≤0.05) between samples, different large letters in rows represent significant differences between temperature

The density of soup samples varied (852.95-1340 kg/m^3) in dependence of temperature and sample type (Table 10). Density decreased in all soup samples when temperature increased. Differences in density between samples were more intense at low (5 and 25°C) than at high temperatures (55 and 100 °C). Significant differences between samples were obtained only at 5°C. The density of all samples was the highest at 5 C and the lowest at 100°C. The highest density values were obtained in the following samples: TT-1 at 100°C, TC-2 at 55°C, TT-2 at 25°C and TC-2 at 5°C. Density values were the lowest in the following samples: TT-3 at 100 and 55°C, and TC-1 at 25°C and 5°C. Differences between densities at different temperatures were significant in all cream soup samples and in only one tarhana soup sample (TT-1). TC-2 sample had the lowest moisture content, the highest viscosity and the highest values of density at 55°C and 5°C.

The obtained values were in agreement with the literature. According to the literature, data density varied in ranges 963-1017 kg/m^3 for tomato cream soups (Skotnicka and Ocieczek 2019, US FDA 2012) and 996.96 – 1050 kg/m3 for tarhana soups (Tahmaz et al. 2023, Celik et al. 2010). Differences occurred as a result of different testing temperatures and different compositions. Obtained density values (Table 10), which were higher and lower than the literature reported were noticed only at 100 and 5 °C, which was expected assuming that mentioned literature values are related to testing temperatures 20 – 55°C.

Thermophysical properties were estimated from moisture or total solid content in reconstructed ready-to-eat soup samples (Table 11). Samples with higher moisture content had higher values of all estimated thermophysical properties, which is in agreement with literature data (Singh and Heldman 2003). Estimated thermophysical properties varied in the following ranges: specific heat capacity above freezing point 3.88-4.05 kJ/kg K, thermal conductivity coefficient 0.554-0.592 W/mK, thermal diffusion coefficient 0.1420.146 mm2/s and freezing point between -1.77 and -0.60°C. As it was expected, the highest values for all thermophysical properties were noticed in the sample with the highest moisture content (TC-1), while the lowest was in the sample with the lowest moisture content (TC-2). There were no statistically significant differences. According to the literature specific heat capacity for similar products has the following values: 4.02 kJ/kg K for fresh tomatoes with 93% moisture, 3.676 kJ/kg/K for tomato concentrate with 81% moisture, and 4.18 kJ/kg K) for water, while thermal conductivity of fresh tomatoes was 0.528 W/(mK). The reported initial freezing point of fresh tomatoes with 93% of water content was -0.7 °C. Thermal conductivity, specific heat capacity, and thermal diffusion coefficient of water at 20°C have the following values: 0.599 W/mK, 4.18 kJ/kg K and 1.43 x 10^{-7} m^2/s (ASHRAE 2006; Singh and Heldman 2009, Toledo 1994). The estimated freezing point for soup samples with 84.85-94.52% of moisture had very similar or slightly lower values in comparison to reported. Lower values of freezing point are related to higher total solids. It is also important to mention that the Guegovs model is suitable for the freezing point of a very huge group of liquid foods with moisture content between 73 and 96.5%. All soup samples had moisture content in the mentioned range. Thermal conductivity was estimated by a model reported by Dickerson which is suitable for food products with water content higher than 50%. Lower values obtained for specific heat capacity and thermal conductivity in comparison to literature could be explained by lower moisture content in samples. Thermal diffusion coefficient also increased with higher moisture content.

Table 11 Results of thermophysical properties

Samples	Specific heat capacity (kJ/kgK)	Thermal conductivity (W/mK)	Thermal diffusion (mm^2/s)	Freezing point (°C)
TC-1	4.05±0.01	0.592±0.00	0.146±0.00	-0.60±0.07
TC-2	3.88±0.21	0.554±0.05	0.142±0.00	-1.77±1.47
TC-3	4.02±0.01	0.585±0.00	0.145±0.00	-0.80±0.04
TT-1	3.96±0.01	0.572±0.00	0.144±0.00	-1.20±0.05
TT-2	4.01±0.05	0.582±0.01	0,143±0.00	-0.90±0.27
TT-3	4.04±0.01	0.589±0.01	0.144±0.00	-0.68±0.20

CONCLUSION

In comparison to tomato cream soup powders, tarhana soup powders had higher large particle amounts (>1mm), higher bulk and tapped density, lower foam capacity, hygroscopicity, angle of repose, Hausner ratio, and Carr index. Tarhana soup powders had higher flowability and lower cohesiveness in comparison to cream soups. According to the Hausner ratio and Carr index flowability of tarhana soup powders was assessed as fair to passable, while tomato cream soups were poor to extremely poor. Considering the angle of repose values flowability was assessed as fair to passable (need to be hung to flow) for cream soup powders and as fair (aid not need to flow) for tarhana. Samples with higher noodle content had lower dispersibility, lower angle of repose, and better flowability. The cohesiveness of soup powders was low to normal, higher in cream soups. According to the angle of repose values, all samples had low cohesiveness. Because of that Hausner ratio and Carr index should be used as better flowability indicators than the angle of repose. Cream soup powders had a thicker consistency, higher rehydration ratio, higher amount of small particles (<0.5 mm), higher viscosity, foam capacity and adhesiveness, lower bulk and tapped density and lower powder flowability in comparison to tarhana soups. The obtained results were in agreement with the literature data. Commercial tarahana soup samples were prepared from nonfermented pasta dough and because of that some properties differed from the literature. The density of reconstituted samples increased when temperature decreased, while thermophysical properties increased with moisture content.

ABSTRACT

Although sweet potato is almost the most important crop in many Asian, African and Latin American countries, there are only sporadic research data on production in some continental European countries (Western Balkan countries). Therefore, this research presents an overview of the morphological traits, yield and sensory properties of three phylogenetically different sweet potato cultivars: Beauregard (orange flesh), Japanese (light flesh) and 414 (purple flesh) under several fertilization regimes: 1. poultry pellet fertilizer – control; 2. $NP_2O_5K_2O$ 100:100:100; 3. NPO_5K_2O 100:100:100 + 50N. The mentioned varieties have thin stems with a strong habitus, which cover more than 50% of the inter-row spacing by the 40th day of vegetation. Morphological characteristics of the plants: the length of the main branch, the length and number of side branches, the number of leaves varies during the growing season regardless of the treatment. However, the increased dose of nitrogen (150N) contributed to a higher total leaf mass measured immediately before harvesting the tubers in all three varieties (1476.7 -2470.0 g/plant) compared to other treatments (1300.7-2359.3 g/plant). Treatment with an increased dose of nitrogen (150 N) had a positive effect on the growth of leaf mass in all three varieties. However, a higher dose of nitrogen only in variety 414 affected the increase in tuber yield (25.2 t • ha $^{-1}$) compared to other treatments. For Japanese (60.2 t • ha $^{-1}$) and Beauregard (38.9 t • ha^{-1}), increased nitrogen rates contributed to a decrease in total yield compared to the fertilization treatment with uniform NPK rates (66.6 t • ha $^{-1}$; 42.6 t • ha $^{-1}$). Poultry manure is not able to satisfy the plants needs for nutrients, so the tuber yields of all three varieties in this treatment are statistically lower. Regardless of the fertilizer treatment, the sensory properties of tubers depend on the characteristics of the variety. The marketable yield of Japanese (82.0-89.8%) and Beauregard (79.3-88.1%) is a quite uniform. The mentioned varieties have a significantly higher market yield compared to 414 (54.1-70.8%) and the reason is the proportion of small and tail roots, as well as tuber deformities. Based on the tasting panel, Beauregard received the highest rating, given that it is a commercial variety and is well known to consumers. After cooking, they have a soft consistency, with less fiber and veins, a pleasant aroma and a sweet taste, reminiscent of pumpkin. Japanese and 414 are less readily available for sale (mainly at local farms and markets), suggesting that advertising and tasting should attract consumers.

Keywords: Sweet potato, Variety, Fertilizer, Morphological characteristic, Yield

INTRODUCTION

Specific nutrients and health-promoting values in food crops are of great interest. Sweet potato (*Ipomoea batatas (*L.) Lam.) is an important food, livestock, industrial and energy crop yielding about 200 million metric tons annually on 9 million hectares (Yu et al., 2020). Edible leaves and tubers provide carbohydrates, fiber, carotene, B vitamins, vitamin A and C (El Sheikha and Rai, 2017), and some functional ingredients such as chlorogenic acid which provide medicinal value through antioxidant, antimicrobial, anti-inflammatory effects (Xu et al., 2012; Liang and Kitts, 2016). Epidemiological studies suggest that regular consumption of plant-based foods plays a key role in the prevention of chronic diseases, such as cancer, diabetes, cardiovascular disease and neurodegenerative diseases. Sweet potatoes are considered low on the glycemic index scale and are categorized as one of the powerful functional foods due to their high content of dietary fiber and phenolics (Boeing et al., 2012). Sweet potato is among the major food crops in the world and is grown in all tropical and subtropical regions, especially in Asia, Africa and the Pacific. The regions of Asia and Africa account for 95% of world production. However, in Serbia and neighboring countries, such as Croatia, Hungary and Romania, sweet potato is a relatively new crop, which is mainly grown on individual farms and small gardens. Intensive production has been noticeable in recent years, and consumers are slowly starting to introduce sweet potato root into their diet (Milenković et al., 2024). Climate change is evident. During the summer of 2024 in Serbia was recorded an increased number of tropical days (t above 30.0C) and tropical nights (t above 20.0C). Years ago the presence of late summer was noticeable (RHMZ), which is the basis for the development of new strategies in agriculture. We are of the opinion that sweet potatoes can occupy a significant place in the economy of our region. Sweet potato is a starchy crop with high potential to meet food security and nutrition needs for a sustainable society in the twenty-first century. Due to its high nutritional content and wide adaptability to marginal lands in areas ranging from tropical to temperate zones, sweet potato is a promising crop to prevent malnutrition and increase food security in developing countries (Kwak, 2019). Farmers from rural areas prefer sweet potato cultivation because it is a rustic, easy-to-maintain and drought-resistant crop with relatively low production costs, minimal inputs and high yields per unit area (Volmann et al., 2021). However, in some countries, low yields are recorded, which are related to the unavailability of nutrients (Nsa et al., 2013; Fernandes et al., 2021). Therefore, Udo et al. (2005) state that the availability of nutrients significantly contributes to a good crop yield and note a significantly lower yield of the tested when no fertilizer was applied, as a consequence of the poor availability of nutrients in the soil, which is common in traditional agricultural systems. By applying appropriate management techniques that should be developed at the local level, higher crop yields can be achieved. It is also necessary to choose varieties whose quantitative and qualitative properties correspond to the needs of the market.

The purpose of this research is to examine the performance of some sweet potato varieties in different feeding regimes in order to achieve a higher total and market yield.

MATERIAL AND METHOD

Sweet potato production was done in a random block system with three repetitions, during the year 2023, on an experimental plot in the village of Moravac near Aleksinac (21°42′, 43°30′, altitude 159 m), on soil with favorable physical and mechanical properties, alluvium type (Table 1). The examination included three varieties: Japanese (light flesh), Beauregard (orange flesh) and 414 (purple flesh) in three feeding regimes: 1. poultry pellet fertilizer – control; 2. $NP_2O_5K_2O$ 100:100:100; 3. $NP_2O_5K_2O$ 100:100:100 + 50N. As nitrogen content is somewhat lower (0.18%), we paid more attention to this element and increased nitrogen doses in the fertilization treatment. A randomized block design with two factors with three replications was employed. The first factor was the genotypes of sweet potato. Three cultivars of SP with different flesh and peel color potatoes ('Japanese'mid-early cultivar with pink skin-white fleshed; 'Beauregard' mid-early cultivar with orange skin-orange fleshed and '414' late cultivar with purple skin purple-fleshed) were provided by company from the east part in Croatia (cadastral area of Ilok) and were included in experiment. The second factor was different plant nutrition; organic (as control) and inorganic fertilized as treatments. Organic poultry manure were used with 900 kg/ha granulate (Italpollina with $N:P_2O_5:K_2O$ 4:4:4, organic carbon 35%, ratio C/N 8/8) and two inorganic fertilizers, first treatment - mineral complex $N:P_2O_5:K_2O$ 100:100:100 and second treatment – $N:P_2O_5:K_2O$ 100:100:100 + 50N was applied. Complex fertilizer of the combination 16:16:16 was used as source of $N:P_2O_5:K_2O$. As a source of additional N fertilizers was used KAN (27%) from the company Genezis. Production is based on using seedlings that at the moment of planting had formed 5-6 leaves. Planting was done on May 20, 2023, with a distance between rows of 120 cm and in a row of 35 cm, with 2.4 plant on. m^{-2}, on banks mulched with PE-foil with a drip irrigation system. The basic plot included 15 plants. Morphological characteristics: length of main and side branches (cm), number of lateral branch, number of leaves, shape of leaves, color, followed are in samples of five plants randomly selected from each plot, 40 and 60 days after planting, based on the descriptors of Huaman (1991). Collection of thickened roots was done 110-120 days after planting when total yield (t ha-1), market yield , as well as yield components: mass of roots per plant (g), number of roots per plant, average root weight (g), length (cm) and width (cm). After harvesting, the taste was evaluated by cooking the samples. Quantitative descriptive analysis was applied to evaluate the samples in terms of the aroma, texture, flavor and aftertaste attributes (Tomlins et al., 2003). The obtained results were statistically processed by analysis of variance and LSD test (MSTAT-C).

RESULTS AND DISCUSSION

Sweet potato (*Ipomoea batatas* L. Lam., 2n=6k=90) has become an accessible source of calories, protein, fiber, minerals, vitamins and flavonoids (Padmaja, 2009), especially in countries in development. As the tuberous root of the plant is most commonly consumed in the western part of the world, leaves are increasingly of interest for human consumption due to their nutritional value (Suarez et al. 2020). Namely, the leaves are a good source of protein, fiber, polyphenols and minerals, and the polyphenols in them are important antioxidants. Also, it was reported that the polyphenol content of the leaves was much higher than that of the whole root, fleshy tissue and skin of sweet potato, as well as the second largest commercial vegetable (Truong et al., 2018). Villareal et al., (1982) indicate that sweet potato leaves are consumed as a vegetable in tropical areas, especially in Southeast Asia, and Sun et al. (2014) suggested that green mass yields are significantly higher than leafy vegetables as an off-season alternative. Since the plants grow quickly in wet conditions, these leaves can be harvested several times a year without adversely affecting the tuber yield. In some communities in Nigeria, Brazil, the leaves are used fresh, heat-treated, dried as a supplement to flour. The yield of leaves in certain varieties can be higher compared to the root, which is also a feature of the described variety 414 in our research.

Although the phylogenetically different cultivars Japanese and Beauregard on the 60th day of vegetation achieve a uniform length of the main branch, a uniform number of side branches, and these values are significantly lower compared to variety 414. Sweet potato is a herbaceous liana plant with alternating leaves and tubular flowers. The leaves are smooth, 10-15 cm lenght and 10-15 cm widht. The shape of the leaves can vary even on the same plant, but basically they are round whole to deeply incised triangular leaves, with slight lobes in 414, smooth edge and smooth surface, quite firm consistency. In variety 414, the veins are reticulate, medium to strongly pronounced. The leaves of the Japanese variety are of a delicate consistency, with a smooth edge and surface, with a moderate nervature, which can potentially be considered a desirable feature as a leafy vegetable (personal observation). Milenković et al. (2023) made a similar conclusion for the O Henry light type variety. Young leaves can be consumed (Antonio et al., 2011). The basic leaf color is green in Beauregard and 414, and lighter green in Japanese. Purple as a secondary color (according to Human, 1991) is observed on the veins and edges of the leaves in all three varieties, but it is most intense in the variety 414. The above-mentioned varieties have mainly prostrate stems with a strong habit, which cover more than 50% of the inter-row spacing by the 40th day of vegetation. The soil coverage with vegetative mass is excellent (Table 2), and branch nodes in contact with the soil develop adventitious roots, resist weeds and reduce soil erosion in case of heavy rainfall. Leaf shape and color, petiole length, and leaf spacing mey make this species useful in ornamental arrangements as well as in eroded landscaping (Loebenstein et al., 2003).

Differences in plant leaf mass between cultivars are very significant, while the difference between types of fertilization was significant (Table 3).The growth of shoots and tubers of plants showed a different response to N availability. N deficiency inhibits vine growth much more than crossgrowth. The differences between the varieties are very significant, so the 414 variety compared to the other two produces a significantly lower yield of tubers, and at the same time gives the highest leaf mass compared to the other two varieties in all variants. Morphological characteristics of the plants: the length of the main branch, the length and number of side branches, the number of leaves varies during the growing season regardless of the treatment, however, the increased dose of nitrogen (150N) contributed to a higher total leaf mass measured immediately before harvesting the tubers in all three varieties (1476, 7 -2470.0 g/plant) compared to other treatments (1300.7-2359.3 g/plant)(Table 3). Varieties react differently to organic fertilization. All morphological parameters vary in the period from 40 to 60 days after planting. The number of leaves on the 60th day after planting in Beauregard was uniform regardless of the treatment. Mineral fertilizers significantly increase the number of leaves at 414. The increased number of leaves of the variety Japanese was initiated by a uniform dose of NPK. The position of the branches on the plant also affects the number of leaves. Increased doses of nitrogen (N150) contributed to a significantly higher yield of leaf mass compared to other nutrient treatments. Nitrogen fed at an early stage of crop development will help build the overall size of the leaf canopy, whereas at later stage of growth, nitrogen helps maintain the greenness of the canopy and maximize yield (Mark et al., 1983).

Considering that there are no significant differences between the fertilizer treatments in 414, the intensive growth of the vegetative mass can be considered a variety al trait. In contrast to this, the Japanese variety formed a significantly higher leaf mass when applying a higher dose of nitrogen compared to the other fertilization treatments. Both mineral fertilizer treatments affected the achievement of uniform leaf mass in the cv.Beauregard compared to the chicken manure treatment. Many studies indicate a positive effect of organic fertilizer application on the yield and quality of sweet potatoes. However, our research showed that the application of chicken manure could not meet the nutrient needs of sweet potatoes compared to mineral nutrients. Basically, organic matter is a key component of soils that affects their physical and chemical properties such as water retention, erodibility, cation exchange capacity and nutrient availability (Rice, 2002; Deksissa et al., 2008). Maintenance of soil organic matter levels and optimization nutrient cycling is essential for the sustainable productivity of agricultural systems (Aiuke et al., 2004; Khan et al., 2013).

Sweet potato leaves are an excellent source of chlorophyll and carotene. Dinu et al. (2021) suggest that the higher content of dry matter contributes to the greater nutrition of sweet potato leaves compared to some other vegetable species, and they should be considered for human consumption.

Villordon et al. (2009), indicate that about 90% of the tuber develops from the first adventitious roots formed immediately after planting. However, unfavorable conditions can cause many or all of these to develop into primary fibrous roots or to lignify and produce pencil roots. Minimizing stresses such as high nitrogen levels, low oxygen or dry conditions impacts many of the cultural practices for sweet potato in highly developed production systems (Troung, 2018). Nitrogen, phosphorus and potassium are among the essential elements required for plant metabolism and improving soil water holding capacity (Wamba et al., 2012). Nitrogen is largely needed during leaf formation and then for increasing tuber growth and size, when it ensures optimal photosynthate production in the leaves (Taffouo, 1994).

Varieties Japanese and Beauregard have a uniform average mass of tubers, regardless of the method of fertilization (Table 4). The variety and method of fertilization do not influence the average number of tubers. The differences in yield between the cultivars are significant, so cultivar 414 compared to the other two achieves a significantly lower yield of tubers..Treatment with a dose of nitrogen 150N contributed to an increase in total yield only in variety 414. Higher mineral N rate increased growth of sweet potato vines (Fernandes et al., 2018). In the case of other varieties, the treatment with uniform mineral nutrients had an effect on the increase of the total yield, but without a statistically significant difference compared to the application of 150N. N fertilization affects the development of sweet potato storage roots and can increase their protein content Ca and Mg. However, N fertilizers are expensive for farmers, and high N rates can reduce starch content in sweet potato roots, increase fibrous root formation, reduce storage growth roots, and increase the yield of unmarketable storage roots (Fernandes et al. 2021).. In our research, we observed the presence of lignified pencil roots in clusters of tubers, which is in accordance with previous statements.

Although in 414 plants achieve a uniform leaf mass when treated with organic and inorganic fertilizers, the mass of tubers is significantly lower when chicken manure is applied. The same treatment contributed to the reduction of the commercial yield of this variety by more than 40%, which is a significantly higher value compared to the other treatments. Commercial yield differences between Japanese and Beauregard cultivars are evident but not significant. In our research, the commercial yield is a part of the total yield that is reduced by the mass of fibrous root formation (pencil root), deformed, damaged tubers by mechanical or soil pests, as well as tubers weighing less than 100g (Chart 1, Chart 2). Fertilization with chicken manure contributed to the highest proportion of non-commercial roots weighing less than 100g in 414, unlike other varieties that have a uniform average weight (within the commercial range) regardless of the method of fertilization. Damage by soil pests was assessed based on the International Potato Center-CIP scale (Gruneberg et al., 2010) and all three cultivars showed some damage in the range of 2-4: minor to moderate (data not shown).

Different authors use different criteria to distinguish commercial roots from non-commercial roots. According to Filgueira (2008), the sweet potato is considered commercial when it presents roots with average mass ranging from 200 g to 400 g. This classification is different from study to Selmane et al.(2024) which suggest that roots weighing less than 100g belong to the non-commercial class. The Japanese variety, as well as most light-type varieties, are high yielding with roots weighing over 500 g. Although large roots (over 1000g) are categorized as non-marketable, consumers prefer to accept them compared to small ones (less than 100g), and they can also find a place in industrial processing. The differences in commercial root yield could be attributed to the genetic variations among the sweet potato varieties in partitioning photosynthesis (Nedunchezhiyan et al.,2007). According to Pedrosa et al. (2010) the total productivity of roots is dependent on the genotype, soil and climate conditions, and cycle duration. Variety 414 is late growing. It is assumed that by changing the date of planting and the method of production (greenhouse production), this variety would improve its genetic potential by increasing the total and commercial yield. The benefits of purple pigmentation varieties have been confirmed in several studies due to the capacity (property) of anthocyanins to provide multiple benefits to the human body. Because 414 forms a longer and thinner tuber compared to Beauregard and Japanese, it is prone to damage at harvest. However, one must be careful during harvesting to avoid skinning or bruising the produce. Skinning and bruising can spoil the roots, making them unappealing to consumers. Farmers must make every effort to minimize mechanical damage, ensuring an appropriate shelf life and acceptance of the product (Todesco et al., 2023).

Important characteristics of the varieties are: resistance to drought, high content of dry matter, resistance to diseases and pests. The color of sweet potato skin ranges from white, cream, yellow, orange, pink, and red to purple, while flesh colors may be white or various shades of cream, yellow, orange, or even purple (Teow et al., 2007; Alam et al., 2016). In Serbia the orange pulp variety is the most common. The sweetness of the root is considered an important flavor attribute. It can also be a complex characteristic, not necessarily directly related to sugar content. The sugar content of the root increases during cooking, as the process promotes the breakdown of starch. Beauregard possesses sweetness (Chart 4).The texture of the thermal processed tuber is an important attribute on which consumer’s acceptance of the tested varieties depends. In Beauregard, the texture is soft, spreadable, moist and denser (pasty) compared to other varieties tested. The pulp is homogeneous, without secondary color diffusion. A less sweet Japanese variety (chart 4). Grainy, moist texture is identified. The taste is neutral, without an aftertaste. In 414, the sweetness is moderate, it is a bit astringent, with a slight earthy after taste. The dietary fiber content of sweet potato roots varies between different cultivars. The proportion of fibers was evaluated in the following order: the highest in variety 414, then Japanese and then Beauregard. Our research has shown that 414 has a significantly higher fiber content compared to Japanese and Beauregard. Leighton et al. (2010) suggested that the Blesbok variety VFSP (white pulp) has a higher fiber content than the variety OFSP (orange pulp). In some varieties, the fiber content can be so high that sweet potatoes are unusable directly as human food and are directed towards industrial processing.

Table 2. Morphological characteristics of the sweet potato plants

Cultivar	Type of plants	Predominant color of branches	Color of the mature leaves	Color of the immature leaves	Color of petiole; length	Main flesh (pulp) color
Beauregard	Spreading; prostrate	Grin / sporadically purple the top of the branches	Grin	Grin with purple edge	Grin with purple nodes; short (10-20cm)	Orange flesh
Japanese	Spreading; prostrate	Grin/ sporadically light purple the top of the branches	Grin	Grin with liht purple edge	Grin with purple nodes(sporadically); Short (10-20cm)	Cream flesh
414	Spreading-exstreamly spreading; prostrate	Grin / purple the top of the branches	Grin/purple	Grin/purple	Grin/purple Short/Intermediate(15-25cm)	Intense purple

CONCLUSIONS

Sweet potatoes responded positively to increased doses of nitrogen fertilizers for all parameters of leaf mass yield in all cultivars in trials. However, the result of our research indicates that fertilization with organic poultry manure does not provide enough nutrients for optimal growth and development of tubers, while fertilization with complex mineral fertilizers with increased nitrogen content (150 N) represents a luxurious diet for sweet potatoes. The response to fertilization was significant in the case of tuber mass per plant, total tuber yield and leaf mass, while no effect was observed on the average tuber mass and tuber number. For optimal yield and quality of sweet potato tubers and leaves, we recommend fertilizing with $NP_2O_5K_2O$100:100:100. In our research, mineral nutrition ensures a uniform commercial yield in Japanese and Beauregard varieties, while it is significantly lower in 414 varieties. Based on the tasting panel, Beauregard received the highest rating. Japanese and 414 are less readily available for sale (mainly at local farms and markets), suggesting that advertising and tasting should attract consumers. Our analysis highlights the significant potential of sweet potato leaves and tubers, suggesting opportunities for expanded cultivation and increased consumer interest in this relatively new type of vegetable in Serbia.

ABSTRACT
Mosquitoes are the first cause of transmission of viral diseases to both humans and animals, as they can transmit some viral diseases. These insects have attracted the attention of specialists, especially in the field of control, because they have controlled their spread in urban areas. Traditionally, they have resorted only to insecticides to eliminate them, and aquatic organisms have long been used to assess the health of aquatic systems. Biodiversity refers to the diversity of organisms in a given area or ecosystem, including species diversity, genetic diversity, and ecosystem diversity including terrestrial, marine, and other aquatic ecosystems. It is important for maintaining healthy and stable ecosystems, as well as for providing humans with food, medicine, and other resources. Mosquito larvae are the immature form of mosquitoes that live in water. It feeds on microorganisms and organic matter in the water and undergoes several molts as it grows and develops into a pupa and then an adult mosquito. The aim of our work is to investigate the effect of 'rosemary oil' on a target species, the larvae of the *Culex pipiens* mosquito. And to determine its effectiveness as an alternative insecticide in order to control mosquito larvae, while reducing the effect on non-target species. In the light of these findings, rosemary oil is considered an effective means to control mosquito larvae and has positive effects on non-target organisms. Its use as a natural pesticide can promote sustainable pest control practices. So it is considered a biological insecticide.
Keywords: Insecticide, Larvae, Extract, Plant, *Culex pipiens*, Mosquito

INTRODUCTION

The diversity of organisms in a particular area or ecosystem, including species diversity, genetic diversity, and ecosystem diversity including terrestrial, marine, and other aquatic ecosystems. It is important for maintaining the health and stability of ecosystems, as well as providing humans with food, medicine and other resources. The goal of our work is to combat the domestic mosquito *Culex pipiens* using the plant extract “rosemary oil”. This study aims to determine the effectiveness of “rosemary oil” as an alternative to insecticides in combating mosquito larvae while reducing its impact on non-target species **(Kramer et al., 2019).**

MATERIAL AND METHOD

Presentation of the study area Garaate Djamel

Garaate Djamel is located in the commune of El Chat, daira of Ben Mhidi on the left side of the wilaya road number 109 connect the wilaya of Annaba with El- Kala, and it's located at 36° .88 N and 07° .90 E. This body of water does not discharge into the sea water which minimizes their variation under the effect of currents (Figure 1).

Figure 1. Location of observation station (Gacem, 2023)

Identification of The *Culex pipiens pipiens* (Northern house mosquito)

Systematic position of the *Culex pipiens pipiens*:

Kingdom: Animalia
Phylum: Arthropoda
Class: Insecta
Order: Diptera
Family: Culicidae
Genus: Culex
Subgenus: Culex
Species: *Culex pipiens*
Subspecies: *Culex pipiens pipiens*

Figure 2. *Culex pipiens pipiens* (personal photo)

Identification of The Rosemary: Rosemary essential oil is a clear to pale yellow liquid that is extracted through steam distillation, typically using direct steam, from the flowers, leaves, and twigs of the Rosemary plant

Systematic position of The Rosmary

Kingdom: Plantae
Subkingdom: Tracheophytes-Vascular plants
Superdivision: Spermatophyta-seed plants
Division : Magnoliophyta-flowering plants
Class: Magnoliopsida-Dicotyledons
Subclass: Asteridae
Order: Lamiales
Family: Lamiaceae
Genus: Salvia
Species*:* *S. rosmarinus*

The Rosmarry oil tests

- The Daphnia and The *Culex pipiens pipiens* larvae were collected from Garaat Djamel lake.
- From the prepared oil (Rosmarry oil). The tests are carried out in plastic boxes (Used for butter conservation) of 500 ml volume . 2 tests of 2 different insects are carried out to determine the effect of the Rossmarry oil. Each test is carried out in 3 repetition and a control.
- The first test concerned 10 individuals of the *Daphnia magna*, 200 ml of the lake water and 0.2 ml of " ROSEMARY OIL" .
- The second test concerned 20 individuals of The *Culex pipiens* Mosquito larva, 200 ml of the lake water and 0.2 ml of " ROSEMARY OIL".
- Mortality was assessed after 24h, 48h and 72h.

Statistical analysis

The results are presented by the mean ± standard deviation and by the percentage of mortality. We used Exel 2010.

RESULTS AND DISCUSSION

For results based on standard deviation and mean:

We conducted a statistical analysis using Excel 2010, which showed that there is a difference between the effect of “rosemary oil” on the species, and the values are summarized in Table 04 and represented in Figure 39. After 24 hours of treatment with “rosemary oil”, the results showed that the average mortality rate in Daphnia larvae was lower than the average mortality rate in Daphnia larvae.

Table 1: The results of the effect of the ROEMARY OIL during 72h ; M±S.

Time / species	24h	48h	72h
Daphnia	1.66±0.57	0±0	0±0
C. Larvae	8.33±1.52	0±0	0±0

A study of "Antimicrobial activity of Rosmarinus officinalis L. essential oil against Gram-positive and Gram-negative bacteria and Candida spp" found that "ROSEMARY OIL" had significant antimicrobial activity against a variety of target species, including Gram-positive and Gram-negative bacteria and Candida spp. The researchers suggested that rosemary oil may be a promising alternative to conventional antibiotics and antifungal agents.(Silva et al.,2018)

A study on “Antimicrobial activity of Rosmarinus officinalis L. essential oil against Gram-positive and Gram-negative bacteria and Candida spp” found that “Rosemary oil” has

Significant antimicrobial activity against a variety of target species, including Gram-positive and Gram-positive. Negative bacteria and Candida spp. The researchers suggested that rosemary oil may be a promising alternative to traditional antibiotics and antifungal agents.

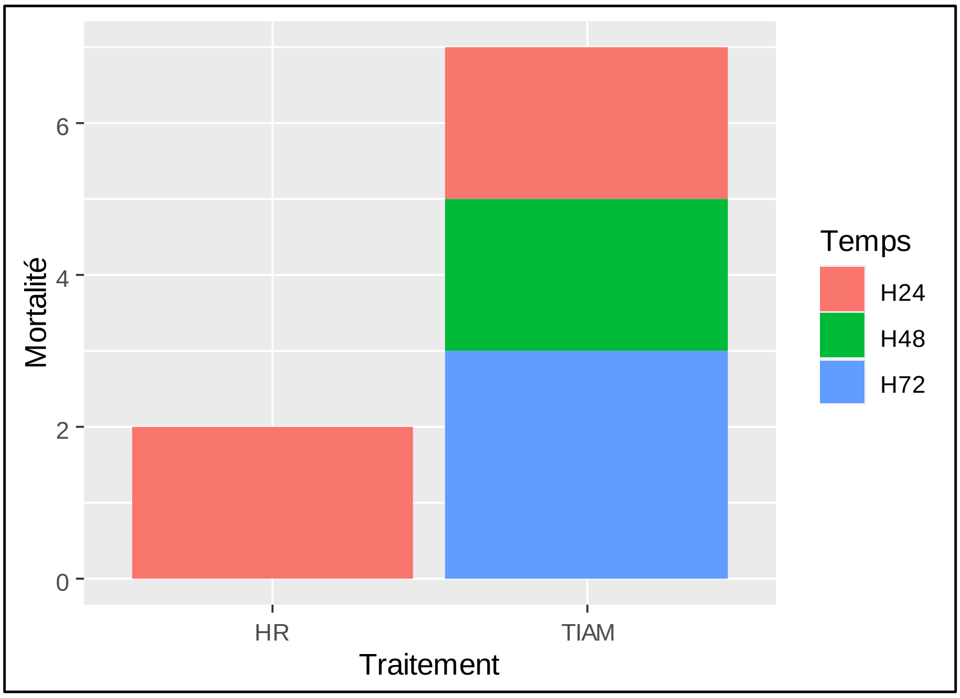

Figure 4: The effect of the "TIAM" insecticide and the "ROSEMARY OIL".

CONCLUSIONS

A study on "Antimicrobial activity of Rosmarinus officinalis L. essential oil against Gram-positive and Gram-negative bacteria and Candida spp" found that "Rosemary oil" has significant antimicrobial activity against a variety of target species, including Gram-negative bacteria and Candida spp. The researchers suggested that rosemary oil may be a promising alternative to traditional antibiotics and antifungal agents.

ABSTRACT

Wheat (*Triticum aestivum* L.) plays a critical role in global agriculture, and herbicides used for weed control, particularly chlorotoluron, have significant effects on wheat. Although chlorotoluron is commonly used to control weeds in wheat, excessive use can lead to accumulation in the soil and toxicity in plants. Studies have shown that chlorotoluron creates oxidative stress in wheat plants, disrupting photosynthesis and negatively affecting plant growth. Additionally, organic matter in the soil that influences the absorption of chlorotoluron can reduce its accumulation and toxicity in plant tissues. However, further research on the toxic effects of chlorotoluron in plants and its environmental behavior is needed to understand the effects of herbicides better and reduce environmental damage. For these reasons, this review aims to provide information on studies and general knowledge related to chlorotoluron in wheat conducted to date.

Key words: Chlorotoluron, Herbicides, *Triticum aestivum* L.

INTRODUCTION

Wheat (*Triticum aestivum* L.) has the highest grain production among all cultivated food crops, with 808.4 Mt produced in 2022, and it covers approximately 219.1 Mha of arable land, making a significant contribution to the global agricultural economy (FAO, 2022). As arable land decreases, sustainable wheat production becomes crucial for global food security. In the development processes of wheat, weed infestation and control represent significant obstacles and threats to wheat production worldwide. The use of herbicides for weed management in both uncultivated soil and fallow areas is highly preferred in developed countries. As a result of the widespread and intensive use of herbicides, the evolution and spread of herbicide-resistant weed species have been observed in many crop production systems, including wheat. According to the International Herbicide-Resistant Weeds Survey, wheat ranks first worldwide in reported resistance cases, with a total of 77 weed species exhibiting resistance to 140 different herbicides (Nakka et al. 2019).

The use of herbicides in agricultural fields is one of the most important practices for controlling weed growth in modern farming. However, recent intensive use of herbicides has led to significant accumulation of these substances in the soil. As herbicides have become one of the most commonly observed organic pollutants in agricultural areas, there are growing concerns about their potential impacts on produced crops, ecosystems, and human health (Song et al. 2007).

The fundamental challenge that agriculture currently faces and will continue to face in the future is providing food for the world's growing population while protecting the environment. Increases in crop yield are often based on the use of pesticides. The competition between plants and weeds makes herbicides the most commonly used type of pesticide for soil nutrients, thereby promoting plant growth and enhancing yield (Marín-Benito et al. 2019).

Herbicides possess physical and chemical properties that allow for their absorption upon initial contact with plant tissues. They are then transported to target areas, where they can cause injury and death in susceptible weed species or cultivated plants. The control of a weed species depends on the mode of action of the herbicide. The mode of action is defined as a series of biochemical and physiological processes that begin when the plant comes into contact with the herbicide and continue until the plant's complete death (Nakka et al. 2019).

Chlorotoluron is a phenylurea herbicide widely used for controlling weeds in cereal, fruit, and cotton production. However, excessive use of this herbicide can lead to its accumulation in ecosystems, thereby causing toxicity in plants. Chlorotoluron [3-(3-chloro-4-methylphenyl)-1,1-dimethylurea], a phenylurea herbicide with high activity and relatively low toxicity, is commonly used to control weeds during production. It is typically applied to the soil and is moderately soluble in water, which allows it to accumulate easily in plants (Song et al. 2007). This substance is particularly effective against broadleaf weeds. Chlorotoluron is a herbicide with low mobility in soil and can therefore be effective for a long time after application to the soil (Smith, J. and Brown, T. 2021).

Effects of Chlorotoluron Active Ingredient on Wheat

Wheat is one of the most widely cultivated crops globally. When weeds are not controlled in wheat fields, yield losses can range from 10% to 50%, depending on the density of the weeds and the duration of the infestation. Herbicide applications for weed control have proven to be very effective and efficient in terms of production costs and benefits. However, repeated use of herbicides for weed management has led to selection pressure and, consequently, the evolution of herbicide-resistant weed species (Nakka et al. 2019).

In wheat, natural resistance to different herbicides varies depending on factors such as variety, application timing (pre-emergence, pre-planting, or post-emergence), soil and environmental conditions, and the use of protective compounds. Therefore, wheat growers should carefully follow label recommendations to prevent crop damage. Typical herbicide damage symptoms in wheat can range from yellowing of leaf tips to reduced spike development and may show more severe symptoms depending on the mode of action of the herbicide (Nakka et al. 2019).

Chlorotoluron provides effective weed control, especially during the wheat growing season. This allows the wheat plant to use its nutrient and water resources more efficiently. However, it should be noted that chlorotoluron may not be effective against some weed species and may need to be combined with other control methods (Smith, J. and Brown, T. 2021).

A study conducted in 1993 examined the metabolism of the herbicide chlorotoluron in wheat cell suspension cultures. The study used the sensitive variety Corin (S) and the tolerant variety Clément (T), along with six genetically similar isogenic lines (9S, 10S, 16S, 17T, 18T, and 24T). These isogenic lines have the genetic background of the Chinese Spring variety, with the 17T, 18T, and 24T lines containing a Sul tolerance gene transferred from the Cappelle-Desprez variety. Both Clément and Corin cell cultures produced similar metabolite patterns. The metabolism rate of chlorotoluron is significantly higher in Clément cell cultures compared to Corin cell cultures. Among the isogenic lines, metabolite patterns are similar, with metabolism rates being equal in 9S, 10S, 16S, 18T, and 24T, but lower in 17T. These findings suggest that there is no different acceleration mechanism between T and S cell cultures and that the selectivity of wheat varieties towards chlorotoluron is related to differences in metabolism (Cabanne ve Snape, 1993).

In a study conducted by Krugman et al. (1997) on bread wheat and wild wheat plants, RFLP markers were used to map the chlorotoluron resistance gene (Su1) in sensitive and resistant plants. The results of the study indicate that the Su1 gene, which responds differently to chlorotoluron, evolved before the wheat was cultivated and did not develop as a reaction to the chemical use.

In a study conducted by Song et al. (2007), a series of experiments were performed to evaluate the toxicity of chlorotoluron in wheat plants (*Triticum aestivum* L.) and to assess the metabolic adaptation to chlorotoluron-induced oxidative stress. Wheat plants were grown in soils containing chlorotoluron at concentrations of 0-25 mg/kg. Chlorotoluron accumulation in the plants showed a positive correlation with the external chlorotoluron concentrations but a negative correlation with plant growth. Chlorotoluron application caused the accumulation of O2− and H2O2 in the leaves and led to plasma membrane lipid peroxidation in the plants. Endogenous proline levels were measured and found to accumulate significantly in the roots and leaves of plants exposed to chlorotoluron.

In a study conducted in 2008, the effects of sludge (SL) and straw (ST) extracts on the absorption and mobility of chlorotoluron in soils were investigated. Applications of SL and ST dissolved organic matter (DOM) reduced the absorption of chlorotoluron and increased its desorption. The addition of DOM increased the mobility of chlorotoluron and decreased its accumulation in plant tissues. FT-IR and fluorescence analyses indicated that ST DOM contained more unsaturated components and amines. These results may help in understanding the role of DOMs in the environmental behavior of organic chemicals (Song et al. 2008).

CONCLUSION AND RECOMMENDATIONS

Ecological factors that are harmful to plants, such as heavy metals, herbicides, pesticides and organic pollutants, can lead to physiological and oxidative stress. Currently, the mechanisms of herbicide-induced oxidative stress have not yet been fully elucidated. To utilize of chlorotoluron importantly push down the emergence of chlorophyll, break the photosynthesis of aim plants (Song et al. 2007). Morever, studies have stated that organic matter applications can reduce the rate and strength of chlorotoluron in plants (Song et al. 2010).

To date, very few studies have been conducted on chlorotoluron. Current studies are not sufficient to completely figure out the mechanisms of oxidative stress reasoned by herbicides, nor are they adequate to fully grasp chlorotoluron. More studies should be performed to learn the treatment of this phenylurea herbicide in plants, its gathering in the plant and soil, the damages of its toxicity, and whether it causes genetic damage in subjected plants.

ABSTRACT

Significant changes were observed in agricultural land use, harvested products and fertilizer consumption between 2014 and 2023 in Van province. While the table grape production area was 320 decares in 2014, it increased to 633 decares in 2023 by an increase of 98 %. Table grape production increased from 78 tons in 2014 to 388 tons in 2023, an increase of 397%. While the apple cultivation area was 24,176 decares in 2014, it increased to 27,785 decares in 2023. While apple production was 7379 tons in 2014, it reached 17632 tons in 2024.While pear production was 1968 tons in 2014, it increased by 57% to 3102 tons in 2023. Watermelon production area, which was 1730 decares in 2014, increased to 1904 decares in 2023. While watermelon production was 4322 tons in 2014, it increased to 6317 tons in 2023 and showed a general increasing trend. While the melon production area was 1842 decares in 2014, it reached 2450 decares in 2023. Melon production increased similarly, reaching 6901 tons in 2023, while it was 3203 tons in 2014.A large increase was observed in the tomato production area which was 4811 decares in 2014 and increased to 9706 decares in 2023. In the same time period, tomato production increased from 11,212 tons to 53039 tons. While the wheat production area was 811674 decares in 2014, it decreased to 645758 decares in 2023, and the barley production area increased from 70824 decares to 451834 decares in the same period. Barley production increased from 94779 tons in 2014 to 109203 tons in 2023. Wheat production increased in a similar way, reaching 61906 tons in 2023, while it was 11364 tons in 2014. While the potato production area was 1666 decares in 2014, it increased to 1692 decares in 2023. While potato production was 4006 tons in 2014, it increased to 5875 tons in 2023, and it generally shows an increasing trend. The sugar beet production area, which was 6610 decares in 2014, increased and reached to 24,666 decares in 2023. Sugar beet production, which was 35755 tons in 2014, increased to 114475 tons in 2023.The sainfoin production area, which was 200,713 decares in 2014, increased to 309,800 decares in 2023. Sainfoin production increased from 107,777 tons in 2014 to 363,152 tons in 2023. A decrease was determined in chickpea, onion and alfalfa production areas between 2014 and 2023. Although the walnut production area increased in the same time period, a decrease in the amount of product was determined. Considering chemical fertilizer consumption, the consumption of urea, ammonium sulfate, calcium ammonium nitrate and ammonium nitrate fertilizers was 879 tons, 149 tons, 411 tons and 1243 tons, respectively, in 2014.In 2023, the consumption of these fertilizers increased and the consumption of urea, ammonium sulfate, calcium ammonium nitrate fertilizers was 1758 tons, 262 tons and 11050 tons, respectively. The consumption of diammonium phosphate fertilizer decreased from 1400 tons in 2014 to 728 tons in 2023.

Keywords: Land use, agricultural production, chemical fertilizer,Van province

INTRODUCTION

Over the last few decades, global agricultural production has increased, and advances in technology are still contributing to increased yields. However, population growth, climate change, water crisis and deforestation threaten global food security (Najafi et.al., 2018).

Soil fertility is the ability of the soil to support crop production, determined by the interaction of its physical, chemical and biological properties and usually measured in terms of yield (Lontoc-Roy et al., 2006).

The main purpose of applying fertilizer to the soil is to improve the nutritional status and quality of the soil by enriching it with missing nutrients (Mani 2002). Fertilizers increase soil fertility so that crop yields are no longer limited by missing amounts of plant nutrients (Cooke,1982). Since the nutrients in mineral fertilizers are relatively high and the release of these nutrients is rapid, there is no need for direct decomposition. Therefore, inorganic fertilizers more rapidly increase the growth rate and plant's overall productivity (Ojeniyi, 2002).

In this study investigated that agricultural land use, crop yield and fertilizer consumption between 2014 and 2023 in Van province.

LAND USE AND CROP YIELDS AMONG 2014 -2023 YEARS IN VAN PROVINCE

Significant changes were observed in agricultural land use, crop yield and fertilizer consumption between 2014 and 2023 in Van province. While the table grape production area was 320 decares in 2014, it increased to 633 decares in 2023 by an increase of 98 %. Grape production increased from 78 tons in 2014 to 388 tons in 2023, an increase of 397% (Figure 1).

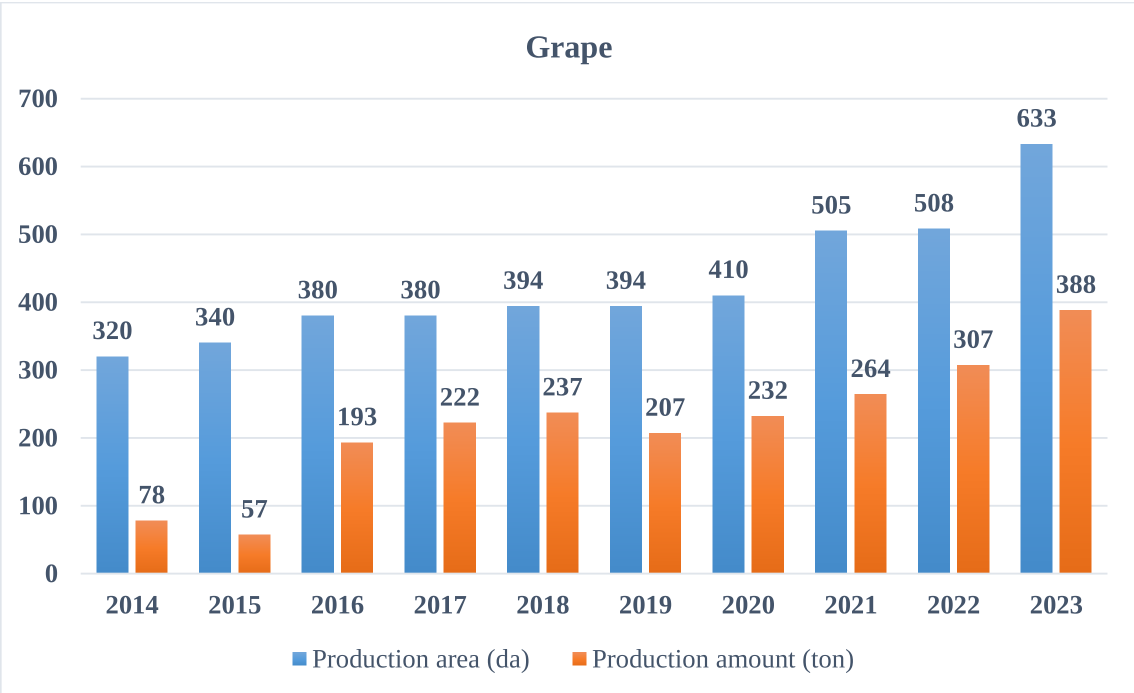

Figure 1. Grape production area and production amount (TUİK 2023)

While the apple cultivation area was 24.176 decares in 2014, it increased to 27.785 decares in 2023. While apple production was 7379 tons in 2014, it reached 17632 tons in 2024 Figure 2).

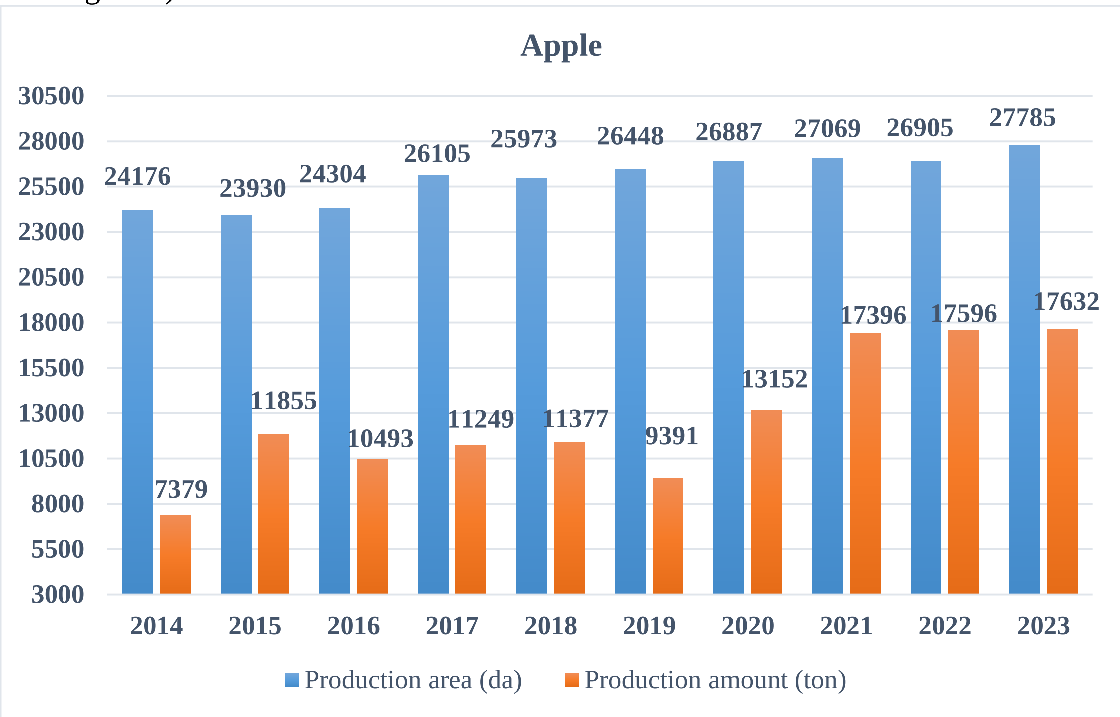

Figure 2. Apple production area and production amount (TUİK 2023)

While pear production was 1968 tons in 2014, it increased by 57% to 3102 tons in 2023 (Figure 3).

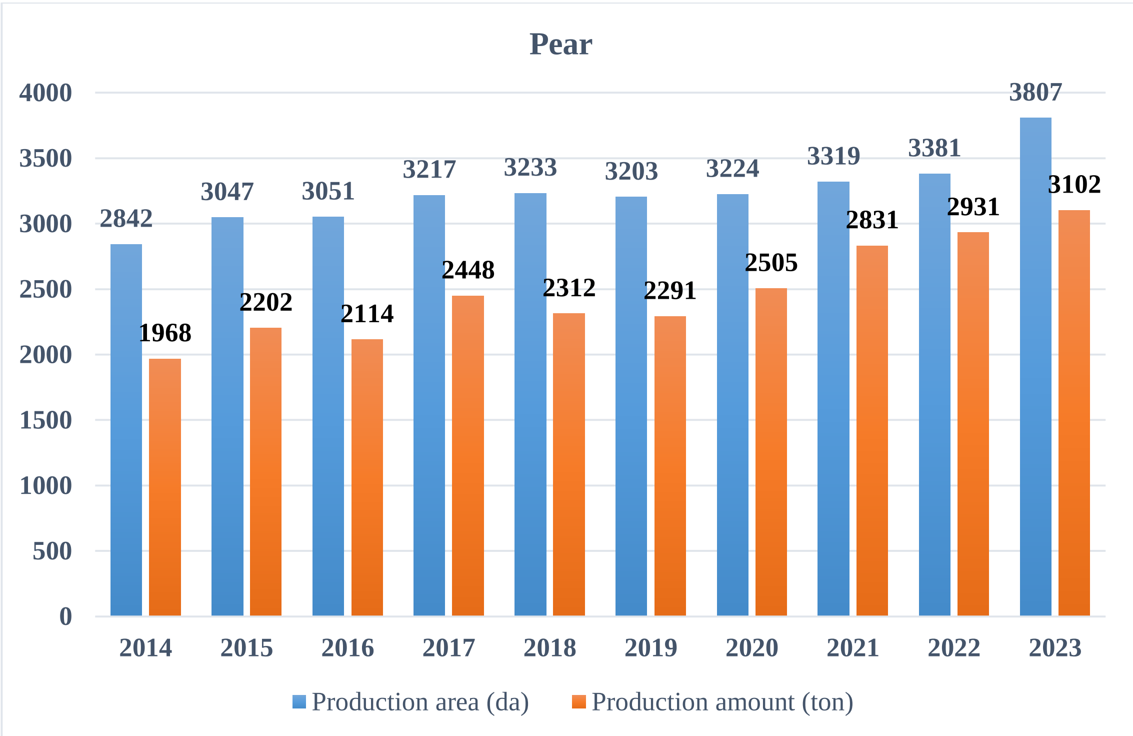

Figure 3. Pear production area and production amount (TUİK 2023)

Although the walnut production area was 2842 decares in 2014 and reached 3807 decares in 2023, walnut production, which was 8001 tons in 2014, decreased slightly to 6817 tons in 2023 (Figure 4).

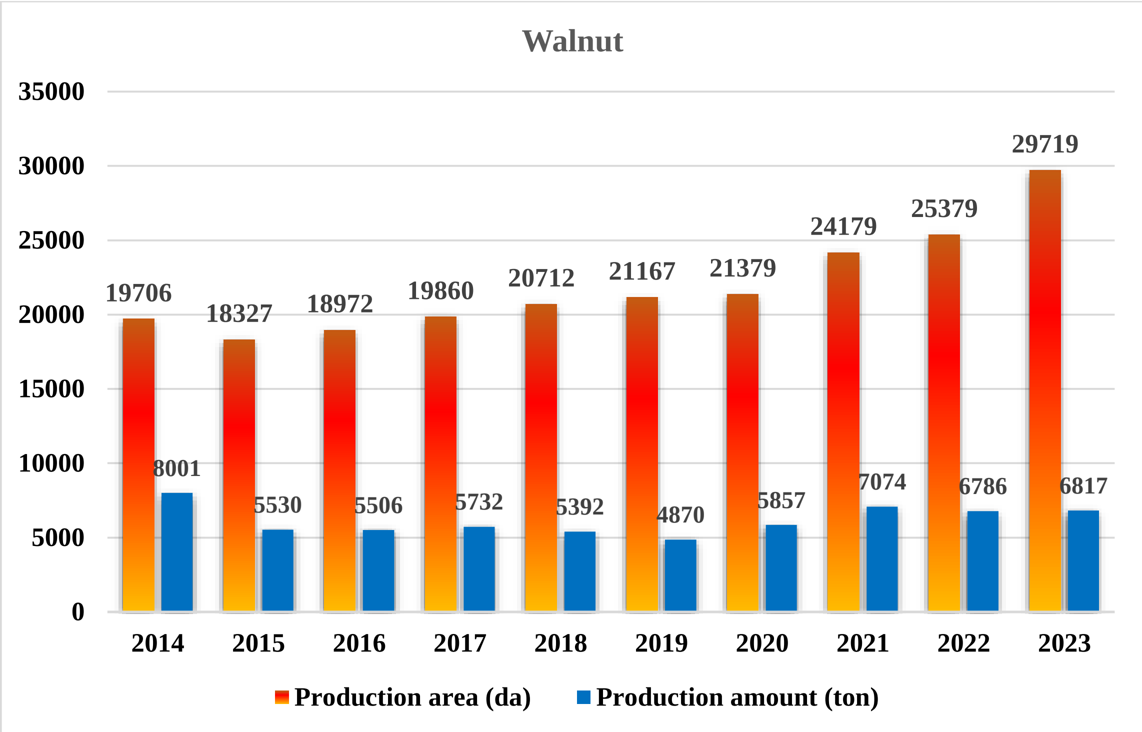

Figure 4. Walnut production area and production amount (TUİK 2023)

Watermelon production area, which was 1730 decares in 2014, increased to 1904 decares in 2023. While watermelon production was 4322 tons in 2014, it increased to 6317 tons in 2023 and showed a general increasing trend (Figure 5).

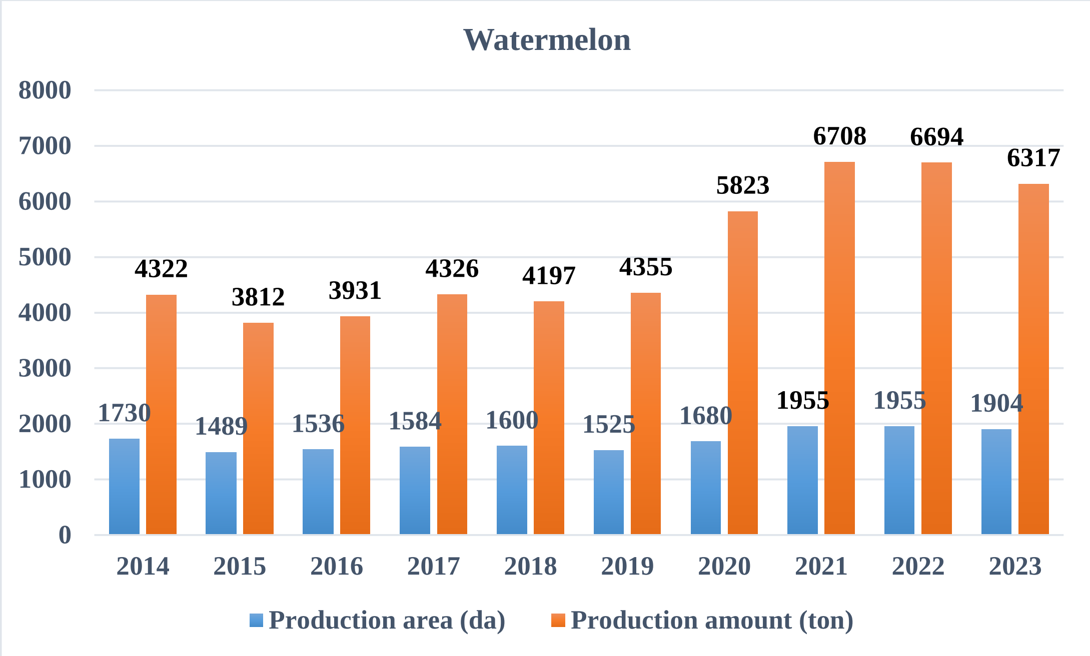

Figure 5. Watermelon production area and production amount (TUİK 2023)

While the melon production area was 1842 decares in 2014, it reached 2450 decares in 2023. Melon production increased similarly, reaching 6901 tons in 2023, while it was 3203 tons in 2014 (Figure 6).

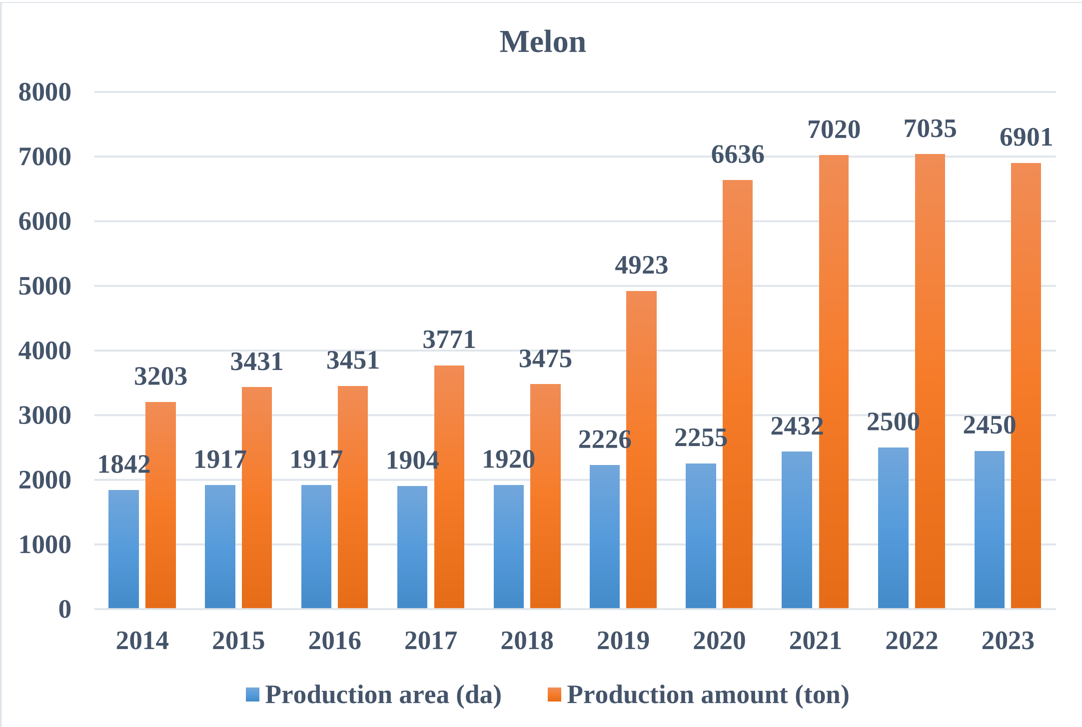

Figure 6. Melon production area and production amount (TUİK 2023)

A large increase was observed in the tomato production area which was 4811 decares in 2014 and increased to 9706 decares in 2023. In the same time period, tomato production increased from 11,212 tons to 53039 tons (Figure 7). This shows that the agricultural and economic importance of tomatoes is increasing (Kumbasaroğlu et all, 2021).

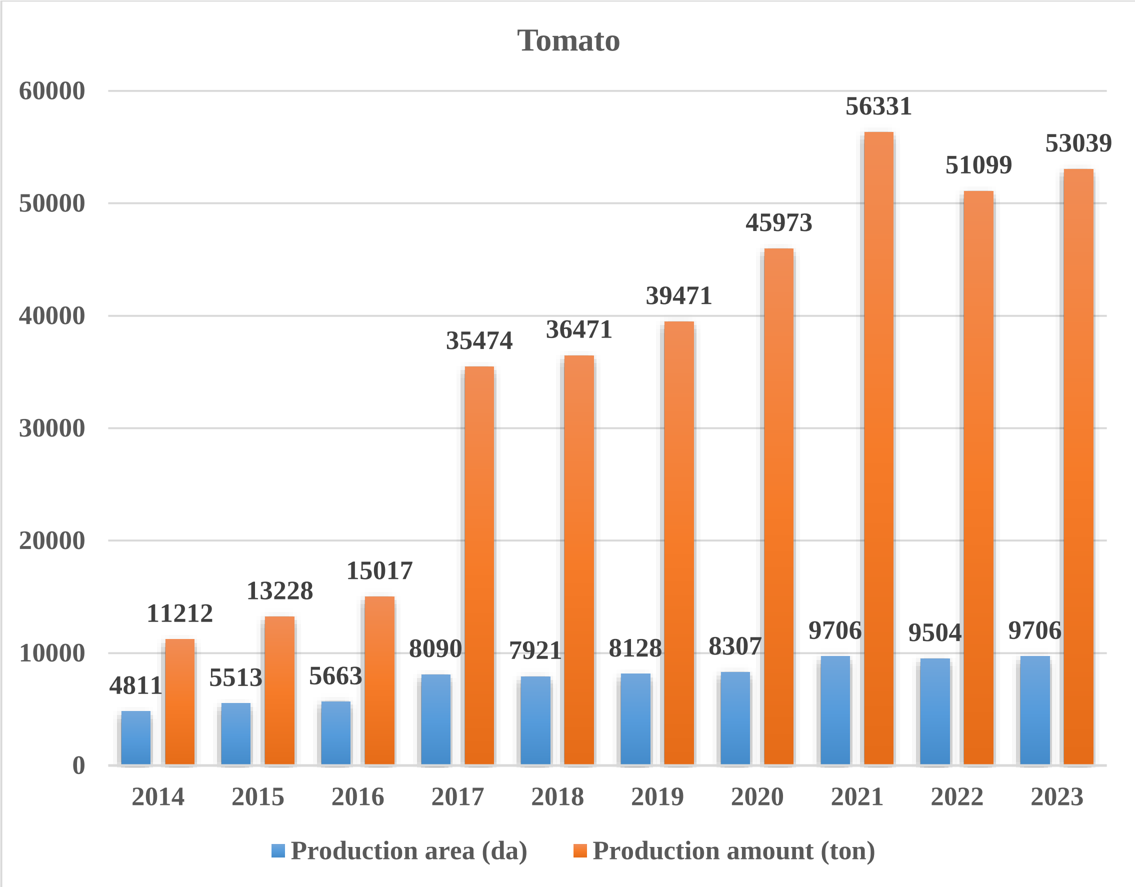

Figure 7. Tomato production area and production amount (TUİK 2023)

While the wheat production area was 811674 decares in 2014, it decreased to 645758 decares in 2023, and the barley production area increased from 70824 decares to 451834 decares in the same period (Figure 8).

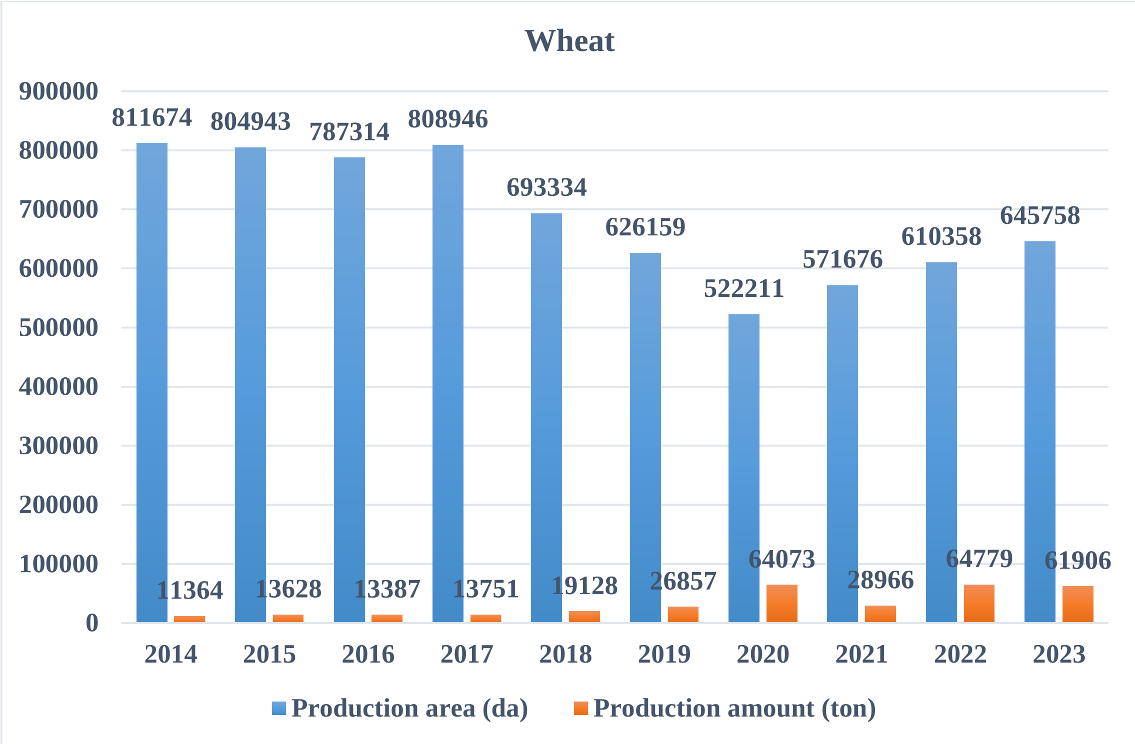

Figure 8. Wheat production area and production amount (TUİK 2023)

Barley production increased from 94779 tons in 2014 to 109203 tons in 2023. Wheat production increased in a similar way, reaching 61906 tons in 2023, while it was 11364 tons in 2014 (Figure 9). This large increase in barley production, in particular, shows that the agricultural value and demand of barley has increased (Kaya and Demir, 2021).

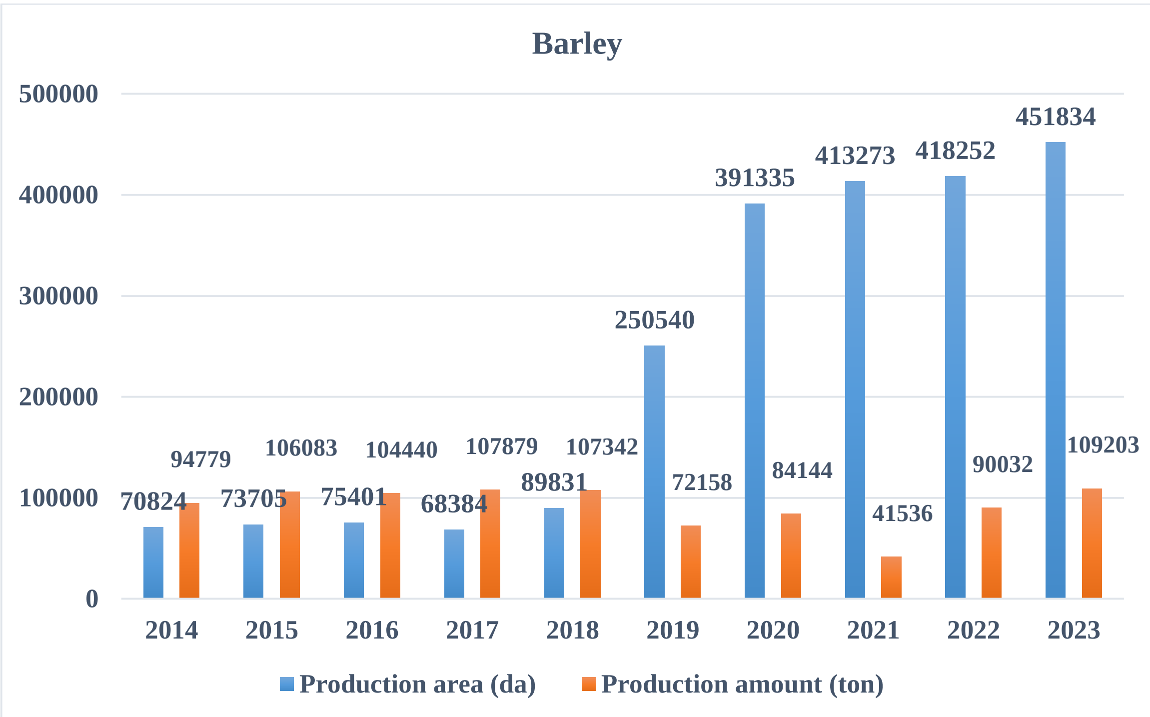

Figure 9. Barley production area and production amount (TUİK 2023)

Chickpea production area followed a fluctuating course, starting with 1620 decares in 2016 and decreasing to 1009 decares in 2023 (Figure 10). While chickpea production was 195 tons in 2016, it decreased to 130 tons in 2023.

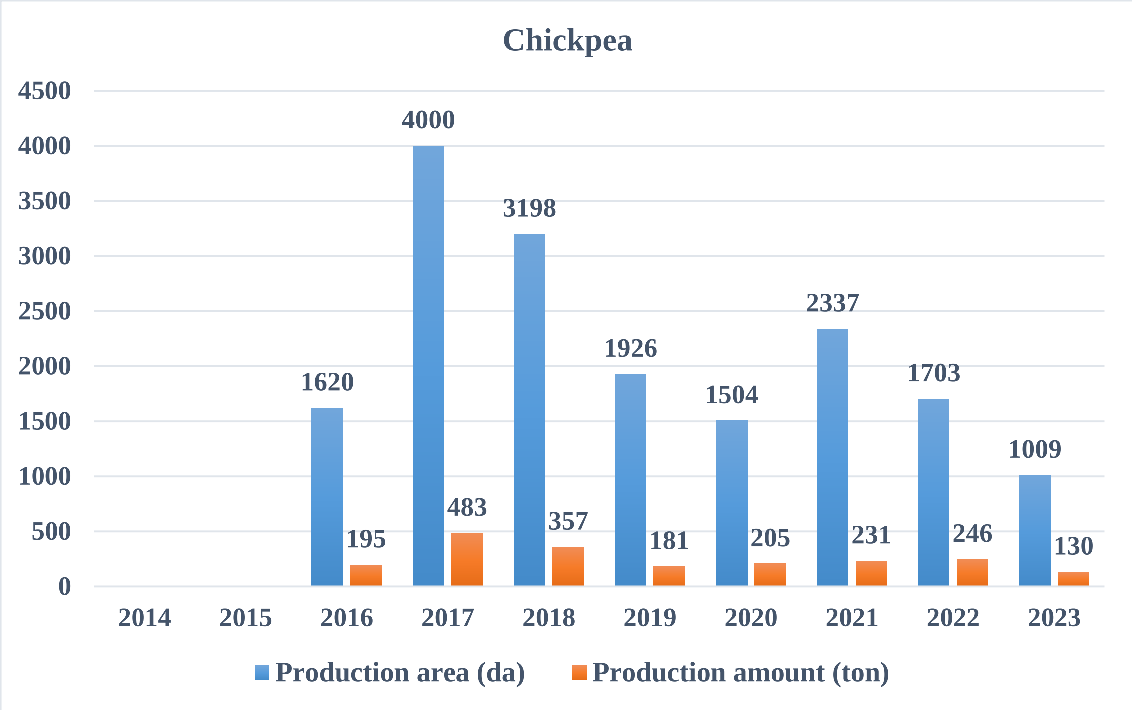

Figure 10. Chickpea production area and production amount (TUİK 2023)

While the potato production area was 1666 decares in 2014, it increased to 1692 decares in 2023. While potato production was 4006 tons in 2014, it increased to 5875 tons in 2023, and it generally shows an increasing trend (Figure 11).

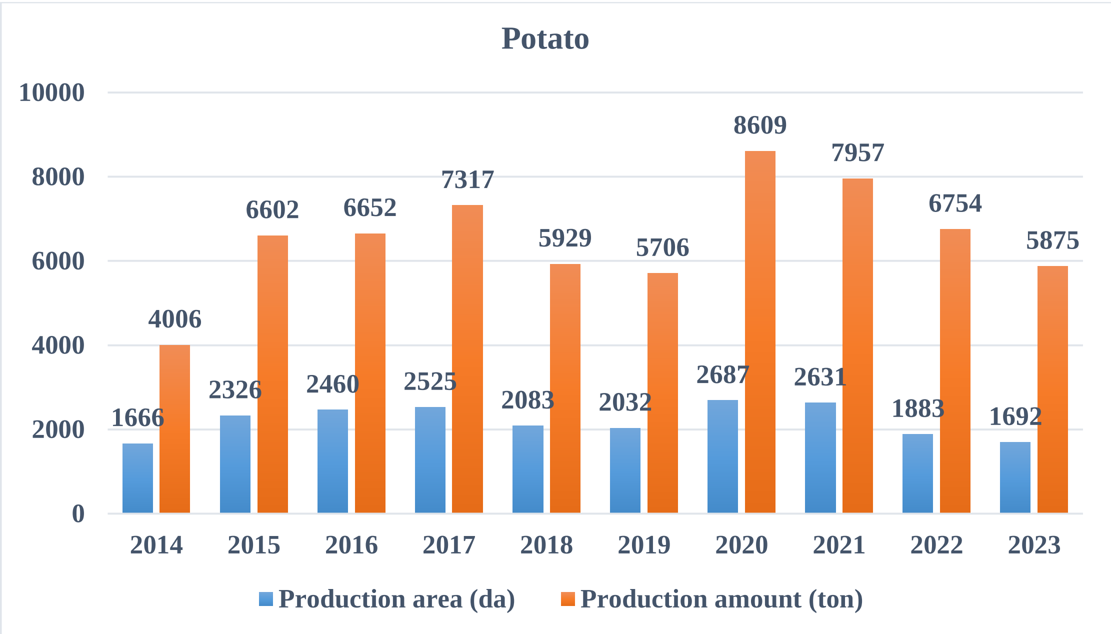

Figure 11. Potato production area and production amount (TUİK 2023)

However, the onion production area decreased from 773 decares in 2014 to 408 decares in 2023. While onion production was 641 tons in 2014, it decreased to 546 tons in 2023. The highest onion production was determined as 1082 tons in 2016 (Figure 12).

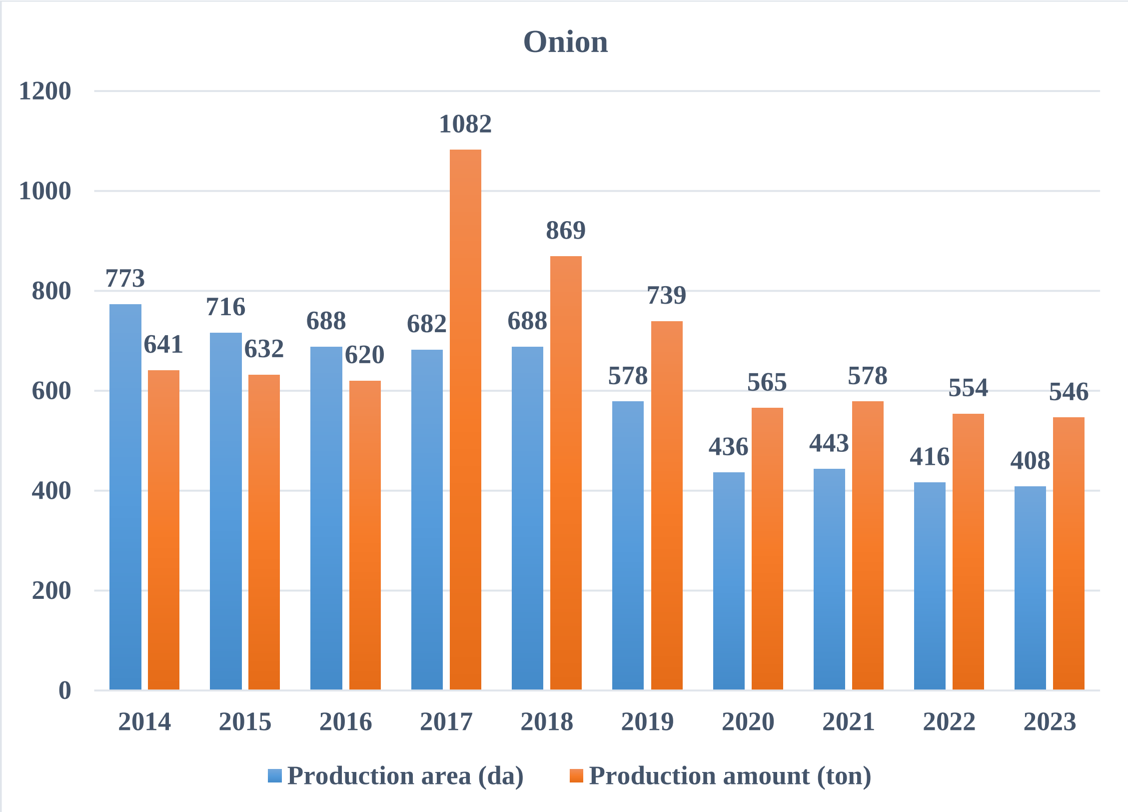

Figure 12. Onion production area and production amount (TUİK 2023)

The sugar beet production area, which was 6610 decares in 2014, increased and reached to 24666 decares in 2023. Sugar beet production, which was 35755 tons in 2014, increased to 114475 tons in 2023.The sainfoin production area, which was 200713 decares in 2014, increased to 309800 decares in 2023 (Figure 13).

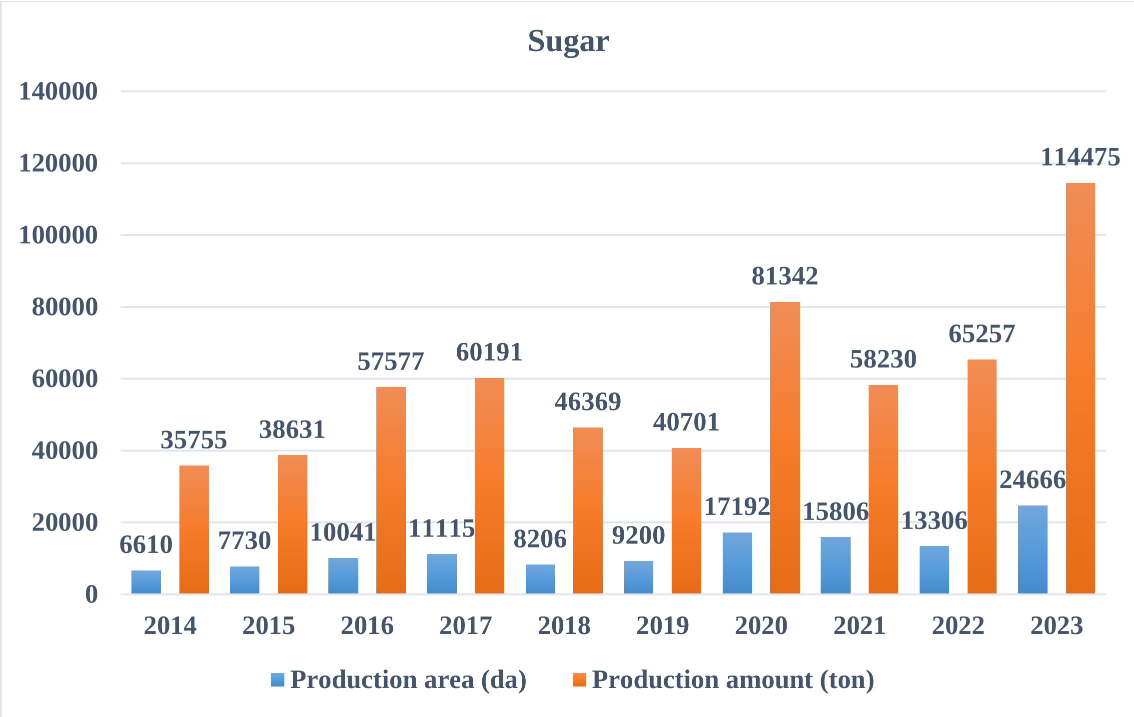

Figure 13. Sugar production area and production amount (TUİK 2023)

The sainfoin production area, which was 200713 decares in 2014, increased to 309800 decares in 2023. Sainfoin production increased from 107777 tons in 2014 to 363152 tons in 2023 (Figure 14).

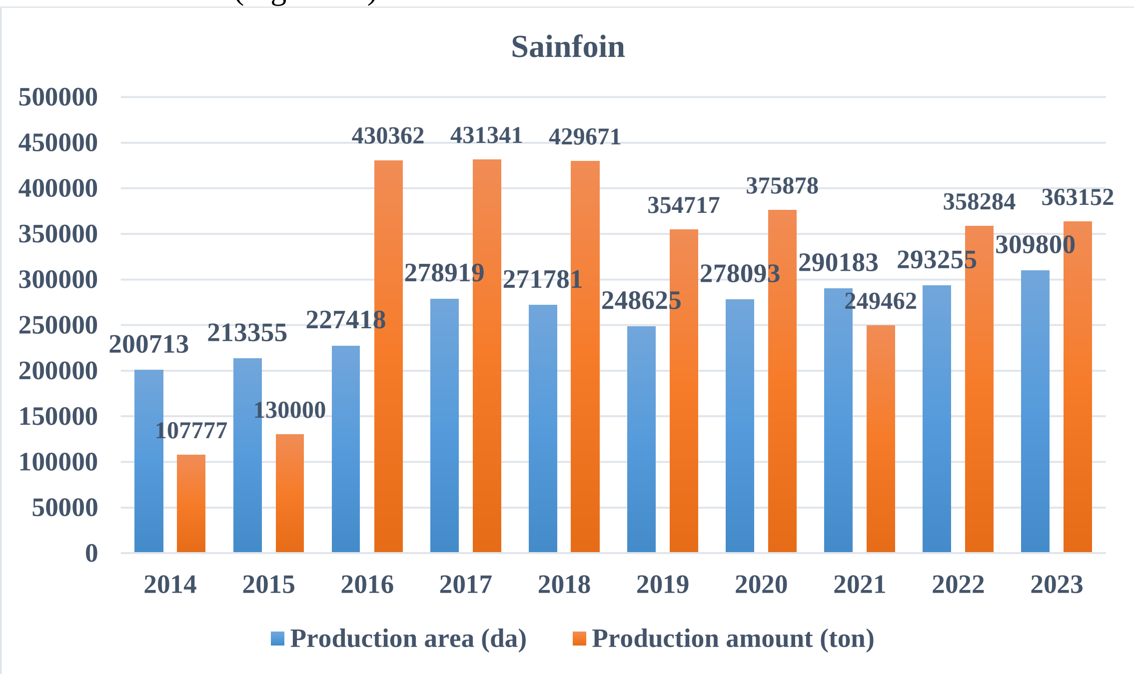

Figure 14. Sainfoin production area and production amount (TUİK 2023)

While alfalfa production was 642523 tons in 2014, it increased to 1020805 tons in 2023. In particular, alfalfa production, which reached its highest level with 2222010 tons in 2016, experienced fluctuations in the following years. While the alfalfa production area was 1048834 da in 2014, it decreased to 741549 da in 2023. The highest alfalfa production area was determined as 1042506 da in 2017. The increase in alfalfa production can be explained by the application of modern agricultural techniques and the effect of agricultural supports (Kaya and Demir, 2021). A decrease was determined in chickpea, onion and alfalfa production areas between 2014 and 2023. Although the walnut production area increased in the same time period, a decrease in the crop yield was determined (Figure 15).

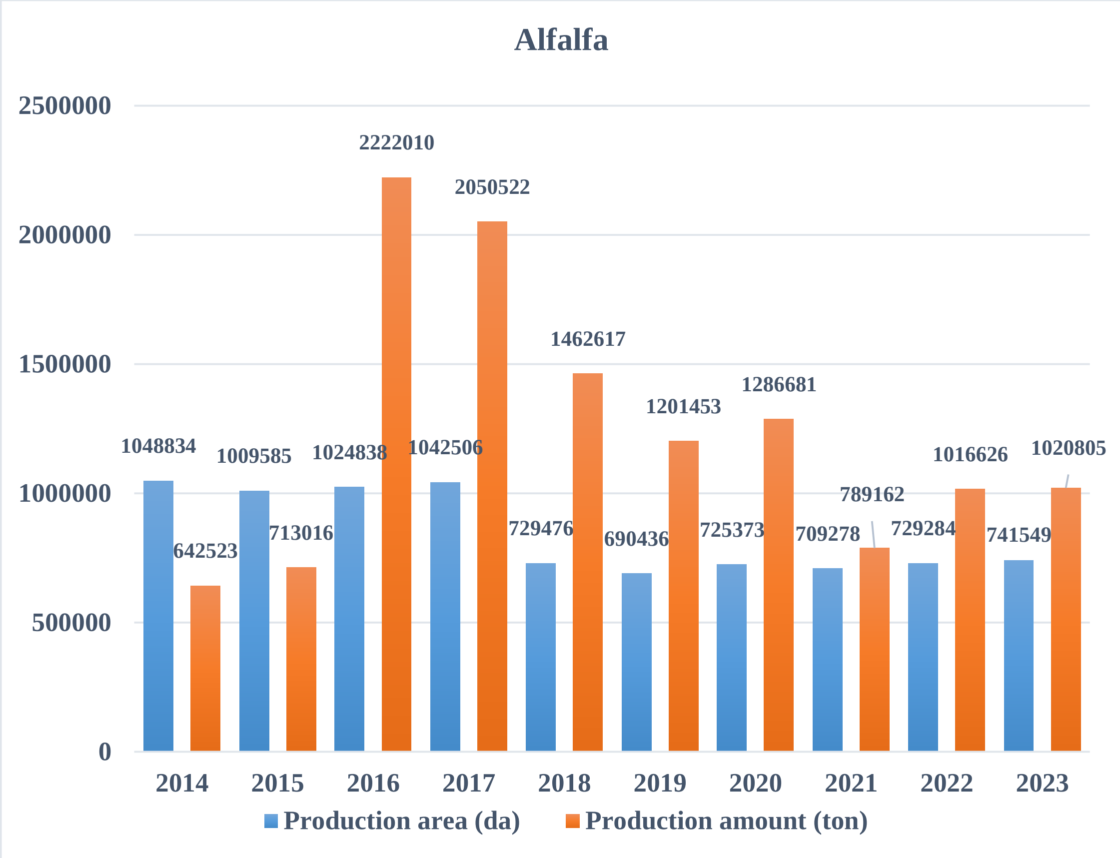

Figure 15. Alfaalfa production area and production amount (TUİK 2023)

Considering chemical fertilizer consumption, the consumption of urea, ammonium sulfate, calcium ammonium nitrate and ammonium nitrate fertilizers was 879 tons, 149 tons, 411 tons and 1243 tons, respectively, in 2014.In 2022, the consumption of these fertilizers increased and the consumption of urea, ammonium sulfate, calcium ammonium nitrate fertilizers was 1758 tons, 262 tons and 11050 tons, respectively. The consumption of diammonium phosphate fertilizer decreased from 1400 tons in 2014 to 728 tons in 2022 (Figure 16).

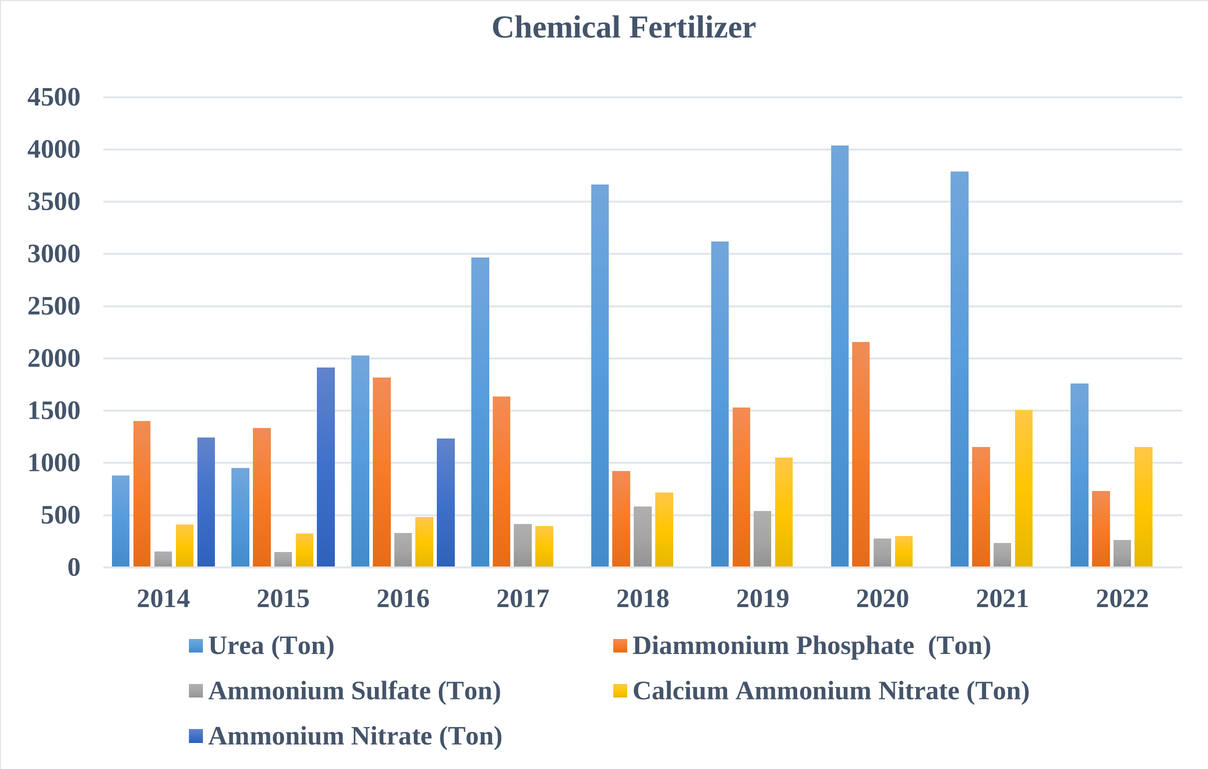

Figure 16. Amount of chemical fertilizer use between 2014-2022 (TUİK 2023)

CONCLUSIONS

In this study it was determined that crop yield belong various agricultural crops generally increased with inorganic fertilizer consumptions from 2014 to 2023 year in Van province. It has been reported that organic matter and nitrogen contents are in low level, available phosphorus level is in low or moderate level, available zinc content is in low level and lime level is high of Van Lake Basin soils by Gülser (1992).
Therefore, it can be concluded that increasing of inorganic nitrogen and phosphorus fertilizer consumptions have been effective on increasing crop yield. The fluctuations and decreases in some crop yields may be caused that differences of meteorological conditions among years.

Finez, et al. (2023) reported that excessive use of inorganic fertilizers, nutrient leaching, deterioration of physical properties of soil, accumulation of toxic chemicals in water bodies, etc. it has caused serious environmental problems and loss of biodiversity, as well as soil, air and water pollution.

Therefore, a balanced approach is needed that considers both the efficiency gains and potential environmental and health risks of using inorganic fertilizers in agricultural practices. As a result, it can be suggested that applying a fertilization program considering soil analyses results and combine applying with organic fertilizers supporting soil quality and health.

ABSTRACT

There are several studies on spiders and insects in Albania; however, only a few papers address their venom, toxicity and medical significance. This paper presents the first comprehensive data on ecology and distribution, including their morphology and habitat preferences, as well as the venom toxicity of medically significant insects and spiders found in Albania. The data presented here has been gathered from an extensive literature review and through citizen science, focusing on social networks, written and verbal media, and observations collected from the online platform iNaturalist. Spiders from the "widow" group (genera *Latrodectus* and *Steatoda*), are frequently mentioned for the severity of their bites due to the potent neurotoxin α-latrotoxin present in their venom. On the contrary, the medical significance of hymenopterans, mainly honeybees (*Apis mellifera*), is due to the anaphylactic reactions induced by their venom. This study presents the first attempt to map the distribution of venomous spiders and insects present in Albania, altogether with detailed information on the morphology, ecology, and venom toxicity.

Keywords: Balkans, arthropods, arachnids, Hymenoptera, venomous, anaphylactic

INTRODUCTION

The subphylum Arthropoda is a diverse group of invertebrate organisms, including arachnids, insects, myriapods, and crustaceans, and account for up to 85% of all known animal species. Their venoms possess great structural diversity, and comprise proteins, peptides, and small molecules (Daly and Wilson, 2018). Most venom compounds studied so far are found in insects, scorpions and spiders. For the latter, it has been predicted that over 10 million bioactive peptides (Saez et al., 2010) are produced by the 52,340 species described so far (World Spider Catalog, 2024). The envenomation causes local and systemic symptoms associated mainly with pain (Vrenozi, 2022). However the characterization of the novel spider venom compounds has revealed therapeutic and insecticidal potential. The spiders best known in Europe for their severe envenomation belong to the family Theridiidae Sundevall, 1833 (Arachnida: Araneae). This family includes 262 species in Europe and 2537 species worldwide. Within the Theridiidae, the "true widow" of the genus *Latrodectus* Walckenaer, 1805 comprises 35 species globally and 9 in Europe (Nentwig et al., 2024; World Spider Catalog, 2024). Members of the genus *Latrodectus* are known for their medical significance and severe envenoming have been reported from black widows, the brown widows, and the redback widows (Keyler et al., 2020; Vrenozi, 2022; Weinstein, 2024). The only *Latrodectus* documented in Albania is *L. tredecimguttatus* (Rossi, 1790) (Vrenozi, 2022). The venom of some false widow spiders (genus *Steatoda*) including *Steadoda grossa* (C. L. Koch, 1838), *S. nobilis* (Thorell, 1875), *S. paykulliana* (Walckenaer, 1806), and *S. triangulosa* (Walckenaer, 1802) has been shown to be toxic to mammals (Carvajal et al., 2023; Maretić et al., 1964; Paolino et al., 2021). At least *S. paykulliana* seems to have a stronger mechanical bite than the *Latrodectus* species (Dunbar et al., 2020b; Maretić et al., 1964). *Steatoda* species documented in Albania include *S. paykulliana*, *S. triangulosa*, and *S. grossa* (Vrenozi, 2012); however, *S. nobilis* is also expected to be present based on a suspicious bitten case and a record observation (Vrenozi pers. com.). The main toxin associated with the widows' envenoming syndrome is the α-latrotoxin, a neurotoxin 15 times more potent than rattlesnake (*Crotalus atrox* Baird and Girard, 1853) venom and far more potent than cobra and coral snake venom (Thill et al., 2022). In addition to the direct toxicity of their venom, studies have shown that *S. nobilis* and *Latrodectus* sp. carry pathogenic bacteria on their body surfaces and fangs, including multidrug-resistant strains that can cause severe bacterial infection, which may develop alongside venom-driven *Latrodectus*-like symptoms. This challenges the long-held belief that spider venoms and venom systems are sterile environments (Dunbar et al., 2020b). Other medically significant but less dangerous spiders in Albania include the yellow sac spiders (family Cheiracanthiidae) *Cheiracanthium punctorium* (Villers, 1789) and *C. mildei* L. Koch, 1864 (Nentwig et al., 2024). Necrosis has been documented following envenomings by the Mediterranean brown recluse *Loxosceles rufescens* (Dufour, 1820) (Vrenozi, 2022). Bites from recluse spiders can cause similar local symptoms as *Ch. punctorium* and *Ch. mildei*, resulting in chronic pain in adults, weakness, numbness, and atypical skin lesions (Vrenozi, 2022).

While the venom of a narrow range of spiders and scorpions is the most medically important, other arthropods produce toxic venom compounds, including ants, beetles, butterflies, caterpillars, honey bees, millipedes, and wasps (Schmidt, 2019). Insects use their venom for prey capture, defence against predators, facilitating parasitism or for digestion purposes. The venom of Hymenoptera (i.e., wasps, ants, and bees) has been extensively investigated due to their medical, agricultural, and ecological importance and high toxicity (Walker et al., 2018). Several species of Hymenoptera are present in Albania, including 32 bumblebees, eight paper wasps, seven hornets, three wasps, one honeybee and 79 fire ants (Mingomataj et al., 2003; Wagner et al., 2018). Typically, bumblebees are more docile than bees or vespid wasps, so stings are much less common. The three most common species of bumblebees in Albania are *Bombus pascuorum* (Scopoli, 1763), *Bombus lucorum* (Linnaeus, 1761), and *Bombus terrestris* (Linnaeus, 1758), which are less aggressive than other insects if their nest is disturbed. Following stinging events, their venom seems to produce less allergic reactions compared to honeybees, and appears to be highly cross-reactive to their venom. Moreover, it is shown that immunotherapy with honeybee venom can protect patients with bumblebee venom allergy (Bucher, Korner, and Wüthrich, 2001). *Apis mellifera* Linnaeus, 1758 (Apidae) is the only species of honeybee present in Albania, with several breeds and hybrids. *Apis mellifera* has three common subspecies occurring in Albania, where *A. mellifera carnica* Pollmann, 1879 are found in northern and eastern Albania (Ruttner, 1988), while *A. m. macedonica* Ruttner, 1988 is present in southeast Albania, and *A. m. cecropia* Kisenwetter, 1860 is found in southern Albania (Infantidis, 1979). Its venom has distinct effects on humans, inducing local symptoms such as pain, redness, and swelling, alongside systemic symptoms affecting the respiratory tract, cardiovascular, and gastrointestinal system, up to eliciting allergic reactions (Bilo and Bonifazi, 2009). Hornets (family Vespidae) are usually larger than most wasps and are known for their ability to deliver more painful stings; however, they also differ in nest type and aggressiveness (Mingomataj et al., 2003). The oriental hornet wasp, *Vespa orientalis* Linnaeus, 1761, is a social insect present in Albania with a public health concern due to their size and aggressiveness as they can inflict multiple, painful stings. Only females have stingers, and workers use these to defend themselves and the colony. This species has strong jaws, which are effective for digging and defence (Cetkovic, 2003). Paper wasps (family Vespidae), of which *Polistes dominula* (Krishti, 1791) is one of the most common and locally well-known species, are present in Albania and are known for building nests made of a paper-like material, which they produce by chewing plant fibres mixed with saliva (Bagriacik, 2012). Hymenopterans with less allergic reactions of their venom are the ants. Fire ants (Formicidae: *Solenopsis*) are known for their unique and painful stinging process, different from bees and wasps as they are capable of stinging multiple times without losing their stinger, causing a burning sensation rather than a typical protein-based sting, due to the alkaloids that is the main component of their venom. Their vernacular name finds its origins in the intense burning sensation that usually follows their stings (Greenberg, 2009). The sting from fire ants can cause unpleasant symptoms and may lead to allergic reactions. *Solenopsis fugax* Latreille, 1798, is a small Myrmicinae ant (1.2-1.5 mm) occurring in Albania.

METHODOLOGY

A systematic search was performed, screening the literature and information on the medically significant spiders and insects in Albania. Google Scholar (https://scholar.google.com/) is mainly used for the literature scanning; however, literature is scanned also from PubMed (https://pubmed.ncbi.nlm.nih.gov/). Several keywords were used to extract papers, some of which are: spiders of Albania, venomous spiders, black widow Albania, black widow bite, black widow envenoming, spider venom toxicity, arachnids and insect venom, araneae, hymenoptera of Albania, hymenoptera reaction, bumblebee sting, distribution of wasp, allergic reaction from honeybee, the venom of *V. orientalis*, morphological features of hornets etc. The observations in the citizen science website, iNaturalist (https://www.inaturalist.org), are scanned for the selected country of Albania using either the name of each species of spiders and insects, or their genus. Users record observations gathered as part of citizen science projects, school projects, or simply personal observations. Observations are uploaded to a publicly accessible "Community ID" system, and community users can suggest taxonomic identifications. However, not all the observations are considered, as we observed suspicious morphological features for the exact identification. Some iNaturalist data is also part of another website, GBIF, which provides information from the datasets of the scientific collections. GBIF which was scanned for the country of Albania using the keywords of the species names of the medically significant spiders and insects known so far in Albania. The verbal and written media including TV interviews from toxicologists and journals in Albanian language (a2news, Balkan web, Lajme.rtsh.al, Shqiptarja.com, Syri TV, ABC news Albania, RTV Klan), the social network of Facebook (https://www.facebook.com/), are checked for the observations in the Facebook home, public Facebook group "Electronic Register of Albanian Species [Regjistri Elektronik i Specieve Shqiptare]", using keywords in Albanian language in brackets, such as: spider [merimanga], black spider [merimanga e zezë], black widow [vejusha e zezë], venomous spider [merimanga helmuese], spiders bites [pickime të merimangave], insects [insekte], honeybee [bletë], wasp [grerëz], ants [milingona], etc. The Latin names of the medically significant spiders and insect species were also used as keywords to search for their records.

The information is extracted from a total of 96 papers, two spider websites (Nentwig et al., 2024; World Spider Catalog, 2024), from citizen science observations (iNaturalist, GBIF), mass media communication (written and verbal media), and from personal observation of the first author.

RESULTS and DISCUSSION

1. The information from the citizen science and mass media communication

The ability of citizens to access the latest information about the risks and management of spider and insect bites may contribute to prompt and responsible action, reducing the incidence of severe reactions and improving overall public health outcomes. Over the past two decades, the development of citizen science platforms has significantly increased public enthusiasm for observing and documenting species occurrence and interactions between organisms. This growing interest has led to the production of large amounts of biodiversity-related data at unprecedented temporal and spatial scales, rendering data of tremendous value to the scientific community (Bonney et al., 2014; Cox et al., 2015; Kittelberger et al., 2021). Recently, the scientific community has increasingly recognized the value of citizen-driven scientific data (Adler et al., 2020). The iNaturalist, established in 2008, is a global network that functions as an online social network and identification system for amateur naturalists based on peer assessment of species identification (Seltzer, 2019). By selecting a taxon in iNaturalist, users can view images, dates, and coordinates, with an accurate interactive distribution map for each taxon observation. The citizen science website iNaturalist is available for species data occurrence, where amateurs have added locality, date, photo, and species name information; while another website, GBIF - the Global Biodiversity Information Facility (https://www.gbif.org/), a noteworthy global repository of biodata with a vast network of users and entities, primarily describe museum collections that publish datasets such as natural history museums, institutions responsible for collections such as universities or research centres, and researchers from these institutions.

Mass media communication (newspapers, television, and social media) is an integral part of society and influences many aspects of human life. It is used to disseminate information for the vast majority of the public audience with a tendency to exaggerate findings, presenting them in sensationalist terms to simplify, and to avoid complex issues (Brechman et al., 2009; Nelkin, 1995). Social media provides citizen science data, documenting species occurrences of wild animals, and mainly Facebook (launched in 2004), the largest network in the world, stores many images altogether and overlapping information with other socials such as Instagram, LinkedIn and Twitter (Anderson et al., 2012; Lister, 2017). Facebook offers the possibility to create specialised groups or pages in which the administrators can help in identifying taxa photographed in the field (Chamberlain, 2018), giving only the name of the location but without geotagging of the posts. Valuable information from the verbal and written media about cases of spider and hymenopteran bites in Albania, rely on the data about their toxicity. However, the information conveyed is not always correct, and therefore further emulates the fear of these species. The media framing of severe envenoming cases (sometimes fatal) due to venomous spiders has alarmed habitants of the areas concerned, leading to strong emotional reactions when a spider is seen, whether it is medically significant or not (Mammola et al., 2020). Mass media communication has played a significant role in the dissemination of information on envenoming cases and the occurrence of venomous organisms in Albania. These data accomplish the citizen science information, where individuals, amateurs and specialists, provide important data on different species (Table 1).

2. Spiders envenoming in Albania

2.1 Morphology and identification criteria

Spiders often display a wide variety of habitats and different body colours. The false widow spider, *S. paykulliana* is often mistaken by amateurs in the social networks for the black widow spider, based on the similar round, shiny, uniformly black abdomen (Nentwig et al., 2024). Instead, the red pattern surrounding the dorsal black abdomen distinguishes *S. paykulliana* from adult females of the black widow spider. *L. tredecimguttatus* has morphological variations not only among various development phases from juveniles to adults, but also among the adults. The typical 13 orange or red patterns on their brownish to blackish abdomen are more consistent for juveniles and subadults (Levy and Amitai, 1983) (Fig. 1B), whereas adults of *L. tredecimguttatus* usually have only one antero-posterior red pattern close to the spinnerets at the end of the round shiny black abdomen (Vrenozi pers. com) (Fig. 1C), and in other cases can be completely black as observed in France (Dugon pers. com.), Israel (Shulov and Weissman, 1959), Iran (Shafaie et al., 2021). Contrarily, *S. paykulliana* has only a red transversal line crossing the antero-dorsal aspect of the black, round, shiny abdomen close to the cephalothorax (Fig. 1G). Other medically significant theridiid spiders of the genus *Steatoda* occurring in Albania have a highly variable body colour from yellow-white to brown with a dorsal pattern, to almost black with a faded dorsal pattern (*S. grossa*) (Fig. 1E), or females purple-brown with white stripes and males beige and white with dark purple folium pattern and four larger reddish impressed spots (*S. nobilis*) (Fig. 1F), to yellowish patterns that sometimes are broken into separate white spots on a brown to black abdomen (*S. triangulosa*) (Fig. 1H). The yellow sac spiders *Ch. punctorium* (Fig. 1A) and *Ch. mildei* have similar coloration with a pale yellow-green abdomen and a dark cardiac mark. In contrast, the Mediterranean brown recluse *L. rufescens* has a brown coloration (Nentwig et al., 2024) (Fig. 1D).

2.2 Spider bites, prevalence and activities associated with envenoming

The venom of Theridiid spiders has mostly evolved to paralyse or kill their arthropod prey, although toxicity toward vertebrates may have evolved as a defensive behaviour against predators and as response to accidental crushing (Rohou et al., 2007). Within this paradigm, widow spiders are not aggressive toward humans, and envenomings occur only when the spider feels threatened. Bites from *Latrodectus* sp. typically occur from females, since they are much larger than males (7-15 mm versus 4-7 mm). Additionally, males are not thought to have the ability to break human skin with their small chelicerae (Nentwig et al., 2024; Peterson, 2006). Considering the small size of widow spiders, only a minute amount of the injected venom, makes it rarely fatal to humans. Moreover, the black widow spider venom is known to kill small mammals in captivity. Thus, the lethal dose of the black widow spiders (*L. tredecimguttatus*) is calculated as 0.013 mg venom per mouse, translated to an overall LD50 of 0.9 mg/kg mouse, with estimation that venom of one spider has enough potency to kill 40 mice (Bettini and Maroli, 1978). During the envenomation, the average amount that the black widows injects to the target, depending on the pressure on spider's legs and body, is respectively between 0.0346 - 0.11 mg of the available venom in a single bite (*L. hesperus*) (Nelsen et al., 2014). Since venom effect tends to be dose-dependent, younger victims with relatively smaller body sizes are more at risk of facing severe symptoms. Recent reports on black widow spider envenomation in Albania have reported 125 patients from 2009 to 2018, where 7.2% of which had severe systemic symptoms (Vrenozi, 2022). The venom itself is physiologically expensive, and spiders are thought to use it carefully (Wigger et al., 2002). This may explain the variations in envenoming symptoms, and the frequent occurrence of "dry bites" during which no venom is injected at all. Some of the more common severe symptoms reported from widow bites may be explained by panic attacks and anxiety resulting from the fear of spiders (i.e, arachnophobia), a phobia that social media have contributed to, since they often provide a distorted perception of the spider bite risk (Mammola et al., 2020). Various documented cases of false widow spider bites of *S. nobilis* have revealed the severity of their venom in bitten patients, which is attributed to the presence of α-latrotoxin, a 'vertebrate-specific' neurotoxin (Dunbar et al., 2018; Dunbar et al., 2020a; Dunbar et al., 2022; Warrell et al., 1991). Another false widow spider, *S. triangulosa*, has been documented to feed on small vertebrates, first immobilizing and wrapping them in silk, then paralyzing them and causing their death, respectively, 10 and 20 minutes after the bite (Vitkauskaite et al., 2021). Therefore, *L. tredecimguttatus* and the false widow spiders are considered medically significant species and a growing threat to public health, especially for patients of small size (Vrenozi, 2022). However, we should distinguish the venom neurotoxicity from the post-bite bacterial infections found on the chelicerae of *S. nobilis*. The infection is most likely to be the result of spider-borne bacterial zoonosis rather than opportunistic infections by commensal skin bacteria. This can cause sepsis which in turn can, in very rare cases, leads to paralysis or amputation (Ahrens and Crocker, 2011; Dunbar et al., 2020b). In addition to neurotoxins, spider venom can have a cytotoxic effect, such as in the case of the brown recluse, *L. rufescens*, which causes necrosis in the bite area (Vrenozi, 2022). Necrosis can leave a post-bite mark, which would require plastic surgery as the ultimate hospitalization phase of an already serious case. Otherwise there is no need to hospitalize bitten patients. Cases of bites from *Ch. punctorium* and *Ch. mildei* are rare, do not require hospitalization, and occur during outdoor activities, since the spider is nocturnal and tends to reside far from inhabited areas. The bite results in an immediate burning sensation reaching maximum intensity after 5-20 minutes, with cutaneous effects of local redness, swelling, itching, numbness, and neurological effects such as insomnia. The local symptoms disappear within 2 hours in adults, except for paraesthesia at the bite site. In children, the pain may persist over 12 hours but complete recovery is expected after three to four days; there is no conclusive association of *Cheiracanthium* envenomings with necrosis (Papini, 2012).

2.3 Habitat preferences and distribution map of venomous spiders in Albania

The growing number of human cases highlights the importance of public awareness and the role of technology in using social media and sharing information to help people take necessary precautions, although spiders are usually mistaken for insects in the media. Moreover, based on misinformation and fear spread from mass media (Mammola et al., 2020), victims usually refer to all cases of insect stings and spider bites as being spider envenoming. Spider bites are a concern, especially during the summer, when temperatures are high. This is further enhanced by the recent increase in temperatures due to global climate change and resulting local heat waves (Vrenozi, 2022). There are eight species of spider with potential medical significance in Albania. However, only envenomings by the black widow *L. tredecimguttatus* might require hospitalisation in Albania. All other spider bites require observation of the bite site and the use of topical treatments (Vrenozi, 2022). In very rare cases hospitalisation might be required due to bacterial infections that might lead to sepsis (as reported for *S. nobilis*, (Dunbar et al., 2020b). During the summer period, various black widow spider bites have occurred and several individual were observed in different regions of Albania, mainly in Berat, Elbasan, Fier, Lushnjë, Rrogozhinë, Tepelenë (Balkan web, Facebook community, iNaturalist community, InFormim.al, Infoweb, lajme.rtsh.al, Lushnja.info, RTK 4+, Shqiptarja.com, Syri TV). Here are found the typical habitats of black widow spiders, such as cultivated farmlands with wheat, been and other crops, but also uncultivated lands as dry habitats or meadows, dunes, sandy beaches, forests with fallen trees, where *L. tredecimguttatus* build their webs on the bases of the lower vegetation under the leaves, stones or fallen trees (Bettini and Maroli, 1978; Vrenozi, 2022). The municipality of Divjaka is the main area in Albania where the black widow spider has the largest numbers of observations and spider bites reported from hospitalised cases (Vrenozi, 2022), and mass media and citizen science where two fatal cases are mentioned in the Bedat village (Facebook community, iNaturalist community, lajme.rtsh.al, Lushnja.info). The area has the most important agriculture in the region, where main products are potatoes, watermelons, and other vegetables that reach national and international markets, and also beans, maize, wheat and other crops for home consumption (Canali et al., 1998). However, there are other observations in the south-eastern villages of Vrinë and Leskovik in the municipalities of Konispol and Korcë respectively (Kůrka et al., 2020) (Table 1) (Figure 2A).

The *Steatoda* species are usually found on and inside buildings, on fences, cellars, caves, cracks in stone walls, and tree trunks (Dugon et al., 2017; Kovács and Szinetár, 2018). Two suspected bitten cases are observed in the suburban areas in the Tirana district (Fresk and Kombinat), with a typical wound of *S. nobilis* with necrosis and infection that in one case had required surgical intervention (Vrenozi pers. com). In addition one field observation of a female individual is posted on Facebook in the rocky area of the village Kaninë in Vlorë municipality. Whereas *S. paykulliana* is rarely encountered in orchards and meadows, and prefers arid and semi-arid habitats, such as dry grasslands, rock crevices, limestones, and stony hills (Nentwig et al., 2024; Vrenozi, 2022). This spider is often mistaken for a black widow due to the black round abdomen in the iNaturalist community and mass media. The distribution area is wider and includes habitats from northern (Dibër and Pukë) to southern Albania (Sarandë). It is based mainly in faunistic papers (Caporiacco, 1932, 1949; Deltshev et al., 2011; Kůrka et al., 2020; Strand, 1919; van Helsdingen and IJland, 2015; Vrenozi, 2012; Vrenozi and Dunlop, 2013; Vrenozi and Haxhiu, 2008; Vrenozi and Jäger, 2013), in iNaturalist community, GBIF.org, and unpublished data of the first author. Recent years (2021, 2023), the false widow spiders of *S. grossa* have been observed in the municipality of Durrës in Albania (GBIF.org), but there are no reported cases of hospitalized patients in Albania. The less significant spider of the false widows, *S. triangulosa*, has a wider distribution inhabiting mainly urban localities, on the walls, stony habitats or lower vegetation (Durrës, Fier, Gjirokastër, Përmet, Sarandë, Vlorë) as observed in iNaturalist community, GBIF.org and several papers (Deltshev et al., 2011; iNaturalist; Naumova, 2020; van Helsdingen and IJland, 2015; Vrenozi, 2012; Vrenozi and Haxhiu, 2008) (Table 1) (Figure 2A).

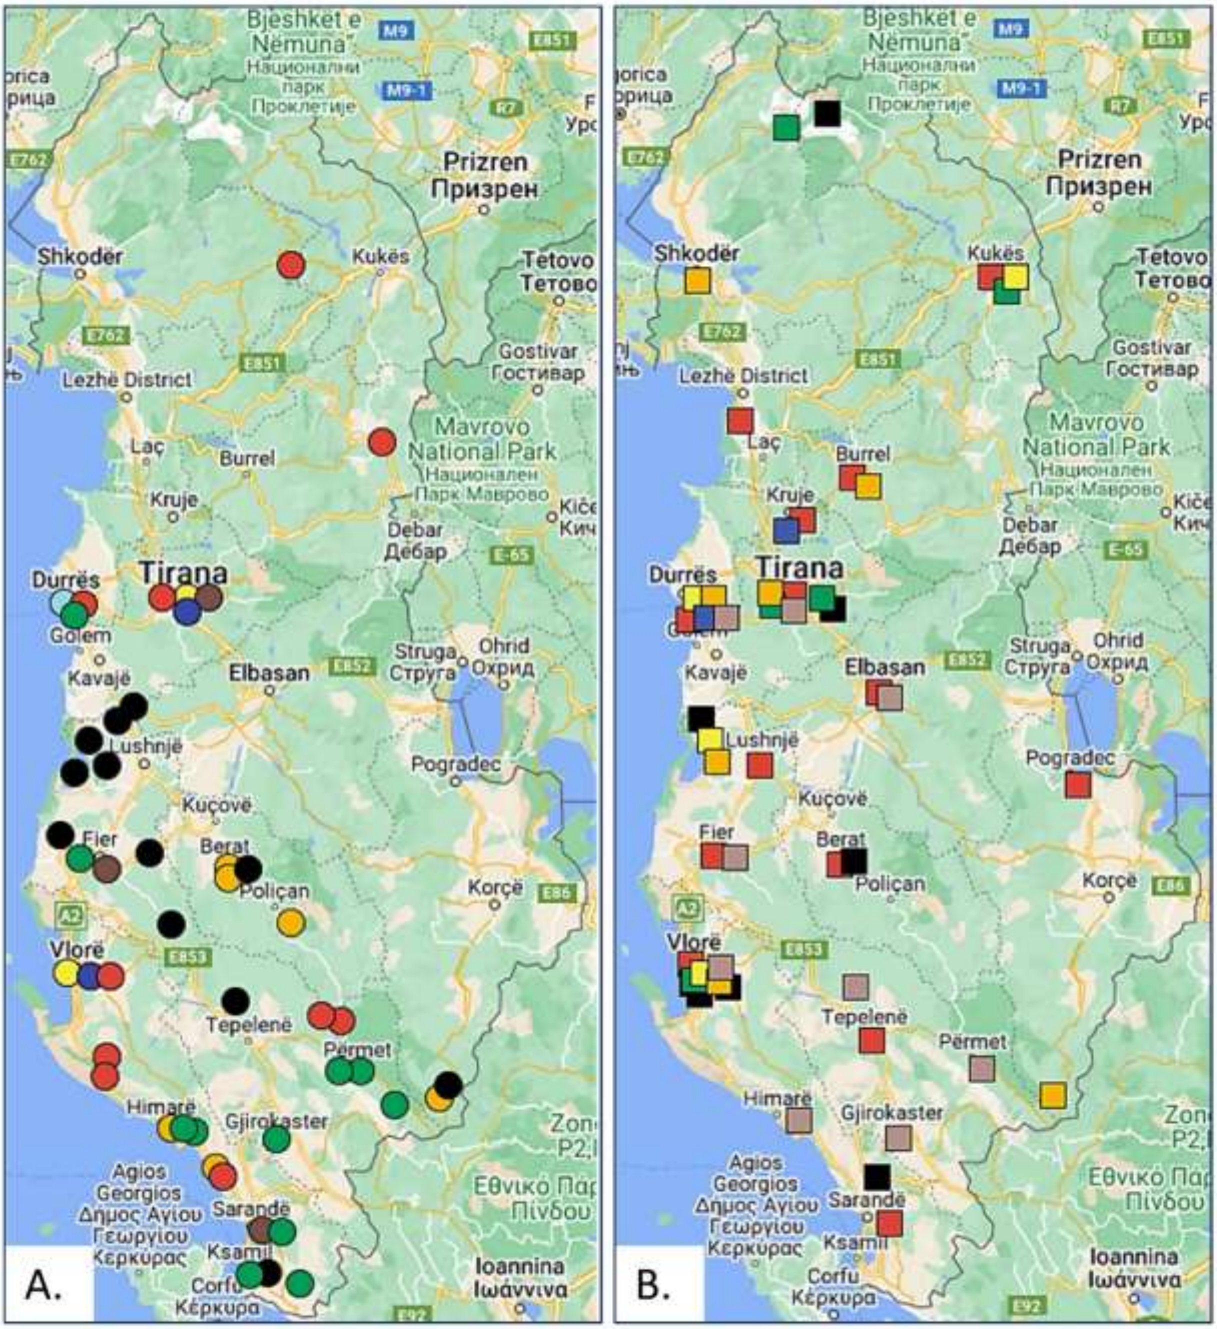

Figure 2. Distribution maps (google.com/maps): **A**— Venomous spiders (circles): *Cheiracanthium punctorium* (yellow), *Ch. Mildei* (orange), *Latrodectus tredecimguttatus* (black), *Loxosceles rufescens* (brown), *Steatoda grossa* (light blue), *S. nobilis* (dark blue), *S. paykulliana* (red), *S. triangulosa* (green). **B**—Venomous insects (quadrates): *Apis mellifera* (red), *Bombus lucorum* (black), *B. pascuorum* (green), *B. terrestris* (yellow), *Polistes dominula* (orange), *Solenopsis fugax* (blue), *Vespa orientalis* (brown)

The brown Mediterranean spider is found in a variety of natural habitats such as dry, under stones, rock crevices, but is widely distributed as a house spider as it is found in and around houses and buildings, making this species easy to transport in vehicles in other countries. This makes *L. rufescens* bites occurring frequently indoors while dressing up and sleeping (Gertsch and Ennik, 1983; Vrenozi, 2022). In Albania, there is reported the necrosis wound of the post bitten cases within the apartment in municipality of Fier, and two observations within a toilette in the city of Tiranë and under stones in Sarandë (Naumova and Deltshev, 2021; Vrenozi, 2022). In contrast, *Ch. punctorium* and *Ch. mildei* inhabit shrubs and trees in warm, open habitats. Consequently, sac spider bite cases are rare, typically occurring during outdoor activities (Hörweg, 2023). Considering that the species can be mistaken with other similar species of the same genus, findings in Albania are based mainly on the faunistic papers (Deltshev et al., 2011; Kůrka et al., 2020; van Helsdingen and IJland, 2015; Vrenozi, 2012; Vrenozi and Haxhiu, 2008), and on one confirmed observation on GBIF.org and the B. Vrenozi pers.com (Table 1) (Figure 2A).

3. Hymenopterans envenoming in Albania

3.1 Morphology and identification criteria

Hymenoptera is a large order of insects and they can be distinguished from other insects by the presence of the waist between the thorax and abdomen, antennae, wings, mouthparts, metamorphosis, sting and social structure, used as identification criteria (Schmidt and Smith, 2006). The common bumblebee, *B. pascuorum* has a yellow or reddish-brown thorax, while the hairs of the first four abdominal segments are grey and the hairs of the fifth and sixth segments are yellow or reddish-brown (Lecocq et al., 2015) (Fig. 3C). The most common large European ground-dwelling bumblebee, *B. terrestris*, is a Mediterranean species known as the owl-tailed bumblebee. Workers of *B. terrestris* have white-bottomed abdomens and darker yellow bands (Fig. 3D) compared to those of *B. lucorum*, that are characterised by a lemon-yellow collar behind the head, a bright yellow band in the middle of the body, and a pure white tail (Bertsch et al., 2004). There exists breeding data for ten subspecies of honey bees *Apis mellifer*a (Fig. 3A) in Albania, as well as hybrid races of several breeds known as Buckfast bees (Kuliçi et al., 2023). Three subspecies are native in Albania, *A. m. carnica*, *A. m. macedonica*, and *A. m. cecropia*: *A. m. carnica*, has a generally dark body colour with a grey tinge, ventral stripes characterized by a lighter grey or brown, short hair that is usually grey compared to other species, and a very high elbow joint; *A. m. macedonica* usually has a dark body with light grey or brown abdominal stripes, short abdomen, and long legs; *A. m. cecropia* has a golden brown coloration, slightly darker than the other honeybees (Gregori and Starman, 2003). *Vespa orientalis* has a reddish-brown colour with thick yellow stripes on the abdomen and characteristic yellow spots between the eyes (Cetkovic, 2003) (Fig. 3G). *P. dominula* differs from other wasp species due to its specific body length, wing dimensions, and distinctive black and yellow coloration. Adult paper wasps have a black and yellow body, several triangular eye-like spots on the dorsal aspect of the thorax and yellow antennae. *P. dominula* possesses a yellow postocular stripe, often narrowed, and the female's mandible is black, sometimes with yellow spots (Tibbetts et al., 2011) (Fig. 3E). The small Myrmicinae ant, *S. fugax*, is a native species in Europe known for its reddish-brown color and their ability to sting in an aggressive behaviour (Fig. 3F).

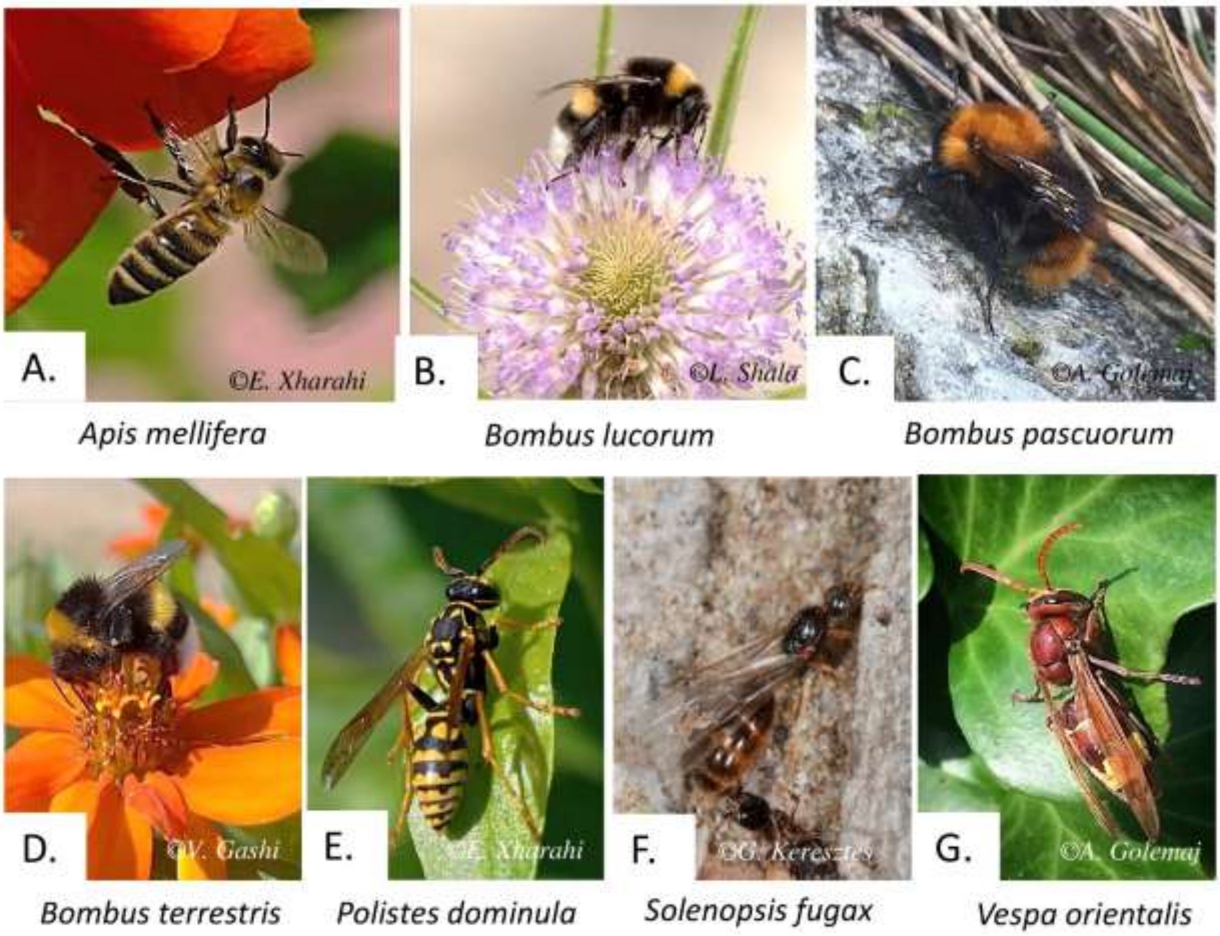

Figure 3. Venomous insects: **A**– *Apis mellifera*, **B**– *Bombus lucorum*, **C**– *B. pascuorum*, **D**– *B. terrestris*, **E**– *Polistes dominula*, **F**– *Solenopsis fugax*, **G**– *Vespa orientalis*

3.2 Hymenopterans stings, prevalence and activities associated with envenoming

Hymenopteran venom is usually stored in reservoirs within the insect's body and can be injected into the victim through an actual sting. Hymenopterans toxins consist of various chemicals or complex combinations of bioactive compounds, including small molecules, polyamines, and peptide toxins that interact with cell membrane receptors to provoke allergic reactions (Mingomataj et al., 2003). Hymenoptera venom allergy is an epidemiologically underestimated condition causing morbidity worldwide. Severe anaphylactic shocks following the stings from honeybees (*A. mellifera*) and wasps can lead to cerebral or myocardial ischemia due to the presence of numerous protein allergens, most of which have enzymatic activities, such as phospholipase A2, hyaluronidase, acid phosphatase and non-enzymatic proteins including melittin, which can trigger strong allergic reactions in sensitive individuals (Burzyńska and Piasecka-Kwiatkowska, 2021; Golden, 2007). We can mention several honeybee reactions such as the appearance of erythema, pruritus, urticaria, and angioedema on the skin; myocardial depression, hypotension, and shock in the cardiovascular system; edema of the larynx and bronchospasm in the respiratory tract; and in the gastrointestinal system the predominant symptoms are nausea, vomiting, and fecal incontinence (Bilo and Bonifazi, 2009). The European honeybee, *A. mellifera*, is the most common species of bee involved in stings and envenomation. Twelve allergens have been identified from its venom so far. *A. mellifera* die after stinging as the barbed stinger with parts of their abdomen remains in the target. This is in sharp contrast with wasps, hornets, and ants, all of which can potentially inflict repeated stings without dying (Fitzgerald and Flood, 2006). Both honeybees and wasps produce one common allergen with hyaluronidase activity that helps spread venom by destroying hyaluronic acid within the skin. Species also possess unique phospholipase-based venom allergens that play a crucial role in breaking down cell membranes and increasing the spread and effect of the venom. Fire ants and vespids possess at least one allergen in common, antigen 5, with unknown biological activity (King and Spangfort, 2000). The venom of *B. pascuorum* have a direct and immediate effect on physiological processes, causing paralysis and instant pain, owing to the presence of different allergenic elements within the venom profile (Casewell et al., 2013). Unlike honeybees, bumblebees can sting multiple times without attachment of the sting apparatus to the skin. The protein content per bumblebee sting is 10–31 μg depending on the species compared with 59 μg per honey bee sting. Allergic reactions to bumble bee stings are much less common than allergic reactions to honeybee stings, and their venom appears to be chemically and antigenically related (Hoffman and Jacobson, 1996). As bumblebees are not aggressive, the risk of being stung is very low in the general population. The worldwide use of domesticated bumblebees as crop pollinators has led to an increasing prevalence of bumblebee venom allergy, especially in greenhouse workers and bumblebee farm employees (Bucher et al., 2001). The stings of female *B. lucorum* can cause localized pain, swelling, and redness due to the mild neurotoxins present in their venom. Symptoms usually are transient, but serious complications such as anaphylaxis, angioedema and toxic reactions could arise without proper treatment. In humans, the bite may result in pain, swelling, and sometimes allergic reactions, but not life-threatening (Bucher et al., 2001). The venom of *V. orientalis* primarily poses a health risk to humans in the form of allergic reactions due to the antihistamine-releasing activity of Mastoparan O, which can contribute to allergic reactions. Usually, stings result in severe pain, local irritation, and urticarial papules (Nakajima et al., 1985). In some cases, individuals may experience more severe symptoms, such as extensive swelling, difficulty breathing, a drop in blood pressure, and anaphylaxis, especially in those who are allergic to wasp stings. Effective treatment can include the administration of antihistamines, pain relievers, and, in severe cases, epinephrine to counteract anaphylactic reactions (Mukund and Gawade, 2011). *P. dominula* and *Vespula* spp. are closely related to allergy-eliciting Hymenoptera species. Stings by the paper wasp *P. dominula* often result in allergic reactions and appears to be potentially cross-reactive, due to their venom allergens composed of homologous proteins present in other wasp venoms too (Grosch et al., 2020; 2021). Fire ants are known for their distinctive and painful stinging process that can cause a burning sensation, swelling, redness and itching. A burning sensation can last a few minutes and the itching can last up to a week. The skin eruption can be completely healed in 2 weeks. They can have a slow venom injection, and the onset of pain from a fire ant sting generally is delayed (Romita et al., 2018). This delay can sometimes prevent an immediate reaction to the sting, potentially allowing the ant to deliver multiple stings. The clinical effects caused by ant stings are associated with clinical manifestations ranging from localized reactions such as pain, papules, vesicles, pustules, and ulcers to systemic reactions with blurred vision, dizziness, vomiting, diarrhea, and anaphylaxis. *S. fugax* has powerful mandibles and retractable sting, which delivers irritant alkaloid venom. Envenoming of human beings by *S. fugax* have reported the most common local symptoms that include severe itching of papular-purpuric eruptions at the location of the stings (Romita et al., 2018; Stingeni et al., 2002). Its venom can cause significant local or systemic reactions, up to fatal cases in humans due to multisystem toxicity in case of multiple stings (Korman et al., 1990), although their sting is mild due to their small size (Graham et al., 2004).

Based on the documented cases in Albania, related to the hospitalized patients from 1987 to 1996, approximately 111 human cases were reported in Albania from patients who were diagnosed with reactions to Hymenoptera sting venom (Mingomataj et al., 2003), and 37 patients with a mean age of 28 years received stings from Hymenoptera, respectively: 59.5% from honeybees, 5.4% from paper wasps and 35.1% from bumblebees (Mingomataj et al., 2002).

3.3 Habitat preferences and distribution map of venomous hymenopterans in Albania

The reported medically significant insect cases in citizen science are not for their bites, but mainly from observation in nature (iNaturalist community, GBIF.org, Facebook community), and partly published in faunistic papers (Cetkovic 2003; Dedej et al., 1996; Mingomataj et al. 2002, 2003) and mass media communication (a2news). Hymenopterans are found in a wide variety of habitats all over Albania. Bumble bees are adapted to a diversity of climates and habitats, and are active even when light intensity is low. They are able to continue foraging even at temperatures as low as 10°C and as high as 32°C, because of their relatively large body sizes and dense pile. Bumblebees (Apidae) are known for their robust body and distinctive, loud buzzing sound when flying; they are larger, hairier, and present more colour variations compared to bees (Apidae) (Bucher et al., 2001). The bumblebee, *B. pascuorum*, is commonly found in the northern Albanian Alps (Shkodër and Kukës), in a wide range of habitats including pastures, meadows, in urban areas, wasteland, near waterways and in forests (Tiranë and Vlorë) (Plowright et al., 1997) (Fig. 2B). This is the closest relative of honeybees and differs among them as they have unique characteristics, such as adaptation to colder climates allowing them to live at higher latitudes and altitudes even when light intensity is low. This ability is attributed to their unique thermoregulatory properties, allowing them to tolerate various climatic conditions while being active even in winter (Pradervand et al., 2011). *B. terrestris* is known for its wide distribution, large colony production, and adaptability to artificial conditions (Velthuis and Van Doorn, 2006). The optimum temperature of *B. terrestris* is 32°C. As they prefer warm climates, they are present in the western areas of Albania (Durrës, Lushnje and Vlorë) and are a native species in the littoral districts of Durrës, Kavaja, and Vlorë (Rasmont et al., 2008). However, they can be active at temperatures below 10°C, in contrast with honeybees that are typically inactive when environmental temperature drops below 16°C (Dafni et al., 2010). *B. lucorum* (Fig. 2B), is more commonly found in the northern (border with Kosovo), and southern (Vlorë) areas of Albania (Goulson et al., 2008; Rasmont et al., 2008). It is widespread in temperate areas consisting of flowering herbaceous meadows, gardens, open forests and urban areas, where they forage for nectar and pollen (Tiranë, Berat, Lushnje Shkodër and Sarandë). Their nests can be very large containing up to 400 workers and are built underground, often in the abandoned nests of old mice (Rasmont et al., 2015). The honeybee, *A. mellifera*, has a wide distribution in various areas in the northern Albania (Kukës and Krujë), also in the western and south part of Albania (Durrës, Tiranë, Fier and Pogradec). The most common honeybee in Albania, *A. m. macedonica*, has morphological features that shows adaptations to the climatic conditions of the Balkan Peninsula from Eastern Albania to Bulgaria, allowing for a better tolerance of a range of temperatures (hot summers and cold winter) and different habitats such as mountains, valleys and areas with abundant wildflowers (Ruttner, 1988). Oriental hornets are large predatory hymenoptera that are colonized in new territories as a result of global warming, the globalized movement of people and goods. These remain as main factors that are facilitating the expansion of historical distribution of *V. orientalis*. The activity patterns of *V. orientalis* are different from the other hornets as these species are the only one able to use solar radiation to produce energy. Their cuticular pigments are able to absorb solar energy in the cuticle (Zucca et al., 2024). They are distributed in different parts of Albania, with more reported observation from iNaturalist in the south part areas as in Përmet, Tepelenë and Gjirokastër. The European social paper wasp *P. dominula,* is a present in the western areas of Albania in Durrës, Lushnje, Tiranë and Vlorë, inhabiting soft, terrestrial habitats such as forest and grassland biomes. These wasps can colonize nearby domestic environments due to abundant resources such as food and nesting materials (Weiner et al., 2012). The fire ant, *S. fugax, appears* to have a wide geographic range, spanning different regions where they prefer warm, dry, open areas with sparse vegetation, building their nests on the ground in rock crevices or under stones (Rigato and Toni, 2011). In Albania they have been reported from iNaturalist only in Krujë and Durrës. This species usually lives in the soil where it can infest crops and occurs in domestic environments due to the soil of indoor plants (Table 1) (Fig. 2B).

CONCLUSIONS

In Albania, some spiders and insects have been known to cause local or systemic symptoms in human victims following envenoming. However, only one spider can cause complications up to fatal cases, such as bites due to the neurotoxins of the venom of the black widow spider *L. tredecimguttatus*. In other species, severe cases may be associated with allergic reactions especially in relation to Hymenopterans. The main contributor to these serious allergic reactions may be the honeybee *A. mellifera*. Considering the importance of their bites and stings in Albania and further afield in the Balkans, and growing misconceptions about envenomings related by social and information media, we suggest that further research be carried to promote awareness and develop remediation plans.

ACKNOWLEDGEMENTS

We acknowledge the authors of the photos of spiders and insects for permitting to use them in this manuscript. The English language is improved using the academic program of Grammarly https://www.grammarly.com. We are thankful to Dr. Michel Dugon, National University of Galway, Ireland, for his valuable comments increasing the quality of this manuscript. National Agency for Scientific Research and Innovation (NASRI), Ministry of Education and Sport, Tirana, Albania, provided financial support for the project "*Venomous spiders of Albania: the black widow Latrodectus tredecimguttatus, distribution map and the importance of her venom in bitten case studies"*, on behalf of the National Program for Research and Development 2023 - 2024.

CONFLICT OF INTEREST STATEMENT.

The authors declare no conflict of interest.

ABSTRACT

Cotyledons are the first photosynthetic organs of plants and play an important role in seedling growth. However, various biotic and abiotic factors can damage cotyledonary leaves shortly after seedling emergence. In this study conducted to determine the effect of cotyledon damage on seedling development in cotton plants, one (50% damage) and two (100% damage) of the cotyledons were removed from 15-day-old seedlings of cotton grown under laboratory conditions. No cotyledonary leaf damage was applied to the control group. Three weeks after the application, shoot length, stem diameter, leaf number, root length, shoot fresh and dry weight, and root fresh and dry weight were measured. The results showed that seedlings with a single cotyledon had higher shoot length by 0.9 cm, root fresh and dry weight by 22 mg plant^{-1} and 67 mg plant^{-1}, respectively. Compared to control plants, root length decreased by 1 cm, stem diameter by 0.3 mm and shoot fresh and dry weight by 260 mg plant^{-1} and 100 mg plant^{-1}, respectively. There was a significant decrease in other characteristics except leaf number in seedlings with both cotyledons removed. It was concluded that the cotton plants could tolerate moderately damaged cotyledon leaves, but development was significantly retarded in plants without cotyledons.

Keywords: *Gossypium hirsutum* L., cotyledon leaf damage, seedling growth

INTRODUCTION

Cotton (*Gossypium hirsutum* L.) is one of the most important industrial plants that provides raw materials for many industrial sectors, such as textile, oil, and feed. Its high adaptability to different environmental conditions allows cotton to grow even in regions with arid and semi-arid climates with irrigation (Ödemiş et al., 2018). Approximately 777 thousand tons of fiber were obtained from 2.1 million tons of seed produced on an area of 470 thousand hectares. Also, 170 thousand tons of cooking oil and 793 thousand tons of oil cake were produced in 2023. Globally, Türkiye ranks sixth in cotton cultivation area, ninth in cotton output volume, third in cotton consumption, and fourth in cotton imports (Anonymous, 2024; TUİK, 2024).

Cotton plants can be damaged by biotic and abiotic factors throughout plant development, especially in the early seedling stage. While herbivorous pests cause physical damage the leaves, stem, flowers and fruits of cotton, abiotic factors such as drought, high temperatures and excessive rainfall cause deterioration in leaf tissue. Damage or loss of cotyledonary leaves significantly impacts plant development and yield (Green and Minton, 1980). Because cotyledons contain both the nutrients needed by the plant in the first development stage and contribute to nutrient accumulation by photosynthesis from the moment, they first emerge from the soil surface. In this way, root, shoot, and leaf growth continue depending on cotyledon leaves (Bisognin et al., 2005).

Damage to cotyledon leaves negatively affects seedling development. It was determined in several studies conducted on 17 plant species by Hanley and May (2006), Iortsuun et al. (2008), Moscardi et al. (2012), Hu et al. (2016) and Chen et al. (2023) that cotyledon loss negatively affects plant height, stem diameter, seedling fresh and dry weight. The aim of this study was to investigate the impact of damage level on cotyledon leaves on seedling development in cotton plants.

MATERIAL AND METHOD

This research was conducted in 2022 at the Seed Science and Technology Laboratory, Department of Field Crops, Faculty of Agriculture, Eskişehir Osmangazi University. The BA 1010 cotton variety from ProGen Seed was used as a plant material. The seeds were sowed in the pots with 9 cm diameter and 14 cm height, containing a mixture of field soil: perlite: vermiculite (6:1:1) to a depth of 3 cm. The pots were kept in a plant growth chamber set at 25℃/15℃ (16/8 hours day/night). In addition, all pots were watered with 10 mL of tap water every day until the research was completed, and 0.5 g of ammonium nitrate fertilizer dissolved in water was given to each pot three times.

On the 15th day of the study (when the first true leaf is just beginning to appear), 3 groups were designed with 4 pots in each group to create cotyledon leaf damage in emerging plants (Figure 1).

Group 1 (Control- 0% damage): Cotyledon leaves were left on the plant,

Group 2 (50% damage): One of the cotyledon leaves was removed from the plant,

Group 3 (100% damage): Both cotyledon leaves were removed from the plant.

On the 40th day after planting, the plants were harvested and shoot length, root length, stem diameter and leaf number, shoot fresh and root fresh weight values were measured. After the seedlings were kept at 80℃ for 24 hours, shoot dry and root dry weight values were weight.

Figure 1. Different cotyledonary leaf damages in cotton plants.

At the end of the research, One-Way ANOVA was performed in accordance with the completely randomized design (CRD) and the differences between the means were determined with the LSD ($p < 0.05$) test using the MSTAT-C (Michigan State University,

v. 2.10) program.

RESULTS AND DISCUSSION

The results showed that cotyledonary leaf damage significantly affected seedling growth of cotton. The variance analysis results of shoot and root length, stem diameter, and leaf number are given in Table 1.

Table 1. Variance analysis of the traits examined in cotton with cotyledon damage

Source of variation	DF	Mean squares			
		Shoot length	Root length	Stem diameter	Leaf number
Leaf damage	2	6.528**	10.901**	0.211**	0.250
Error	9	0.099	0.706	0.012	0.167
Total	11				

**: Significant at $p < 0.01$.

Shoot length, root length, stem diameter, and leaf number in cotton were significantly influenced by different cotyledon damages, and significant differences were detected at $p < 0.01$ (Table 1). The mean values and differences of these examined traits are summarized in Table 2.

Table 2. Changes in shoot and root length, stem diameter and leaf number of cotton seedling under cotyledon damage.

	Shoot length (cm)	Root length (cm)	Stem diameter (mm)	Leaf number (number)
Control	6.50^{b}	15.2^{a}	2.21^{a}†	3.3
50% damage	7.43^{a}	14.2^{a}	1.93^{b}	3.0
100% damage	4.90^{c}	12.0^{b}	1.76^{b}	2.8

†: Different letters indicate significance levels at $p < 0.05$.

Damage to cotyledons significantly affected both shoot and root growth in cotton. Especially, the removal of both cotyledonary leaves significantly reduced the shoot and root lengths of seedlings (Table 2). Cotyledons are the first photosynthetic organs of the plant, which are necessary for the initial growth stage and dry matter accumulation in plants. Many studies have suggested that even if cotyledons are damaged due to different biotic or abiotic sources, the remaining cotyledons can still support seed germination and contain sufficient nutrients to support early growth of seedlings (Xiao et al., 2013; Chen et al., 2023). In addition, shoot and root growth are thought to have different developmental responses in cotyledon damage. Bisognin et al. (2005) reported that shoot growth in cucumber seedlings was less dependent on cotyledon leaves than root growth. Since root growth occurs using nutrients produced by cotyledons, it was determined that plants with completely removed cotyledons (1.76 cm) had shorter roots than the control (2.21 cm) (Table 2). Similar results were obtained in the number of leaves and stem diameter as well as the decrease in plant height. Chen et al. (2023) also found that the leaf growth and stem diameter of *Quercus acutissima* decreased significantly in cases of cotyledon damage.

Table 3. Variance analysis of the traits examined in cotton with cotyledon damage

Source of variation	DF	Mean squares			
		Shoot fresh weight	Root fresh weight	Shoot dry weight	Root dry weight
Leaf damage	2	1.737**	0.191**	65815**	12482**
Error	9	0.004	0.005	222	105
Total	11				

**: Significant at $p < 0.01$.

The variance analysis results for shoot and root fresh weight and shoot and root dry weight are given in Table 3. All the traits examined were found to be statistically significant at $p < 0.01$. The mean values and significance levels of these traits are given in Table 4.

Table 4. Changes in shoot and root fresh weight and shoot and root dry weight of cotton seedling under cotyledon damage.

	Shoot fresh weight (g plant^{-1})	Root fresh weight (g plant^{-1})	Shoot dry weight (mg plant^{-1})	Root dry weight (mg plant^{-1})
Control	2.12^{a}	0.90^{a}	363^{a}	136^{b}†
50% damage	1.86^{b}	0.92^{a}	263^{b}	203^{a}
100% damage	0.87^{c}	0.53^{b}	108^{c}	92^{c}

†: Different letters indicate significance levels at $p < 0.05$.

The fresh and dry weights of shoot and root were significantly depressed by cotyledon damages. The highest shoot fresh weight (2.12 g plant^{-1}) was determined in control plants, while the lowest shoots (0.87 g plant^{-1}) were obtained from plants treated with 100% cotyledon damage (Table 4). Similar results were determined in root fresh weight. The results of Kaya and Bayramin (2013) support our findings, who found a significant reduction in plant fresh weight of sunflower.

Since cotyledons are both seed storage organs and photosynthetic organs, they are of great importance in meeting the energy and nutrient needs of young seedlings. Therefore, cotyledon damage that may occur at the early seedling stage negatively affects plant growth and development (Wallace and Eigenbrode, 2002; Kitajima, 2003). Damage to all or part of the cotyledons means that a large part of the storage reserves is also damaged, especially for seedlings that have not reached sufficient photosynthetic area to compensate for this damage (Kennedy et al., 2004; Hanley and Fegan, 2007). In this study, a 27% decrease in shoot fresh weight occurred in the case of removal of a single cotyledon, this rate was 70% in plants where both cotyledons were removed. The lowest dry weight (92 mg plant^{-1}) was determined in cotton plants damaged by 100% cotyledonary leaf removal (Table 4).

CONCLUSION

Cotyledonary leaf damage may have hazardous effects on seedling growth and later stages of plant development. In this study, the effects of different levels of cotyledon damage on early seedling development in cotton were investigated. It was concluded that cotyledon damage had a negative effect on seedling growth of cotton. Seedlings with one cotyledon removed showed significant reductions in other traits except shoot length and root fresh and dry weight. Root growth was more sensitive to cotyledon damage than shoot growth. When both cotyledons were removed, all the seedling growth parameters were lower than the control. As a result, there would be a significant delay in seedling development and that the plants could tolerate 50% cotyledon damage if all cotyledons were damaged.

ABSTRACT

Plant genetic resources (PGR) play an important role in maintaining global food security, conserving biodiversity and promoting sustainable agriculture. International cooperation between genebanks has become crucial in ensuring the conservation and sustainable use of PGR. The paper aims to evaluate the role of the European collaboration for development of local PGR collection of Bulgaria, based on the long-standing mission of conserving, evaluating and using plant diversity. By sharing experiences, best practices and standardization of the genebank activities the collaboration in ECPGR aims to increase the use of national collections in line with the EU Biodiversity Strategy for 2030. In the area of digitalization, the partnership aims to improve the quality of data management in accordance with the FAO/Bioversity descriptors and to make it free accessible according to the Nagoya Protocol. The results include development of optimized databases supporting equitable sharing of benefits from the use of genetic resources under the International Treaty on PGR for Food and Agriculture. European collaboration contributes to environmental and traditional food protection through valorization of indigenous PGR and their reintroduction to farms in line with the national conservation strategies.

Keywords: Plant diversity, Landrace, Collection, Data base, European collaboration.

INTRODUCTION

Plant genetic resources (PGR) play an important role in maintaining global food security, conserving biodiversity and promoting sustainable agriculture (Halewood et al., 2018). International cooperation between genebanks has become crucial in ensuring the PGR documentation and sustainable use of their biological potential (Tienhaara et al., 2019; Kotni et al., 2023; Shaw et al., 2023). By sharing experiences, best practices and standardization of the genebank activities the EU collaboration aims to increase the use of national collections in connection with the PGR Strategy for Europe (ECPGR, 2021). The program for digitalization of plant biodiversity in the European partnership is focused on improvement the quality of data management system following the FAO standards and to make it free accessible according to the Nagoya Protocol (CDB, 2011) and International Treaty on PGR (ITPGRFA, 2009).

Plant biodiversity is preserved through a global system of national and international genebanks. *Ex situ* storage and collection management requires systematic documentation of passport data, characterization and evaluation information for PGR accessions (Mendel et al., 2019). Maintaining interoperability in the European area is an important prerequisite for the implementation of cooperation between genebanks. Artificial Intelligence have great potential to support the improvement of the processes for access, exchange and use of stored PGR (Doukovska, 2021). In this context, 21st century genebanks are required to provide complete information about germplasm collections to their users – researchers, crop breeders, other stakeholders (Treuren and Hintum, 2014; Weise, 2021).

Open access platforms such as EURISCO (Weise et al., 2017), AEGIS (2022), GENESYS (2015), WIEWS (FAO, 2020) provide centralized international databases with the possibility of searching accessions conserved in genebank collections by standard criteria based on taxonomy, botanical and agronomic characteristics of plant species. The portals have electronic references to the collections in the national genebanks, but still this system has a high level of complexity and requires specific knowledge from the PGR users. In accordance with the principle of "Open Science", it is necessary to take more and more effective actions to make the genebanks information accessible for society, that will increase the valorization of research work, as well as the opportunities to use the potential of the conserved plant gene pool.

The research work aims to evaluate the role of European collaboration for digitalization of Bulgarian genebank collection, based on the long-term mission of conservation, evaluation and use of local PGR in connection with EU Biodiversity Strategy for 2030.

MATERIAL AND METHOD

The Information Center for plant genetic resources at IPGR-Sadovo has been established in 1982 and completely renovated in the period 2021-2023. It works according to the international standard of FAO/Bioversity (2017).

The National Genebank of Bulgaria, situated at IPGR-Sadovo, was built with the financial support from FAO in 1984 and carries out a scientific program for the long-term preservation of germplasm through seeds under controlled conditions.

Annually, expeditions in different geographical regions of the country are conducted by different national and international projects and valuable local varieties and crop wild relatives are collected (Velcheva and Uzundzhalieva, 2022).

The National Genebank is nominated as a focal point in the European Search Catalogue for Plant Genetic Resources – EURISCO (*http://eurisco.ecpgr.org*). EURISCO is an open access network, providing information about *ex situ* plant collections in Europe. Central Crop Databases are *on line* available in the ECPGR cooperation system. Through EURISCO the information about the Bulgarian National Inventory is transferred and accessible in other international databases, such as A European Genebank Integrated System – AEGIS, FAO WIEWS and Electronic Platform for Plant Genetic Resources for Food and Agriculture, Conserved in Genebanks Worldwide – GENESYS (Velcheva et al., 2017).

RESULTS AND DISCUSSION

The program of Department of Plant Genetic Resources in IPGR-Sadovo is responsible for conservation of PGR and representing Bulgaria at international cooperation in ECPGR. The research activity includes:

(1) enrichment of the *ex situ* collections with new germplasm;
(2) documentation by FAO/Bioversity standard;
(3) study, evaluation and characterization by ECPGR descriptors by crop groups;
(4) storage under long-term conditions;
(5) maintenance, propagation and free exchange of PGR;

(6) conservation of crop wild relatives in lively *in vivo* collections;
(7) *in situ/on farm* conservation of wild, semi-wild, local varieties and populations;
(8) sustainable use of PGR.

Information activities are essential part from genebank management system and they are historically presented in the Table 1.

Table 1. Information and documentation activities in Bulgarian Genebank

Before 1982	• field books • no computerization – data management on paper
1982-2000	• Info & Doc center – data management on paper and database • Accession data managed in isolated files • Passport data; C&E data under UPOV descriptor lists
Since 2000	• Phyto 2000 DB in MS Access file format – passport data • C&E data in MS Excel file format under UPOV, IBPGR, ECPGR descriptor lists
2021-2023	• Bulgarian Genebank Documentation System – collaboration between IPGR-Sadovo with Plovdiv University, Department of Computer Science and Institute of Information and Communication Technologies of Bulgarian Academy of Science
2024-2026	• DIGIVALPGR Project – collaboration between Bulgarian and Slovakian genebanks

Data management system Phyto 2000

IPGR-Sadovo has an electronic register PHYTO 2000 in Microsoft access 2003 format (Figure 1). It contains all the information about the seed accessions kept in the genebank. Each accession has a unique number and passport characterization to be clear enough where the accession is – in base collection (long-term) in exchange collection (medium term), work collection, *in vitro*, *in vivo* collections. The data management system is outdated, unsecure and difficult to maintain so it had needed a full reengineering. In the context of the conservation of plant genetic resources, secure and well-structured documentation of the material is essential (Weise et al., 2020).

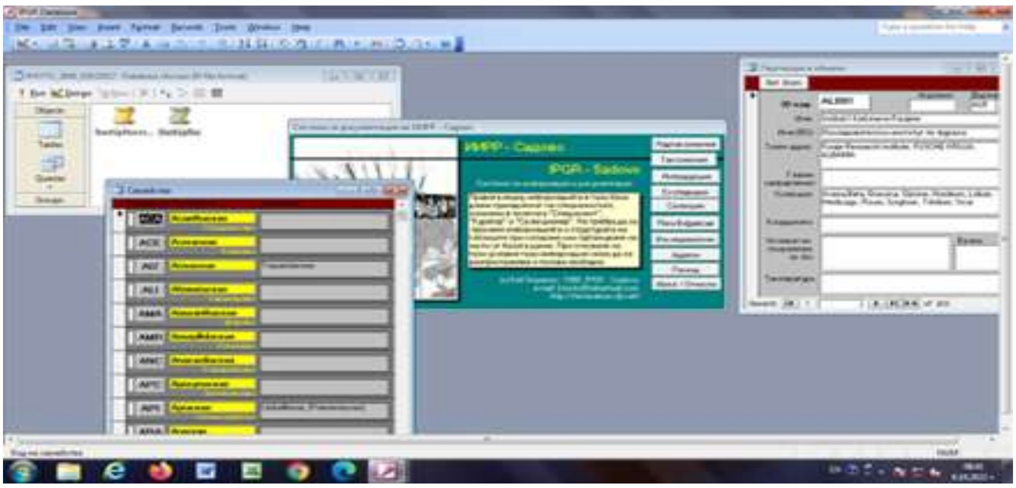

Figure 1. Electronic register PHYTO 2000 of Bulgarian genebank

Bulgarian Genebank Documentation System

In 2023 intelligent documentation system with specialized software, functional ontologies for free access to PGR for all stakeholders and assured security of records through blockchain technologies is established (*https://genbank.uni-plovdiv.net/login*). Starting with the use of field books, a gradual development of electronic data base as national register, nowadays the intelligent data management system aims to improve the availability of conserved seed accessions in genebank to users. The information system was created using Java program in Vaadin Platform. Database is MySQL. The structure of the ontology and metadata are exhibited along with each of the concepts and properties in order to present knowledge about plant genetic resources using the capabilities and benefits of ontologies. The ontology was developed on the basis of the taxonomy for plant genetic resources and the European standard EURISCO. The use of blockchain technologies provides the necessary level of security, completeness and reliability in the input and use of information related to the Bulgarian Genebank. The main tasks in the environment development are the digitalization of the Bulgarian Genebank and the creation of a web portal providing information and services to different groups of users.

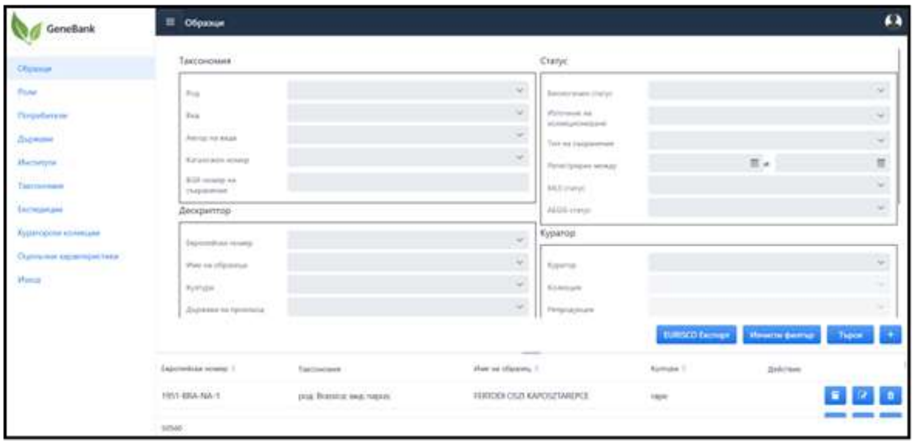

Figure 2. Genebank Bulgaria Documentation System

The Genebank Documentation System present basic information on PGR – accession number, genus, species, name of accession, as well as information about holding institute code, country of origin, status of accessions, source of the material, date of collection, type of storage, whether the genotype has safety duplication in another genebank, etc. Passport descriptors also contain information about wild material received from collection missions such as the collector‘s institute name, collection number, collection name, geographic data and description of the collection site.

Open access of local PGR diversity

As well an electronic platform with free access for local plant gene pool has been created, which includes accessions from traditional crops, used by local communities collected through expeditions (*https://plantsdigcatalog.agriacad.bg/*).

European collaboration on PGR digitalization

The passport data of the Bulgarian genebank is transferred to the global system for plant genetic resources in Europe – EURISCO.

According to EURISCO, data check September 2024, there are 66,399 preserved seed accessions in IPGR-Sadovo from 70,834 totally registered plant germplasm in Bulgaria (*http://eurisco.ecpgr.org*), where 18,846 accessions are with local origin (Table 2).

Table 2. Bulgarian National Inventory in EURISCO

INSTCODE	Holding institute name	Number of accessions	Accessions of Bulgarian origin
BGR001	Institute for Plant Genetic Resources, Sadovo	66,399	16,998
BGR005	Institute of Rose and Essential-oil Plants, Kazanlak	563	4
BGR007	Institute of Maize, Knega	13	13
BGR015	Institute of Forage Crops, Pleven	2	2
BGR029	Dobrudja Agricultural Institute, General Toshevo	3,857	1,829
	Total	70,834	18,846

By signing in 2009 the Memorandum of understanding for the establishment of a European Genebank Integrated System - AEGIS, IPGR-Sadovo participates in the establishment of "virtual" EU genebank with free access collection of unique local germplasm accessions (*http://aegis.cgiar.org*). The status of the Bulgarian AEGIS collection amounts to 391 landraces, including 326 accessions *Triticum sp.*, 15 acc. *Secale sp.*, 9 acc. *Lathyrus sp.* and 41 acc. medicinal plants.

During the last 20 years, there have been significant efforts to intensify cooperation between genebanks in order to sustainable conservation of plant biodiversity. Information networks have been established and they have been an important basis for the development of international systems such as GENESYS and FAO WIEWS, which serve as central entry points for the search for plant genetic resources.

In order to meet the requirements of the innovative research landscape, which is characterized by constant digitalization and big data, the information systems of the genebanks have to be able to make their data free available. The free access to plant biodiversity leads to Open science to new knowledge about plant genetic resources, which ultimately improves their usability and the reputation of the genebanks.

The free access of Bulgarian National Inventory data is following the program for digitalization and smart agriculture in Bulgaria. Nevertheless, Bulgaria is quite behind from other EU members in regards to introduction of digital technologies in the economy and society taking one of the last places in EU in terms of Integral Index for Introduction of Digital Technologies in the Economy and Society (Bachev, 2020).

CONCLUSIONS

In this research, an overview of the used documentation systems and EU cooperation of Bulgarian Genebank was given.

Databases supporting public access and equitable sharing of benefits from the conservation of plant gene pool under the International Treaty on PGR for Food and Agriculture and Nagoya Protocol were established.

At international level, EU plays an active role, contributing to ensure the achievement of the global appointments for biodiversity and PGR conservation.

The main goal of the EU programs is to improve the coordination in conservation activities in Europe and to facilitate the access to PGR and the information about them.

Digitalization of plant genetic resources assist the transfer, use, and dissemination of research results for sustainable agriculture.

ACKNOWLEDGMENTS

This research work was carried out with the support of Bulgarian National Science Fund under the project DIGIVALPGR “Digitalization and valorization of local plant genetic resources in Bulgaria and Slovakia in the framework of maintaining compatibility and interoperability in the European area”, Contract number KP-06-Slovakia/9/13.08.2024.

ABSTRACT

The value of biodiversity for food security and dietary balance has been underlined as priority by FAO and Bioversity International. The study aims to evaluate the underutilized local Plant Genetic Resources (PGR) in Bulgaria and to extensively document the traditional food and seed systems in which PGR are used in order to promote their use for the benefit of farmers and consumers. The two basic concepts related to this general objective are: (1) to retrieve the embedded knowledge of local communities, in order to enhance awareness on PGR values; and (2) to support a chain-perspective approach in PGR study and management, aimed at development of *on farm* conservation. The results include harmonizing concepts of PGR international treaties; enrichment of current PGR collections; enhancing the documentation of the databases; prompting the urban consumers' awareness on the value of PGR for nutrition, biodiversity and sustainable agriculture. Main outcome is the creation of thematic networks and knowledge base aimed at promoting the durable use of local PGR and *on farm* conservation.

Keywords: Genebank, Accession, Expedition, *On farm* conservation, Climate change.

INTRODUCTION

The modernization of agriculture and the spread of intensive cultivars led to processes that replaced the rich diversity of traditional varieties. Farmers are motivated to grow high-yielding cultivars to maximize their income. At the same time, in a competitive market environment, breeding companies produce seeds only of those varieties and crops that they trust will generate profits for them and promote their new cultivars with a rich arsenal of marketing techniques. However, the fact is that climate change is changing the environmental conditions and more and more farmers are looking for sustainable yields and a bigger assortment of varieties and crops to guarantee income even in less favorable conditions (Reidsma et al., 2010; Villanueva et al., 2017; Borrell et al., 2019). Therefore, it is very necessary to protect biodiversity – landraces that has evolved in local agricultural systems (Shelef et al., 2017).

The value of biodiversity for sustainable agriculture, food security and dietary balance has been underlined as priority by EU Biodiversity Strategy for 2030 (EU, 2020a). The efforts to conserve PGR *ex situ* in the genebank are prevalent to guarantee plant diversity preservation (Scarascia-Mugnozza and Perrino, 2002). Integrating *ex situ* and *in situ/on farm* conservation is the best approaches in the management of local diversity (Engels and Ebert, 2021). The *on farm* conservation of local varieties is the most effective activity to preserve their specific characteristics in the specific agro-climatic conditions that formed this diversity. It is imperative to establish close links between local farmers and researchers to achieve an integrated model for PGR conservation (Knüpffer, 2002; Arndorfer et al., 2009; Galluzzi et al., 2010).

According to Knüpffer (2016), the Balkan Peninsula is characterized by a very high level of plant biodiversity. The geographical position, climatic conditions and relief determines a rich species diversity, well adapted to the agro-ecological local regions. Preliminary survey for mapping the distribution of local varieties in Bulgaria by using the national register of plant genetic resources was done from Velcheva (2022).

Valorization encompasses the process by which plant landraces become a symbol, playing an important role in the construction of local identity and the specific flavor of a certain area (Ganeva-Raycheva et al., 2018; Britwum and Demont, 2022). The European Farm to Fork Strategy for a fair, healthy and environmentally-friendly food system support this goal as a priority policy of EC (2020b).

The study aims to evaluate the status of local plant genetic resources (PGR) in Bulgaria and to extensively document the traditional food and seed systems in which PGR are used in order to promote their use for the benefit of farmers and consumers.

MATERIAL AND METHOD

The research activities of Department of Plant Genetic Resources in IPGR-Sadovo part from Agricultural Academy are mainly aimed at collection, documentation, study, conservation and sustainable use of plant diversity of Bulgaria. In the Institute is situated the National Seed Genebank, which stores long-term local and introduced accessions according to the Standards of FAO (2014). Enrichment of *ex situ* collections with new PGR is carried out through expeditions, international free germplasm exchange and storage of breeding materials, deposited from Bulgarian Institutes of the Agricultural Academy and similar scientific organizations of the country. The collecting missions for enrichment the genebank with local varieties and populations is according to the Guidelines of FAO (2019). The inventory plan includes the following information: farmer's variety/landrace names, farmer information, site data, crop data, socio-economic data. The survey includes characterization and evaluation data. *On farm* conservation activities are according to Veteläinen et al., (2009) and the Concept of ECPGR (2017).

RESULTS AND DISCUSSION

Local germplasm collecting activities were first initiated from N.I. Vavilov and his colleagues at the Russian Institute of Plant Genetic Resources (VIR) during the 1920s and 1930s. It was also based on the concerning evidence emerging in the mid-1930s that traditional crop varieties and adapted landraces were being replaced by new improved varieties. In the 1970s *ex situ* collections were promoted by international institutions, in recognition of the importance of plant genetic resources for global food security. FAO and Bioversity International play key roles in this regard.

Two basic hypotheses are related to the general objective of the local diversity sustainable conservation and use: (1) to retrieve the embedded knowledge of local communities, in order to enhance awareness on PGR values; and (2) to support a chain-perspective approach in PGR study and management, aimed at development of *on farm* conservation.

Inventory of local PGR collection, stored in the National Genebank

During the period from 1982 to August, 2024, 11,083 local accessions have been collected from home gardens and small farms, as well as crop wild relatives from their natural habitats, and conserved at the genebank of IPGR-Sadovo. The status of collection and the genera with the biggest number of local accessions in Bulgarian genebank is presented on the Figure 1. As a result of enrichment, collections were enriched with high number of farmer's variety/landrace from the genus *Phaseolus*, *Capsicum*, *Allium*, *Cucurbita*, *Lycopersicon*, *Vicia*, etc. Local varieties originating from Bulgaria compares 28% of the fund of National Genebank.

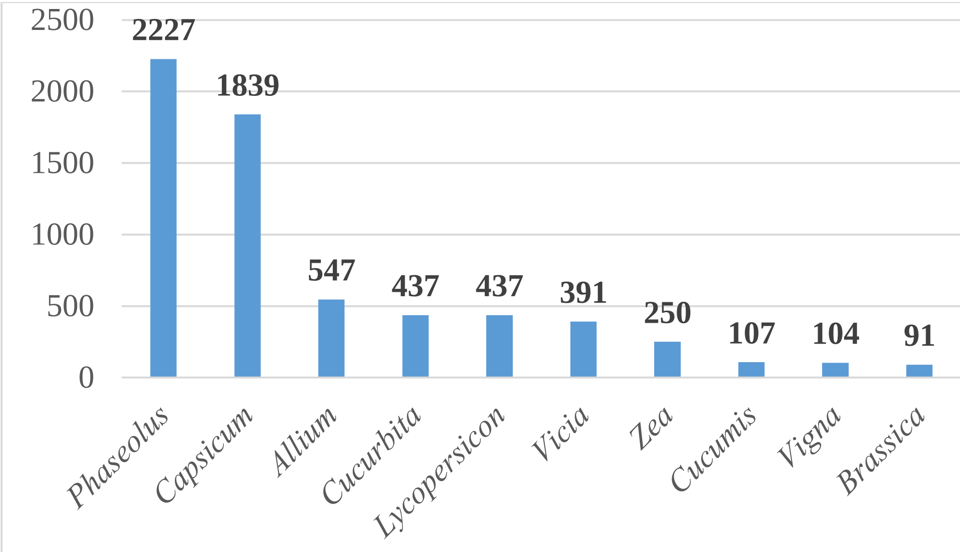

Figure 1. Crops with the biggest number of local accessions in Bulgarian genebank

Socio economic analysis of PGR-based local food chain systems and traditional products

As a result of the explored datasets of the National register of PGR it was found that local diversity grown in rural areas of Bulgaria is still characterized by a large number of crops: grain legumes, vegetables, medicinal species. The role of access to information on conserved plant biodiversity for achieving sustainable development of the regions can be considered in several directions – their participation in the agro-food chain, for production of traditional products, provide varietal diversity in local markets, as well as in rural tourism. Traditional varieties have potential in relation to return the interest of people to rural areas, to increase hobby gardening and organic production. The role of documentation and access to local PGR comes into focus on the biological, agricultural, social and economic prospects for use of these resources and traditional knowledge related to their cultivation, a time when society is sensitive to ecology and challenges, caused by climate change, with a growing need for higher yields and more well adapted crops.

Such is the example of traditional large beans, sweet diverse forms peppers and tomato “heart” type, which were not subject to intensive cultivation and wide commercialization, now they become a value, a "trademark" and are associated with the name of a settlement. This is the result of complex factors, economic and socio-cultural prerequisites, and is an example of how valorization can be a stimulus for the activation of local communities, the revival of traditions in the region of origin and the development of agritourism in localities. It is the sustainable storage of these valuable resources and access to passport, characterization and evaluation information that is at the heart of preventing their loss and preserves the possibility of their return to the agro-food chain in the region of origin.

From August, 2024 IPGR-Sadovo implements 24 months DIGIVALPGR project. The specific challenge is to promote the use of farmer's variety/landrace as traditional resources for agricultural diversity and the agro-food chain through research and innovative technology following different tasks and activities (Figure 2).

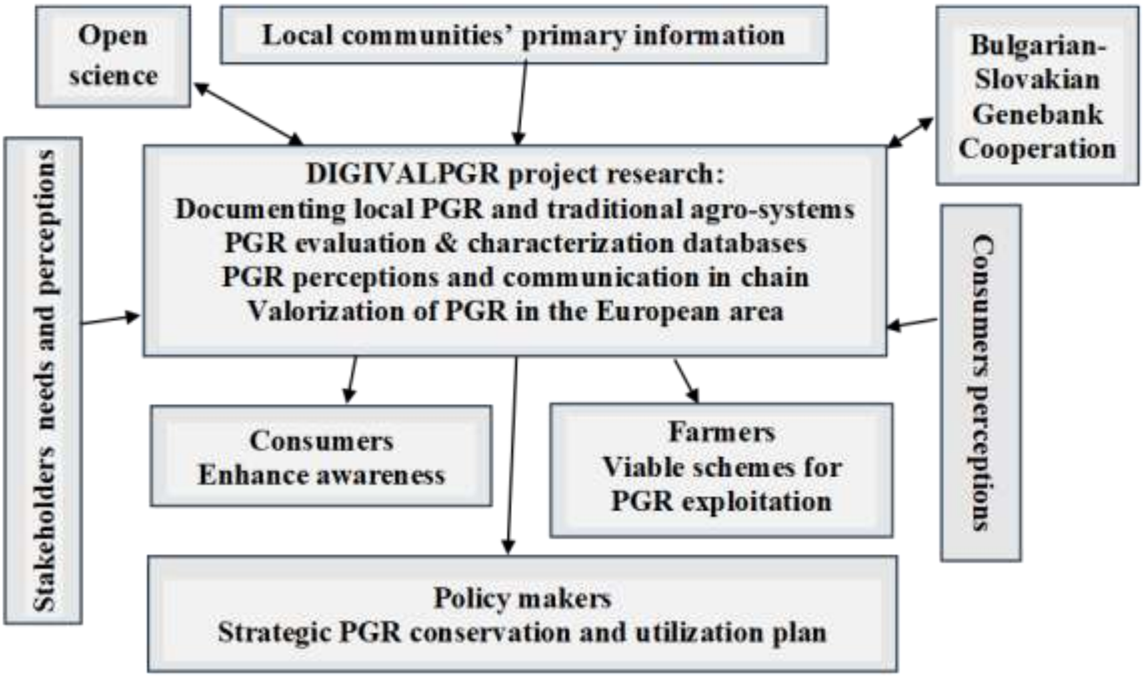

Figure 2. DIGIVALPGR project research tasks and activities

The regional food chains will be analyzed considering: 1) the role of local systems in preserving food security; 2) the role of economic valorization of local systems in preserving local PGR; 3) the role of economic valorization of local systems in improving capacities and infrastructures at local level; 4) social effects, deriving from the economic valorization of local food systems.

Documentation and conservation approaches of DIGIVALPGR project

- **Development of a farmer's variety/landrace database** in partnership with Slovakian genebank, based on the existing general European plant germplasm catalogue (EURISCO). The farmer's variety/landrace register is envisaged to function as a bio-cultural heritage information resource.
- **Collecting of landraces and crop wild relatives**. Collecting missions in Bulgaria and Slovakia will be set up for the selected traditional crops. The inventarization data will be stored in the national information systems, that will be uploaded in European catalogue EURISCO and global plant genetic resources system GENESYS.
- **Description and survey of the farmer's variety/landrace**. This activity consists of the characterization and evaluation of the varieties, collected by ECPGR descriptor lists.
- **Conservation of seed and free access**. The regenerated seeds from collected accessions during the expeditions will be stored in the genebank, according to best practices for *ex situ* management of collections and included in the exchange collection by SMTA (Standard Material Transfer Agreement).
- **Dissemination of results according to the Open science principals**.

A questionnaire for collecting data during the expeditions was created, according to ECPGR (2017) and Guidelines of FAO (2019):

QUESTIONNAIRE for collecting data during the collecting missions for farmer's variety/landrace by DIGIVALPGR project	
1	Accession number
2	Collection date
3	Researcher who collected the accessions
4	Collection site/place 1) Country/city/village/locality 2) Latitude 3) Longitude 4) Altitude 5) Characteristics of the area - flat, mountainous, semi-mountainous, etc. 6) Climatic features - temperatures, precipitation during the growing season
5	Farmer information 1) Name and surname 2) Age 3) Main activity
6	Crop/taxonomic description
7	Local accession name
8	Biological status 1) Wild / Crop wild relatives 2) Local / traditional variety, population 3) Old variety (with reduced use)
9	Characteristics of the accession 1) Agronomic - cultivation technology, early maturity, yield, etc. 2) Product quality – shape, color, taste, etc. 3) Resistance to diseases, enemies, drought, etc. 4) Irrigated / non-irrigated conditions 5) Specific features – distinguishing qualities and signs 6) Where the accession was obtained from and how long it has been grown on the farm
10	Farm information 1) Total area of used agricultural land in the farm 2) Area on the farm occupied by the accession 3) Reasons for growing the accession – traditional, cultural/religious, market, palatability, early maturity, disease resistance, etc. 4) Direction of production – for domestic consumption, local market, ecotourism, for the country/abroad, direct market/through an intermediary, etc. 5) How do they get seeds - do they collect themselves, from neighbors or from the local market
11	Traditional recipes for using the accession and other additional information
12	Photo of accession

CONCLUSIONS

European collaboration through different initiatives contributes to traditional food protection through valorization of landraces and their reintroduction to agricultural practice in correspond with the international conservation strategies.

ECPGR has brought genebanks together to exchange experiences, draft common descriptor lists, set up various joint projects and improve their documentation developing strong working relationships and initiatives supporting *ex situ* and in situ/on farm PGR community.

Local varieties originating from Bulgaria consist 28% of the fund of National Genebank, but there is opportunity to increase their part through collecting missions in rural areas by DIGIVALPGR project.

The socio-economic analysis identifies the strengths and critical issues related to the exploitation of genetic resources in local/regional agri-food systems. The analysis informs policy-makers on the activity options that can support agro-biodiversity conservation and foster economic development in current climate change conditions.

ABSTRACT

Propolis produced by honeybees is known to possess antifungal properties against fungal pathogens that cause yield losses in cultivated plants. This has created the opportunity to use propolis as an alternative application to pesticides, which are harmful to the environment and ecological balance. This study investigates the effect of propolis extract (Api10), developed by Tekirdağ Namık Kemal University Technopark (Tekirdağ/Türkiye), on *Fusarium proliferatum*, which causes root and root crown rot in pumpkin (*Cucurbita pepo* L.), a commonly grown plant in Türkiye. Initially, the effects of the extract at different concentrations on the mycelial growth and daily growth rate of the pathogen on Potato Dextrose Agar (PDA) were examined. After seven days of incubation, mycelial growth of the pathogen was inhibited by over 70% at the last three concentrations (0.925, 1.025, 1.125%), with the minimum inhibitory concentration (MIC) being 1.125%. The effective concentration for 50% inhibition of mycelial growth (EC_{50}) of the extract was determined to be 0.335%. While the growth rate in control plates without extract was 1.23 cm/day, no growth was observed at the 1.125% concentration, and the growth rates at 0.925% and 1.025% concentrations were 0.35 and 0.21 cm/day, respectively. Three concentrations found effective against the pathogen's mycelial growth were applied to pumpkin seeds along with the pathogen, and disease severity was measured in seedlings after a one-week incubation period. Disease severity was most effectively inhibited by concentration of 1.125% with a reduction rate of 44.13%. The authors suggest that the propolis extract, whose antifungal effect as seed treatment in pumpkin against *F. proliferatum* is identified for the first time in this study, is promising for integration into pot and field trials.

Keywords: Pumpkin (*Cucurbita pepo*. L.), Propolis extract, *Fusarium proliferatum*, Antifungal effect, Seed treatment

INTRODUCTION

Propolis produced by honey bees has a rich composition that may vary depending on the bee species, collection time, region and plant (Marcucci, 1995; Ghedira et al., 2009; Haile and Dekebo, 2013; Toreti et al., 2013). Propolis is composed of 50-70% balsam and resin, 30% beeswax, 10% essential oils, 5-10% pollen and 5% sugar, as well as vitamins (B, C, E), minerals, phenolic acids and flavonoids. In addition to the aforementioned compounds, it contains a variety of other chemical substances, including aldehydes, ketones, alcohols, aromatic compounds, steroids, inorganic compounds and amino acids (Easton-Calbaria et al., 2019; Bankova et al., 2001; Hunag et al., 2014; Escriche and Juan-Borras, 2018; Bayram et al., 2020; Salatino and Salatino, 2021). The chemical properties of propolis make it an important component of human health (Marcucci, 1995; Tosi et al., 2006; Toreti et al., 2013; Araujo et al., 2016). Furthermore, given the extensive use of fungicides for the prevention of fungal diseases in agricultural crops, propolis is being investigated as a potential alternative for the management of plant diseases, with the aim of protecting the environment and human health. In this context, the majority of propolis-related tests have been conducted *in vitro* conditions, with a focus on the ability of propolis to inhibit conidial germination (Ghaly et al., 1998; Mattiuz et al, 2015) and mycelial development (Quiroga et al., 2006; Meneses et al., 2009; Yang et al., 2011; Haile and Dekebo, 2013; Mattiuz et al., 2015; Özyiğit et al., 2018; Dudoit et al., 2020; Çakar et al., 2022; Ouahab et al. 2023). In some studies, the values for the effective concentration for 50% inhibition of mycelial growth (EC_{50}) or minimum inhibitory concentration (MIC) were determined (Quiroga et al., 2006; Mohammadzadeh et al., 2007; Curifuta et al., 2012; Moreno et al., 2020; Ristivojevic et al., 2020). The pathogenic fungal species used in these tests included; *Alternaria alternata, Aspergillus carbonarius, A. flavus, A. niger, Botryodiplodia theobromae, Botrytis cinerea, Colletotrichum gleosporioides, C. musae, Fusarium equiseti, F. oxysporum, F. proliferatum, F. solani, F. sporotrichiodes, F. subglutinans, F. verticillioides, Monilia fructigena, Penicillum digitatum, P. expansum, P. italicum, P. notatum* and *Trichoderma reesei*. Quantification of the inhibitory effects of propolis on fruit infection by several pathogens has been conducted in limited number of studies. These include studies on quince by *M. fructigena* (Özyiğit et al., 2018), on banana by *C. musae* (Dudoit et al., 2020), and on raspberry by *Penicillum* spp., *A. alternata*, *A. carbonarius* and *B. cinerea* (Moreno et al., 2020).

Fusarium proliferatum, a polyphagous species with a wide host range, is among the pathogens that cause significant yield reduction (Logrieco et al., 1995; Desjardins et al., 1997; Abdalla et al., 2000; Pérez et al., 2011; Yamazaki et al., 2013; Ren et al., 2015; Borrero et al., 2019; Yu et al., 2021; Sevinç and Özer, 2023). A recent study (Demir et al., 2023) found that 51.07% of pumpkin plants exhibited root and crown rot as a result of infection by *F. proliferatum.* No fungicide is currently registered for use in the treatment of the disease. The objective of this study was to investigate the antifungal effect of Api10 propolis extract, developed by Tekirdağ Namık Kemal University Technopark (Tekirdağ/Türkiye), on *F. proliferatum.*

MATERIALS AND METHODS

Materials

The pathogenic fungus used in the study was *Fusarium proliferatum* (FusP9), an isolate obtained by Demir et al. (2023) from naturally infected pumpkin (*Cucurbita pepo* L.) seeds. The TG38 pumpkin cultivar, which has been demonstrated to be susceptible to the pathogen (Sevinç and Özer, 2023), was supplied from AYFA Tarım AŞ. The propolis extract Api10 is a product of Tekirdağ Namik Kemal University Technopark, having a patent (Patent application number 2020/05364; inventor Prof. Dr. İbrahim PALABIYIK, Tekirdağ Namik Kemal University, Faculty of Agriculture, Department of Food Engineering, Tekirdağ/Türkiye)

Methods

In the *in vitro* assays, propolis extract was added to 100 ml Potato Dextrose Agar (PDA) medium at 50^{o}C in an erlenmeyer flask at nine different concentrations (0.325%, 0.425%, 0.525%, 0.625%, 0.625%, 0.725%, 0.825%, 0.925%, 1.025%, 1.125%) and poured into 8.5 cm diameter sterile Petri dishes. Once the medium had solidified, a 7 mm diameter agar disc, from the pathogen culture grown in PDA medium at 25°C in the dark for seven days, was put in the centre of the Petri dish. A control group was constituted by

Petri dishes lacking propolis extract and consisted solely of an agar disc containing the pathogen. The petri dishes incubated at 25ºC in the dark. Following the completion of mycelial colony development in the control, the diameter of the pathogen's mycelial growth was measured in the treated Petri dishes. The precentage of mycelial growth inhibition (MGI%) was calculated as MGI: [(mc-ma)/mc × 100], where mc is the mean of mycelial growth diameter in control and ma is the mycelial growth diameter in treatment (Deans and Svaboda, 1990). Additionally mycelial growth diameter were measured every 48h in petri dishes containing the ranges of concentrations differing from 0.625% to 1.125% (concentrations that inhibit mycelial growth by more than 70) of propolis extract and in control. Mycelial growth rate (cm/day) was calculated. The experiments were desigined in a randomized plot design with five replications (one petri dishes per replicate). The EC_{50} (the effective concentration for 50% inhibition of mycelial growth) value of the propolis extract was determined by applying the percentage growth value calculated according to the control to log-probit paper (Delen et al., 1984). The concentration at which no development of the pathogen was observed yielded the MIC (Minimum Inhibitory Concentration) value.

In order to ascertain the impact of propolis extract on disease severity in seedlings, the concentrations that inhibited mycelial development by over 70% were employed. The seeds were subjected to a seven-minute immersion in a 2% solution of sodium hypochlorite (NaOCl), followed by three rinses with sterile distilled water and a subsequent 30-minute drying period on sterile blotting paper. Seeds that had been subjected to surface disinfection were placed in a mixture of propolis extract and a suspension of *F. proliferatum* conidia (1 x 10^6 conidia/ml) and shaken at 25°C for one hour. A conidia suspension of the pathogen only, in which 0.1% Tween 20 was added, was treated to control seeds. The treated seeds were placed in 8 cm diameter Petri dishes containing PDA, with eight seeds placed in each dish. The experiment was conducted in 13 replicates, with one Petri dish included in each replicate. The seedlings were evaluated using the 0-4 scale (0: Healthy, well-developed seedling, 1: Roots well developed, brown spots on root tip; 2: Browning of root tip, as well as poor root development; 3: Complete browning of roots; 4: No germination and seed completely colonised by fungus) (Figure 1) obtained by modifying the 0-5 scale defined by Demir et al. (2023). Disease severity was calculated using the formula described by Townsend and Heuberger (1943): Disease severity, %: [∑(Disease level x number of seed showing disease at that level)]/[total number of seed × highest severity level × 100]. The efficacy of propolis extract was calculated based on Abbott Formula [% effectiveness C-P)/ C × 100], where in C refers to disease severity in control and P refers to disease severity in the treatment.

Statistical Analysis

The homogeneity of variances and normality of distribution were firsty determined by Levene’s test and Shapiro-Wilk test , respectively, using SPSS, version 23 (IBM SPSS Statistics for Windows, IBM Cora., Armonk, Ny, USA). All in the experiments satisfied the assumptions of ANOVA test. The least significant Difference (LSD) test was used to compare means of treatments at p=0.05 level using Software JMP Version Pro 17 for Windows (Cary, North Carolina, USA).to those of the treatment.

RESULTS AND DISCUSSION

In the study, propolis extract was employed at nine different concentrations, and it was observed that the pathogen did not exhibit growth in the medium containing 1.125% propolis extract, resulting in 100% growth inhibition (Figure 2). This dose was considered to be the MIC value of the extract. The development of the pathogen was observed at concentrations lower than this concentration, but the diameter of the mycelial colony at all doses was significantly lower than in the control (Table 1). Following the concentration of 1.125%, the lowest mycelial growth diameter (1.28 cm) was observed at the 1.025% concentration, which was then succeeded by the 0.925% concentration (2.30 cm). These concentrations inhibited the mycelial growth diameter by 84.94% and 72.94%, respectively. The EC_{50} value of the extract was determined to be 0.335%.

Figure 1. 0-4 scale used in the study. 0: Healthy, well-developed seedling, 1: Roots well developed, brown spots on root tip; 2: Browning of root tip, as well as poor root development; 3: Complete browning of roots; 4: No germination and seed completely colonised by fungus

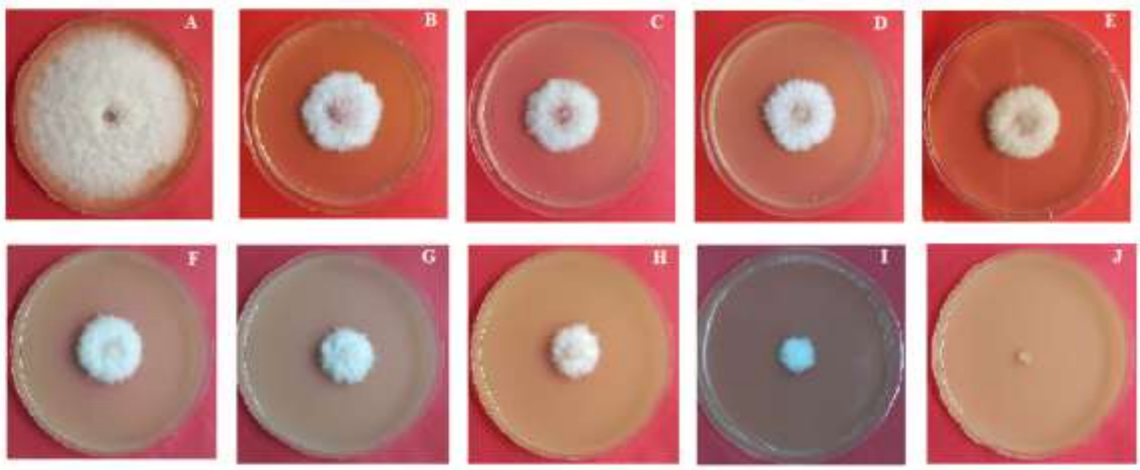

Figure 2. Mycelial growth of *Fusarium proliferatum* in the increasing concentrations of propolis extract (A: Control, B: 0.325%, C: 0.425%, D: 0.525%, E: 0.625%, F: 0.725%, G: 0.825%, H: 0.925%, I: 1.025%, J:1.125%)

Table 1. Effect of different concentrations of propolis extract on mycelial growth of *Fusarium proliferatum*

Concentration (%)	Mycelial Colony Diameter (cm)	Inhibition (%) of mycelial growth
0.325	4.26±0.06b	49.88±0.86
0.425	3.87±0.07c	54.47±0.86
0.525	3.62±0.05d	57.41±0.63
0.625	3.60±0.06d	57.64±0.77
0.725	3.12±0.02e	63.29±0.30
0.825	2.57±0.01f	63.76±0.14
0.925	2.30±0.05g	72.94±0.59
1.025	1.28±0.09h	84.94±1.03

Control	8.50±0.00a	-

*Each value is the mean ± standard error (SE) of five replications. Means in each column followed by different letters differ significantly at P<0.05 according to LSD test.

In the assays where in the growth rate of the pathogen was evaluated, it was observed that the growth rate was 1.23 cm/day in the control Petri dishes (Figure 3). However, a statistically significant reduction in growth rate was observed at concentrations ranging from 0.625% to 1.125%, with no growth occurring at the 1.125% concentration. Furthermore, the growth rates were found to be markedly low at concentrations of 1.025% (0.21 cm/day) and 0.925% (0.35 cm/day).

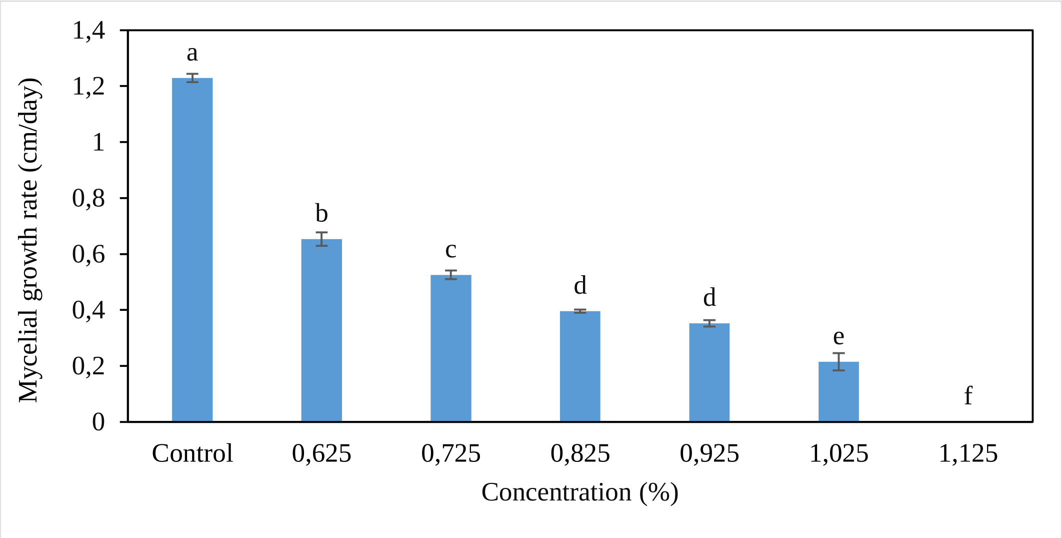

Figure 3. Mycelial growth rate of *Fusarium proliferatum* in different concentrations of propolis extract. Values are means ± standard error (SE) and bars shows SE. Bars topped by a different letter differ significanty based on the LSD test at P<0.005

A review of the scientific literature revealed only one previous study that examined the effect of propolis extract on the mycelial development of *F. proliferatum*. The related study examined the effect of an ethanol extract of propolis on *F. proliferatum* isolated from anise seed, determining the MIC value to be 0.004 mg/ml (Rostivotevic et al., 2020). The isolate *F. proliferatum* was obtained from pumpkin seeds in the current study, and the minimum inhibitory concentration (MIC) of the non-alcoholic propolis extract was found to be 1.125% for this isolate. In a study conducted by Quiroga et al. (2006), it was reported that propolis extracted with ethanol at a concentration of 1.16 mg/ml demonstrated a 55.6% inhibition of the colony diameter of *F. oxysporum*. In a separate study (Ouahab et al., 2023), it was proposed that acetone-extracted propolis (APE2) exhibited inhibitory effects on the colony diameter of the same species, with an inhibition rate of 73%. This indicates that there are variations between the isolates and extracts employed. The alcohol-free Api10 propolis extract employed in this study was observed to inhibit the mycelial growth of *F. proliferatum* by 70-100% at concentrations ranging from 0.925% to 1.125%. To the best of our knowledge, our study is the first to examine the effects of propolis extract on the mycelial growth rate of *F. proliferatum*.

The three concentrations of propolis extract, which inhibit mycelial growth above 70% (0.925%, 1.025%, 1.125%), were separately mixed with the conidia suspension of the pathogen and applied to the seeds of the pumpkin. Among the concentrations, 1.125% (Figure 4) was observed to have the lowest disease severity (42.70%) and to prevent disease severity by the highest rate (44.13%).

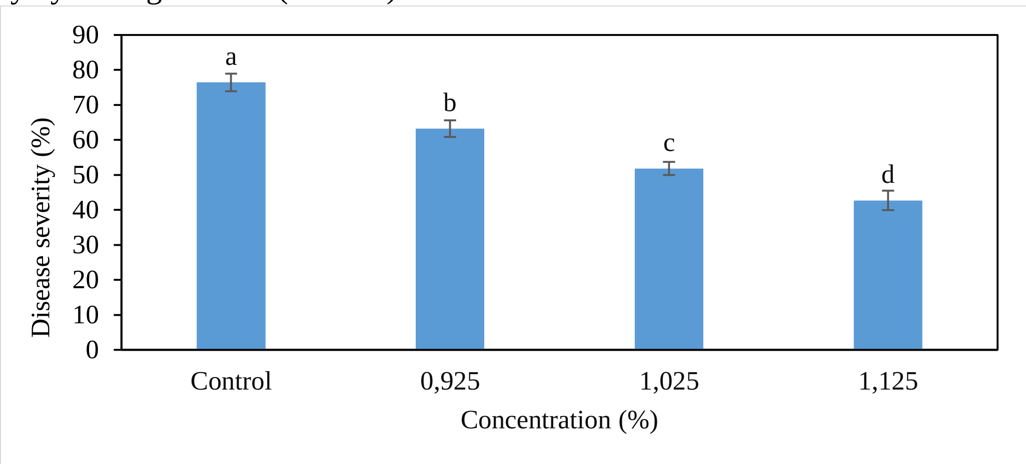

Figure 4. Disease severity of *Fusarium proliferatum* in different concentrations of propolis extract: Values are means ± standard error (SE) and bars shows SE. Bars topped by a different letter differ significanty based on the LSD test at P<0.005

The effects of various propolis extracts on diseases caused by *Colletotrichum gloeosporioides* in mango fruit (Mattiuz et al., 2015), *Monilia fructigena* in quince fruit (Özyiğit et al., 2018), *C. musea* in banana fruit (Dudoit et al., 2020), *Penicillum* spp., *Alternaria alternata* and *Botrytis cinerea* in raspberry fruit (Moredo et al., 2020) have been investigated. However, no study has yet investigated the potential of propolis extract to prevent the seedling rot caused by *F. proliferatum* in any plant species. In this context, the results of the present study on the effect of propolis extract against seedling rot caused by *F. proliferatum* in pumpkin represent the first findings.

CONCLUSION

Considering problems such as the increasing use of fungicides in recent years, environmental pollution and resistance of fungal species to fungicides, the present study includes an environmentally friendly application and is important in terms of sustainability in agriculture. It was determined that the propolis extract used in the current experiments inhibited mycelial development of *F. proliferatum* at increasing concentrations and had fungicidal activity against seedling root and crown rot caused by the pathogen. It also contributes significantly to the development of biocontrol strategies that can be applied under field conditions with seed coating. It also provides a basis for testing the efficacy of propolis in various agricultural crops other than pumpkin. It is expected that the results obtained will provide important contributions to the pot and field trials to be conducted later.

ACKNOWLEDGEMENTS

We would like to express our gratitude to Prof. Dr. İbrahim PALABIYIK for kindly providing samples of his lactic acid-based propolis (Api10) extract (Patent No: 2020/05364) for the purposes of this study. Furthermore, the authors would like to express their gratitude to AYFA Agriculture for providing the TG38 cultivar used in this study.

ABSTRACT

Image processing techniques, which are the subject of research in many fields in the world and in our country, have made great progress in recent years, especially in the field of agriculture. As the human population grows, so does the need for food. For this reason, it is particularly important to prevent fungal losses in crop production per unit area. Timely and proper control minimizes losses due to fungal diseases. Thanks to the developing technology, diseases can be easily identified with image processing techniques and a strategy to combat them can be determined. Plant fungal diseases can be detected quickly, accurately and conveniently using machine vision technology. By increasing the number of these identification studies and integrating them with drone technology, it will be possible to provide sustainable control of plant fungal diseases by saving both time and labor over very large areas. In this study, the history, importance, stages of application of image processing and some studies on its use in the detection of plant fungal diseases were mentioned.

Keywords: Agriculture 4.0, Smart agriculture, Drone technology, Artificial intelligence.

INTRODUCTION

In crop production, many factors, especially diseases, affect product quality and quantity. In addition, in crop production, inaccurate adjustment of practices and inputs, such as the use of diesel oil, chemicals, irregular irrigation, and failure to properly set the harvest date, may result in failure to obtain the desired product. With the introduction of modern technology in agriculture and the availability of unmanned aerial vehicles, the trend towards image processing techniques has also increased. It has become imperative to integrate agricultural production with technology. Agricultural production is almost as old as humanity (Teke et al., 2016). With the use of precision agriculture applications along with unmanned aerial vehicles and image processing facilities, studies on plant disease detection have also gained significant progress (Altaş et al., 2023; Matese et al., 2015; Zhang et al., 2002

Invisible wavelengths of light have many applications, particularly in the highly accurate detection of early-stage disease in crops (Chen et al., 1989; Chen et al., 2010). In today's world, where sustainable and good agricultural practices are gaining importance day by day, image processing techniques are used in areas such as leaf area determination, fruit maturity determination, plant disease diagnosis and differentiation, and disease severity calculation due to the integration of information technologies with agriculture (Karabacak, 2007; Mustafa et al., 2008; Örge, 2012; Sabancı and Aydın, 2014; Zhao et al., 2009).

In this review, the importance of image processing technology in the historical development of agriculture, the history of image processing, methods and steps, the importance of image processing in the detection of plant fungal diseases were emphasized and examples of some studies in this field were given.

HISTORY OF IMAGE PROCESSING

Remote sensing, which began in the 1800s, began with the first photograph taken by Joseph Nicephoce Niepce (Figure 1.A) and Gaspard Tournachon, who photographed a village in Paris from a flying balloon (Figure 1.B). In the 1860s, Professor Sam King and James Wallace Black took aerial photographs of the city of Boston from a balloon at an altitude of 1200 feet (Figure 1.C) (Baumann, 2001). To observe the course of the war from the air during the Civil War period in the United States, kites, pigeons (Figure 1.D) and various mechanisms were placed on weather balloons to obtain images (Colwell, 1983). The first aerial photograph was taken by Arthur Batut in 1989. He used a device attached to a kite. In 1903, pigeons were used for a similar process. During World War I, the photographic images were obtained through the use of airplane. (Figure 1.E). In the 2nd World War more advanced techniques were used. This was the first time that civilians had access to aerial photography (Lillesand and Kiefer, 2000). In 1929, a liquid-fueled rocket was launched into the air in the United States, and a camera and barometer were attached to (Figure 1.F) to take aerial photographs. The advent of the rocket, balloon, kite, pigeon and aeroplane marked a pivotal moment in history. The term 'remote sensing' was first coined in 1960, followed by the launch of the inaugural remote sensing satellite in 1972 (Bilgi, 2007).

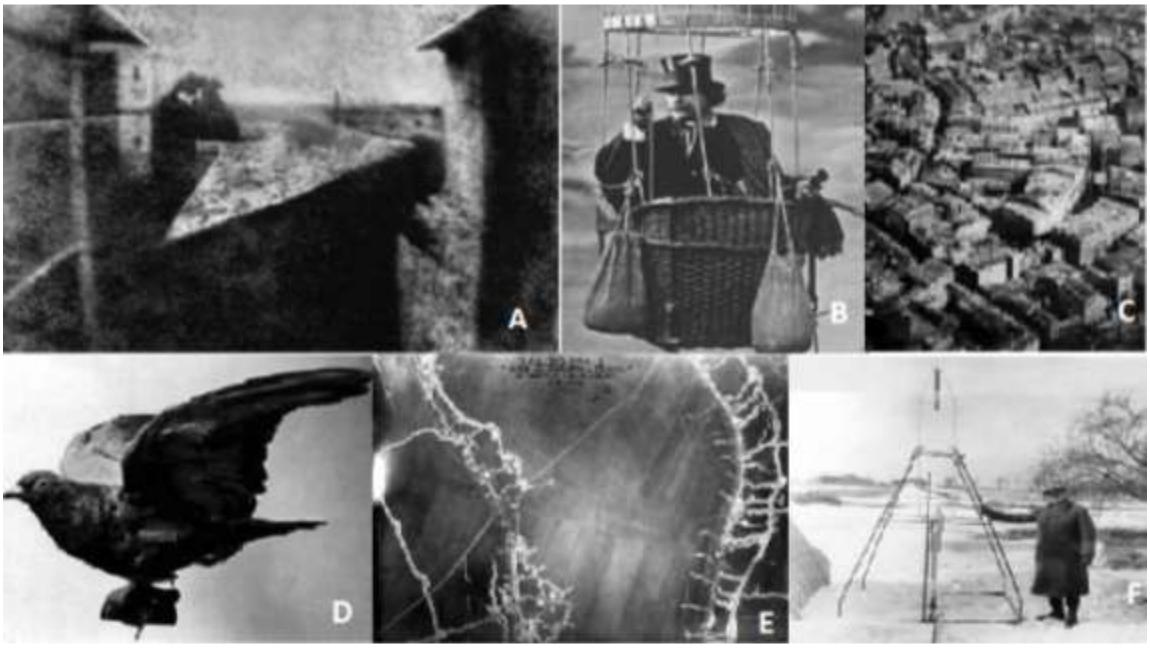

Figure 1. The first photograph taken by Joseph Nicephoce Niepce (A), the person who took the first aerial photograph in Paris (B), an aerial photograph of the city of Boston (C), a pigeon with a camera attached (D), an aerial photograph taken from an airplane during World War II (E), a camera attached to a rocket to take photographs (F) (Bilgi, 2007).

IMAGE PROCESSING METHODOLOGY

The main purpose of image processing is to identify and classify signs or objects that have common features or can be related to each other using previously identified features or characters (Demir et al., 2016). In light of the data obtained, it is possible to realize full-time and autonomous machines by bringing together various applications such as artificial intelligence, deep learning, modeling, machine learning, and simulation under a single roof. The digitization of the image is based on the process of converting the image in the camera into electrical signals with an optical-electrical mechanism (Solak and Altınışık, 2018). Image processing is employed in the field of agriculture for a multitude of purposes. These includes the detection of diseases, pests and weeds, the measurement of leaf area, the analysis of color, the classification of crops, the determination of yield, the creation of drought maps, the tracking of cattle and sheep, the assessment of soil fertility and moisture value (Dalen, 2004; Keefe, 1992).

IMAGE PROCESSING STEPS

The process of image processing, which can be divided into three fundamental stages, begins with the conversion of the original image into a digital format. This is followed by the editing of the digital image to achieve the desired format, and finally, the performance of the necessary analysis and evaluation of the results In these methods, the rays that identify the object or objects are converted into electrical signals in the camera device. In this manner, the image is converted to an analog format, which is a physical representation. In the final stage of the process, the image is converted into a digital format, enabling it to be processed within a computer environment. The aforementioned steps necessitate the utilisation of image sensors and systems that are capable of transforming the signals generated by the sensors into a digital format. In the event that the signals obtained from the sensors are in analog form, they are converted to digital format with the assistance of analog-to-digital converters. Analog signals are continuous signals that are functions of continuous variables, such as space, signal, or time. The value is generally constant. In the context of an analog image, regardless of the degree of magnification or the angle of observation, the colors that comprise the image remain unaltered. In order for a computer to process continuous functions or parameters, the functions must be digitized. A digital image is an analog image represented as a function of spatial coordinates (x, y) expressed in terms of discrete samples and represented as a function of spatial coordinates (x, y) (Karakoç, 2012).

IMAGE PROCESSING TECHNIQUES

The data obtained from the data libraries, created by obtaining thousands of images, are applied in three different ways. Firstly, in the context of the white-gray scale technique, it can be defined as a histogram representation of the white-gray balance. The objective is to reveal the shape in the image by utilising the white-grey scale in the obtained digital image. Given that each point in the image is distinct, the positioning of the bits required for each illumination level is also variable. The images of varying levels are expressed in gray-level or gray-level scale. The second technique is based on the identification of the digital image using the RGB values, which are the primary colors. All colors in the color spectrum can be derived from the combination of three primary colors: red (R), green (G), and blue (B). In this logic, referred to as the additive color space, the image is constructed from a combination of red, green, and blue light emitted by the pixels. Each pixel is assigned a reflectance or brightness value within the range of 0 to 255. If one of the red, green, or blue values is set to 255, while the others are set to 0, then one of the RGB values is present. In the event that all RGB values assume the value of 255, the resulting color is perceived as white. Conversely, if all RGB values assume the value of 0, the resulting color is perceived as black. The formation of other colors is a consequence of the combination of red, green, and blue (RGB) components within the range of values between 0 and 255. The thresholding process enables the removal of pixels with a specific value or outside the desired range. Finally, the obtained image is divided into squares, the desired region is selected and processing is performed in the selected region (Şin et al., 2019). Once the optimal technique and program have been selected for specific purposes and areas of use, the data must be processed, interpreted, and prepared for utilization. In order to facilitate the correct definition of data libraries, it is necessary to increase the number of images that are prepared for use. The data libraries facilitate the instantaneous reading, processing, interpretation, and detection of the image.

DISCRIMINATION OF HEALTHY AND SICK PLANTS USING IMAGE PROCESSING TECHNIQUE

All green, leafy plants engage in photosynthesis as a means of survival. Furthermore, the process of photosynthesis is influenced by external stress factors that are encountered throughout the various stages of plant development. The absorption of visible light by chlorophyll in plant leaves is a prerequisite for the continuation of photosynthesis. The cell structures present in the leaf enable it to reflect near-infrared light with great intensity. In the near infrared (NIR) spectrum, healthy, vibrant, and greener plants appear brighter than sick, lifeless, and spindly plants. In brief, the wavelength of light is also influenced by the health status of the plant (Teke et al., 2016). The Normalized Difference Vegetation Index (NDVI) is a metric used to analyze the life history of plants (Deng et al., 2018; Thenkabail et al., 2000; Wang et al., 2020). In the calculation of NDVI, the utilization of near infrared (NIR) and red (RED) light wavelength bands is employed, with the formula being calculated as NDVI= (NIR-RED) / (NIR+RED) (Tucker, 1979). The Normalized Different Vegetation Index (NDVI) assumes values within the range of -1 to +1. Figure 2 illustrates the vitality indicator scale. On this scale, a value of -1 to 0 indicates the objects or dead plants, a value of 0 to 0.33 indicates unhealthy plants, a value of 0.33 to 0.66 indicates moderately healthy plants, and finally a value of 0.66 to 1 indicates very healthy plants.

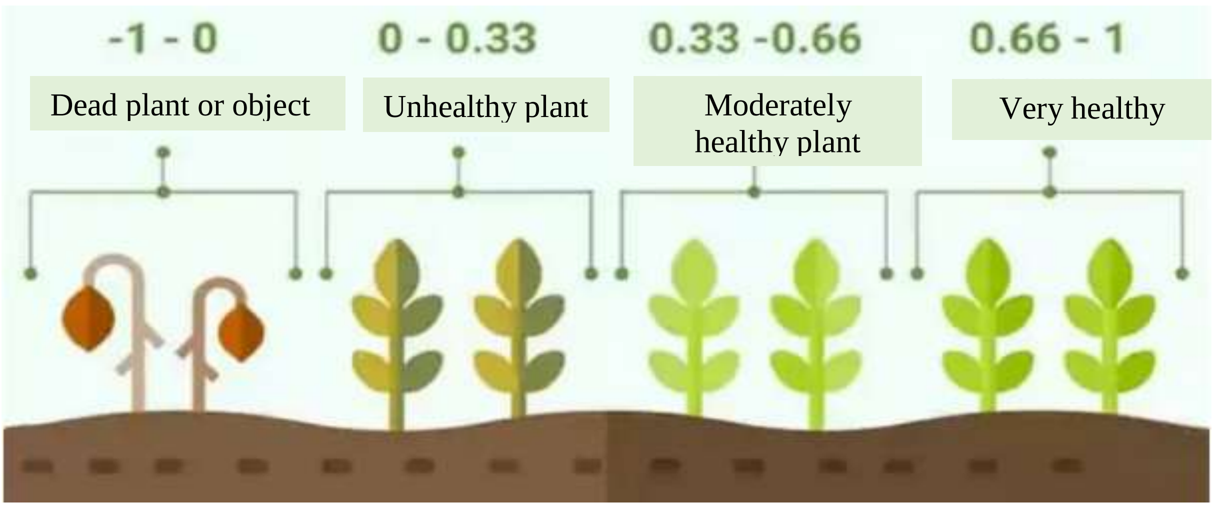

Figure 2. The plant vigor indicator scale (Anonymous, 2022)

STUDIES ON THE DETECTION OF FUNGAL DISEASES USING IMAGE PROCESSING TECHNIQUES

In the first study about the determination of fungal diseases with image processing techniques Wang et al. (2012) proposed a hybrid system based on image descriptors for the detection of four diseases such as grapevine downy mildew (*Plasmopara viticola* Berk. Et. Curt, Berl et de Toni), grapevine powdery mildew (*Uncinula necator* Schw. Burr.), wheat yellow rust (*Puccinia striiformis* f. sp. *tritici* West) and brown rust (*Puccinia recondita* f. sp. *tritici* Rob. Et Desm.). The diseased regions were delineated through the application of image segmentation, balancing, and k-means clustering algorithms. Subsequently, 50 feature vectors were derived through the utilisation of shape, colour, and texture-based methodologies. The efficacy of the aforementioned features, as determined through the utilisation of back propagation networks, was quantified. Consequently, the detection of vineyard and wheat diseases exhibited a 100% accuracy rate.

Quin et al. (2016), have selected the features using the methods of ReliefF, 1-Rule, Correlation-based feature selection (CFS) to define the symptoms of alfalfa leaf spot (*Pseudopeziza medicaginis* Libb, Sacc) (Figure 3A), alfalfa rust (*Uromyces striatus* J. Schroöt.) (Figure 3 C), Leptosphaerulina leaf spot (*Leptosphaerulina briosiana* (Pollacci) Graham et Luttrell) (Figure 3E) and Cercospora leaf spot disease (*Cercospora medicaginis* Ellis & Everh) (Figure 3G), the selected features were identified using ReliefF, 1-Rule, Correlation-based feature selection (CFS) methods. In the subsequent stage, the researchers created disease recognition models using random forest support vector machine (SVM), K nearest neighbour (KNN) supervised learning methods in accordance with the selected features. The results of this study indicated that the ReliefF method is the most effective for feature selection, while the SVM model is the optimal choice for the 45 features identified as most critical for recognition. The recognition accuracy of the training set and test set were calculated as 97.64% and 94.74%, respectively, for this model. The method enabled the generation of segmentation images of the symptoms of four alfalfa leaf diseases (Figure 3 B, D, F, H). It was suggested that the identification and recognition of the diseases exhibited a very high accuracy rate.

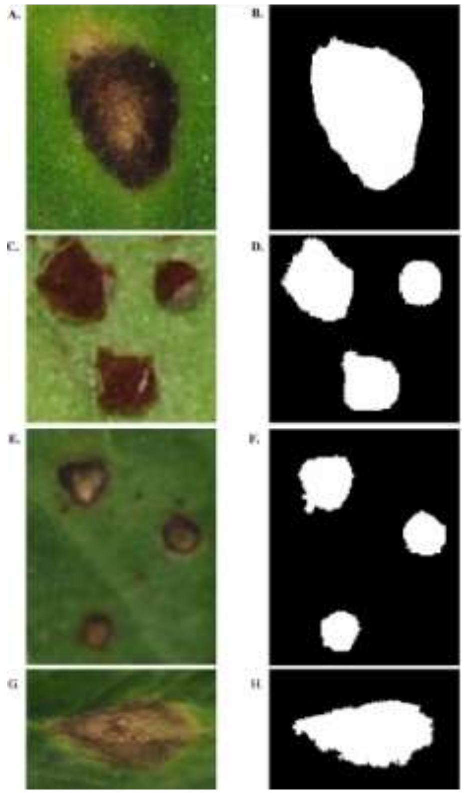

Figure 3. The symptoms (input) and segmentation (output) of some leaf diseases in alfalfa. A: Image of alfalfa leaf spot, B: Segmentation of alfalfa leaf spot, C: Image of alfalfa rust, D: Segmentation of alfalfa rust, E: Image of leptosphaerulina leaf spot, F: Segmentation of leptosphaerulina leaf spot, G: Image of cercospora leaf spot, H: Segmentation of cercospora leaf spot (Quin et al., 2016)

Sladojevic et al. (2016) identified 13 different foliar diseases, including powdery mildew (*Uncinula necator* Schw., Burr.), which is common in vineyard areas. In the study, more than 30,000 samples were used for convolutional neural networks. The results of the experimental studies indicated an accuracy rate of 91.11%. In the following year, Singh and Misra (2017) used genetic algorithm for image segmentation, which is an important feature in automatic detection and classification of plant leaf diseases. By combining image processing with different techniques, the presence of leaf spots was revealed as a result of segmentation of the image of the symptom caused by *Alternaria* spp. on bean leaves (Figure 4A) according to colour characteristics (Figure 4B). This approach was employed in order to identify plant diseases at an early or initial stage. Ramcharan et al. (2017), used a transfer learning approach based on deep convolutional neural networks for the detection of three disease agents in cassava plants. One of the diseases that can affect plants is brown leaf spot disease, which is caused by fungi. Using the pre-programmed Inception-v3 model, features were identified from diseased plant samples, the performance of these features was calculated using SVM and k-ECK classifiers, and as a result of experimental studies, 93% accuracy was obtained with the proposed approach and SVM classifier.

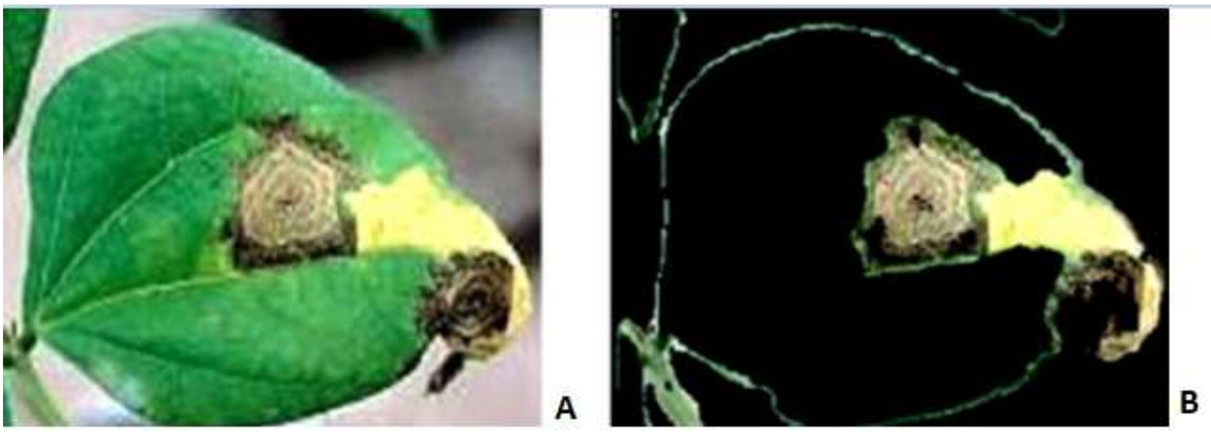

Figure 4. Leaf spot caused by *Alternaria* spp. on a bean leaf (A), and the leaf segmentation that was performed on the same leaf (Singh and Misra , 2017).

Türkoğlu and Hanbay (2018) used deep learning models such as Vgg 16, Vgg19 and AlexNet based on programmed convolutional neural networks (CNN) for the detection of freckle disease (*Wilsonomyces carpophilus* (Lev.) M.B. Ellis) in apricot and classified the deep features obtained from these models using the K-Nearest Neighbour (KNN) method. In addition, the dataset was contained a total of 960 images consisting of images of healthy and diseased apricots. As a result of the results obtained, the highest level of accuracy was obtained with the Vgg16 model, at 94.8%. In the same year, Walleling et al. (2018) proposed a new model based on deep neural networks for the classification and detection of brown spot (*Septoria glycines* Hemmi) disease in soybean. For the classification of the disease, the LeNet model was used. The PlantVillage database contained 12,673 leaf images, including four classes of healthy leaf images. As a result, the accuracy of the model used was 99.32%. This model was found to be able to extract important features and classify plant diseases from the captured images. Zhang et al. (2018) visually assessed the symptoms of leaf spot and mammalian rust diseases caused by *Alternaria* spp. (Figure 5 A) and *Gymnosporangium* spp. (Figure 5 B) in apple, respectively, and determined that incidence of disease was at the rate of 85.64%. KMSNN, SIFT and IRT image processing methods were then applied using the segmentation results (Figure 5 E, F) and disease detection rates of 75.87, 80.63 and 80.82% were achieved respectively. For *Colletotrichum orbiculare* (Berk. & Mont) Arx, (Figure 5 C) and *Erysiphe cichoracearum* (DC.) (Figure 5 D) in cucumber, the same methods were applied using the segmentation data (Figure 5 G,H) and while the disease detection rate obtained by the observer was 87.55%, this rate was 79.65% with KMSNN, 82.98% with SIFT and 84.08% with IRT. Through different methods, a new diseased leaf segmentation algorithm is proposed by integrating super pixel clustering and K-means clustering, which greatly reduces the computational cost.

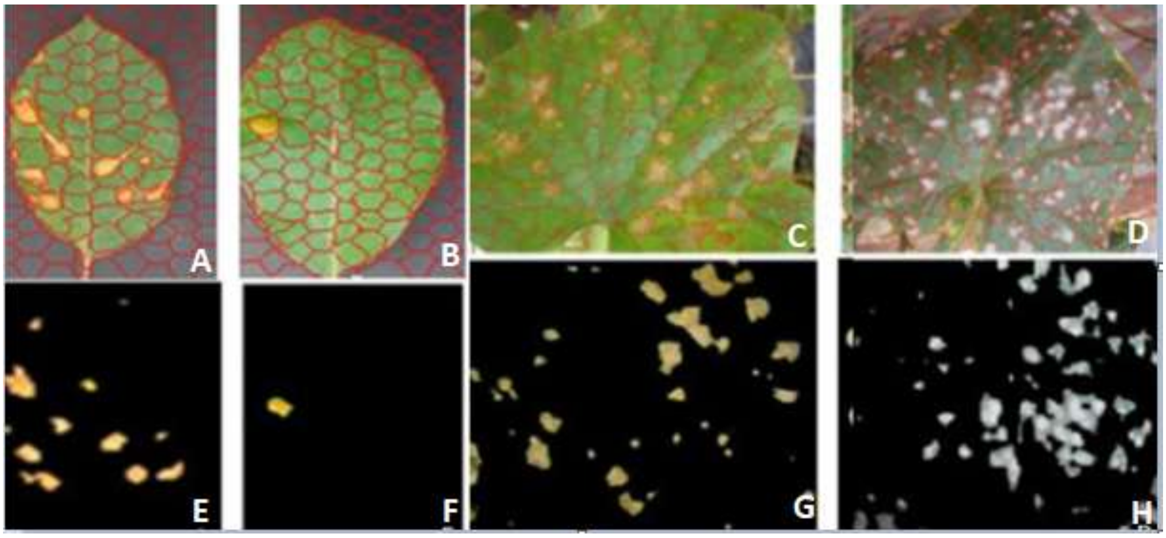

Figure 5. Images and segmentation of different fungal pathogens on the leaves. A: *Alternaria* and E: segmentation on apple leaf; B: *Gymnosporangium* spp and F: segmentation on apple; C: *Colletotrichum orbiculare* (Berk. & Mont) Arx, and G: segmentation on cucumber; D: *Erysiphe cichoreacearum* (DC.) and H: segmentation on cucumber (Zhang et al., 2018)

Altaş et al. (2019) determined sugar beet leaf spot (*Cercospora beticola* Sacc.) disease using segmentation process (Figure 6 A, B, C). They stated that a value of 48% was calculated with the image processing method on a leaf where 50% disease severity was calculated with the expert assessment result, and this value was very close to the expert assessment. The researchers used an image-processing algorithm they developed to calculate the exact location of the diseased areas. As a result of the study, it was emphasised that the imaging method can be preferred by obtaining precise values rather than observing. Özgüven and Adem (2019) proposed an updated, faster R-CNN model developed by changing the parameters of a CNN model for automatic detection of the same disease (Figure 7). When the proposed method was programmed with 155 images, the accuracy of the tested method was found to be 95.48% and it was reported that the proposed approach gave better results than the modern methods in the literature. Liang et al. (2019) used a convolutional neural network (CNN) model for disease detection of paddy leaf blight (*Pyricularia oryzae* Cav.). A data set with a total of 5808 samples has been designed for the testing and training of the model. As a result of the qualitative and quantitative experiments carried out to determine the effectiveness of the model, it was found to be the best performer. Zhang et al. (2019) developed a new three-channel ESA model for the classification of some problematic diseases, such as powdery mildew of cucumber (*Erysiphe cichoracearum* (DC.)) and Septoria leaf spot of tomato (*Septoria lycopersici* Speg.) (Figure 8 A, B, C, D). In this model, the proposed model is applied to each channel (R,G,B) of diseased plant leaf images and the learned weights obtained with the fully connected fusion layer are determined. To test the model, 15,817 coloured images of cucumber and tomato leaves were used. The images had 8 classes. As a result, it is confirmed that the proposed model has a better performance compared to the most recently developed methods.

Figure 7. Testing process against sugar beet leaf spot (*Cercospora beticola* Sacc.) disease in sugar beet field using the proposed R-CNN model (Özgüven and Adem, 2019).

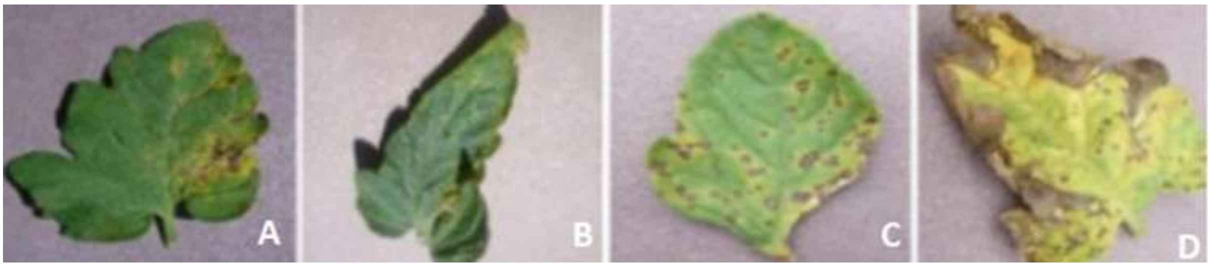

Figure 8. Different leaf samples (A, B, C, D) infected with Septoria leaf spot (*Septoria lycopersici* Speg.) in tomato (Zhang et al. 2019).

Aksoy et al. (2020) used convolutional neural network (CNN) models for detection of rust (*Gymnosporangium* spp.), black spot (*Venturia inaequalis* (CKe) Wint.) and black rot (*Alternaria* spp.) in apple with artificial intelligence. In this study, the best F-score, sensitivity, accuracy and specificity values of DenseNet-1, AlexNet, ResNet-34, Squeezenet1_0 and VGG16-BN models in CNN were determined by evaluating their performance according to the confusion matrix. As a result of the study, it was reported that the F-score, sensitivity, accuracy and specificity values were 98.62%, 97.64%, 99.52% and 99.54% respectively, and the best model was ResNet-34. Aslan (2021) tested a dataset of 327 colour images of monilia disease (Figure 9) in peach trees with the ESA AlexNet model and stated that the detection was made with an accuracy rate of 99.30% as a result of experimental studies.

Figure 9. Monilia disease on peach (Aslan, 2021).

Göksu et al. (2021) developed two models, namely EfficientNetB5 network and convolutional neural networks for the detection of corn rust (*Puccinia sorghi* Schwein) (Figure 10 A), northern (*Exserohilum turcicum* (Pass.) K.J. Leonard & Suggs) (Figure 10 B) and southern (*Bipolaris maydis* (Nisk. Miyale)) (Figure 10 C) leaf blight. The number of images in the performance matrices of the models has been increased using data multiplication techniques. As a result, the prediction rates obtained from the EfficientNetB5 transfer learning model and the developed deep learning model were 92.12% and 89.88% respectively.

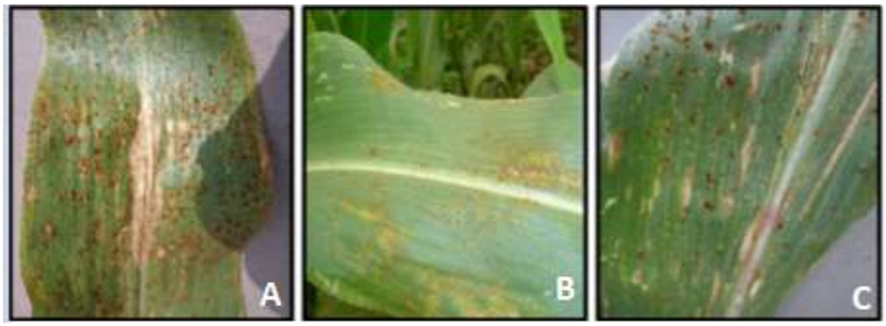

Figure 10. Some leaf diseases on the leaves of of maize. A: Rust (*Puccinia sorghi* Schwein); B: Northern (*Exserohilum turcicum* (Pass.) K.J.) leaf blight; C: Southern (*Bipolaris maydis* (Nisk. Miyale)) leaf blight (Göksu et al., 2021).

Atik (2022) used ResNet-18, ShuffleNet, SqueezeNet, AlexNet and GoogleNet models among the deep convolutional neural network (ESN) models for the detection of early leaf blight (*Alternaria solani* Sorauer), late leaf blight (*Phytophtora infestans* (Mont) de Bary) and Septoria leaf spot (*Septoria lycopersici* Speg) on tomato. The data set in the analyses is divided into 15% test data, 15% validation and 70% training. The accuracy rates of the models were 81.79%, 94.82%, 94.29%, 93.93% and 95.18% for ResNet-18, ShuffleNet, SqueezeNet, AlexNet and GoogleNet respectively. As a result of the analyses, GoogleNet was found to be the best performing of the pre-trained networks. Soydan and Taner (2022) used a total of 250 images, both ground and aerial for the identification of rice blight (*Pyricularia oryzae* Cav.) (Figure 11) using image processing techniques. The Levenberg-Marquardt training algorithm was used to train the neural networks, and the MCITG and MCRITD models were preferred to classify. The success rates of the MCITG and MCRITD models were 92.2% and 100% respectively. As a result, the applicability and effectiveness of the proposed method were determined. Ökten and Yüzgeç (2022) used a convolutional neural network (DNN), one of the machine learning methods for disease detection, to check for disease in rice plants. 5000 data sets of the leaves of the paddy plant were obtained from the Kaggle website. A total of two classifications were used for disease detection: infected plants with brown spot or leaf blight of rice and healthy plants. By modifying the hyperparameters of the ESA for disease detection, they achieved a success rate of 91.54%. The researchers obtained a total of 8000 images from the images in the dataset by means of a data augmentation method. After training on images for ESA, the success rate increased to 94.87%, and after training with ESA by preprocessing on the images in the dataset, this rate increased to 97.57%.

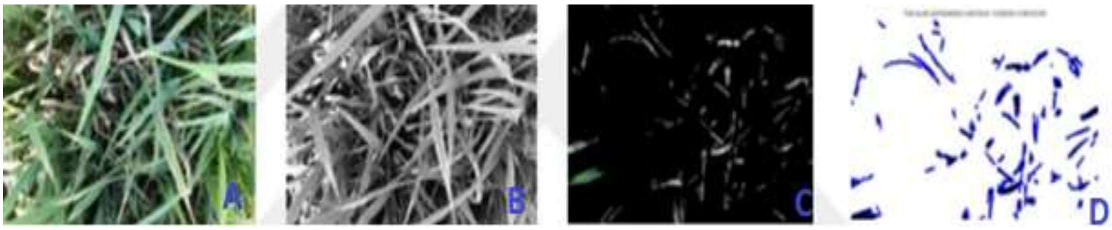

Figure 11. Disease symptom on the leaves (A) and segmentation according to colour characteristics (B, C, D) of rice blight caused by *Pyricularia oryzae* (Soydan and Taner, 2022).

Altaş et al., (2023), used faster R-CNN Model, which is an artificial intelligence approach, to detect and categorise some fungal diseases in vineyard, such as powdery mildew (*Uncinula necator* Schw, Burr.) (Figure 12 B), downy mildew (*Plasmopara viticola* Berk. Et. Curt, Berl et de Toni) (Figure 12 C) and Phomospis cane and leaf spot (*Phomopsis viticola* Sacc.) (Figure 12 D) in grapevine. They programmed with a total of 11000 images and compared them with healthy plants(Figure 12 A). As a result of the study, the accuracy rates of the diseases were calculated as: powdery mildew 95.83%, powdery mildew 96.61%, dead arm 97.12%. It is found that the proposed approach gives better results than other methods in the literature.

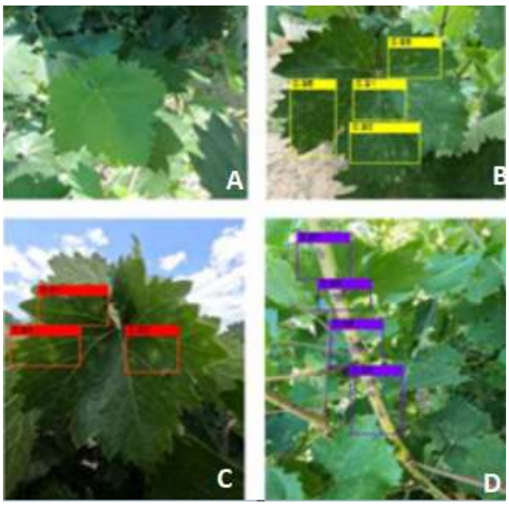

Figure 12. The process of applying the deep learning model A: healthy plant, B: powdery mildew (*Uncinula necator* Schw., Burr.), C: mildew (*Plasmopara viticola*

Berk. Et. Curt, Berl et de Toni), D: Phomospis cane and leaf spot (*Phomopsis viticola* Sacc.) (Altaş et al., 2023).

CONCLUSIONS

A review of previous studies shows that image processing techniques have been applied to many diseases, pests and weeds in the context of crop protection. However, in some cases, symptoms caused by abiotic or biotic factors may be confused and laboratory tests are required to make a definitive diagnosis. This highlights the importance of multidisciplinary studies. It is believed that researchers using imaging techniques will improve the quality and accuracy of their studies using the opinions of experts in the field of agriculture. Photographs taken in the field have been used with great success to identify plant samples under controlled conditions. However, when used in open terrain, success rates drop, so it is thought that the accuracy of the studies will increase as more use is made of the developing drone technology. To facilitate future studies, the number of data libraries on plant fungal diseases should be increased and studies should be given all kinds of support and assistance to keep up with the technological times in which we live.

ABSTRACT

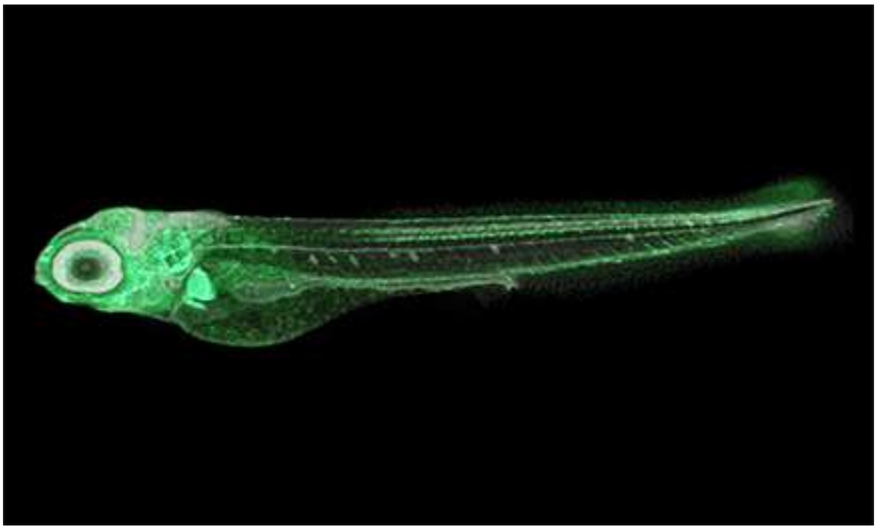
Various animal species have important roles as experimental models to advance biomedical research. Animal models play an important role in ensuring the consistency and validity of research results obtained from in vitro studies or studies with rodents. Today, zebrafish are considered a suitable model to investigate development, genetics, immunity, behaviour, physiology and nutrition. *Danio rerio,* the Latin name for zebrafish, formerly *Brachydanio rerio,* is a small tropical freshwater fish originating from the Ganges River and its tributaries in northern India. The annual number of publications on zebrafish as a model for biomedical research has increased significantly in recent years. The most advantageous features of zebrafish are its fully sequenced genome, easy manipulation of its genome, high fecundity, short generation time (about 3 months), rapid embryonic development (24 hours) and external fertilisation. The translucent zebrafish embryo allows the study of different developmental stages starting from the early stage of embryogenesis. Furthermore, zebrafish embryos form complete organ systems, including heart, intestine and blood vessels, within 48 hours after fertilisation. More than 10,000 mutants in protein-coding genes have been produced and several transgenic zebrafish lines have been constructed to study human diseases. The large number of zebrafish species available is another important advantage of this species. In addition, it is very economical to keep large numbers of zebrafish in a relatively small amount of laboratory space. In this review, information on the use of zebrafish as a bio-medical model, especially in areas related to diet-related diseases, metabolic disorders, liver diseases and intestinal diseases in humans, is compiled.

Keywords: Biomedical model, Metabolic disorders, Zebrafish

INTRODUCTION

For more than 200 years, fish have been used as model organisms by researchers. In this context, the oldest model species is the goldfish (Carassius auratus). Goldfish have primarily been used for applied studies in aquatic toxicology. However, other fish species such as zebrafish (*Danio rerio*), medaka (*Oryzias latipes*), roach (*Rutilus rutilus*), three-spined stickleback (*Gasterosteus aculeatus*), pufferfish (*Takifugu rubripes*), and swordtail (*Xiphophorus hellerii*) have also been utilized in research (Ribas & Piferrer, 2014). Each fish species has its own unique advantages and disadvantages. For example, goldfish have been used in research on growth, stress, immunology, and reproduction. Medaka fish have become popular as a model species for genetic, reproductive, and developmental studies. In recent years, the use of zebrafish as a model organism has increased due to its suitable characteristics (Kutluyer and Aksakal, 2013).

The most advantageous features of zebrafish include: a fully sequenced genome, ease of genome manipulation, high fertility, short generation time (about 3 months), rapid embryonic development (24 hours), and external fertilization. The transparent zebrafish embryos allow for the study of different developmental stages from the early stages of embryogenesis (Figure 1). Additionally, zebrafish embryos develop complete organ systems, such as the heart, intestines, and blood vessels, within 48 hours of fertilization.



More than 10,000 mutants have been produced in protein-coding genes, and various transgenic zebrafish lines have been developed to study human diseases (Howe et al., 2013). The availability of numerous zebrafish strains and their economic maintenance in the laboratory are other significant advantages of this species. Despite its importance as a biomedical model, zebrafish have some limitations. For example, some organs, such as the respiratory and reproductive systems, do not completely overlap with human organs. Thus, using zebrafish as models for human respiratory or reproductive systems can be challenging. Additionally, because zebrafish live in an aquatic habitat, screening for some water-soluble drugs is another limitation (Song et al., 2016).

Various human diseases have been successfully modeled in zebrafish, including Duchenne muscular dystrophy, human melanoma, acute lymphoblastic leukemia, polycystic kidney disease, nephronophthisis, acute kidney disease, Parkinson's disease, Huntington's disease, Alzheimer's disease, myocardial infarction, and some metabolic disorders. This review focuses on common human metabolic diseases that have been successfully modeled in zebrafish, including obesity, type II diabetes mellitus, non-alcoholic steatohepatitis, and atherosclerosis (Gut et al., 2017).

General Characteristics of the Zebrafish

The scientific name of the zebrafish is *Danio rerio*, and it was previously known as *Brachydanio rerio*. This species is a small tropical freshwater fish native to the northern parts of the Ganges River and its tributaries in India (Tavares and Santos Lopes, 2013). In their natural habitats, zebrafish are typically found near the bottom of the water to minimize the risk of predation. The morphology of male and female zebrafish is illustrated in Figure

1.

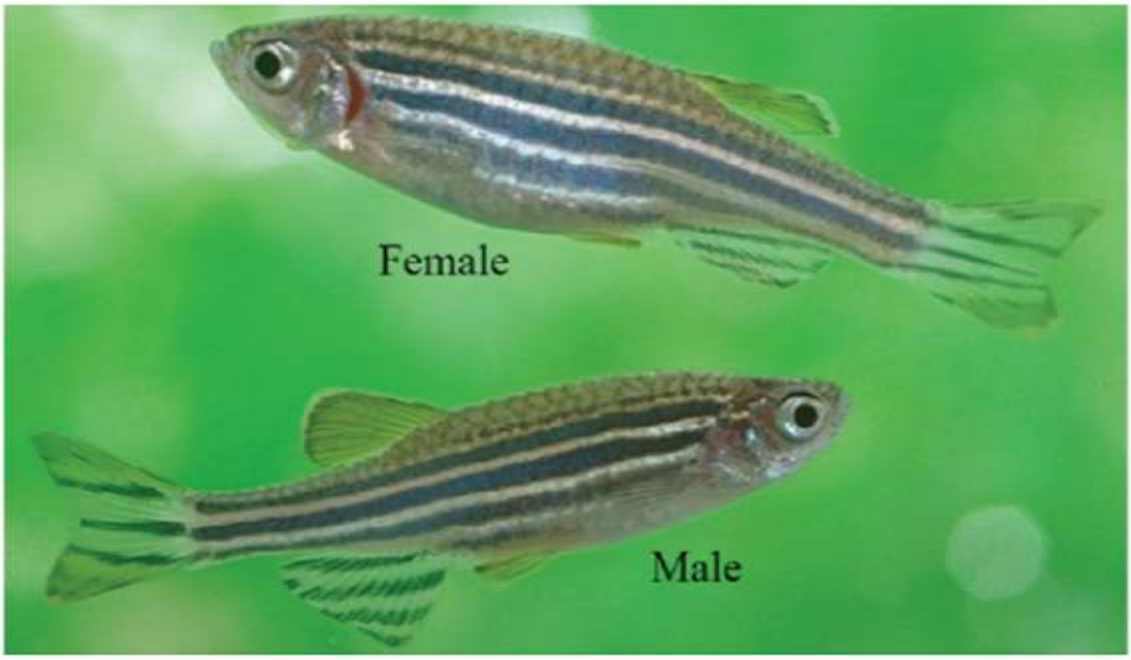


Figure 1. Adult male and female AB strain of zebrafish

Zebrafish Species and Research Usage

Despite the existence of numerous zebrafish species worldwide, the most commonly used varieties in biomedical research include AB, Casper, Ekkwill, Nadia, Wild Indian Karyotype, wild-caught, and Tubingen strains. According to the ZFIN website, over 800 biology laboratories around the world are conducting fundamental and applied research with zebrafish (https://zfin.org/search?q=Zebrafish+lab+oratories&category). In many of these laboratories, zebrafish are used to study human diseases such as neurological disorders, cancer, infectious diseases, cardiovascular diseases, kidney diseases, diabetes, blindness, deafness, digestive disorders, hematopoiesis, and muscle disorders (Figure 2).

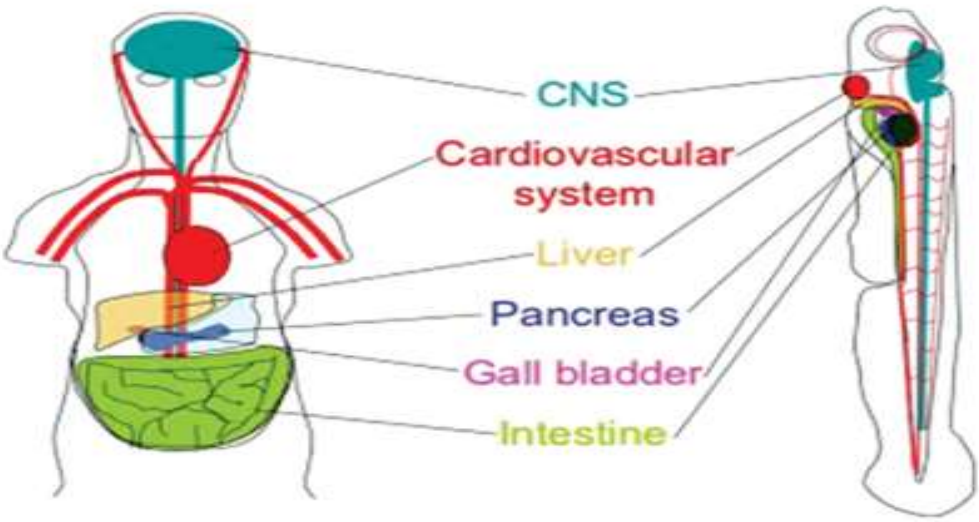

Figure 2. Some of the conserved organ systems between zebrafish and humans

Mutant zebrafish are created by knocking out specific genes, thereby generating new biomedical models. For instance, researchers interested in studying metabolic disorders can introduce different mutations in metabolism-related genes in zebrafish and track changes in gene expression using various molecular techniques. The short generation time of zebrafish complicates the production of stable transgenic adults or homozygous mutant embryos, often taking around 4 months. Recently, scientists have developed several technologies to accelerate the transgenic process (Burger et al., 2016). However, the presence or absence of genomic duplication events in zebrafish can complicate the study of certain human diseases.

Zebrafish as a Model for Metabolic Diseases

The disruption of the normal process of converting food into energy within cells can lead to various metabolic disorders. Although zebrafish (*Danio rerio*) have dietary requirements that differ from humans, they are considered a suitable model organism due to the conservation of many metabolic mechanisms. Various organs, such as the brain, intestines, liver, skeletal muscle, and adipose tissue, play roles in maintaining the balance between energy production and consumption. Zebrafish are particularly useful for studying metabolic dysfunctions due to their conserved lipid storage system and their ability to regulate appetite and insulin (Nishio et al., 2012).

According to the World Health Organization, cardiovascular diseases are currently among the leading fatal metabolic disorders (Lozano et al., 2012). Obesity (Ng et al., 2014), type 2 diabetes mellitus, and non-alcoholic fatty liver disease (LaBrecque et al., 2014) increase the risk of cardiovascular diseases. Zebrafish, with their similar metabolic organs such as digestive organs, adipose tissue, and muscles, are popular for studying metabolic disorders. Additionally, new tools and approaches, such as TALENs, CRISPR/Cas9 (Wu et al., 2018), compound therapies (Poureetezadi et al., 2016), mass spectrometry-based polar metabolomics and lipidomics (Zhang et al., 2018), and in vivo imaging with fluorescent dyes (Minchin et al., 2018), enable researchers to explore the molecular mechanisms of metabolic processes in zebrafish. Researchers have used zebrafish to study various metabolic diseases, including congenital metabolic errors, hyper and hypothyroidism, hypothalamic-pituitary-adrenal axis disorders, circadian rhythm disruptions, and cancer metabolism (Gut et al., 2017).

Zebrafish as a Model for Diet-Induced Obesity

The primary cause of diabetes mellitus is the inability of pancreatic β-cells to produce insulin, resulting in insulin deficiency. These functions and processes show similarities between zebrafish and humans. Zebrafish rapidly develop obesity and obesity-related diseases when exposed to hypercaloric and high-fat diets, activating metabolic pathways similar to those in humans. When glucose is present in the diet, the pancreas produces insulin, which inhibits gluconeogenesis through the downregulation of genes involved. In the absence of glucose in the bloodstream, gluconeogenesis is induced by glucagon. Capiotti et al. (2014) found a 41% increase in fructosamine (glycated protein) levels in the eyes of zebrafish immersed in a high-glucose solution (111 mM) for 14 days, along with decreased mRNA levels for insulin receptors in the muscles and the development of hyperglycemia. Zang et al. (2017) developed a zebrafish type 2 diabetes mellitus model by overfeeding with a high-calorie diet (408 calories per fish per day). Gene expression profiling in the liver and pancreas indicated a shared pathway for type 2 diabetes mellitus development between zebrafish and humans.

Connaughton et al. (2016) examined the relationship between age and type 2 diabetes mellitus and noted that younger zebrafish (4 to 11 months old) developed hyperglycemia more slowly compared to older zebrafish despite increased glucose concentrations. The glucose concentration in homeostatic organs can be increased by immersing zebrafish embryos in a glucose solution. Gleeson et al. (2007) demonstrated that immersing adult zebrafish in a 1% glucose solution for 24 hours raised blood glucose levels up to 400 mg/dL. Zang et al. (2017) developed two transgenic insulin resistance models, including one with dominant-negative IGF-I receptor expression in skeletal muscle and another with liver-specific knockout of the insulin receptor gene using CRISPR/Cas9 (Yin et al., 2015). These results highlighted zebrafish as a suitable model for studying glucose-related human diseases. Marín-Juez et al. (2014) developed a zebrafish model for hyperinsulinemia by injecting recombinant human insulin into zebrafish larvae. These studies revealed upregulation of the negative immune modulator protein tyrosine phosphatase non-receptor type 6 in insulin-resistant larvae. Yang et al. (2018) found that mutant zebrafish with insulin receptor gene knockouts fed a high-carbohydrate diet (%41) exhibited symptoms similar to human lipodystrophy, including hyperglycemia, decreased growth hormone signaling, increased visceral adiposity, and fatty liver development. Glucose levels in zebrafish can be measured using two types of glucose meters designed for diabetic patients (Eames et al., 2010). Additionally, fasting can be used for postprandial glucose and intraperitoneal glucose tolerance tests. Various methods, such as q-PCR (Michel et al., 2016), insulin antibody staining (Kimmel et al., 2015), or semi-quantitative dot-blot (Olsen et al., 2012), are available for measuring insulin levels in zebrafish. Insulin sensitivity can also be assessed by intraperitoneal insulin injection in hyperglycemic zebrafish (Capiotti et al., 2014).

Zebrafish as a Model for Dyslipidemia and Atherosclerosis Diseases

Increased levels of cholesterol, triglycerides, or high-density lipoprotein cholesterol lead to dyslipidemia, which can result in atherosclerosis. Given the well-known dietary requirements of zebrafish, many researchers have created various models by modifying standard diets (e.g., feeding zebrafish high-fat diets to induce obesity, hyperglycemia, and dyslipidemia). Zebrafish fed a high-cholesterol diet show histopathological changes similar to those observed in human atherosclerosis (Fang and Miller, 2012). The formulation of high-cholesterol diets plays a crucial role in dyslipidemia studies (Oka et al., 2010). Miyares et al. (2014) used the stages of yolk metabolism in zebrafish embryos to define lipid and lipoprotein metabolism and demonstrated that the inclusion of exogenous fatty acids in the circulatory system was dependent on lipoprotein production.

Zebrafish Model for Non-Alcoholic Fatty Liver Disease and Other Liver Disorders

Non-alcoholic fatty liver disease (NAFLD) is characterized by excessive fat accumulation in the liver and is not related to excessive alcohol consumption. This condition can lead to steatosis, steatohepatitis, fibrosis, cirrhosis, and hepatocellular carcinoma. NAFLD is associated with insulin resistance, high-fat diets, drug-induced liver damage, and metabolic syndrome. Various studies have shown that zebrafish develop hepatic steatosis when exposed to hepatotoxic chemicals, starvation, or excessive dietary fat, cholesterol, or carbohydrates. These mechanisms are similar in zebrafish and humans. Interestingly, the first article on zebrafish development (Roosen, 1937) investigated the effects of different toxins, alcohol, and various levels of carbohydrate or fat diets on zebrafish embryos, larvae, and adult developmental stages. Applying toxins to fish tanks is a simple technique, making zebrafish a popular model for chemical screening mechanisms. The zebrafish liver closely resembles the human liver in cellular structure, function, and genetics. This observation has led researchers to use zebrafish for detailed embryological and genetic studies related to human liver development, as well as exploring potential treatments for liver disorders and diseases. Developing liver tumors in zebrafish using carcinogenic substances and comparing gene expression with human liver tumors emphasizes the significance of zebrafish as a biomedical model. Tonin et al. (2018) showed that zebrafish immersed in 6% fructose developed hepatic steatosis similar to symptoms seen in humans on a high-carbohydrate diet. Yang et al. (2019) demonstrated that overfeeding led to fatty liver development and accelerated carcinogenic processes. Additionally, the leptin hormone responsible for obesity was not regulated in oncogenic and overfed zebrafish. They found it possible to reduce muscle wasting phenotype by downregulating leptin signaling. The development of a mutated kazal liver gene in zebrafish has led scientists to investigate hepatic steatosis development and related molecular mechanisms. Furthermore, the development of gonzo mutant zebrafish has shown that sterol regulatory element-binding proteins mediate alcohol-induced hepatic steatosis (Passeri et al., 2009). Shimada et al. (2015) used a diet-induced obesity model in zebrafish liver to apply transcriptomic and proteomic methods to isolate genes responsible for hepatic steatosis. These studies revealed upregulation of fatty acid-binding protein 3 and transcription factors (E2F) in hepatic steatosis zebrafish. Howarth et al. (2013) developed two models using zebrafish to investigate steatosis caused by tunicamycin or ethanol, leading to liver failure. They prevented ethanol-induced steatosis by blocking the activation of sterol regulatory element-binding proteins using mutant zebrafish. These studies found hepatocyte dysfunction even without lipid accumulation. Imran et al. (2018) tested the role of membrane remodeling in hepatotoxicity using zebrafish larvae and found that exposure to benzo[a]pyrene and ethanol together caused in vivo hepatotoxicity through membrane remodeling. These findings have led scientists to develop treatments for non-alcoholic fatty liver disease and associated risk factors.

Zebrafish as a Model for the Study of Intestinal Diseases and Host-Microbe Interactions

The zebrafish intestine is a long, tube-like structure consisting of three main regions: the foregut, midgut, and hindgut, which folds twice in the abdominal cavity. The intestinal epithelium contains three different cell types: absorptive enterocytes, mucus-secreting goblet cells, and hormone-producing enteroendocrine cells. As zebrafish develop, the intestinal epithelium undergoes various changes, including differences in the composition of intestinal microflora (Sanders et al., 2019). The intestinal microbiota helps digest dietary components and contributes to maintaining homeostasis. Studying intestinal microbiota in zebrafish is a powerful tool for understanding the pathogenesis of intestinal diseases and host-microbe interactions. Additionally, zebrafish provide a suitable model for studying the effects of diet on the gut microbiome. By manipulating the diet of zebrafish, researchers can identify interactions between dietary factors, the gut microbiome, and the development of diseases such as irritable bowel syndrome, colitis, and colorectal cancer.

CONCLUSION

Thanks to its completely sequenced genome, high fertility, external fertilization, clarity of genetic manipulation, rapid development, and almost transparent embryos, the zebrafish is a superb model organism for biomedical research, including research into biological processes and diseases common to humans. Zebrafish have all major organs involved in the metabolism process and can be used to study various human metabolic disorders such as non-alcoholic fatty liver disease, type 2 diabetes, dyslipidaemia and other liver diseases. Zebrafish will continue to be an important biomedical model in the future with innovations and advances in molecular techniques.

ABSTRACT

The aim of the study was to evaluate the influence of the number of plants and the distance between the rows on the production of fodder pea. The experiment was conducted in 2020-2023. Fodder pea "Voskopoja" (landrace with the greatest spread in this area of Korçë district, Albania), was studied by applying three sowing densities (60, 80 and 100 seeds per 1 m^2), with three row spacings (20, 30 and 40 cm), in four replicates in 24 m^2 plots. The R factor, row spacing showed statistically significant influence on the number of seeds per pod, seed weight per pod and seed yield of fodder pea. Factor D planting density showed statistically significant effect on number of pods per plant, number of seeds per pod, seed weight per pod and seed yield of forage pea. The R x D interaction showed statistically significant effects on the number of seeds per pod, seed weight per pod and seed yield of forage pea. The number of plants and the distance between rows did not reflect significant changes in the weight of 1000 seeds. These factors did not reflect significant changes in protein content. This study showed that the interaction between the factors plant number and row spacing in winter pea modifies the yield of green mass, seeds, plant height and seed yield.

Keywords: Forage pea, Number of plants, Row spacing, Yield, Protein.

INTRODUCTION

Fodder pea "Voskopoja", named for its prevalence in the Voskopoja region, emerged from a selection of wild pea plants around 1980. This cultivar exhibits unique properties that make it particularly suitable for mountainous Mediterranean climates. Its most notable characteristic is its resistance to low temperatures, making it the only cultivar capable of autumn planting in these regions, particularly at altitudes exceeding 1200 meters. Farmers often cultivate "Voskopoja" alongside rye and potatoes, contributing to the overall sustainability of agricultural ecosystems in these challenging environments. (Mirzad et al., 2023)

Despite its resilience, "Voskopoja" faces challenges in maintaining consistent forage yields due to the fluctuating climatic conditions of mountainous Mediterranean regions. However, its ability to thrive in these harsh environments makes it an invaluable resource.

Leguminous crops like "Voskopoja" hold significant promise for diversifying food sources and enhancing the sustainability of agricultural systems, particularly in Europe. (Ditzler et al., 2021) No other annual legume demonstrates comparable resilience and adaptability to the ecological constraints faced by "Voskopoja".

The nutritional value of "Voskopoja" is substantial. As a forage crop, it serves as a valuable source of protein in livestock diets. Analyses reveal that "Voskopoja" contains approximately 25.04% crude protein and 48.54% starch. (Trupa et al., 2018) Further analysis of the grains indicates a composition of 84% dry matter, 26.8% protein, 2.3% fat, 14.1% cellulose, 48.7% non-nitrogenous extracts, and 8.1% ash. This rich nutritional profile underscores its significance as a high-quality feed source.

Beyond its use as green fodder, dry fodder, or fodder meal, "Voskopoja" seeds offer further versatility. Studies have demonstrated the positive effects of incorporating processed peas into dairy cow diets, highlighting their potential as a partial substitute for soy flour. (Volpelli et al., 2010)

The nitrogen-fixing capabilities of "Voskopoja" further enhance its value. Unlike other legumes, this cultivar does not form symbiotic relationships with nitrogen-fixing bacteria. Instead, it directly enriches the soil with approximately 80-100 kg/ha of biological nitrogen, acting as an excellent precursor for crops like wheat, barley, and rye. This natural fertilization process contributes to soil health and reduces reliance on synthetic nitrogen fertilizers. (Kumar and Goh, 2000)

The adaptability of "Voskopoja" extends to sloping terrains, where it maintains high productivity while mitigating erosion risks. This characteristic, coupled with its nitrogen-fixing abilities, positions it as a key player in promoting sustainable agricultural practices and reducing environmental impact. Moreover, its role in enhancing soil fertility through symbiotic nitrogen fixation significantly contributes to the sustainability of mountainous ecosystems, making it an exceptionally valuable crop for farmers in these regions. (Sallaku et al., 2016)

"Voskopoja" exhibits remarkable drought resistance, a crucial trait in rain-fed agricultural systems. (Kachout et al., 2021) Unlike other cultivars, its autumn planting allows for a period of intensive growth during the favorable temperatures of May and June.

Plant density is determined by the number of seeds planted per m^2. Plant density is one of the factors that affects the morphological and productive development of plants. From a biological point of view, the density of plants affects the competition between plants for lighting and food elements. Adequate plant density is also important against winter damage, especially for fall plantings. (Knott and Belcher, 1998)

The distance between rows is one of the important technical elements that affects the progress of plant development. The optimal distance between rows also varies between cultivars of the same species. It is conditioned by the different biological characteristics of the cultivars and by other agrotechnical factors. Cultivation of fodder pea "Voskopoja" in hilly lands and in the absence of irrigation is another element that shows influence. Therefore, it can only be determined experimentally.

Optimum density in fodder pea planting ensures better competitive ability with weeds by increasing interspecific competition.

Different plant density significantly modifies yield, plant height and number of pods/plant in forage pea. (Krizmanic et al., 2020), Yucel, 2013)

This study aimed to investigate how row spacing and planting density influence the yield of fodder pea "Voskopoja" in the Korçë district of Albania.

MATERIALS AND METHODS

Experimental Design and Site Description

This study, investigating the impact of row spacing and planting density on the yield of fodder pea "Voskopoja", was conducted over three consecutive years (2020-2023) in Trestenik, Devoll, Korçë, Albania (40°34'55"N; 21°01'36"E) at an altitude of 955 meters. The experiment was implemented on medium clay soil characterized by calculated fertility, utilizing a wheat-pea crop rotation system.

Fodder pea "Voskopoja" (landrace with the greatest spread in this area of Korçë district, Albania), was studied using a randomized complete block design with four replications. A total of nine treatment combinations were evaluated, encompassing three row spacings (20 cm, 30 cm, and 40 cm) and three planting densities (60, 80, and 100 seeds per m^2). Each plot measured 24 m^2 (2.4 m x 10 m), resulting in 12, 8, and 6 rows per plot for the respective row spacings. Seed quantities, based on a 1000-seed weight of 150g, were adjusted to 9g, 12g, and 15g per m2 for the corresponding planting densities. Planting was consistently carried out between September 20th and 30th throughout the experimental period.

Climatic Conditions

To assess the potential impact of climatic factors, particularly temperature and rainfall, on the experiment, monthly climate data were obtained from bulletins and publications of the Institute of Geosciences for the years 2020-2023. Additionally, to provide a broader context, climate data spanning the preceding decade (2013-2023) were analyzed. (Maho et al., 2023)

Analysis of the climate data revealed significant interannual variability in temperature and precipitation patterns. A consistent trend of increasing temperatures throughout the year was observed. However, no clear trend in precipitation amounts was discernible. This observed pattern of rising temperatures aligns with broader climate change trends observed over the past decade (2013-2023).

The period from April to June is particularly critical for plant productivity, as it encompasses key developmental stages such as flowering, pod set, and grain filling. During this period, average temperatures for the study years (2020-2023) were notably higher compared to the 30-year average (1991-2020). Specifically, average temperatures for May and June were 1.6°C and 0.3°C higher, respectively. Overall, the average temperature increase for the April-June period during the experimental years was 1.4°C above the 30-year average.

Monthly rainfall patterns during the April-June period also exhibited considerable variation. The highest cumulative rainfall for this period occurred in 2023, while the lowest was recorded in 2021.

Table 1. Weather conditions at the experiment site.

Field Observations and Measurements

To evaluate the influence of row spacing and planting density on plant development and yield, comprehensive field observations and measurements were conducted throughout the growing season.

Phenological Observations: Key phenological stages were monitored visually and recorded, including:

1. Planting date
2. Date of germination (beginning and complete)
3. Flowering (beginning and ending)
4. Seed maturation (beginning and complete)

The initiation of each phenological stage was defined as the point when 10% of the plants within a plot exhibited the characteristic, while complete stages were recorded when 75% of plants reached the specific stage. Flowering completion was documented when 90% of plants had finished flowering, and full seed maturation was defined as the point when 75% of plants had the majority of pods ripened.

Biometric Measurements: Biometric measurements were taken from designated plants **at full seed maturation to assess plant growth and yield components. These measurements** included:

1. Number of pods with seeds and without seeds per plant
2. Number of grains per plant
3. Height of the first pod from the ground
4. Pod length, width, and thickness
5. Number of grains per pod
6. Grain-to-pod ratio (in the analyzed plants)
7. Pea seed yield was determined at 14% moisture content.

Agronomic Practices: Consistent agronomic practices were applied across all experimental plots to ensure uniformity, with variations only in row spacing and planting density. Key practices included:

- **Tillage:** Soil tillage was performed at a depth of 25-30 cm, followed by milling to create a friable seedbed.

- **Basic Fertilization:** Prior to planting, 50 kg/ha of phosphorus (P) and 70 kg/ha of potassium (K) were applied as base fertilizers.

- **Planting:** Planting was conducted manually between September 20th and 30th at the designated row spacings and planting densities. Seeds were sown at a depth of 3-5 cm.

- **Cultural Practices:**

- **Weed Control:** Two to three weeding operations were performed at 10–12-day intervals, as field conditions allowed.

- **Supplementary Fertilization:** One application of supplementary nitrogen fertilizer (1 kg/ha) was applied during the second weeding. The specific fertilizer rate was determined based on soil nutrient analysis

Data analysis methods

Data were collected from the two-factor experiment in randomized complete blocks with four replications. Two-way analysis of variance (ANOVA) was used for statistical evaluation; while the significance of the results was verified with the HSD (honestly significant difference) Tukey test at the level of significance $\alpha = 0.01$ and 0.05.

RESULTS AND DISCUSSION

The influence of the factors taken in the study (factor number of plants and distance between rows) was evaluated after processing the experimental data collected in 3 years. At the same time, the change in plant productivity as a result of climatic factors was evaluated.

Pea Yield Components

Indicators of pea yield components were significantly influenced by both environmental conditions and agronomic practices, specifically row spacing and planting density. (Table 2).

The average number of pods per plant varied across the study years, ranging from 2.4 in 2021 to 2.79 in 2023. This variation aligns with the observed rainfall patterns during the April-June period, with 2023 receiving more favorable rainfall for pea production. This finding is consistent with previous research highlighting the critical role of rainfall during this key developmental period. (Karadaş and Ceyhan, 2023). Climatic characteristics, particularly precipitation during April-June when vegetative growth is most active, significantly influence pea yield components.

Climatic variations observed in this study led to significant changes in green mass yield, number of seeds per pod, and seed weight per pod. However, no significant differences were observed in the number of pods per plant or the weight of 1000 seeds. Similarly, (Prusinski and Borowska, 2022)found that rainfall distribution during the growing season was the most critical factor influencing pea yield component values.

Row spacing significantly impacted yield component traits. Wider row spacing (30 cm) resulted in a significantly higher number of pods per plant, seeds per pod, seed weight per pod, and 1000-seed weight compared to narrower spacing (20 cm).

Planting density also played a significant role in shaping yield components. The highest average number of pods per plant (3.17) was observed at a planting density of 60 plants per m^2. However, the highest values for the number of seeds per pod, seed weight per pod, and 1000-seed weight were recorded at a higher planting density of 80 plants per m^2.

Table 2. Pea yield components depending on row spacing and plant density across the years.

Factor		No. of Pods per Plant	No. of Seeds per Pod	Seed Weight per Pod (g)	Weight of 1000 Seeds (g)
	2021	2.4	3.35	0.491	146.6

2. No. of Seeds per Pod
3. Seed Weight per Pod (g)
4. Weight of 1000 Seeds (g)

Pea Seed Yield

In our study, data processing shows that the distance between rows has a significant effect on the yield of pea seeds. The plants show the highest seed productivity at a distance of 30 cm with 1148.7 kg/ha and the lowest at a distance of 20 cm with 869.3 kg/ha. At the width between the rows of 20 cm only resulted in an increase in the biomass yield of peas.

Planting density had a significant effect on plant productivity. The plants show the highest seed productivity at the planting density of 80 seeds/m2 and the lowest at the planting density of 60 seeds/m^2. The same position is taken by researchers Bitew et al, 2014 who emphasize that the space between and within the rows together leads to growth and decreases seed yield. (Inter and intra row spacing together leads to increase and decrease the seed yield)

Important changes in the yield of pea seeds also appear due to climatic factors. The change from year to year in temperature and precipitation showed significant changes in the yield of pea seeds. Significant differences are observed in the yield of pea seeds in terms of the interaction of the factors (R × D), distance between rows (R) and planting density (D).

The collected data were systematized for the purpose of statistical analysis. General data are presented in Table 3.

Table 3. Table of the influence of three factors: climate (Y), Row spacing factor (R), Planting density factor (D) on the yield of pea grains (kg/ha)

Factor Years (Y)	Factor Row spacing (R)	Factor Planting density (D)			Amount	Avarege
		60 seeds	80 seeds	100 seeds		
2021	20 cm	782	854	862	2498	832.6
	30 cm	944	1087	1045	3076	1025.3
	40 cm	823	957	914	2694	898
2022	20 cm	821	865	884	2570	856.7
	30 cm	996	1146	1124	3266	1088.7
	40 cm	860	1058	1032	2950	983.3
2023	20 cm	896	906	954	2756	918.7
	30 cm	1186	1430	1380	3996	1332
	40 cm	1167	1285	1204	3656	1218.7
Amount		8475	9588	9399	27462	9154.3
Avarage		941.7	1065.3	1044.3	3051.3	1017.1

To evaluate the related influence of the distance between the rows (R) and the planting density (D), the three-year experimental data obtained from the processing are presented in Table 4.

Table 4. Table of the influence of two factors on the yield of pea grains (kg/ha) Row spacing factor (R) and Planting density factor (D).

Factor Row spacing (R)	Factor Planting density (D)			Amount	Avarage
	60 seeds	80 seeds	100 seeds		
20 cm	833	875	900	2608	869.3
30 cm	1042	1221	1183	3446	1148.7
40 cm	950	1100	1050	3100	1033.3
Amount	2825	3196	3133	9154	3051.3
Avarage	941.7	1065.3	1044.3	3051.3	1017.1

Two-way analysis of variance (ANOVA) was used for statistical evaluation; while the significance of the results was verified with the HSD (honestly significant difference) Tukey test at the level of significance α = 0.01 and 0.05. The data analyzed with the ANOVA method are presented in Table 5.

Table 5. Effect of row spacing and planting density on the seed yield (kg·ha^{-1}) in 2021–2023

Factor		**Year**			**Mean**
		2021	**2022**	**2023**	
Row spacing (R)	20	832.6	856.7	918.7	869.3
	30	1025.3	1088.7	1332	1148.7
	40	898	983.3	1218.7	1033.3
Planting density (D)	60	849.7	892.3	1083	941.7
	80	966	1023	1207	1065.3
	100	940.3	1013.3	1179.3	1044.3
	Mean	918.6	976.2	1156.5	1017.1
	Y	**	**	**	**
	R	**	**	**	**
	D	**	**	**	**
	R × D	*	*	*	*

Values of a parameter followed by the same small letter in columns and big ones in rows did not differ significantly (ANOVA followed by Tukey's HDS test, $p < 0.01$ and 0.05). ANOVA results: * $p < 0.05$; ns, not significant.

Our study revealed a significant effect of both rows spacing (R) and planting density (D) on pea seed yield. The highest average seed yield (1148.7 kg/ha) was achieved with a 30 cm row spacing. Reducing the row spacing from 40 cm to 20 cm increased pea biomass yield but did not result in a corresponding increase in seed yield. This finding aligns with the observations of (Karadeniz and Bengisu, 2022), who reported similar results.

Factor D, Planting density also significantly influenced pea seed yield. The highest average seed yield (1065.3 kg/ha) was obtained at a planting density of 80 seeds/m^2.

Pea Protein Yield

There is no significant effect on average protein yield of pea by R factor row spacing and D factor planting density. The average protein content in pea grains for the years 2021-2023 was on average 26.8%.

DISCUSSION

Structural indicators of pea yield depended significantly on row spacing and planting density.

The average number of pods per plant was 4.6, and in 2023, the most favorable year in terms of April - June rainfall, it was higher than in the less favorable years 2021 and 2023, similar to pea seed yield. Favorable rainfall conditions affect seed yield, and number of seeds per pod and seed weight per pod.

The R factor, row spacing showed statistically significant influence on the number of seeds per pod, seed weight per pod and seed yield of fodder pea.

Factor D planting density showed statistically significant effect on number of pods per plant, number of seeds per pod, seed weight per pod and seed yield of forage pea.

The R x D interaction showed statistically significant effects on the number of seeds per pod, seed weight per pod and seed yield of forage pea.

According to (Salter and Williams, 2015), seed weight per plant in pea decreased regularly with increasing planting density which is consistent with our experimental data.

Among the many factors affecting pea grain yield, plant density and row spacing are important. (Bitew et al, 2014)Regarding the distance and number of plants with the best influence on the yield of pea grains, different researchers have different conclusions. We think that in this regard these conclusions are not contradictory since the yield of pea grains is significantly affected from cultivar qualities, planting time as well as climatic factors which show variability from area to area.

The optimal density of plants which is determined by the distance between the rows and the number of seeds sown from a biological point of view is explained by intra and inter competition between plants for light and food factors. (Sibhatu et al, 2016)

Therefore, it is very important for the production of legumes to find the optimal density of plants, where the competition between plants does not affect the yield reduction.

According to a wider row spacing of 60 cm resulted in a significantly higher number of pods/plants, compared to a 30 cm row spacing.

A lower plant density increased the number of pods/plants, and a higher plant density decreased the amount of pods/plant. (Ibrahim et al, 2019)

Reducing the distance of planting within the row, determined a higher plant growth, which can be explained by the competition of plants for light. Similar results were reported by (Yucel 2013)

Planting density had a significant effect on most structural components of pea yield. Number of pods, seeds per pod and seed weight per pod were significantly higher when peas were planted in 30 cm rows than in 20 and 40 cm rows.

CONCLUSIONS

Forage pea productivity is affected by several factors. Plant density and row spacing are the most important.

Plant density is determined by the number of seeds planted per m^2. Plant density is one of the factors that affects the morphological and productive development of plants. From a biological point of view, the density of plants affects the competition between plants for lighting and food elements.

The optimal distance between rows also varies between cultivars of the same species. It is conditioned by the different biological characteristics of the cultivars and by other agrotechnical factors. Cultivation of fodder pea "Voskopoja" in hilly lands and in the absence of irrigation is another element that shows influence.

Optimum density in fodder pea planting ensures better competitive ability with weeds by increasing interspecific competition.

The R factor, row spacing showed statistically significant influence on the number of seeds per pod, seed weight per pod and seed yield of fodder pea.

Factor D planting density showed statistically significant effect on number of pods per plant, number of seeds per pod, seed weight per pod and seed yield of forage pea.

The R x D interaction showed statistically significant effects on the number of seeds per pod, seed weight per pod and seed yield of forage pea.

ABSTRACT

This study investigated the effects of exogenous enzymes on the nutrient composition of fermented olive pomace in the solid-state fermentation method. The research was conducted in a 3 x 2 factorial experiment, with three different fermentation periods (3, 5 and 7 days), two different enzyme additions (yes, no) in each period, and five replicates in each group for a total of 35 samples, including the control group. Before fermentation, the olive pomace was ground to a particle size of 1 mm and added to the fermenter. Subsequently, 100 g of the ground olive pomace and 500 ml of distilled water were added to each fermenter. The enzyme used in this study comprises a combination of phytase, xylanase, and beta-glucanase. The enzyme was then added to a quantity of 1 g to each fermentation media and sterilized via UV light. 1 ml of the *L. acidophilus* culture (10^8 cfu/ml) was added to the sterilized fermenters. The inoculated samples were fermented at 30 °C for the specified duration (3–5–7 days). The study concluded that the nutrient composition of olive pomace was positively affected. Overall, crude protein and ether extract levels increased significantly ($P<0.001$). Additionally, a fermentation time x enzyme interaction was observed regarding nutrient composition ($P<0.001$). At the end of fermentation, the highest crude protein level was determined in fermented samples for three days with enzyme supplementation or five days without enzyme supplementation ($P<0.001$). The lowest crude fiber level was observed in the non-fermented sample ($P<0.001$). In contrast, the second lowest crude fiber level in the fermented samples was observed in the sample fermented for seven days without enzyme supplementation ($P<0.001$). The most effective fermentation time of olive pomace with *L. acidophilus* was three days with enzymes.

Keywords: Solid-state fermentation, olive pomace, *L. acidophilus*, enzyme

INTRODUCTION

Meat and meat products are essential protein sources for ensuring adequate and balanced nutrition for the human population. Due to global population growth, demand for meat products is projected to increase by approximately 58% (Makkar et al., 2014). Turkey's broiler chicken production is critical in meeting the rising global demand. However, the production rate must be increased to meet the increasing demand for broiler chickens. This increase will also result in an increased demand for feedstuffs. Furthermore, given that some feedstuffs used in animal nutrition are also used in human nutrition, it is vital to develop alternative sources.

In poultry production, feed costs represent approximately 60-70% of total costs. Using alternative materials and feed additives instead of the feedstuffs typically used in animal feeds can help reduce feed costs. Antibiotics, used as growth factors in broiler feeds, can increase the risks and leave residues in the product. Consequently, since 2006, various alternative additives have been developed to enhance performance in broiler chickens, protecting intestinal health and providing additives. Among these additives, the use of various raw materials classified as agricultural waste has been a topic of interest in recent years.

The olive (*Olea europaea*) is a plant species belonging to the olive family (*Oleaceae*). This tree, native to the Mediterranean climate, exhibits a shrub form or a structure that can reach a height of up to 10 meters. The plant exhibits a densely branched, spreading top and evergreen leaves. The global olive tree population is estimated to be approximately 900 million, distributed across 11 million hectares. This yields an average of 22 million tonnes of olives annually (FAO, 2023). The countries that produce the majority of olives are Spain, Italy, Greece, Turkey, Tunisia and Morocco.

Fermentation effectively increases nutrient availability in various feed materials, by-products, waste products, and medicinal plants (Altop et al., 2017; Altop et al., 2018; Güngör et al., 2021). This process involves the chemical change caused by microorganisms on organic matter, which results in an improved nutrient composition. Several studies have demonstrated that agricultural waste can be utilized in animal nutrition through fermentation, enhancing animal performance, and various other parameters (Wang et al., 2018; Saleh et al., 2021). Furthermore, fermentation has been demonstrated to enhance the properties and bioavailability of phytochemicals, which are responsible for the biological properties of plants. These include antioxidant, antimicrobial, and anti-inflammatory activity (Nawaz et al., 2011; Yang et al., 2012). This study investigated the effects of exogenous enzymes on the nutrient composition of fermented olive pomace in the solid-state fermentation method.

MATERIAL AND METHOD

The research was conducted in a 3 x 2 factorial experiment, with three different fermentation periods (3, 5 and 7 days), two different enzyme additions (yes, no) in each period, and five replicates in each group for a total of 35 samples, including the control group. The experimental plan of the research is presented in Table 1.

Table 1. Plan of the research

		Days			
		0 days	3 Days	5 days	7 days
Enzyme	With enzyme		Fermented with enzyme for 3 days	Fermented with enzyme for 5 days	Fermented with enzyme for 7 days
	Without enzyme	Control	Fermented without enzyme for 3 days	Fermented without enzyme for 5 days	Fermented without enzyme for 7 days

The olive pomace used in the study was obtained from a local business, and the samples were dried at 75 °C. The samples were stored at 4 °C until use in the study. The microbial inoculant, *L. acidophilus* (ATCC 4356), was obtained from the American Type Culture Collection (ATCC).

Before fermentation, the olive pomace was ground to a particle size of 1 mm and added to the fermenter. Subsequently, 100 g of the ground olive pomace and 500 ml of distilled water were added to each fermenter. To facilitate microbial growth, 85.5 g of nutritional salt (glucose:urea:(NH4)2SO4:peptone:KH2PO4:MgSO4.7H2O = 4:2:6:1:4:1) was added to 1 lt of distilled water (Cao et al., 2012). Subsequently, the samples were sterilized at 121 °C for 15 minutes. The enzyme used in this study was obtained from a private company and comprises a combination of phytase, xylanase, and beta-glucanase. The enzyme was then added to a quantity of 1 g to each fermentation media and sterilized via UV light.

L. acidophilus was incubated in a shaking incubator at 30 °C and 120 rpm for 48 hours using MRS broth (Güngör & Erener, 2020). Then, 1 ml of the L. acidophilus culture (10^8 cfu/ml) was added to the sterilized fermenters. The inoculated samples were fermented at 30°C for the specified duration (3–5–7 days). Once the fermentation process had been completed, dry matter, ash, crude protein, crude fiber, and ether extract analyses were conducted by Akyıldız (1984).

The data obtained from the research was subjected to analysis of variance using the GLM ANOVA/MANOVA procedure in the statistical software Statistica (1984) in a 3 x 2 factorial arrangement. This involved three fermentation periods (3, 5 and 7 days), two enzyme additions (yes or no), and a randomized-block design. Once the statistical significance of the differences between the groups had been established ($P < 0.05$), Tukey's HSD test was used to identify the specific group to which the difference applied ($P = 0.05$).

RESULTS AND DISCUSSION

The study concluded that the nutrient composition of olive pomace was positively affected. The results obtained were comparable to those reported by Altop et al. (2019). Overall, crude protein and ether extract levels increased significantly ($P<0.001$). Additionally, a fermentation time x enzyme interaction was observed regarding nutrient composition ($P<0.001$). The crude fiber level, which is an anti-nutritional factor, especially for monogastric animals, decreased ($P<0.001$), while the crude protein and ether extract levels increased ($P<0.001$). At the end of fermentation, the highest crude protein level was determined in fermented samples for three days with enzyme supplementation or five days without enzyme supplementation ($P<0.001$). The nutrient composition of feedstuffs is positively affected by the solid-state fermentation method (Wang et al., 2017; Altop et al., 2018). In a study by Li et al. (2020), soybean meal fermented with *L. acidophilus* demonstrated an increase in crude protein level, consistent with the results mentioned above. The reason for this increase is microbial protein production.

The lowest crude fiber level was observed in the non-fermented sample ($P<0.001$). In contrast, the second lowest crude fiber level in the fermented samples was observed in the sample fermented for seven days without enzyme supplementation ($P<0.001$). The increase in crude fiber in the fermented samples is attributed to the alteration in the nutrient composition of the olive pomace. In a study conducted by Güngör et al. (2017), it was reported that cherry kernels fermented with different subspecies of microorganisms affected the crude fiber levels in different ways. There may have been a relative increase in crude fiber rates due to a lack of microorganism-substrate compatibility or a decrease in other nutrients (carbohydrates).

CONCLUSION

Fermentation has been demonstrated to positively affect the nutrient composition of various agricultural wastes, including olive pomace. This process allows for the increased use of feedstuffs in diets while also conferring additional benefits due to the probiotic effects of microorganisms. This research also supports this result, as crude protein levels increased while ether extract levels were maintained and crude fiber levels decreased. The most effective fermentation time of olive pomace with *L. acidophilus* was three days with enzymes.

ABSTRACT

Antibiotic growth promoters have long been used in animal nutrition. However, this widespread and intensive use has led to the emergence of antibiotic-resistant bacterial species that threaten human health and life. For this reason, antibiotic growth promoters in poultry feeding have been banned in many countries, including the European Union, since 2006. The ban on antibiotics has led to aggravation of bacterial infections and decreased performance in poultry. For this reason, research has focused on finding natural antibiotic alternatives. For this purpose, various growth-promoting alternatives such as beneficial microorganisms (probiotics and prebiotics) and herbal additives and their extracts have been tested and used in the nutrition of poultry and livestock. Herbal additives, also known as phytobiotics, are phytochemical compounds and are substances obtained from the leaves, roots, seeds, flowers, buds, bark of plants or their extracts and have pharmacological effects. Leaves of olive and mulberry trees are among the plants used as phytobiotics in poultry feeding. In this study, we tried to give information about the studies in the last fifteen years on the use of tree-shaped olive and mulberry leaves, which are used as tea, in the nutrition of broiler diets.

Keywords: Olive leaf, mulberry leaf, phytobiotics, broiler

INTRODUCTION

Intensive use of antibiotics for animal nutrition has led to the emergence of antibiotic-resistant bacterial species. For this reason, the use of antibiotics for growth purposes in poultry feeding has been banned in many countries, including the European Union, since 2006 (Alagawany et al. 2020). After the ban, various growth-promoting alternatives such as beneficial microorganisms (probiotics and prebiotics), many plants, herbal additives and their extracts were tested as safe alternatives to antibiotics, and they began to be used as natural feed additives in the nutrition of poultry and farm animals (Abd El-Hack et al. 2017, 2022; Chen et al., 2019, Rahman et al., 2022). Phytogenic feed additives, among these feed additives, have a great potential in the poultry industry.

Phytogenic feed additives are natural plant-based feed additives used in animal nutrition and are obtained from herbs, spices, other plants and their extracts and essential oils. In other words, herbal supplements, also known as phytobiotics, are phytochemical compounds obtained from the leaves, roots, seeds, flowers, buds, bark or their extracts of plants and have been used in human medicine since ancient times and show pharmacological effects (Martel et al., 2020, Deminicis et al., 2021, Rafeeq et al., 2023). The chemical compositions of phytogenic feed additives vary significantly depending on the effects of climatic conditions, location where plants are grown, harvest stage, as well as storage conditions of different plant extracts. Phytogenic feed additives can also be defined as plant-derived compounds that are added to animal feed to increase animal productivity by improving host digestibility, increasing nutrient absorption, and ensuring the elimination of various pathogens from the animal intestine (Samantaray and Nayak, 2021).

OLIVE (*Olea europaea* L.) LEAF

Olea europaea L., which is an evergreen tree member of the Oleaceae family and covers a total area of 10.8 million hectares, is grown in 41 countries, especially in the Mediterranean basin. The leaves (An agricultural waste) are gathered throughout the year. Olive leaf has all same healthful qualities of olive oil without the fat and in higher concentrations. It has antioxidant properties that protect the body from the continuous activity of free radicals. Olive leaves, especially leaf extract, are used as additives in medicine, cosmetics and many food products. Olive tree is one of the plants that has attracted attention recently (Cayan and Erener, 2015). Olive leaf has many biological activities, including phenolics and flavonoids, as a low-cost essential source of antimicrobials. Over the past few decades, numerous studies involving green technologies have been conducted to isolate active compounds from olive leaves (Selim et al., 2022). Olive leaves are agricultural residues obtained from olive trees (*Olea europea* L.) during fruit harvest. Olive leaves are rich in phenolic compounds such as tyrosol and hydroxytyrosol, especially oleuropein (Silva et al., 2006, Jabri et al., 2017). Additionally, it has immunostimulating, antibacterial (Bisignano et al., 2001), antifungal, anti-viral (Fredrickson, 2000), anti-inflammatory, antibacterial activity (Korukluoğlu et al., 2010) and antioxidant properties (Mujić et al., 2011; Hamad , 2015) has various pharmacological properties.Addition of olive leaves to broiler mixes resulted in increased live weight and improved feed utilization (Fayed et al., 2009; Erener et al., 2020 and Lee-Huang et al., 2011).

El-Damarawy et al (2013) observed that the addition of 2.0% olive leaves to Mandarah chick rations improved performance and most of the immunological and biochemical properties.

MULBERRY (*Morus alba* L.) LEAF

The increasing costs of conventional feedstuffs like corn, soybean meal and fish meal for poultry diets is pushing to find less expensive alternatives. One possible feed alternative is tree fodder mulberry leaves (*Morus alba*). Mulberry belongs to the genus *Morus* contains 16 species family of Moraceae and 11 species are found in China. Genus Morus is one of such example that consists of over 150 species, among these *Morus alba* L. is dominant (Ustundag and Ozdogan, 2015). The mulberry plant (*Morus alba*) is a fast-growing shrub, deciduous perennial woody plant, and its leaves are utilized as the primary food source for silkworms. Mulberry grows well in the tropics and subtropics, and is reported to have excellent nutritional value. Mulberry leaves are very rich in protein (15-35%), minerals [2.42-4.71% calcium (Ca); 0.23-0.97% phosphorus (P)] and metabolizable energy (1130-2240 kcal/kg) with absence of or negligible anti-utritional factors. The amino acids composition of mulberry leaf meal indicates it is a good source of essential amino acids especially lysine 1.80% and leucine 2.58% (Al-Kirshi et al., 2009, Al-Kirshi et al 2013). Mulberry leaves and their extracts have been used in folk medicine due to their therapeutic properties, particularly for their anti-inflammatory, anti-diabetic, and antioxidant properties (Chen et al., 2019). The active components of mulberry leaves can also help regulate the antioxidant capacity of laying hens. Although mulberry leaves are widely used in poultry and livestock, their effects on growth, production performance, gut microbiota, and immunological parameters remain unclear (Geng et al.,2024). Its leaves are considered as a high-quality forage plant resource because of its phytosterols, flavonoids, alkaloids, polysaccharides and other bioactive substances. However, due to the high content of crude fiber in mulberry leaves and branches and the presence of anti-nutritional factors such as tannin, the excessive addition of mulberry leaves and branches may be affect the production performance and health of livestock and poultry (Ding et al., 2021).

CONCLUSION

The ban on the use of antibiotics in many countries due to their side effects on both poultry and humans has made the use of herbal natural growth promoters that do not have any negative effects important. In recent years, many studies have been conducted to evaluate the effect of various plants as alternatives to antibiotics on animal production performance and quality of products. Various parts, extracts and essential oils of plants are added to poultry feed to increase appetite, stimulate the secretion of endocrine and digestive enzymes, and stimulate antimicrobial, anti-inflammatory, antioxidative and immune activity. In this study, we tried to give information about the use of tree-shaped olives (*Olea europaea*) and mulberry leaves (*Morus* spp.), which are used as tea in the mixed feeds of broiler chickens, in the nutrition of broiler chickens. Different results have been obtained in studies on the use of olive and mulberry tree leaves. The difference between the results may be due to the doses of plant leaves used in the experiments, the geographical location where the plants are grown, the type of plant, the characteristics of the soil in which it is grown, weather conditions, altitude, season, harvest procedure, storage conditions, phenolic substance contents of the plants, physiological states of the animals, growing conditions and experimental approaches. Therefore, before deciding to use olive and mulberry leaves in the nutrition of broiler chickens, it is necessary to take into consideration the above-mentioned issues in order to get high efficiency from broiler chickens.

ABSTRACT

This study investigated the effects of exogenous enzymes on the nutrient composition of fermented black carrot pulp in the solid-state fermentation method. The research was conducted in a 3 x 2 x 5 factorial experiment. Three different fermentation periods were employed: 3-5 and 7 days. Two different enzyme additions (yes, no) were made in each period. Five replicates were conducted for each treatment group, with the total number of samples reaching 35, including the control group. Before fermentation, the black carrot pulp was ground to a particle size of 1 mm and added to the fermenter. To facilitate microbial growth, 85.5 g of nutritional salt (glucose:urea:(NH4)2SO4:peptone:KH2PO4:MgSO4.7H2O = 4:2:6:1:4:1) was added to 1 lt of distilled water. The samples were sterilized at 121 °C for 15 minutes. The enzyme used in this study was obtained from a private company and comprises a combination of phytase, xylanase, and beta-glucanase. The enzyme was then added to a quantity of 1 g to each fermentation media and sterilized via UV light. *L. acidophilus* was incubated in a shaking incubator at 30 °C and 120 rpm for 48 hours using MRS broth. Then, 1 ml of the *L. acidophilus* culture (10^8 cfu/ml) was added to the sterilized fermenters. At the end of the study, the nutrient composition of black carrot pulp exhibited a positive effect. Furthermore, a significant interaction between the factor of fermentation time and the enzyme was observed about the nutrient composition ($P<0.001$). The highest crude protein content was observed in the group that fermented for three days without adding an enzyme ($P<0.001$). The highest level of ash was observed in all samples that fermented for three and five days ($P<0.001$). The lowest level of crude fiber was observed in the non-fermented sample ($P<0.001$). The lowest level was observed in the fermented samples, specifically in the groups that seven days of fermentation without enzymes and three days without enzymes ($P<0.001$). The highest level of ether extract was observed in the non-fermented and Five-day fermented with enzyme addition samples ($P<0.001$).

Key Words: Solid-state fermentation, black carrot pulp, *L. acidophilus*, enzyme

INTRODUCTION

As indicated by Çenesiz et al. (2017), feed costs represent approximately 70% of the overall expenses associated with broiler breeding. In this context, the costs associated with feed significantly impact the rising prices of white meat and eggs. In light of these considerations, it is necessary to investigate the potential of utilizing alternative feedstuffs in broiler feeding. Agricultural waste has significant potential for animal nutrition, with many studies demonstrating its efficacy (Assis et al., 2004; Nazok et al., 2010).

The black carrot (Daucus carota ssp. sativus var. atrorubens Alef.) is a plant cultivated primarily for human consumption. Turkey is a significant producer of this crop (Kamiloglu et al., 2018). The black carrot, cultivated in our country to produce turnips, has been demonstrated to possess antioxidant and anti-inflammatory properties (Gajewski et al., 2007; Ahmad et al., 2019; Yoo et al., 2020). Additionally, it has been demonstrated that the compounds responsible for the carrot's pigmentation function as antioxidants (Chorong et al., 2007). The residue remaining after the squeezing process of black carrot is referred to as pulp and is regarded as agricultural waste in our country, contributing to environmental pollution. An examination of the nutrient content of black carrot pulp reveals the presence of 8-10% crude protein, 20-30% crude fiber, 0-2% ether extract, and 2-5% ash.

Furthermore, its structure's anthocyanins and phenolic compounds render it a highly promising feedstuff for use in animal nutrition. The high level of crude cellulose has a limiting effect, particularly in poultry nutrition. Accordingly, the quality of the feedstuff can be enhanced by implementing the solid-state fermentation method.

Solid-state fermentation (SSF) refers to microorganisms' growth and metabolic activity on moistened solid substrates devoid of free water (Mitchell et al., 2000). SSF enables the conversion of nutrients through the enzymatic interactions of microorganisms on waste material (Steudler et al., 2019). This process has been demonstrated to enhance the nutrient composition of plant material, reduce anti-nutritional compounds, and increase bioavailability. Solid-state fermentation has been demonstrated to improve the digestibility of waste material (Özlü & Altop, 2023) and increase the bioavailability of nutrients (Güngör & Erener, 2023). In studies of fermentation, bacteria, fungi, and yeasts, or combinations thereof, are typically used as inoculants (Adeyemi et al., 2008; Akinfemi, 2010; Ari & Ayanwale, 2012; Ari et al., 2012). This study investigated the effects of exogenous enzymes on the nutrient composition of fermented black carrot pulp in the solid-state fermentation method.

MATERIAL AND METHOD

The research was conducted in a 3 x 2 x 5 factorial experiment. Three different fermentation periods were employed: 3-5 and 7 days. Two different enzyme additions (yes, no) were made in each period. Five replicates were conducted for each treatment group, with the total number of samples reaching 35, including the control group. The experimental plan of the research is presented in Table 1.

The black carrot pulp used in the study was obtained from a local business, and the samples were dried at 75 °C. The samples were stored at 4 °C until use in the study. The microbial inoculant, *L. acidophilus* (ATCC 4356), was obtained from the American Type Culture Collection (ATCC).

Before fermentation, the black carrot pulp was ground to a particle size of 1 mm and added to the fermenter. Subsequently, 100 g of the ground black carrot pulp and 500 ml of distilled water were added to each fermenter. To facilitate microbial growth, 85.5 g of nutritional salt (glucose:urea:(NH4)2SO4:peptone:KH2PO4:MgSO4.7H2O = 4:2:6:1:4:1) was added to 1 lt of distilled water (Cao et al., 2012). Subsequently, the samples were sterilized at 121 °C for 15 minutes. The enzyme used in this study was obtained from a private company and comprises a combination of phytase, xylanase, and beta-glucanase. The enzyme was then added to a quantity of 1 g to each fermentation media and sterilized via UV light.

Table 1. Plan of the research

CONTROL	Enzyme -/1	Enzyme -/2	Enzyme -/3	Enzyme -/4	Enzyme -/5
3 Days	Enzyme +/3-1	Enzyme +/3-2	Enzyme +/3-3	Enzyme +/3-4	Enzyme +/3-5
	Enzyme -/3-1	Enzyme -/3-2	Enzyme -/3-3	Enzyme -/3-4	Enzyme -/3-5
5 Days	Enzyme +/5-1	Enzyme +/5-2	Enzyme +/5-3	Enzyme +/5-4	Enzyme +/5-5
	Enzyme -/5-1	Enzyme -/5-2	Enzyme -/5-3	Enzyme -/5-4	Enzyme -/5-5
7 Days	Enzyme +/7-1	Enzyme +/7-2	Enzyme +/7-3	Enzyme +/7-4	Enzyme +/7-5
	Enzyme -/7-1	Enzyme -/7-2	Enzyme -/7-3	Enzyme -/7-4	Enzyme -/7-5

L. acidophilus was incubated in a shaking incubator at 30 °C and 120 rpm for 48 hours using MRS broth (Güngör & Erener, 2020). Then, 1 ml of the *L. acidophilus* culture (10^8 cfu/ml) was added to the sterilized fermenters. The inoculated samples were fermented at 30°C for the specified duration (3–5–7 days). Once the fermentation process had been completed, dry matter, ash, crude protein, crude fiber, and ether extract analyses were conducted by Akyıldız (1984).

The data obtained from the research was subjected to analysis of variance using the GLM ANOVA/MANOVA procedure in the statistical software Statistica (1984) in a 3 x 2 factorial arrangement. This involved three fermentation periods (3-5-7 days), two enzyme additions (yes or no), and a randomized-block design. Once the statistical significance of the differences between the groups had been established ($P < 0.05$), Tukey's HSD test was used to identify the specific group to which the difference applied ($P = 0.05$).

RESULTS AND DISCUSSION

At the end of the study, the nutrient composition of black carrot pulp exhibited a positive effect. Furthermore, a significant interaction between the factor of fermentation time and the enzyme was observed about the nutrient composition ($P < 0.001$). The highest crude protein content was observed in the group that fermented for three days without adding an enzyme ($P < 0.001$). The highest level of ash was observed in all samples that fermented for three and five days ($P < 0.001$). The lowest level of crude fiber was observed in the non-fermented sample ($P < 0.001$). The lowest level was observed in the fermented samples, specifically in the groups that seven days of fermentation without enzymes and three days without enzymes ($P < 0.001$). The highest level of ether extract was observed in the non-fermented and five-day fermented with enzyme addition samples ($P < 0.001$). The findings align with those reported by Altop et al. (2019). In general, there was an increase in the levels of crude protein and crude fat. The nutrient composition of feedstuffs is enhanced by the application of the solid culture fermentation method (Wang et al., 2017; Altop et al., 2018). In a study conducted by Li et al. (2020), the crude protein level of soybean meal fermented with *L. acidophilus* was observed to increase, a result that is consistent with the findings presented here. This increase can be attributed to microbial protein production. The observed increase in crude cellulose in the fermented samples can be attributed to alterations in the nutrient composition of the feedstuff. In a study conducted by Güngör et al. (2017), it was reported that the fermentation of cherry pits with different subspecies of microorganisms resulted in varying impacts on HS levels. It is possible that there was a relative increase in crude cellulose rates due to a lack of microorganism-substrate compatibility or a decrease in other nutrients (carbohydrates).

CONCLUSION

Fermentation has been demonstrated to positively impact the nutrient composition of various agricultural waste materials, including black carrot pulp. The optimal fermentation period for black carrot pulp with *L. acidophilus* was three days without enzyme.

ABSTRACT

This study investigated the effects of exogenous enzymes on the nutrient composition of fermented sunflower seed hulls (SSH) in the solid-state fermentation method. The research was conducted in a 3 x 2 x 5 factorial experiment. Three different fermentation times (3-5 and 7 days) and two different enzyme additions (yes, no) were made in each replicate. Five replicates were conducted for each treatment group, with the total number of samples reaching 35, including the control group. Before fermentation, the SSH was ground to a particle size of 1 mm and added to the fermenter. The samples were sterilized at 121 °C for 15 minutes. The enzyme used in this study was obtained from a private company and comprises a combination of phytase, xylanase, and beta-glucanase. The enzyme was then added to a quantity of 1 g to each fermentation media and sterilized via UV light. *L. acidophilus* was incubated in a shaking incubator at 30 °C and 120 rpm for 48 hours using MRS broth. Then, 1 ml of the *L. acidophilus* culture (10^8 cfu/ml) was added to the sterilized fermenters. The research findings showed that the nutrient composition of SSH was improved through solid-state fermentation with enzymes. This enhancement led to an increase in crude protein levels and a notable decrease in crude fiber levels. Notably, a significant relationship between fermentation time, enzyme utilization, and all parameters was observed ($P < 0.001$). The sample fermented for five days with enzymes exhibited the highest crude protein and lowest crude fiber levels ($P < 0.001$). Conversely, the non-fermented sample had the highest crude fat levels ($P < 0.001$). . This study confirms increased crude protein and reduced crude fiber levels after fermentation. The ideal fermentation period for SSM with *L. acidophilus* is five days, supplemented with enzymes.
Key Words: Solid-state fermentation, sunflower seed hulls, *L. acidophilus*, enzyme

INTRODUCTION

The sunflower (*Helianthus annus* L.) is a plant that is cultivated under a variety of environmental conditions and utilized in the production of numerous products, including oil, meal, and biodiesel (Kallivroussis et al., 2002; Yegerov et al., 2019). One of the byproducts of these products is sunflower seed husk (SSH). It is utilized as agricultural waste in worldwide (Casoni et al., 2019). In Turkey, the husk is used as a solid fuel or as an alternative to straw for animal feeding.

The nutritional value of sunflower seed husk (SSH) is considerably lower than that of sunflower seed meal (SSM). The nutrient content of SSH varies according to the method of obtaining it, just like SSM (Golob et al., 2008). The crude protein level is between 4 and 8 percent, while the crude fiber content is between 50 and 55 percent (Cancalon, 1971). Although these fiber levels represent an alternative feedstuff for ruminant animals, their low protein content limits their use. Furthermore, its use in poultry nutrition is also very limited (Kasaeizadeh et al., 2024). Given these considerations, it is important to identify and implement strategies for utilizing such agricultural byproducts in animal nutrition, particularly in light of their environmental impact (Xie et al., 2016). One such method is solid-state fermentation (Mitchell et al., 2000).

The term "solid-state fermentation" refers to the biological and chemical activities of microorganisms on various substrates under suitable environmental conditions (temperature, pH, humidity, etc.) (Steudler et al., 2019). The microorganisms used are typically probiotic, which confers advantages to raw materials in numerous ways (Adeyemi et al., 2008; Akinfemi, 2010; Ari & Ayanwale, 2012; Ari et al., 2012; Güngör & Erener, 2023; Özlü & Altop, 2023). Consequently, solid-state fermentation enables the recycling of raw materials classified as waste and possessing nutritional properties (Altop et al., 2022). This study aimed to investigate the effects of exogenous enzymes on the nutrient composition of fermented SSH in the solid-state fermentation method.

MATERIAL AND METHOD

The study conducted a 3 x 2 x 5 factorial experiment involving three fermentation periods - 3, 5, and 7 days. Each period had two enzyme addition options: yes or no. For each treatment group, there were five replicates, giving a total of 35 samples, including the control group. Refer to Table 1 for the experimental layout.

Table 1. Plan of the research

CONTROL	Enzyme -/1	Enzyme -/2	Enzyme -/3	Enzyme -/4	Enzyme -/5
3 Days	Enzyme +/3-1	Enzyme +/3-2	Enzyme +/3-3	Enzyme +/3-4	Enzyme +/3-5
	Enzyme -/3-1	Enzyme -/3-2	Enzyme -/3-3	Enzyme -/3-4	Enzyme -/3-5
5 Days	Enzyme +/5-1	Enzyme +/5-2	Enzyme +/5-3	Enzyme +/5-4	Enzyme +/5-5
	Enzyme -/5-1	Enzyme -/5-2	Enzyme -/5-3	Enzyme -/5-4	Enzyme -/5-5
7 Days	Enzyme +/7-1	Enzyme +/7-2	Enzyme +/7-3	Enzyme +/7-4	Enzyme +/7-5
	Enzyme -/7-1	Enzyme -/7-2	Enzyme -/7-3	Enzyme -/7-4	Enzyme -/7-5

SSH, sourced locally, was dried at 75°C and stored at 4°C until the study. *L. acidophilus* (ATCC 4356) was procured from the American Type Culture Collection (ATCC) as the microbial inoculant.

Prior to fermentation, the SSH was ground to a 1 mm size and placed in the fermenter, along with 100 g of the pulp and 500 ml of distilled water in each. Microbial growth was facilitated by adding 85.5 g of nutritional salt to 1 lt of distilled water. After sterilization at 121°C for 15 minutes, a blend of phytase, xylanase, and beta-glucanase enzymes from a commercial source was added to each fermentation medium and sterilized using UV light.

The *L. acidophilus* culture (at 108 cfu/ml) was incubated in MRS broth at 30°C and 120 rpm for 48 hours. Subsequently, 1 ml of the culture was added to the sterilized fermenters. The inoculated samples underwent fermentation at 30°C for 3-5-7 days. Post-fermentation, analysis for dry matter, ash, crude protein, crude fiber, and ether extract was carried out as per Akyıldız (1984).

Data from the study underwent analysis of variance utilizing the GLM ANOVA/MANOVA function in Statistica (1984) with a 3 x 2 factorial setup representing the three fermentation periods, two enzyme adoptions, and a randomized-block design. Upon establishing statistical significance ($P < 0.05$) among the groups, Tukey's HSD test identified the specific group with significant differences ($P = 0.05$).

RESULTS AND DISCUSSION

The research findings showed that the nutrient composition of SSH was improved through solid-state fermentation with enzymes. This enhancement led to an increase in crude protein levels and a notable decrease in crude fiber levels. Notably, a significant relationship between fermentation time, enzyme utilization, and all parameters was observed ($P < 0.001$). The sample fermented for five days with enzymes exhibited the highest crude protein and lowest crude fiber levels ($P < 0.001$). Conversely, the non-fermented sample had the highest crude fat levels ($P < 0.001$). Additionally, Chi and Cho (2016) noted a reduction in ether extract content in soybean meal fermented with *L. acidophilus*.

The main goal of fermentation studies on animal feeds is to lower crude fiber levels and boost crude protein levels (Wu et al., 2015). The rise in crude protein content is likely due to microbial protein production by microorganisms (Özlü & Altop, 2023). These results align with those of Hajimohammadi et al. (2020), who fermented sesame meal with S. cerevisiae and *L. acidophilus*, significantly increasing crude protein levels. Crude fiber components are structural carbohydrates in plant cell walls and are abundant in agricultural residues (Graminha et al., 2008). Crude fiber comprises cellulose, hemicellulose, lignin, pectin, and xylan compounds (Özlü & Altop, 2023). Decreasing these compounds enhances feed digestibility. Reducing crude fiber content in solid-state fermentation is achievable through enzymes like cellulase, hemicellulase, and β-glucosidase (Wu et al., 2015). Enzymes and microorganisms achieve this reduction (Chuang et al., 2019; Maiorano et al., 2022).

CONCLUSION

Fermentation enhances the nutrient composition of agricultural wastes like SSM, promoting better feed utilization and offering probiotic benefits. This study confirms increased crude protein and reduced crude fiber levels after fermentation. The ideal fermentation period for SSM with *L. acidophilus* is five days, supplemented with enzymes.

DESIGN AND IMPLEMENTATION OF AN AUTONOMOUS PC POWER MANAGEMENT SYSTEM

Mustafa ÇETİNGÖZ

Trakya University, Institute of Natural Sciences, Department of Computer Engineering, Edirne, Türkiye

Corresponding author e-mail: mustafacetingoz@trakya.edu.tr

ABSTRACT

This paper presents a Autonomous Power Management System designed to reduce the energy consumption of PCs by automating the process of switching them on and off. The system comprises an access point (AP), a PC, and a mobile application. When a user enters the range of the AP, the mobile app automatically connects to it and sends a Wake-on-LAN (WoL) packet to wake up the PC. Upon powering on, a PC agent begins running, enabling smooth communication between the PC and the user's smartphone. When the user departs and communication drops, the PC agent initiates a sleep process after a predefined timeout period. This system operates autonomously, without user intervention, and contributes to significant energy savings.

Keywords: Power management, Energy saving, Wake-on-LAN, PC agent, Mobile application

INTRODUCTION

The global demand for electricity has risen sharply due to factors such as population growth, urbanization, and the widespread use of electronic devices, raising concerns about energy security, environmental sustainability, and rising costs. Increased energy consumption has negatively impacted the environment through air and water pollution, greenhouse gas emissions, and climate change. As a result, many countries have adopted energy conservation and efficiency strategies as key policy objectives to reduce environmental harm and improve energy security (Otsuka, 2023). Governments are promoting energy-efficient technologies to encourage reduced consumption and lower greenhouse gas emissions (An et al., 2016). In this context, energy efficiency—defined as reducing energy use without compromising productivity—plays a crucial role in lowering energy bills, reducing grid strain, and protecting the environment. Technological advancements, such as smart energy management systems, provide significant opportunities to enhance efficiency, reduce costs, and promote sustainability (Pandiyan et al., 2023).

Various strategies have been proposed to reduce energy consumption, including the development of Home Energy Management Systems (HEMS), which allow users to optimize energy use in residential settings. HEMS help customers adjust energy consumption to reduce utility costs and enhance energy efficiency, while maintaining comfort and convenience (Liu et al., 2022). These systems manage electrical appliances based on variables such as energy costs, load profiles, and environmental considerations, scheduling device usage to minimize consumption during peak demand periods (Ben

Slama & Mahmoud, 2023). Smart plugs, a key component in these systems, offer a practical solution for monitoring and controlling appliance energy use. These devices can be remotely managed via smartphone apps or voice-activated assistants, providing a simple means to reduce energy waste (Shakeri et al., 2020). A key benefit of using a smart plug is switching off appliances when on stand-by or unused, thus reducing energy consumption.

Numerous studies in the literature have explored smart home energy management systems and smart plugs. Horvat et al. proposed a BLE-enabled smart plug solution to control household devices and monitor energy consumption via mobile devices, eliminating the need for a gateway (Horvat et al., 2015). Thongkhao et al. introduced a Wi-Fi-based smart plug system controlled through a web application, demonstrating high accuracy in energy measurement for reliable management (Thongkhao & Pora, 2016). In an office environment, Choi et al. utilized BLE beacons to detect user presence, automatically switching smart plugs on or off to manage energy consumption remotely. However, the system faced challenges with smartphone battery drain (Choi et al., 2015).

There have been a number of studies on the subject of PC power control over IP networks. The study introduces EnergySave, a sophisticated energy-saving system that utilizes the established Wake-on-LAN (WoL) protocol to enable the remote activation of PCs from a centralized management server (Ricciardi et al., 2013). Upon registration of a client PC, its IP and MAC addresses are stored on the server, facilitating secure and effective power management for both local and remote IP-based computer networks. The system's capabilities are further enhanced by the development of a mathematical model for energy savings, which allows for simulation-based assessments of the potential energy reductions achievable through its implementation.

This study (Byon et al., 2015) introduces a model of suspended mode combined with remote wake-up functionality aimed at reducing idle power consumption in PCs. This model is centered around a system architecture that includes components such as a Wakeup Server, network infrastructure, and PCs. The Wakeup Server plays a critical role by gathering detailed state information from connected PCs and sending Wake-on-LAN messages to initiate the wake-up process when necessary. The network device, operating at layer 2, is responsible for forwarding these WoL messages from the server to the respective PCs. Users can remotely interact with their PCs through the Wakeup Server, which enables them to wake up their devices from a suspended state and subsequently use them after the wake-up process is completed.

Polisave, as described in (Chiaraviglio & Mellia, 2010), is a client-server-based system that allows users to schedule the power states of their PCs, providing remote control over turning them on or off. The system provides users with the ability to power their PCs on or off interactively from a distant location. The client-side application installed on the PC periodically transmits information such as the IP address and MAC address to the server. The server then aggregates the status data from multiple PCs and responds with a message that specifies an action—such as hibernate, standby, power-off, or wait—along with the reporting interval. The shutdown process is initiated based on the server's instructions.

In this study, we developed an Autonomous Power Management System for PCs aimed at enhancing convenience, improving efficiency, and reducing energy consumption by automating the power control of PCs. The system consists of two key components: a smartphone application and a PC agent. The smartphone application scans for available Wi-Fi SSIDs, establishes a connection upon detection, and transmits a Wake-on-LAN packet to initiate the PC's power-on process. The PC agent enables communication between the PC and the smartphone application. Not only does this system save time by providing automatic power control without the need for an additional device, but it also reduces energy consumption by automatically turning off the PC when the user leaves the vicinity.

In the following section, a comprehensive overview of the Materials and Methods is provided, detailing the Wake-on-LAN network protocol that plays a critical role in the proposed system. This section also outlines the architectural components of the system. The subsequent section presents the experimental study and its outcomes. Finally, the paper concludes with a summary of key findings and a discussion of the system's implications.

MATERIAL AND METHOD

This section introduces the Wake-on-LAN network protocol, a key element in the proposed system for remotely powering on PCs. Additionally, the proposed system architecture is presented, which includes a mobile application and a PC agent, both working together to facilitate seamless control and communication between the user's smartphone and their PC.

2.1. Wake-on-LAN

To reduce PC power consumption, both active and idle time management strategies are applied. During low activity periods, methods such as lowering CPU voltage and clock frequency are employed. Additionally, operating systems like Linux and Windows use suspended modes to minimize idle time consumption. When a PC exceeds a defined idle period, it transitions to suspended mode, where key components, including the CPU and graphics card, are powered down, significantly reducing energy use. The two primary suspended states are "suspend to RAM" and "suspend to disk." In suspend-to-RAM, execution data is stored in memory, while most hardware components are powered off. In suspend-to-disk, data is saved to the disk. However, during suspension, PCs cannot respond to external network requests, requiring remote wake-up methods like Wake-on-LAN to ensure they can be reactivated when needed.

Wake-on-LAN is a network protocol that facilitates the remote activation of a personal computer. This feature allows a computer in a low-power state, such as sleep or hibernate, to be powered on via a network signal, eliminating the need for manual interaction. WoL operates through the computer's network interface card (NIC) and requires appropriate configuration within the motherboard's BIOS settings. When connected to a local area network (LAN) with WoL enabled, the NIC remains in a standby mode, continuously awaiting a "magic packet." This packet, containing the computer's unique Media Access Control (MAC) address, is sent by another device on the same network. Once the correct magic packet is received, the targeted computer is triggered to power on. Although the packet is broadcast to all devices on the network, only the machine with the corresponding MAC address will respond to the signal, initiating the power-up process.

2.2. Proposed System Archıtecture

This section outlines the architecture of the proposed Autonomous Power Management System for PCs, consisting of two primary components: a mobile application and a PC agent. The main architecture of the whole system is shown in Figure 1 and is designed to optimize the power management of computers in a home or office environment.

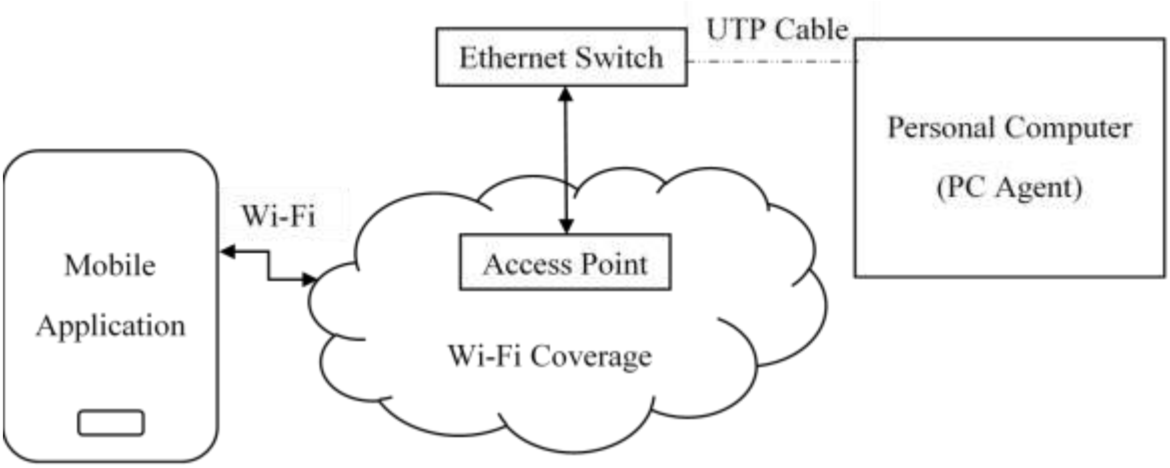

Figure 1. Architecture of autonomous PC power management system

2.2.1 Mobile application

Most modern smartphones support Wi-Fi technology and almost which is designed to drastically minimize battery usage during wireless communication. The mobile application developed in this study operates by scanning available Wi-Fi SSIDs in the background. Upon detecting a preconfigured SSID, the application attempts to establish a connection with the access point (AP). Once successfully connected, the app transmits a WoL packet to the target PC. Users have two options within the mobile app: to automatically initiate the power-on process or to power on the PC following user approval. The WoL packet includes critical network information, such as the IP address, MAC address, and subnet mask of the PC. Upon receiving the WoL packet, the PC initiates the power-on process and prepares to activate the PC Agent. Following the PC's power-up, the PC Agent is automatically launched and begins awaiting periodic heartbeat signals from the mobile application.

2.2.2 PC Agent

Personal computers (PCs) represent a significant proportion of IT devices in both office and home environments and are essential for users' daily tasks and overall productivity. In office settings, PCs and monitors offer substantial opportunities for energy conservation (Choi et al., 2015). The developed PC Agent operates in the background, continuously awaiting periodic heartbeat signals from the mobile application to confirm the device's active state. Upon receiving these signals, the agent acknowledges that the PC is functioning and communicates this status back to the mobile application.

The PC Agent monitors the regular receipt of heartbeat signals from the mobile app. In scenarios where the mobile app exits the Wi-Fi coverage area or disconnects from the network, the heartbeat timeout value increases incrementally. Once this value exceeds a predefined threshold, the PC Agent initiates the power-saving procedure, either by putting the system into sleep mode or triggering the hibernation process. This mechanism ensures energy efficiency by automatically reducing power consumption when the user is no longer in proximity. Main screen of PC Agent software is shown in Figure 2.

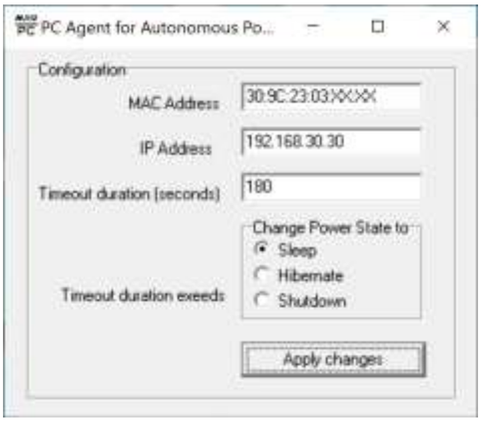

Figure 2. Main screen of PC Agent

EXPERIMENTAL STUDY AND RESULTS

The experimental study was conducted in a real-world office environment, involving five employees, each utilizing a personal computer (PC) for daily tasks. The office infrastructure featured an access point (AP) that provided Wi-Fi connectivity for mobile devices, while the PCs were connected to the network via UTP cables to ensure stable and fast data transmission. To facilitate the energy-saving mechanism, a PC Agent software was installed on each PC. Once the PC agent software had been installed, the PC's MAC and IP address information was recorded for input into the mobile application.

For mobile device integration, the mobile application was installed on each employee's smartphone. The app settings were configured using key details such as the Wi-Fi SSID, username, password, and the respective PC's MAC and IP addresses. Employees were instructed to run the mobile application continuously in the background. This mobile application ensured the smooth operation of the proposed autonomous power management system by communicating with the access point to detect the presence of the user and trigger PC power states accordingly.

The implemented system resulted in a fully automated process for managing the PCs' power states. When employees arrived at the office and their smartphones connected to the designated Wi-Fi network, the mobile application detected their presence and automatically sent a Wake-on-LAN packet, powering on the associated PCs. Conversely, when employees left the office, the application recognized the departure and initiated a shutdown process for the PCs, reducing idle power consumption and enhancing overall energy efficiency. This automated system demonstrated significant potential in optimizing energy usage in office environments.

CONCLUSIONS

This study introduces an Autonomous Power Management System aimed at minimizing PC energy consumption through automated control of power states. The system effectively integrates a mobile application, an access point (AP), and a PC, leveraging Wake-on-LAN technology to remotely activate PCs as users enter the AP's vicinity. Once activated, the PC agent facilitates seamless communication between the PC and the user's mobile device. When the user departs and communication ceases, the system autonomously transitions the PC into sleep mode after a preset period. This self-sustaining solution not only eliminates the need for manual intervention but also offers substantial energy savings by optimizing power states based on user presence.

A BLE-BASED MONITORING SYSTEM FOR WHEAT STORAGE

Mustafa ÇETİNGÖZ

Trakya University, Institute of Natural Sciences, Department of Computer Engineering, Edirne, Türkiye

Corresponding author e-mail: mustafacetingoz@trakya.edu.tr

ABSTRACT

In agricultural practices, wheats are sometimes stored in warehouses situated on farms or near residential areas. However, excessive moisture or water leakage within these storage environments can lead to the deterioration and mold growth of stored wheats, presenting significant challenges for their long-term preservation. If such issues are not promptly detected, they can result in severe degradation of wheat quality. This paper introduces the design and implementation of a temperature, humidity and CO2 control system to address these risks. The system consists of two primary components: Bluetooth Low Energy (BLE)-based sensor module and a mobile application. The sensor module periodically transmits temperature and humidity data, and owing to the low energy consumption of BLE technology, the module can function on battery power for more than one year. The mobile application receives the BLE broadcasts and stores the collected data. In the event of elevated moisture or temperature levels during storage, the application alerts the user, enabling timely corrective actions.

Keywords: Temperature control, Wheat storage, Humidity detection, BLE in agriculture, Mobile application

INTRODUCTION

Agriculture remains a cornerstone of many national economies, serving as a primary source of income for a significant portion of the population. In several countries, a substantial percentage of the economy is driven by agricultural activities, with wheat being one of the most essential crops. Wheat's versatility, used in producing bread, pasta, spaghetti, and numerous other food items, makes it one of the most widely consumed grains globally. Despite this, a significant portion of agricultural produce, including wheat, fails to reach consumers due to damage incurred during farming, transportation, or storage. One of the most critical challenges in maintaining wheat grain quality is the inability of farmers to detect early signs of moisture or fungal contamination, which promotes mold growth and leads to gradual spoilage. Beyond moisture and mold, pests such as worms and fungi also contribute to grain degradation, reducing the storage life of wheat. These issues often result in shortages of wheat-based products, leading to increased market prices and economic losses, which underscore the importance of effective monitoring systems for wheat storage.

Several storage methods, such as bags, warehouses, and silos, are used by both individuals and larger organizations to store grains. However, these solutions can be cost-prohibitive for small-scale producers and farmers. Many farmers opt to store their wheat in warehouses located on farms or near residential areas, often lacking the specialized knowledge required to establish optimal storage conditions. Effective monitoring and management of these grains are crucial to ensuring their longevity and reducing post-harvest losses. Therefore, improving storage supervision through better understanding and research is critical to addressing the ongoing global issue of grain loss after harvest.

The Internet of Things (IoT) refers to a network of interconnected objects that communicate wirelessly without requiring human intervention. IoT has found widespread application in agriculture, with precision farming being a key example of its significant impact on the industry (Dholu & Ghodinde, 2018). The development of IoT-based systems integrated with smartphone applications has proven to be an efficient and practical approach for addressing grain storage monitoring challenges. Beyond grain storage, IoT applications are utilized across various sectors, including indoor environmental monitoring (Assante & Fornaro, 2019), healthcare (Abdulmalek et al., 2022), traffic management (Soni & Saraswat, 2017), smart buildings (Jia et al., 2019), and smart cities (Brincat et al., 2019).

In agriculture, Bluetooth Low Energy (BLE), a key IoT technology, plays a critical role due to its low energy consumption, and there are many IoT-based studies in the literature. In (Kodali et al., 2020), a smart monitoring system was developed to enhance food storage and reduce wastage by using IoT technology. The system, detailed in the paper, integrates a microcontroller with various sensors to track temperature, humidity, and food quality across multiple stages, including the farm, processing plants, warehouses, and markets. Additionally, the system actively moderates the storage environment by controlling fans and cooling units to maintain optimal conditions. By following a first-in, first-out strategy, the system also minimizes food grain expiration and waste, thereby improving efficiency and sustainability in the food supply chain.

A study introduced an intelligent warehousing system that leverages RFID technology for automated data collection across various processes, including goods arrival, inbound and outbound deliveries, and transfers (Yang, 2019). This system enhances efficiency by integrating with ERP software, enabling real-time data management and reducing operational costs. A study focused on the safe storage of cereal grains, particularly for long-duration space missions, by addressing the risks of moisture-induced spoilage. It introduced a printed circuit board (PCB) capacitive fringing field sensor to detect moisture imbibed by corn kernels, as moisture can lead to germination, spoilage, or microorganism growth (Dean et al., 2019).

This paper outlines the design and implementation of a BLE-enabled smart grain storage monitoring system using an ESP32 microcontroller connected to a temperature and humidity sensor (DHT11) and a carbon dioxide sensor (MQ-135). The ESP32 microcontroller serves as the core of the system, broadcasting data through BLE. The second critical component is a smartphone application that receives these BLE broadcasts and alerts the user if any environmental data exceed predefined thresholds.

The following section of this paper addresses the materials and methods, with a focus on BLE technology, the ESP32 microcontroller, and the sensors utilized for monitoring humidity, temperature, and CO2. The subsequent section covers the experimental study.

MATERIAL AND METHOD

This section introduces Bluetooth Low Energy (BLE), a fundamental technology in the proposed system, designed for efficient data transmission with minimal power consumption. Additionally, it presents the key component of the system architecture, the ESP32 microcontroller, which functions as the core of the sensor module.

2.1. Bluetooth Low Energy Technology

Bluetooth Low Energy (BLE) is a wireless communication technology engineered to prioritize low power consumption, making it particularly suited for battery-operated devices. In contrast to other wireless technologies such as Wi-Fi and ZigBee, BLE's lower energy usage makes it ideal for applications in which power efficiency is critical. Although Wi-Fi typically offers a longer range, the coverage provided by BLE is adequate for many applications, especially in confined spaces like homes, offices, and other indoor environments. Smartwatches, PCs, tablets, smartphones, and other Internet of Things devices are just a few of the devices that use BLE technology. Low power consumption, low cost, and the use of simpler radio transceiver circuits are given top priority in the design of BLE technology (Shahzad & Oelmann, 2014).

Data and advertising are the two main types of radio frequency channels used by BLE (Taskin et al., 2018). Channels 0 to 36 are used for data transmission, while channels 37, 38, and 39 serve as advertising channels, which are employed for discovering devices, broadcasting data, and initiating connections (de Cerio et al., 2017). A key feature of BLE technology is its ability to transmit data via advertising without the need for establishing a dedicated peer-to-peer connection. These advertising packets, typically short and concise, enable rapid transmission while minimizing energy consumption. Adjusting the advertising intervals allows for a trade-off between power consumption and update frequency: shorter intervals provide more frequent updates at the cost of increased power consumption, while longer intervals conserve energy but reduce the update rate (Liu et al., 2013). Devices equipped with scanning capabilities can listen for these advertising packets and extract relevant information without requiring a formal connection, further enhancing BLE's efficiency in low-power environments.

2.2. ESP32 Microcontroller

The ESP32, developed by Espressif Systems and introduced in 2016, is a highly capable microcontroller that integrates both Wi-Fi and Bluetooth Low Energy (BLE) functionalities (Singh & Kapoor, 2017). Designed for use in mobile electronics, handheld devices, and Internet of Things (IoT) applications (Mishu et al., 2021), the ESP32 has become a popular choice for developers due to its versatility and power efficiency. Its wide range of low-power modes makes it particularly suitable for battery-operated devices, enabling developers to program the microcontroller to enter sleep modes and periodically wake up, thereby conserving energy. The ESP32 supports a broad array of peripheral interfaces, such as SPI, I2C, UART, and PWM, which allow for seamless integration with various sensors, displays, and external components.

2.3. Main Archıtecture of Wheat Monitoring System

The proposed monitoring system aims to continuously monitor environmental conditions within wheat storage facilities to safeguard grain quality and ensure safe storage. The system architecture is composed of two primary components: the sensor module and the mobile application. The sensor module is responsible for collecting environmental data such as temperature, humidity, and CO2 levels using integrated sensors. Meanwhile, the mobile application, compatible with BLE-enabled smartphones, serves as the user interface, receiving real-time data broadcasts from the sensor module. The system's overall architecture is depicted in Fig. 1, illustrating the interaction between the sensor module and the mobile app.

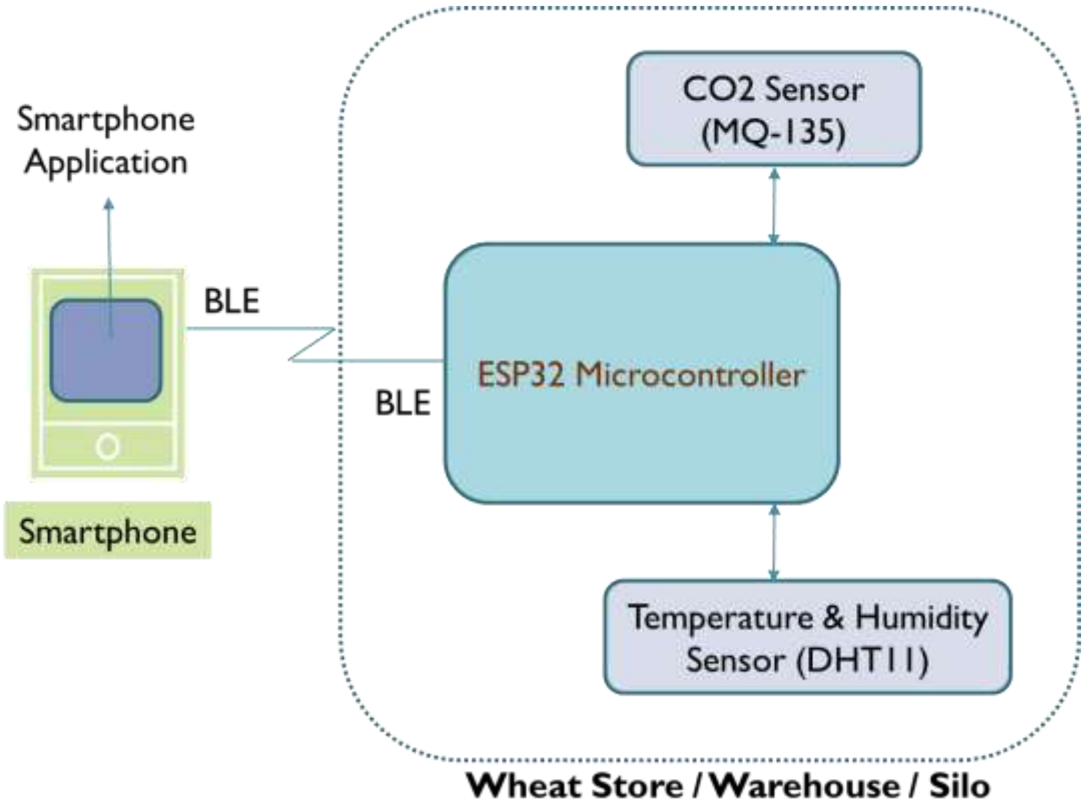

Figure 1. Architecture of wheat monitoring system

2.3.1 Sensor module

The core of the sensor module is the ESP32 microcontroller, which integrates a DHT11 sensor to measure temperature and humidity, alongside an MQ-135 sensor for detecting CO2 levels. These sensors enable the system to monitor environmental conditions that could potentially compromise the quality of stored wheat grain.

The DHT11 sensor, a low-cost solution for monitoring both humidity and temperature, has been integrated into the sensor module due to its ease of interfacing with the ESP32 microcontroller. The DHT11 operates within a temperature range of 0 to 50 degrees Celsius with an accuracy of ±2 degrees, while its humidity measurement capabilities cover a range of 20 to 80 percent relative humidity with a precision of ±5 percent. With a sampling rate of 1Hz, the sensor provides readings once per second, making it suitable for real-time monitoring in the proposed system.

Mold growth in stored grains can result in the emission of carbon dioxide (CO2), and similarly, pests such as rats, mice, and insects that consume the grains also release CO2 through respiration. To monitor such activity, the sensor module in the proposed system utilizes the MQ-135 sensor for CO2 detection. When elevated levels of CO2 are detected, indicating potential contamination or pest presence, the ESP32 microcontroller broadcasts this data wirelessly using Bluetooth Low Energy (BLE) technology, enabling real-time transmission to the user’s smartphone for prompt response. The BLE-based communication framework ensures efficient data transmission with minimal power consumption, making the system well-suited for long-term monitoring in storage environments.

2.3.2 Mobile application

The mobile application developed forms the other essential component of the proposed system architecture. Designed for BLE-enabled smartphones, the app receives

BLE advertising packets transmitted by the sensor modules, enabling continuous monitoring of environmental conditions. The app also incorporates a notification system that alerts users when temperature, humidity, or CO2 levels exceed predefined thresholds. If critical values are detected, the application sends an immediate alert to the user, ensuring timely action to safeguard the quality of the stored grain.

EXPERIMENTAL STUDY AND RESULTS

The prototype system was deployed in a wheat storage room located in a rural village, beneath the farmer's house. The farmer, who is typically occupied with daily activities such as cow feeding and other tasks in the garden, was provided with a smartphone that had the mobile application developed for this study installed. The farmer was instructed to keep the application running in the background to facilitate real-time data reception from the sensor module.

During the experiment, it was observed that the sensor module consistently transmitted environmental measurements to the smartphone via Bluetooth Low Energy (BLE). When the temperature and other measurement values exceeded the predefined threshold, the system successfully generated a notification on the mobile app, alerting the farmer to take appropriate action. This demonstrated the system's ability to provide timely alerts based on environmental conditions.

CONCLUSIONS

The proposed IoT-based system effectively addresses the challenge of monitoring and controlling environmental anomalies in wheat storage facilities. Using sensors to measure temperature, humidity and CO2 levels, the system enables early detection of conditions that could threaten grain quality. The integration of BLE technology allows for real-time data transmission, ensuring that storage conditions are continuously monitored and any abnormal variations are promptly detected.

A key feature of the system is the mobile application, which enhances user notifications by delivering real-time alerts when environmental conditions exceed predefined thresholds. This functionality allows users to take immediate corrective action, preventing spoilage and reducing losses in grain storage. The system's low power architecture and BLE connectivity make it ideal for grain monitoring applications. It provides an affordable and efficient solution for wheat storage monitoring. Future enhancements could focus on incorporating additional IoT sensors to expand the system's capabilities and further improve its response to abnormal situations.

ABSTRACT

The study aimed to identify the capacity of women farmers in adopting the technology of utilizing suckermouth catfish into animal feed so that it has added value through processing technology innovation and can contribute to increasing the productivity of livestock businesses. The research was conducted in Soppeng Regency, South Sulawesi Province. The determination of female farmers as respondents was done by purposive sampling, using the criteria that women have a village chicken livestock business, with a total of 30 respondents. The research data was collected by conducting a survey using collection techniques, namely interviews using questionnaires, focus group discussions, and in-depth interviews (in-depth study) with several key informants. The results showed that, in general, female farmers (80% of respondents) did not know the technology in the management of suckermouth catfish into animal feed, and more than 60% of the respondents needed the technology of processing suckermouth catfish into animal feed. However, female farmers are not well informed about the technology. It can be seen that the number of farmers who know the technology of utilizing broom- sweep fish into animal feed raw materials is still low. For this reason, efforts need to be made to improve and optimize the application of the technology of utilizing broom-sweep fish technology into animal feed raw materials in order to reduce production costs so as to increase the income and welfare of farmers in rural areas.

Keywords: : capacity of farmers (women), adoption, technology, utilization of predatory suckermouth catfish, animal feed

INTRODUCTION

The livestock sector has an important role in the rural economic system. One type of livestock that is widely cultivated in rural areas is free-range chickens. Free- range chickens

are potential germplasm and genetically have high adaptability to the environment. Iskandar S (2010) stated that free-range chicken farming is
livestock that has the potential to be developed because it can be used as a source of animal protein from eggs and meat. This indicates that free-range chickens have a fairly large role in the development of livestock in Indonesia, as well as being the economic basis for rural farmers for the meat (free-range chicken) needs of the community .

Suprayogi et al, (2018), stated that livestock business is a business that will continue. Livestock products such as meat, milk, eggs and others have extraordinary market potential. Therefore with potential Large ones require high input, especially feed requirements because the feed factor requires large input in the livestock business. Abdullah (2019) , stated that to support success in the livestock business, quality feed is an important factor. Good feed will provide good production so that optimal production can be achieved and farmers get results.

The need for quality feed is a dilemma in developing a livestock business. Therefore, a strategy is needed. application of cultivation technology and feed processing technology that utilizes local feed resources so that they can be easily absorbed by farmers in rural areas . One of the local feed resources that can be used as alternative animal feed is the utilization of predatory catfish.

Suckermouth catfish or The more familiar name Gecko fish in South Sulawesi, has not been used by the wider community because, apart from having hard skin, which makes it quite difficult to handle, the presence of the Tokke fish is also very disturbing for fishermen, because it can disrupt their activities, damage fishing gear, especially gill nets. One of the causes of this is fish develop multiply Because No own mark sell, so if caught by fishermen, they tend to be thrown away and return to the water, not utilized Because there is no interest as food fish; as a result, besides No bring income for fishermen, also resulted in disturbance health environment, so although results from the catch Lots from fishermen, this fish No own mark sell, so Lots give rise to anxiety for public mainly fisherman with the presence of broomstick fish this, though results Usman's research, 2014 stated that fresh broomstick fish that is dried and then floured has high protein content quite high up to 52.7%, even the meat protein reaches 75.5%, even though the skin is quite hard and has a fairly high ash content of around 31.9 -35.1% but Still can processed become flour. Based on matter, the so for answer problem in provision feed cattle requires effort with utilize potential resources based on potential local like the broom fish, so that the broom fish This mark plus make use of discarded broom fish that can be obtained made as material standard feed livestock that can reduce cost need livestock will feed 70 – 80% of cost production , which can pressing cost production cultivation cattle or other with more price low from feed commercial so that can increase income and welfare public breeder .

The use of broomstick fish technology as animal feed in the development of free-range chicken farming is very important, supported by a high level of technology adoption in order to increase the productivity of free-range chicken farming. However, apart from the technology for using predatory broomstick fish as animal feed, the role and capacity of breeders as farming actors, especially in adopting technology, plays an important role and the technology applied is easy to carry out/apply, the materials used are available at the breeder's location, and at a reasonable cost. cheap. Abdullah and Syamsu (2008) stated that the success of livestock business development is largely determined by the farmer's resource capacity. Development of livestock capacity is carried out by raising awareness among breeders, where all activities in livestock development are carried out by and for breeders. Farmer development is carried out with a participatory nuance so that the principles of equality, transparency, responsibility, accountability and cooperation become new contents in empowering breeders.

Empowering farmers in the livestock sector involves many women in carrying out farming businesses, especially family farming businesses. Lestariningsih et.al., (2018) stated that the role of female workers is very much needed because the livestock sector requires patience and tenacity so that female workers are more suitable. Women not only act as housewives but also as workers in the livestock sector. Many women participate or make real contributions to livestock businesses run by their families. The involvement of women in carrying out livestock activities is often carried out in free-range chicken farming businesses, because the free-range chicken farming business is an alternative business that does not require a lot of capital and large land, and can be used as a source of income for village communities in addition to a source of animal protein for the family. Abdullah and Amrawati, (2008) stated that the involvement of women in livestock farming activities is an effort to increase family economic security and efficient use of local resources.

Utilizing local resources and potential such as the predatory broomstick fish to be used as raw material for animal feed will have positive cultural, social and economic impacts, namely livestock cultivation will become more efficient with the availability of feed that can be carried out continuously and sustainably. Apart from that, the social problems that occur due to predatory fish which can become waste because they are thrown around waters which have been causing pollution can be overcome to become products that are useful as feed, and have a good economic impact on female farmers, resulting in business efficiency. Therefore, efforts are needed to develop the capacity of female breeders in utilizing existing resources, namely the use of the predatory broomstick fish so that it has added value through innovation in processing technology and can contribute to increasing the productivity of livestock businesses.

RESEARCH METHODS

The research was carried out in Soppeng Regency, South Sulawesi Province. The determination of farmer farmers as respondents was carried out using purposive sampling with a total of 30 female farmers who were engaged in raising free-range chickens as respondents. Research data was collected by conducting a survey using data collection techniques through interview questionnaires. The questions in the questionnaire are closed questions and open questions. Apart from that, focus group discussions were also held, namely conducting focus group discussions with female farmers to dig deeper and identify various actual problems and conditions that occur in the development of free-range chicken farming businesses. Apart from that, in-depth interviews were conducted with several key informants.

The variables in this research are breeder characteristics, breeder capacity (attitude, knowledge, and skills) in the free-range chicken farming business, and breeder capacity in using predatory suckermouth catfish as animal feed. Measurement of research variables is carried out by measuring indicators for each research variable/sub-variable in question. Qualitative variable indicators are measured using a Likert scale consisting of four levels, each given a score of 1, 2, 3 and 4. The measurement of each indicator is obtained by taking the average value of the scores of all parameters. Analysis of existing condition data obtained from the survey begins by tabulating the data, and carrying out descriptive analysis of the data by looking at means, percentages and frequencies which are processed with the help of SPSS software.

RESULTS AND DISCUSSION

The general characteristics of respondent farmers are related to age, education, family size, farming experience, and livestock ownership as shown in Table 1. Table 1 shows that most of the breeders are in the range of 31-50 years with 70% of all respondents. This shows that female farmer respondents who work in developing free-range chicken farming businesses are in the productive age category. The age factor is usually identified more with work productivity, and if someone is still of productive age, their productivity tends to be high. Age is an indicator that shows a person's physical abilities. The age of the workforce influences work productivity, age is also closely related to the mindset of workers in determining the management system that will be applied in activities or at work. Abdullah and Amrawati, (2008) stated that the younger the breeder (productive age 20-45 years), generally the curiosity about something is higher and the interest in adopting the introduction of technology is higher.
The level of education has an influence on livestock businesses both technically, management and management of livestock businesses in absorbing new technology. With a high level of education it is hoped that breeders will be able to carry out their livestock business activities better because they are supported by increasingly broader knowledge and insight (Lestariningsih, et al. 2018) . Judging from the level of formal education, there are variations from the lowest not having completed elementary school and the highest having completed college. The education level of breeders is dominated by those who have not completed or completed elementary school (36.7), the remainder have completed junior and senior high school respectively 33.3 % and 26.7 %, and only 3.3 % have completed their education at university. The higher the farmer's education level, the higher the quality of human resources, which in turn will be the higher the productivity of the work they do . With this level of education, it can be assumed that the farmer's ability to know and adopt skills in the context of developing a livestock business will experience obstacles and difficulties. An adequate level of education will have an impact on increasing the performance and management capabilities of the livestock business being run (Zahidah, et al., 2021). The level of education will increase knowledge and skills so that it will increase work productivity and will determine the success of a livestock business so education is very much needed in running a business because it has an impact on the mindset in managing a chicken farming business (Sudrajat and Isyanto, 2018).
Based on the level of experience of farmers, the research results show that the majority of female farmers have experience in raising chickens and ducks for up to 10 years (60.%) of the total respondents , and the remaining 40.0 % have experience in raising more than 10 years . Generally, experience in raising free- range chickens is passed down from their parents from generation to generation.

Table 1. The general condition of respondent farmers

No	Description	Number of people)	Percentage (%)

1	Breeder Age (years)		
	< 30	6	20.0
	31 - 40	10	33.3
	41 - 50	11	36.7
	>50	3	10.0
2	Education		
	Did not graduate/finished elementary school	11	36.7
	Finished high school	10	33.3
	Finished high school	8	26.7
	Graduated from College	1	3.3
3	Number of Families (people)		
	< 3	5	16.7
	3 – 4	8	26.7
	5 – 6	10	33.3
	> 6	7	23.3
4	Ownership of livestock (tail)		
	<10	5	16.7
	10-15	9	30.0
	16-20	10	33.3
	>20	6	20.0
5	Livestock experience (years)		
	≤5	8	26.7
	>5-10	10	33.3
	>10-15	9	30.0
	>15	3	10.0

Having long-term farming experience provides an indication of the knowledge and skills of female farmers regarding the management of free-range chicken farming have better abilities. This is in accordance with the opinion of Kurniawati, et al., 2022) , that farming experience is an important capital for the success of a farm, but the level of experience of each farmer is different as well as their mindset in applying innovation to their livestock business activities .
Characteristics of the ability or knowledge capacity and skills of female farmers in the free-range chicken farming business are as shown in Figure 1.

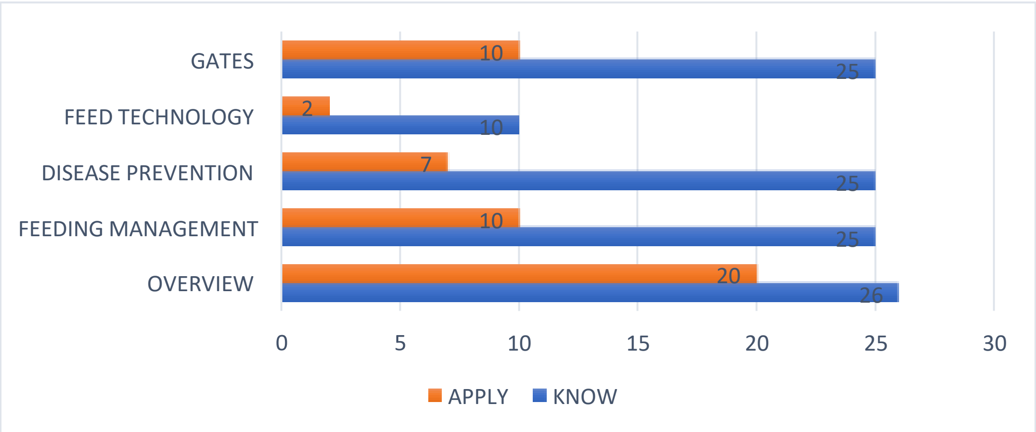

Figure 1. Knowledge capacity of farmers in managing chicken farming businesses village

Figure 1 shows that female farmer respondents know quite high cage technology, 83%, but the % of farmers who apply it is 30.2% of those who know. This shows that farmer knowledge of cages is quite good, but implementing cage management is still lacking; this is because the business of raising native chickens in rural areas is more extensive, so farmers only let their livestock out by utilizing the yard as a livestock pen. Likewise, farmer knowledge in preventing disease is still lacking; respondents are of the opinion that native chickens are rarely affected by disease. This is in accordance with (Setianan, 2010), which states that native chickens have characteristics that are easy to maintain and rarely get sick, so it is one of the advantages of native chickens. In addition, native chickens have characteristics that are more popular with certain market segments. For farmer knowledge of feed technology and feed management, farmers have known about the technology more than 50%, but the number of farmers who apply it is still less than 50% of those who know. This shows that in general, the respondent farmers have a good understanding of the technology in managing native chicken farming businesses such as cages, feed technology, disease prevention, feed management and hatching as much as 80%, but they are still lacking in the application of the technology they know.
Figure 2 shows the characteristics of farmers' capacity in terms of knowledge and skills in utilizing local broomstick fish resources as raw material for free-range chicken feed. In general, it appears that more than 80% of the respondents do not know that broomstick fish can be used as raw material for animal feed. Thus, breeders do not know well about this technology. This shows that the number of breeders who know the technology is still less than 20%, and only 10% of those who know about the use of broomstick fish technology as a raw material for animal feed apply it. For this reason, efforts need to be made to improve and optimize the application of free-range chicken farming technology by using broomstick fish as a source of raw material for free-range chicken livestock feed at the community farm level.

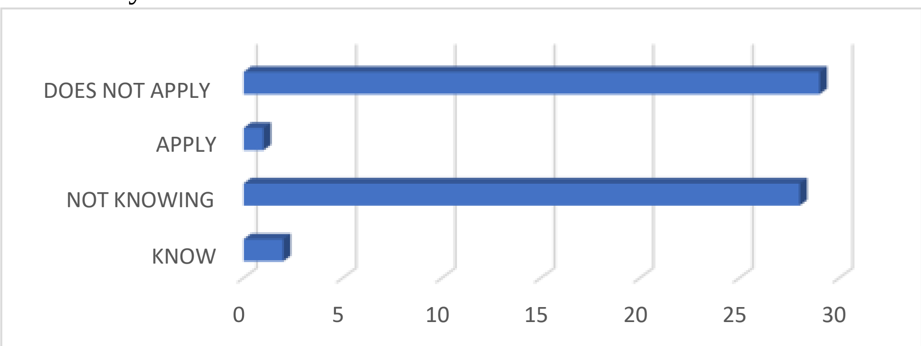

Figure 2. Characteristics of technological knowledge capacity for using broomstick fish as raw material for free-range chicken feed

CONCLUSIONS AND RECOMMENDATIONS

In general, female farmers (80% of respondents) already know the cultivation technology of native chicken businesses but are still lacking in applying the technology. The same applies to the technology of utilizing suckermouth catfish as raw material for animal feed. More than 60% of the respondents need technology to utilize predatory fish as raw material for animal feed. Thus, it turns out that farmers are not well informed about the technology. This can be seen from the low number of farmers who know the technology, which is 20%. For this reason, efforts need to be made to improve and optimize the application of village chicken business technology, as well as the utilization of predatory broom fish as raw material for animal feed products at the smallholder farm level.

ACKNOWLEDGMENT

The authors would like to thank the Director General of Vocational and the Rector of Hasanuddin University for the research funding assistance through the Fiscal Year 2024 Matching Fund Program, so that this research can be carried out.

ABSTRACT

This case report presents a rare condition in dogs involving congenital bilateral shoulder luxation and bilateral hip luxation, primarily affecting toy breeds. It is characterized by a malformed glenoid cavity, congenital dislocation of hips, leading to persistent discomfort and lameness. Hip dislocation, usually craniodorsal, is more common, typically resulting from trauma or hip dysplasia. Observing both congenital bilateral shoulder and hip dislocations at the same time is rare. This case report refers to a 4-year-old male, toy breed dog presented with severe right shoulder pain and reduced range of motion, moderate back limbs lameness. Radiographic examinations shows bilateral congenital luxation in the shoulder joints with ipoplastic glenoid cavity and humeral head deformity and congenital luxation of both hip joints with bilateral flattening of the acetabular cavities and severe modification of femoral heads. The dog was diagnosed with bilateral hip and shoulder congenital luxation. The right shoulder showing more instability and severe pain and lame. There is no definitive evidence directly linking hip and shoulder luxation, genetic predispositions and environmental factors contributing to overall joint health can influence the occurrence of both conditions in dogs. Surgical intervention was required to correct the dislocations by using the Vaughan technique for extracapsular stabilization of the shoulder, Femoral Head Excision (FHO) technique was performed for the stabilization of hip luxation, followed by a strict rehabilitation plan. This report discusses the clinical presentation, diagnostic process to evaluate this condition, surgical approaches, and post-operative outcomes, emphasizing the challenges posed by managing such cases in small toy breeds. The simultaneous congenital dislocation of the hip and shoulder joints in this case is important since it is a case of a condition not before reported in the literature, highlighting the importance of an adequate orthopedic assessment in toy breeds.

Keywords: Congenital, Hip luxation, Shoulders luxation, Extracapsular stabilization.

INTRODUCTION

In dogs, congenital shoulder luxation is an uncommon disorder that frequently affects both shoulders. It is characterized by a malformed or hypoplastic glenoid cavity, persistent discomfort, and lameness. Small and toy breed dogs are prone to medial congenital luxations(Ciro Marra et al., 2018). Hip dislocation is the most frequent type of dislocation in dogs and is generally caused by a traumatic event or secondary to hip dysplasia(Demko et al., 2006; Kieves et al., 2014). The majority parts of cases are due to road traffic accidents or secondary to hip dysplasia. The direction of luxation is mostly craniodorsal due to the strength of gluteal muscles(Basher et al., 1986; Bone et al., 1984).
Rarely, dislocation can be congenital and due to its rarity, it is poorly reported in the literature and is associated with missing of acetabular cavity and serious osteoarticular changes. Observing a

congenital bilateral shoulder dislocation and a bilateral hip dislocation at the same time is an event that should be considered very rare.

Clinical Case Description:

A male dog, 4 years old, Barebone Toy breed was presented to the hospital of Surgery and Animal Reproduction Section, University of Bari "Aldo Moro" with the anamneses below: As a puppy he showed a slight lameness in the back limbs but that time the owners thought that it was not a serious situation regarding to the young age and growing time of the dog. At the age two, he began to complain sporadically of pain while was playing, walking and running. The dog was brought for clinical visit due to severe pain in the right shoulder on which a serious functional disorder was observed with reduced range of motion and difficulty in extension. Orthopedic evaluations of the contralateral limb demonstrated joint instability but there was no severe pain so the animal transfer weight on this limb. After the short anamneses indicated by the owner and the orthopedic visit, we decided to perform X-rays to the anterior and posterior limbs, to evaluate first of all the pain of the posterior limbs, even the pain in neck and difficulty in extension of anterior limbs. From this radiographic examination of the pelvis and shoulders, we have some incongruency evidences in the articular joints between head of humerus and glenoidal cavity of shoulders (Figure 1.B and 1.C) and also both head of femurs were out of acetabulum (Figure 1.A).

Figure 12 Radiographic examination: A) VD projection of hip joint, B) DV projection of left shoulder joint, C) DV projection of right shoulder joint

After the radiographic examination and interpretation of X-rays findings, the dog was diagnosed with bilateral hip luxation and bilateral shoulders luxation. Regarding bilateral hip luxation, the right head of femur was more craniodorsal and out of acetabulum than the left one. In front limbs were presence of bilateral shoulders luxation and flattening of glenoid cavity, the head of humerus were deformed and out of glenoid cavities. The right limb showed severe pain and lame and for that reason we decided to stabilize the shoulders. The surgical technique used for treatment of shoulders luxation was Vaughan technique(Vaughan, 1967) as showed in Figure 2, that consist in an extracapsular stabilization used also for the stabilization of the recurrent dislocation of the shoulder joint . About the stabilization of back limbs was chosen to perform the FHO (Femoral Head Ostectomy) technique which consist in the excision of femoral head of both back limbs, after that the gluteal muscles around will create a false joint around this articulation and the animal will be pain free.
All the surgeries were not performed in the same time but step by step starting from shoulders, one surgery every 1 or 2 months after the previous surgery depending from the condition of dog, so in this way the dog can hold the body weight in three limbs.

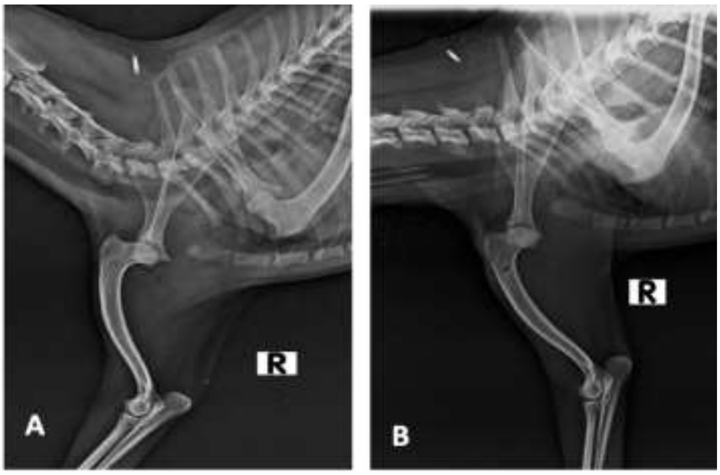

Figure 2 Right Shoulder articulation: A - Before surgery, B - After surgery

DISCUSSION AND CONCLUSION

This clinical case was selected like a case report because is a rare case in which is presented in the same time an orthopedic pathology known as congenital luxation of hip and congenital luxation of shoulders joints, also because is a congenital pathology in toy breeds due to the presence of strange structure of glenoidal cavity. There is no definitive evidence directly linking hip and shoulder luxation, genetic predispositions and environmental factors contributing to overall joint health can influence the occurrence of both conditions in dogs. There are some correlations between others pathologies as osteoarthritis and dysplasia in articulation structure. According to the study of *Swenson et al.,1997, Maki et al., 2000, 2002* two prevalent developmental orthopedic abnormalities in dogs that can result in permanent impairment are elbow and hip dysplasia. Both conditions are regarded as complicated illnesses that are influenced by a combination of environmental variables and several genes(Mäki1 et al., 2002; Swenson et al., 1997). Also, a case report from *Castelli et al., 2019*, show a correlation of hip luxation with patellar luxation in a toy breed dog(Castelli et al., 2019). So, in this case there are no bibliographic evidences regarding to the presence of bilateral congenital shoulder luxation and bilateral congenital hip luxation in the same time. In our daily work we have been confronted with some congenital and non-congenital diseases in toy breed dogs that have been presented even before and starting from this case report we have to be more careful during the orthopedic evaluation and to see if there is any correlation between different structures. This case report serves as an initial signal of a scientific research regarding bone pathologies, mainly articulations and correlations that may exist in the presence of the same pathology in different bone structures.

ABSTRACT

This study investigates the effects of sequential fermentation using selected non-Saccharomyces (*M. pulcherrima*) and Saccharomyces yeasts on the polyphenols and anthocyanin content in red wines. The consumers interest in quality wines with enhanced health benefits and richer color profiles is growing, therefore understanding the role of different yeast strains in wine fermentation and modification of vinification schemes become increasingly important. This research involves conducting fermentation trials where *M. pulcherrima* selected strain are initially used at a concentration of $log10^7$, followed by commercial strain of Saccharomyces cerevisiae in a sequential manner added after 48 and 72 hours. A control trial used only the Saccharomyces cerevisiae strain. The total polyphenols and anthocyanin content of resulting wines are analyzed using the spectrophotometry. The results demonstrated that sequential fermentation significantly boosts these compounds compared to traditional fermentation methods, leading to wines with improved antioxidant properties and deeper color intensity. These first findings suggest that the utilization of selected non-Saccharomyces yeasts in conjunction with Saccharomyces, can enhance the quality and health benefits of red wines, offering valuable insights for winemakers seeking to innovate and improve their products.

Keywords: polyphenol, anthocyanin, color intensity, non-saccharomyces yeasts.

INTRODUCTION

Albania has a rich history of viticulture, dating back to ancient times. The country's Mediterranean climate, characterized by warm summers and mild winters, along with diverse soil types, makes it ideal for growing a variety of grapevines. Among the indigenous varieties, Kallmet stands out as one of the most important red grapes in Albania. Mostly cultivated in northern areas, especially in the districts of Lezhë, Shkodër, and Mirdita. Nowadays, the consumer's interest in quality wines with enhanced health benefits and richer color profiles is growing, therefore understanding the role of different yeast strains in wine fermentation and modification of vinification schemes become increasingly important. Several factors impact wine quality, including grape variety, vineyard management, climatic conditions, soil composition, winemaking procedures, and yeast strain selection (Pangzhen Zhang 2021). These components work together to impact the wine's fragrance, taste, color, and texture, establishing its overall character and aging potential. Kallmet wines are usually made with commercial Saccharomyces cerevisiae yeast, producing high-quality dry wines with high alcohol concentration (13-15%). Previous research has shown that Kallmet wines contain a sufficient amount of anthocyanin and a reasonably high mean degree of polymerization (mDP). The wine's color is largely attributed to polymerized pigments, which ensure good color stability during storage (Peçuli 2018). However, there is a lack of studies in Albania on the impact of innovative winemaking techniques, particularly sequential fermentation with selected non-Saccharomyces yeasts, on the polyphenol content and color stabilization in Kallmet red wine. Maceration, sulfiting, temperature, and microbial populations all have an impact on the amount and content of polyphenols in red wines (Ana C. Correia 2018). Hornedo-Ortega, 2021). Polyphenols are a class of naturally bioactive substances found in grapes that influence the flavor, color, and mouthfeel of wine. They are split into two categories: flavonoids and nonflavonoids (D. Violeta Ivanova, 2011). Polyphenols contain antioxidant capacities that are recognized for their potential positive health effects. Anthocyanins are a kind of polyphenol responsible for the color red, purple, and blue in grapes. They play a crucial role in the color and stability of red wines (Raúl Ferrer-Gallego 2014). Recent research has highlighted the importance of selecting yeast strains not only for their fermentation capabilities but also for their ability to enhance the wine’s color, texture, aroma, and potential health benefits (Antonio Morata 2016, Anna L. Carew 2013, Pangzhen Zhang 2021). In modern winemaking, certain strains of Saccharomyces cerevisiae and non-Saccharomyces yeasts are often used to accomplish desired results. These yeasts influence wine's final color characteristics through a variety of mechanisms, including the release of pectinase and beta-glycosidase during maceration, which can affect phenolic extraction from grapes and hydrolyze the glycosidic bonds of phenolic compounds, respectively (Alimardani-Theuil 2011). Furthermore, yeasts can promote chemical interactions between their cell walls and polyphenols. Previous study has shown that various non-Saccharomyces yeasts used in sequential inoculation with Saccharomyces cerevisiae can generate different aroma profiles and increase the phenolic content of red wines. (Morata Antonio 2016; R. Escribano 2018).

The purpose of this study is to explore into the impact of sequential fermentation with selected non-Saccharomyces (M. pulcherrima) and Saccharomyces yeasts on the polyphenol and anthocyanin content of Kallmet wine. This study will involve fermentation trials in which M. pulcherrima selected strains are utilized at a log107 concentration, followed by commercial Saccharomyces cerevisiae strains introduced sequentially after 48 and 72 hours. A control test only utilized the Saccharomyces cerevisiae strain. The total polyphenol and anthocyanin content of the resultant wines are measured using spectrophotometry techniques.

MATERIALS AND METHODS

Yeast Strains and Fermentation trails

In this study is used *M. pulcherrima* (AS3C1) strain isolated from grape must and belongs to the culture collection of the Di.A.A.A (Department of Agricultural, Environmental and Food Sciences, University of Molise, Campobasso, Italy). Before use the strain it was grow in YPD medium at 20^0C under aerobic condition for 48 h. The commercial strain of *S. cerevisiae Zymaflore F15 (*LAFFORT Co., Bordeaux, France) was used as control yeast. The cultures were centrifuged at 5000 rmp for 10 min at 4 ^{0}C, washed twice with sterile physiological solution (0.9% NaCl) before used, and inoculated in Kallmet grape juice to concentration of 7.0 log CFU/ml. For the fermentation trails red grapes (*Vitis vinifera* cv. Kallmet) were taken in North of Albania, at Koplik village in collaboration with “MEDAUR” winery. The fermentation trails are conducted at Research Food Center, faculty of Biotechnology and Food. The grape juice was used for three different schemas of inoculation, first trail was initially inoculated with *M. pulcherrima* (10^7 CFU/ml) and after 48 h was added the S. *cerevisiae* F15 to finish the fermentation. In second trail the S. *cerevisiae* F15 was added after 72 h and the third trail was fermented only with S. *cerevisiae* F15 as control test. The alcoholic fermentation process was conducted at control temperature 23-24ºC and was monitored every day by measuring the sugar consumption and temperature.

Chemical analyses and Polyphenols

At the end of alcoholic fermentation the wine from every trails was subject to chemical analysis pH, alcohol (%v/v), total acidity (g/L ac. Tartaric), and volatile acidity (mg/L ac. Acetic) were performed according to International Organization of Vin and Wine (OIV) methods. Glycerol and acetaldehyde were determined using enzymatic kit according the instruction of the company. Total polyphenols were analyzed with spectrophotometer according to the method (M. S. Violeta Ivanova 2010) with some modification using The Folin–Ciocalteu. The absorbance of the samples was measured at a fixed wavelength of 750 nm against distilled water as the blank. A calibration curve was constructed using Gallic acid standard solutions (0–100 mg/L). The concentration of total phenolic is expressed as the Gallic acid equivalent ml/ L. All samples were prepared in triplicate. The total anthocyanin content was analyzed according to Puissant-Leon (Puissant and Léon, 1967). The samples were diluted with a solution of 1N HCL and the absorbance was measured at 520nm. The color intensity and tonality was determined by measurement the absorbance of wine samples directly at 420, 520 and 620 nm using a 2 mm optical path according (M. S. Violeta Ivanova 2010). From this was calculated the color intensity (CI) as sum of the absorbance at 420, 520 and 620 nm, tonality or tint (CT) was calculated as the ratio A420/A520, and gives a measure of the "tint" or redness of the wine.

Statistical Analysis

Analysis of variance (ANOVA) was applied for the data obtained from the experiments, using the SPSS software. The data represent three replicates for each trial fermentation (n=3). The data were considered significant if P-values ≤ 0.05.

RESULTS AND DISCUSSION

Chemical parameters and Polyphenols

The result of chemical parameters and polyphenols content for the samples of the wines obtain from the alcoholic fermentations from three trails are presented in able 1. The data obtained indicate that **MP48h** (sequential fermentation with M pulcherrima) exhibited significantly higher glycerol content and lower levels of volatile acidity and acetaldehyde compared to the second trail **MP72h** and control trial **SC3**. These results are consistent with previous studies on the use of MP (*Metschnikowia pulcherrima*) in sequential fermentation, highlighting its beneficial role in improving the chemical composition of wine (Chen 2018, Testa 2021).

Polyphenols are important compounds in wine that contribute to its organoleptic and antioxidant properties. The result among the samples, MP48h has the highest concentration of total polyphenols, compare to MP72h and control test SC3. Anthocyanins are pigments that contribute to the red, purple, and blue hues in wine. Test MP48h and MP72h has the highest anthocyanin content, indicating it might have the most intense red color and potentially better color stability compare to control SC3 which has the lowest anthocyanin content, suggesting it may have a lighter color compared to the others

Table 1: Chemical parameters and Polyphenol content obtain from sequential fermented of Kallmet red wine: SC3 (control fermentation); MP48h (sequential fermentation M.pulcherrima + S.cereviseae); MP72h (sequential fermentation M.pulcherrima + S.cereviseae)

Parameters	SC3	MP48h	MP72h
pH	3.69±0.005	3.75±0.026	3.72±0.005
Total acidity (g/L ac. Tartaric)	5.2±0.100	5.6±0.057	5.8±0.100
Volatile acidity(g/L ac acetic)	0.40±0.015	0.24±0.010	0.29±0,010
Alcohol (% v/v)	12.34±0.05	12.0±0.11	11.79±0.010
Glycerol (mg/L)	3.0±0.057	4.5±0.057	3.5±0.057
Acetaldehyde (mg/L)	10.22±0.011	4.23±0.057	6.27±0.010

Total Polyphenols (mg/L)	2520±0.577	2640±0.577	2520±0.577
Anthocyanin (mg/L)	199.03±0.01	261.17±0.025	227.03±0.060
Colour intensity (CI)	5.97±0.057	9.98±0.057	10±0.057
Tonality (T)	0.66±0.000	0.77±0.000	0.8±0.000

Data are express as mean values (n=3) ±standard deviation
.

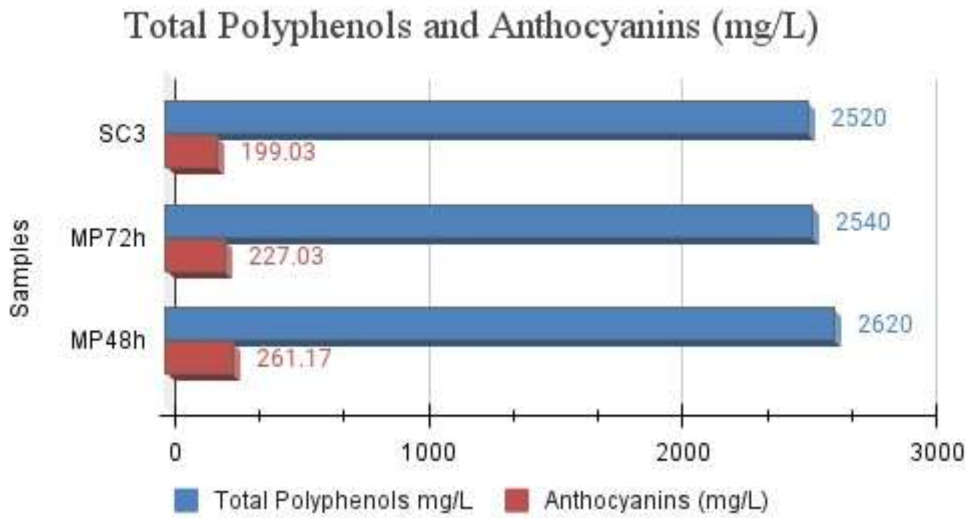

Figure 1 Total Polyphenol and Anthocyanin content on the samples of Kallmet wines

Color intensity is a measure of how dark or intense the wine's color is. Tonality provides information about the wine's hue. From the results MP72h and MP48h have similar and higher tonality and color intensities, indicating they are likely darker wines, while SC3, with a lower CI of 5.97 and tonality, is probably lighter in color.The results for color intensity (CI) and Tonality (T) for the analyzed sample are presented in Figure1.

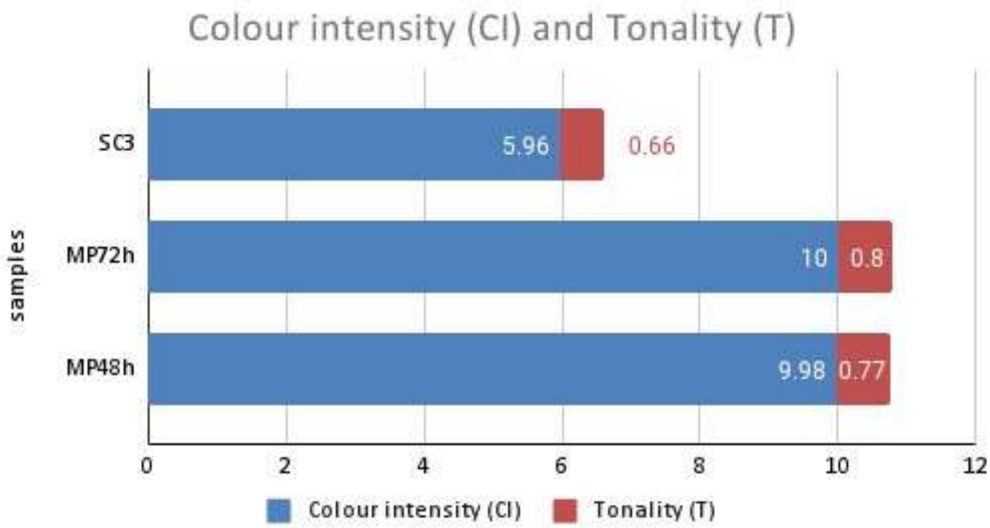

Figure 2 Color Intensity and Tonality on the samples of Kallmet wines

The use of M. pulcherrima starter in combination with S.cerevisiae can contributed to improve the color and phenolic content in wine due to its reach enzymatic activity such has been reported in previous researcher (Anna L. Carew 2013, Antonio Morata 2016, Ana C. Correia 2018).

CONCLUSION

Sequential fermentation with selected non-*Saccharomyces* yeast strains represents a promising green strategy for addressing challenges in winemaking, such as enhancing flavor complexity, improving wine stability, and reducing the need for chemical additives, while promoting more sustainable production practices.

This is the first research in Albanian winemaking to use a particular strain of Metschnikowia pulcherrima in the sequential fermentation of Kallmet wine, with the aim of analyzing its effects on chemical parameters and color composition. The findings suggest that this approach can result in high-quality wine with a fuller body, color, and aromatic complexity.

Future study will look at the volatile and non-volatile compounds found in these wines using advanced methods like Gas Chromatography-Mass Spectrometry (GC-MS) and High-Performance Liquid Chromatography (HPLC). Furthermore, will conducted sensory evaluations by an expert panel to completely analyze the wines' sensory characteristics and overall quality.

ABSTRACT
The most important way to combat global climate change is to use renewable energy sources as much as possible instead of traditional energy. Using renewable energy sources instead of fossil energy makes a significant contribution to countries' energy policies in every field. Due to our country's location in the world, it is in a very good situation in terms of solar energy and wind energy in coastal areas. It is suitable for generating electrical energy with wind turbines and solar panels. In this context, in the Marmara Region, renewable energy sources can be used in livestock enterprises that are far from settlements and the electricity grid. A fan-pad system will be applied to ensure appropriate environmental conditions in animal barns. For this reason, an evaporative fan-pad system was designed in animal barns in Tekirdağ conditions. There are 70 cattle in the barn where the project will be carried out and the dimensions of the barn are 10.4 x 46.1 (479.4 m^2). To cool this barn, a pad area of 19.2 m^2 is required and a 0.2 kWh circulation pump is required to cycle the water to evaporate. The number of aspirators to be used in ventilation is 9 and their efficiency is 9500 m^3h^{-1}. Electricity consumption is 0.75 kWh. The power value calculated in the ventilation and cooling system is 6.95 kWh. However, solar and wind energy production systems change throughout the day. For this reason, a system of 9-10 kWh, which is 25-30% more than the calculated power, should be installed. 5 kWh of this should be solar panels and 5 kWh should be wind turbine systems. With a 5 kWh solar panel system, 10.035 kWh of electrical energy can be obtained per year, and with a wind turbine system, 9.125 kWh of electrical energy can be obtained per year. With this hybrid system, a total of 19.160 kWh of electrical energy can be produced annually. This will prevent the release of 18.010,4 kg (19.160 x 0.94 = 18.010,4 kg) of CO_2 gas into nature. A 10 kWh hybrid energy system in Tekirdağ conditions prevents significant CO_2 gas emissions into the atmosphere.
Keywords: *Hybrid energy, Animal barn, Wind turbine, Solar panel, Fan-pad system*

INTRODUCTION

One of the most important problems the world faces in the 21st century is the increasingly growing demand for energy. The main factors behind this are population growth, urbanization, industrialization, and the advancement of technology. Today, the majority of energy needs are met by fossil fuels. The widespread use of fossil fuels has been driven by their economic affordability, rapid advancements in production systems, and their widespread availability. The use of fossil fuels, starting with coal and later followed by a significant increase in the consumption of oil and natural gas, has risen dramatically. Today, the continuous rise in the price of fossil-based energy, transportation issues, the tendency of reserves to decrease, and the fact that they will eventually be exhausted are seen as major problems (Yılmaz, 2012). Additionally, the increase in CO_2 emissions, leading to global warming and a heightened risk of climate change, has increased the demand for renewable energy in energy policies and highlighted the importance of this issue. "Renewable energy source can be defined as an energy source that can be naturally replenished the very next day as part of nature's own evolution." Renewable energy sources, considered as alternatives to fossil energy sources, are environmentally friendly, continuously available in nature, and provide clean and sustainable energy (Yılmaz and Can-Öziç, 2018).

The use of renewable energy sources alongside other energy sources, forming hybrid systems, provides a significant advantage. The fact that solar energy is only available during the daytime and wind is not constant limits the independent use of these systems. As a solution, it is possible to install the system with high capacity and store energy in batteries, allowing the stored energy to be used when the system is not generating power (Türkdoğan et al., 2020). Renewable energy sources can diversify a country's energy resources and enhance its energy security. By utilizing renewable energy sources, energy imports can be reduced. In this way, the country's energy sector independence is increased, and by reducing the current account deficit in the national budget, it contributes to economic development (Koçaslan, 2010).

The sole use of wind and solar energy systems may pose challenges in terms of energy supply security. For this reason, their use in a hybrid manner can ensure uninterrupted energy supply. Additionally, there is a higher potential for wind energy during the winter months and a higher potential for solar energy during the summer months. A wind-solar hybrid power plant is an important alternative for sustainable energy supply. These types of hybrid energy systems generally have better efficiency, economic benefits, and environmental values compared to independent systems (Rezai et al., 2018).

It is stated that solar energy systems and wind energy systems can be used in the agricultural production and livestock sectors (Yüksel and Türkboyları, 2018; Türkboyları and Yüksel, 2024a). The energy needs in the livestock sector are even more significant because they are located in areas far from the electricity grid. Because livestock enterprises must be established far from settlement centers. It will be easier to meet the energy needs of animal barns located in off-grid and remote areas using solar-wind hybrid systems. This is because these systems complement each other in the summer and winter months (Türkdoğan et al., 2020).

Livestock farming is an agricultural production sector that requires significant effort both globally and in Turkey. It is an economically and socially significant sector that provides animal proteins needed by people, such as meat, milk, yogurt, and butter. In other words, it ensures the balanced intake of calories, proteins, fats, and carbohydrates that the body needs for a balanced diet (Karacan, 2017). Since Turkey's meat production, which is a source of animal protein, is not sufficient, meat is occasionally imported from other countries. Turkey's per capita meat consumption is seen to be low compared to developed countries. According to 2019 data, Turkey's per capita meat consumption is 36.1 kg (beef 13.6 kg, poultry 21.0 kg, sheep 1.5 kg) (BESD-BİR, 2023).

Considering the population growth in Turkey and the world, increasing the quantity and quality of animal and plant products in parallel is also an important issue. When evaluating meat and milk production in the world, it is observed that cattle alone account for 90% of milk production and 25% of meat production (Şahin and Ulutaş, 2011; Uğur, 2014).

This study focuses on meeting the energy needs of animal barns, which are part of agricultural production structures, through solar-wind hybrid energy systems. Providing suitable environmental conditions in animal barns is crucial for increasing productivity. According to the law, barns must be constructed outside of residential areas. This requirement hinders access to the electricity grid.

Therefore, a project has been developed to meet the electricity needs of the fan-pad system used to provide environmental conditions in the barn. Additionally, the implementation of the proposed energy system will significantly reduce the emission of CO_2 gases into the atmosphere.

Environmental Conditions in Animal Barns

Agricultural production is an important sector in our country, as well as in the world, for the nutrition of both humans and animals. In many of the leading agricultural countries, the proportion of livestock activities within agricultural production is at a significantly high level. However, when evaluated in terms of ecology, geography, and farming culture, Turkey is a country that is quite suitable for livestock farming. Despite all these positive conditions, animal production in Turkey ranks after plant production (Ören and Bahadır, 2005; Turan et al., 2017).

The genetic structure of animals and the environmental factors they are exposed to are two elements that affect productivity in animal production. In addition to being genetically high-yielding, an animal must have an environment that provides the necessary conditions to express its genetic potential in terms of productivity (Tugay and Bakır, 2009). Suitable environmental conditions in the barn can only be achieved through proper ventilation of the barn. Ventilation in animal barns is achieved in two ways: naturally and mechanically. Natural ventilation can be defined as the process by which the air inside the barn is replaced with outside air due to the temperature difference between the outside and inside air, as well as the humidity and wind effects. The natural ventilation system does not operate during times of high and stagnant air temperatures. In this case, mechanical ventilation should be implemented to prevent a decrease in productivity in animals. Mechanical ventilation requires electrical energy.

Inadequate ventilation slows down the growth of animals and reduces their productivity. At the same time, it also increases the risk of diseases.

With ventilation, the air inside the barn is refreshed, ensuring the climatic and chemical environmental conditions within the barn. Temperature and humidity inside the barn are generated through the animals' skin and respiration. Therefore, the temperature inside the barn increases, and the humidity level rises. The dust from the roughage and straw given to the animals affects the physical properties of the air. The gases (CO_2, NH_3, and H_2S) produced as a result of the metabolism of the animals in the barn, along with microorganisms, elevate the properties of the air inside the barn to undesirable levels. The negative physical and chemical properties of the air can only be transformed into the desired condition through mechanical ventilation (Yüksel and Şişman, 2015).

The energy required for the ventilation system can be provided in remote areas and rural regions by utilizing solar-wind hybrid energy systems, through photovoltaic panels and wind turbines. In areas where grid electricity is available, the same systems can be used during power outages or to reduce energy and consumption costs.

The Potential of Turkey's Solar-Wind Hybrid Renewable Energy Resources

Due to its geographical location, Turkey has a much higher potential for solar energy and coastal areas for wind energy compared to many countries. However, these energy systems are intermittent, fluctuating, and complementary in nature. During the summer months, when the sunlight is very bright and strong, wind energy is low. In the winter months, when solar energy is low, wind speeds are high. The efficiency of energy generation from wind and solar energy systems varies from year to year and from day to day (Özdamar et al., 2005). In other words, solar energy is utilized when wind speeds are low, and wind energy is harnessed when solar energy is insufficient. Thus, the continuity of energy production in the system is ensured. The solar-wind hybrid power system is shown in Figure 1 (Atik and Sekin, 2022).

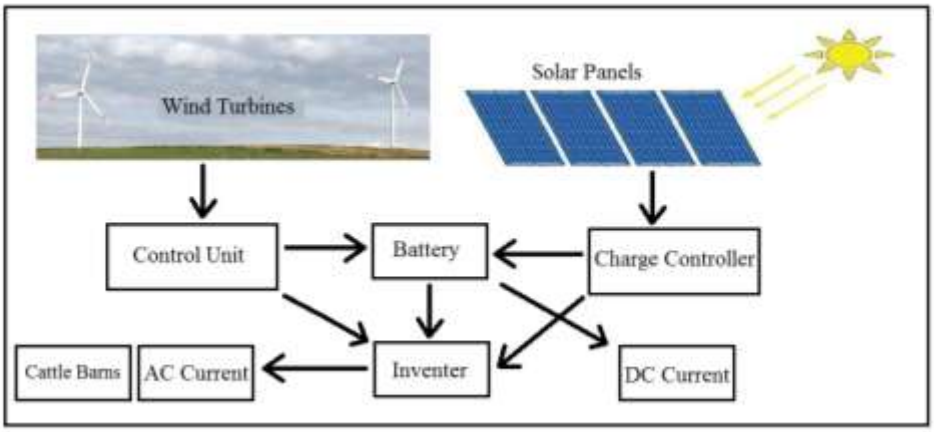

Figure 1. Off-grid solar-wind hybrid power system diagram (Atik and Sekin, 2022)

Hybrid systems can be established as grid-connected (on-grid) or independent from the grid (off-grid). In an on-grid system, the electricity generated is not stored in batteries but is directly transferred to the grid. This generated energy can be connected to the central grid through inverters (Wang et al., 2015). The most important reason for installing this system is its ease of installation. Additionally, the absence of a requirement to use batteries eliminates the cost of energy storage. Since the system is connected to the grid, if the generated energy is not sufficient, energy is directly drawn from the grid to meet the energy needs.

In animal barns, off-grid systems, which are independent of the grid, provide the necessary energy in situations where there is no access to the electricity grid. The requirement for animal barns to be located in rural areas can also create challenges in accessing electrical energy. Even if the barn is close to the grid, a renewable energy-based system can be installed to provide power during outages or to reduce the energy costs of the operation. Since the system is off-grid, it must be supported with batteries. When the hybrid system is unable to generate enough electricity, the energy needs are met by the batteries.

MATERIAL AND METHOD

Methods

The study was conducted in Tekirdağ Central, located in the Thrace peninsula of Turkey's European continent. The Thrace peninsula is situated in the northwest of Turkey, between 26°-29° eastern longitudes and 40°-42° northern latitudes. Tekirdağ is located on a peninsula surrounded by the Black Sea, the Bosphorus, the Sea of Marmara, the Dardanelles, and the Aegean Sea. Its area is 6.313 km². Tekirdağ has a topographically undulating surface. It has a semi-humid climate, with dry summers and rainy autumn, winter, and spring seasons. It is windy in summer and winter (Anonymous, 2023a). According to Turkey's Solar Energy Potential Atlas (GEPA) and Wind Energy Potential Atlas (REPA), Tekirdağ and the Marmara coasts in our country have significant solar and wind energy potential (Anonymous, 2024a; Karık et al., 2017; Tunus, 2019). Therefore, Tekirdağ is highly advantageous in terms of generating electricity from solar energy in the summer and wind energy in the winter.

A project has been developed in Tekirdağ to utilize solar and wind energy in a hybrid manner for ventilation and cooling purposes in beef cattle barns. A mechanical ventilation and cooling system has been designed for a 70-head beef cattle barn where the project will be implemented. The dimensions of the project barn are 10.4x46.1=479.4 m² (Yüksel and Şişman, 2015).

For the cattle barn, which has dimensions of 10.4x46.1=479.4 m² and houses 70 cows, a project will be designed to include ventilation fans, cooling pads (wet pads), and energy production systems using solar panels and wind turbines.

Design of Solar-Wind Hybrid Energy Systems for Animal Barns

Turkey, situated between two continents and composed of two peninsulas, is far more advantageous in terms of solar and wind energy compared to many other countries. In this context, utilizing renewable energy sources in plant and animal production helps reduce production costs. Despite the high initial investment cost of these production systems, the absence of raw material costs, low maintenance expenses, and their long lifespan contribute to reducing energy production costs as well. Studies have shown that solar and wind energy sources can be used economically in livestock enterprises (Yüksel and Türkboyları, 2018; Orhan and Şahin, 2022).

The solar panel system consists of solar cells that convert sunlight directly into electrical energy. They are made from materials such as silicon, which exhibits semiconductor properties. To use silicon as a solar cell, it can be doped with phosphorus and aluminum. The use of inorganic-based solar cells is more common, and their efficiencies range from 15% to 20% (Grätzel, 2009).

Wind turbines are the fundamental components of wind energy plants. They are machines that convert the kinetic energy of moving air into electrical energy. The wind turbine generates electrical energy between the lowest (2-4 ms^{-1}) and the highest (25-35 ms^{-1}) wind speeds. The maximum wind energy from the system can be obtained at the nominal wind speed (10-15 ms^{-1}) (Anonymous, 2023b).

In the structure of solar and wind turbine hybrid systems, depending on the application, there may be solar panels, a wind turbine, accumulators, a charge regulator, an inverter, various circuits, fuses, and a control center (Toprak, 2011; Şenel and Koç, 2015). In this system, the solar panel and wind turbine system needed for power are used as energy sources. There is a mismatch between the supply and demand of solar and wind energy. In other words, due to the inability to produce energy when needed, batteries are connected to the system. The battery group is used as a backup system. The batteries provide energy to the system when there is no sunlight or wind. The charge regulator added to the system prevents the batteries from being overcharged and discharged. By using a charge regulator, the lifespan of the batteries is extended, which also reduces their depreciation values. Electric devices and equipment such as lighting and motors used in Turkey are produced for alternating current. Additionally, if the system is to supply electricity to the grid, it must include an inverter. The inverter converts the direct current (DC) obtained from hybrid solar and wind energy systems into alternating current (AC).

Ventilation and Cooling Systems in Animal Barns

In the cooling of animal barns, a ventilation system with a fan-pad system can be used (Figure 2) (Yüksel and Yüksel-Türkboyları, 2018; Yüksel and Şişman, 2015).

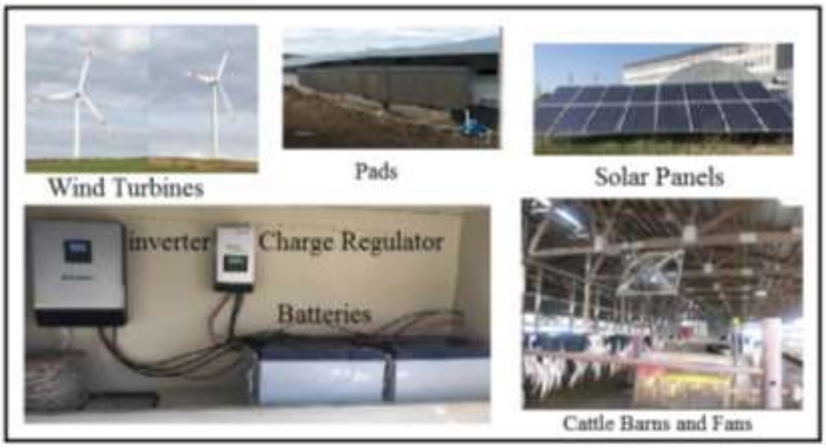

Figure 2. Cooling systems in animal barns using a solar-wind hybrid energy system.

The components of the cooling system include fans, wet pads, circulation pumps, water transport pipes, and a water source. In cooling the animal barn with water, the energy that the water absorbs from the environment, specifically from the air, during evaporation is utilized. Since water absorbs latent heat from the air's sensible heat during evaporation, it also reduces the temperature of the air entering the barn through ventilation (Boyacı et al., 2012; Yüksel and Şişman, 2015; Yüksel and Türkboyları, 2018). The energy required for the cooling system is supplied by the solar-wind hybrid energy system. The system is arranged such that the pads are placed on the opposite side of the walls where the fans are installed inside the barn. When the fans start to operate, the air inside the barn is expelled, creating a low pressure within the barn. The humid and cooled air enters the barn through the openings of the pad on the opposite wall, lowering the temperature of the air inside the barn.
The amount of ventilation in an animal barn can be calculated in two ways. The first method can be calculated based on the internal volume of the barn, and the second method can be calculated according to the number of animals in the barn. The more suitable of these calculations is the one based on the number of animals.
In the conditions of Tekirdağ, ventilation is needed to some extent in every season. The increased need for ventilation in hot seasons is less than in cold seasons. Ventilation should be combined with cooling during June, July, and August when the outside air temperature rises above 22-24°C (Yüksel and Şişman, 2015; Yüksel and Türkboyları, 2018).

RESULTS AND DISCUSSION

Design of Fan-Pad Systems to Be Used in Animal Barns

To design the wet pad to be used for cooling the barn, the dimensions of the barn must be known. The width of the barn for the wet pad project is 10.1 m, and the length is 46.1 m, designed for 70 beef cattle (Yüksel and Şişman, 2015).
In the design of wet pads, 1 m² of wet pad area is required for every 25 m² of floor area (A_1) in the animal barn. For a cattle barn with a floor area of 479.4 m² (A_b) (10.1 x 46.1 m), the required pad area (A_p) can be calculated as follows (Equation 1).

$$A_p = A_b/A_1 = 479.4/25 = 19.2\ m^2 \tag{1}$$

The daily water requirement of the wet pad varies depending on the air temperature, but on hot days, it is around 30-40 L per 1 m² of pad area (Bucklin et al., 1993). The water needed for cooling the pad is taken from the water source with a circulation pump and delivered to the pad. The circulation pump with a power of 0.2 kWh is sufficient.

There are various factors that affect the ventilation rate in animal barns. These include geographical location, seasons, and most importantly, the number of animals in the barn. For large livestock with a live weight of 500 kg, the ventilation rate per animal can be considered as 400 m^3h^{-1}. This value is for the northern regions of Turkey. However, since the average weight of fattening cattle is 700-750 kg, the ventilation rate should be taken as 600 m^3h^{-1} per animal (Q_1) (Türkboyları and Yüksel, 2024b). Accordingly, the ventilation amount (Q_t) based on the number of animals in the barn (n) can be calculated as follows (Equation 2).

$$Q_t = Q_1 \times n = 600 \times 70 = 42000\, m^3h^{-1} \tag{2}$$

The exhaust fans in the barn can be operated in varying numbers based on the needs. In animal barns, exhaust fans with a diameter of 60 cm that produce low noise should be preferred. Their power is 0.75 kWh, and their efficiency (Q_a) is 9500 m^3h^{-1} (Anonymous, 2024b).

The number of exhaust fans (n_a) to be used in the system can be calculated using Equation 3.

$$n_a = Q_t/Q_a = 42000/9500 = 4.4{\sim}5 \text{ piece} \tag{3}$$

The number of exhaust fans to be used in the barn is higher due to the length of the barn. There should be a distance of 15-20 meters between the exhaust fans for proper air movement within the barn. In this barn, two exhaust fans are needed at 15-17 meters and two more at 35-36 meters, making a total of four additional fans required. Thus, the system should have a total of 9 exhaust fans (Yüksel and Türkboyları, 2018).

The total energy requirement of the system can be calculated using Equation 4.

$$0.75 \times 9 + 0.2 = 6.95\, kWh \tag{4}$$

Approximately a 7 kWh solar or wind energy system is required. However, if the systems are considered separately, the solar panel system cannot produce enough energy at night, on cloudy days, and during rainy weather. In the wind turbine system, fluctuating wind speeds or a complete lack of wind can create issues for energy production (Tunus, 2019). Therefore, the systems are kept 25-30% larger than the calculated value. The designed system should be converted into a 9-10 kWh system. Therefore, the total energy production of the solar panel and wind turbine systems should be considered as 10 kWh. The energy system should be designed as a 5 kWh solar panel system and a 5 kWh wind turbine system.

Impact of Solar-Wind Hybrid Energy System on CO_2 Emissions

Countries' electricity generation has primarily started with non-renewable energy sources, particularly coal. Later, various renewable energy sources such as natural gas, hydropower, geothermal, biomass, and nuclear energy have also been integrated into the system. The non-renewable energy sources that are largely used in electricity generation pollute the environment with various waste products. Due to the negative effects of these waste products on the climate, there has been a shift towards renewable energy sources as clean energy alternatives. Among these sources, solar and wind energy play a leading role.

Coal is an important source of electricity generation in Turkey. Approximately 21% of electricity production is derived from coal (Orhan and Şahin, 2022). In thermal power plants used for electricity production, coal is used as fuel, resulting in significant CO_2 emissions into the environment. According to the Carbon Neutral Charitable Fund (CNCF, 2023), the amount of CO_2 released into the atmosphere by thermal power plants to produce 1 kWh of electrical energy is approximately 0.94 kg. Accordingly, the amount of CO_2 prevented from being released into the atmosphere can be calculated by multiplying the energy amount in kWh produced from solar and wind energy systems by 0.94. Thus, the use of renewable energy sources helps to protect nature as well.

It has been determined that a 10 kWh energy system is needed for the project. In other words, the hybrid system should produce 10 kW of electrical energy per hour. Since the system is designed as a hybrid, it will consist of a 5 kWh wind turbine system and a 5 kWh solar panel system. Both energy systems may operate for longer or shorter periods on certain days. In other words, there may be fluctuations and interruptions in energy production. When the systems operate efficiently for extended periods, the excess energy is sent to the grid in an on-grid system, and stored in the battery in an off-grid system. In times when energy production is insufficient, the stored energy is utilized. It can be assumed that the wind turbine energy system operates for approximately 5 hours a day (Türkboyları and Yüksel, 2024b). Given that the power of the wind turbine is 5 kWh and its daily operating time is 5 hours, the amount of energy it can produce annually is calculated using Equation 5.

$$5\ kWh \times 5\ hours\ day^{-1} \times 365\ days\ year^{-1} = 9.125\ kWh \tag{5}$$

With the wind turbine energy system, approximately 8.577,5 kg (9.125×0.94=8.577,5kg) of CO_2 emissions into the atmosphere are prevented.

To determine the relationship between CO_2 emissions and the solar panel energy system, which is the other power source to be used in the trial, it is necessary to know the sunshine durations of Tekirdağ province (Anonymous, 2024c). These values are provided in Table 1.

Table 1. Sunshine duration of Tekirdağ province (hours) (Anonymous, 2024c)

Months	**1**	**2**	**3**	**4**	**5**	**6**	**7**	**8**	**9**	**10**	**11**	**12**	**Total**
Sunshine duration	2.7	3.3	4.2	5.8	7.3	8.6	9.4	8.5	6.8	4.6	3.2	2.5	66.9

In calculating the amount of electrical energy that can be produced in Tekirdağ with the projected 5 kWh photovoltaic panel system, the total average daily sunshine hours on a monthly basis can be calculated by multiplying the monthly number of days by the power of the panel system (Equation 6).

$$66.9\ hours\ month^{-1} \times 30\ days\ month^{-1} \times 5\ kWh = 10.035\ kWh\ year^{-1} \tag{6}$$

With the installation of a 5 kWh solar panel system, 10.035 kWh of electricity can be generated annually. This produced electricity can prevent the release of 9.432,9 kg (10.035 x 0.94 = 9.432,9 kg) of CO_2 into the atmosphere.

A hybrid renewable energy system, intended for agricultural use in animal barns, can significantly prevent CO_2 emissions. With a 10 kWh hybrid energy system consisting of solar panels and a wind turbine energy system, 19.160 kWh of electricity can be produced annually (9.125 kWh from the wind turbine and 10.035 kWh from the solar panel system). With the produced electricity, 18.010,4 kg of CO_2 emissions can be prevented annually. With the use of renewable hybrid energy sources, the release of harmful waste gases caused by fossil fuels in energy production is significantly prevented from being released into the atmosphere.

CONCLUSION

In Turkey, energy consumption is increasing primarily due to population growth, along with various other reasons. The increasing energy demand also poses a significant burden on the national economy, contributing to the budget deficit. In the livestock sector, energy demand constitutes the largest expense item. This energy is used for ventilation, cooling, and heating (Arslan, 2024).

Renewable energy sources can be utilized to provide economic benefits to the national economy and livestock enterprises. Because the Marmara region, where the project is carried out, is one of the areas with high solar and wind energy potential. However, these energy sources are not being utilized sufficiently. The reason for this is the high initial investment cost of solar and wind energy systems (Emiroğlu et al., 2021).

In the Marmara region, electricity can be generated and utilized in animal barns using solar and wind hybrid energy systems. In addition to providing energy from renewable sources to agricultural enterprises in rural areas, a significant amount of CO_2 emissions into the atmosphere can be prevented.

Animal barns should be ventilated and cooled according to the season to obtain high yields. The energy costs of the operation can be covered by utilizing the energy obtained from the designed hybrid systems. The surplus energy produced in the facility can be used in other units of the operation or supplied to the national electricity grid, providing financial benefits to the operation (Türkboyları and Yüksel, 2024b).

With the use of renewable energy sources in agriculture, CO_2 production, which contributes to climate change, can be reduced, thereby slowing down the pace of climate change.

ABSTRACT

The article presents the results of the study of the transport scheme and the routes from the vegetable market in the village of Plodovitovo to the villages located up to 25 km from it. The small farmers in each of the villages have been identified, their planted areas with lettuce expected to appear on the market at the same time. The mass of one piece of salad was measured m_z = 684g, the mass of one transport package with salad m_k = 7.368 kg. The average yield of 1da - Q_{cc} = 1694.3 kg/da was determined. Based on the determined routes and quantities for daily transport from each village to the vegetable exchange, the transport work for each route was calculated. A recommendation was made to monitor stock in the stock exchange and the market situation in order not to prepare production that would remain and thus generate losses for everyone in the chain.

Keywords: Salad, transport work, means of transport, routes of movement

INTRODUCTION

Vegetable production is a branch whose products occupy a significant part of the country's food supply. This determines the important place of vegetable production in the national economy. This industry is not only economically important for feeding the population, but also a way of livelihood and life for a significant part of it.

Nowadays, lettuce is widely consumed worldwide due to its beneficial health properties. Lettuce is rich in fiber, the consumption of which regulates the gastrointestinal tract and reduces the risk of colon cancer. In addition, lettuce is vegetable rich in natural antioxidants, such as quercetin, kaempferol, luteolin, and ascorbic acid (Llorach, Martínez-Sánchez, Tomás-Barberán, Gil, & Ferreres, 2008; Pereira, Rodrigues, & Ramalhosa, 2013).

Agricultural products are grown in farms of different sizes. Small farms in the country, as part of the European Union, are of interest. Small farms continue to be a key element of Union agriculture, as they play a vital role in supporting rural employment and contributing to territorial development (https://agriculture.ec.europa.eu …). Cultivation of areas planted with lettuce in the Republic of Bulgaria is in two ways: "greenhouse cultivation" and "field cultivation".

Greenhouse cultivation is accompanied by additional costs for the farmer for materials, labor and heating of the greenhouses. Lettuce grown in greenhouses reach marketable size by the 3rd week of February. The last greenhouse salads are available for sale until the beginning of April. On the other hand, the production that came to the market earlier has a higher selling price and before the direct vegetable competitors of the salads - tomatoes and cucumbers. This is confirmed by the fact that the Bulgarian sharply reduces the consumption of lettuce at the moment when the selling prices of tomatoes and cucumbers fall to the levels of his purchasing power.

The harvesting period of the salads ready for the market is 20-25 days depending on the climatic conditions.

The production from the field cultivation begins to be offered on the market with some overlap with that from the greenhouse production (end of March - beginning of April). This means that at some point the last batches of greenhouse lettuces and the new production from the fields will be delivered to the exchange at the same time. This overlapping period varies in duration and calendar time of occurrence. It mainly depends on two factors:

– climatic conditions that change every year;

– the financial and time estimates of individual producers of greenhouse lettuce.

Another indisputable fact that needs to be taken into account is the yield fluctuations within each farm.

The import factor of lettuce from abroad has its influence on the volume of transport.

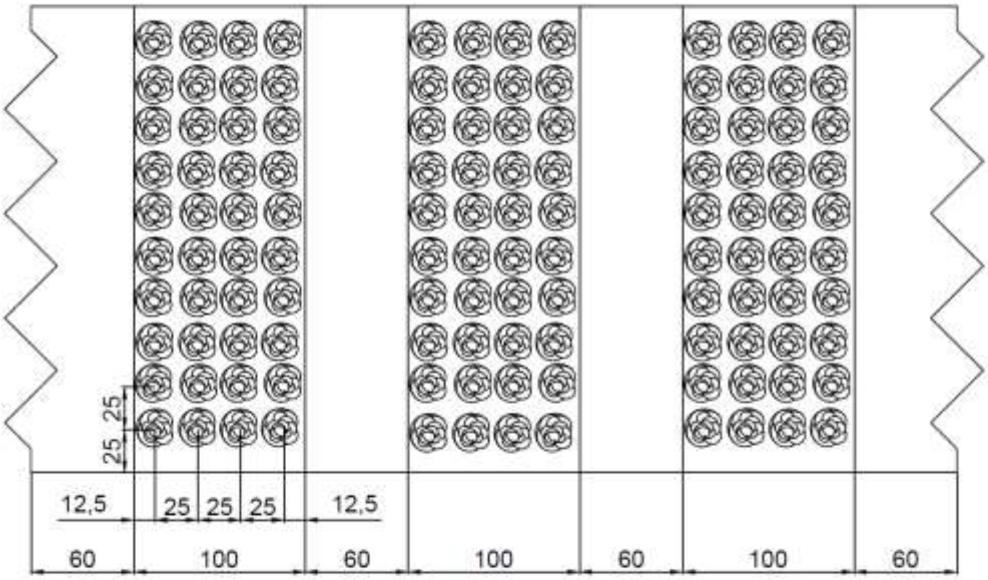

Figure 1. Lettuce planting scheme 25x25 cm

Transport is a major structure-determining branch (Barbov et al., 1993; Vasilev, 2004; Directives of the EU regarding transport policy, by types of transport; Tsankov, 1994; Zahariev, 2023) According to Radkov (2005) the factors that have a direct or indirect influence on the state and development of transport can be generally defined as internal and external. External factors can be conditionally divided into global, regional and external to the transport system within the country. Internal ones in the context of international integration are of national and local importance.

According to https://eurocode.bg/... the volumetric weight for salads is γ=5.0 kN/m3 = ~ 500 kg/m3 in free bulk (volumetric weight of loosely (disorderly) bulked or accumulated in large quantities of products).

When preparing lettuce for commercial purposes, 8-10 pieces are arranged in the transport package, depending on the variety and size.

Due to the wide distribution of banana packaging - cartons and their reusability are also used as transport packaging for lettuce. To protect the carton from moisture damage, a plastic bag is placed inside the carton and then the salads are arranged.

According to ORDER No. 16 of 31.05.1999 on physiological norms and rules for manual work with weights, the weight of the load does not exceed 15 kg for women and 50 kg for men for a single load when lifting, supporting, moving and carrying a distance of 2 m and 4,000 kg for women and 10,000 kg for men - total for change (https://www.gli.government.bg …; Zahariev, I. 2023; Zahariev, I. 2024).

The location of the wholesale market for fruits and vegetables near the village of Plodovitovo and the road connections with neighboring settlements are shown in fig. 2.

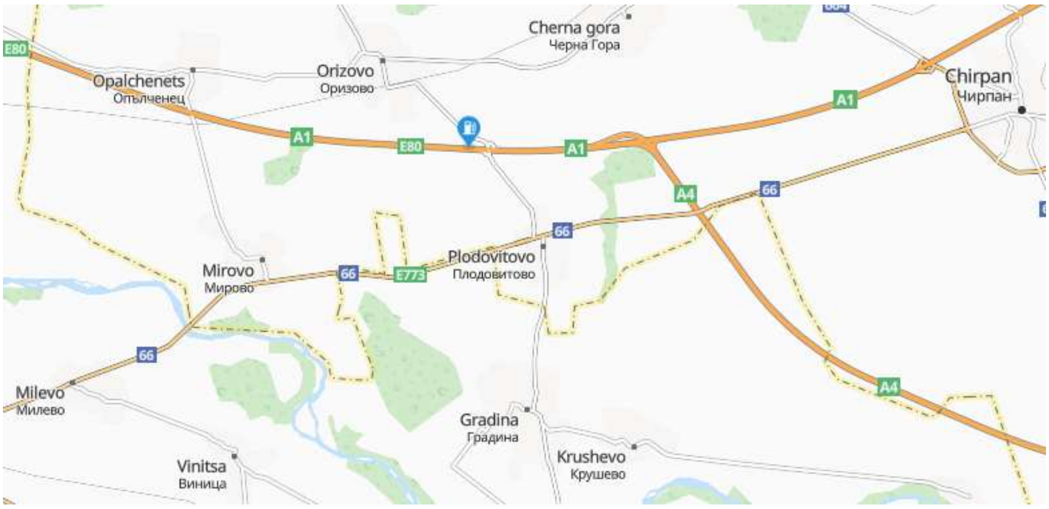

Figure 2. Location of Plodovitovo village (https://www.viamichelin.com/ …)

According to data posted on the website https://titul.bg/... Plodovitovo Vegetable Exchange is open 24 hours a day on all days of the week. According to data from the Administrative Register of the Republic of Bulgaria (https://iisda.government.bg …) the village of Plodovitovo belongs to Bratya Daskalovi municipality, Stara Zagora district. Highway A1 (Sofia-Burgas) passes by the village, which branches off to the east and there begins highway A4 (to Svilengrad and the border with the Republic of Turkey). The national road 66 Plovdiv - Stara Zagora passes through the village. The surrounding settlements around the village of Plodovitovo are connected by an asphalt road.

MATERIAL AND METHOD

The settlements within a radius of 25 km from the village of Plodovitovo are determined using electronic road maps. A diagram of the location of the villages in relation to the village of Plodovitovo is drawn and the transport connections between them are determined. The distance and travel time from Plodovitovo to each settlement are recorded in tabular form. On the basis of the collected data, the transport scheme, the carrying capacity of the means of transport and the ready quantities prepared for loading by the various manufacturers, the transport routes are made. After determining the routes, the distance and travel time from Plodovitovo to the most extreme point is calculated, taking into account that the vehicle moves without loads and along the shortest distance. On the way back, it starts from the farthest point through the intermediate stops to Plodovitovo:

$$L_{TM} = L_{P\_B1} + \sum_{i=1}^{n} L_{Bi} + L_{P\_B2} \quad (1)$$

where: L_{P_B1} is the shortest distance from Plodovitovo to the first holding, km. During this time, the vehicle moves without load, km; L_{Bi} – distance between two neighboring holdings from which it is loaded, km; L_{P_B1} - distance from the last holding from which it is loaded to Plodovitovo, km.

To the total delivery time is added the sum of the downtime and loading of the production in the individual farms:

$$T_{TM} = T_{P\_B1} + \sum_{i=1}^{n} T_{Bi} + \sum_{j=1}^{m} T_{Tj} + T_{P\_B2} \quad (2)$$

where: T_{P_B1} is the travel time from Plodovitovo to the first farm, min; T_{Bi} – duration of movement between two neighboring holdings from which the load is taken, min; T_{Tj} – duration of stay for processing documents and loading at the j-th farm, min; T_{P_B1} – travel time from the last farm from which it is loaded to Plodovitovo, min.

According to Vezirov & Kozlev (2002 and 2006) the carrying capacity coefficient of the vehicle is determined by the dependence:

$$K_T = min\{1, max[V_1,\ V_2, \dots\ V_i\,, \dots] * \rho * \psi\} \quad (3)$$

where: V_1, V_2, … V_i, … are the capacity volumes without or with different superstructures.

With a known load density ρ (kg/m3) and a volume utilization factor ψ, choose the one from the above capacities for which K_t ~1.

Of course, according to the law on road traffic - art. 126 "When transporting goods, the mass of the loaded road vehicle must not exceed the permissible maximum mass reflected in its registration certificate" (Vezirov Ch., Kozlev R. 2002; Vezirov Ch., Kozlev R. 2006; https://lex.bg …; https://rta.government.bg …; https://legislation.apis.bg …; https://iacp- …; Zahariev, I. 2024). For most vehicles, it is less when driving outside the permanent road surface network.

According to Zahariev (2023 and 2024) the volume of transport activities Q, t.km, for each operation is determined by the dependence:

$$Q = L.M, \qquad (4)$$

where: L – transport distance, km; M – mass of transported material, t.

The mass of one salad m_z, kg is determined by measuring 200 pieces of salad (taken at random from the observed arrays) with an electronic scale with a range of 5 kg ±1g. The resulting values are added together. The sum is divided by 200.

RESULTS AND DISCUSSION

Settlements up to 25 km from the village of Plodovitovo

The settlements within a radius of 25 km from the village of Plodovitovo have been determined. The data are placed in Table 1.

Table 1. Distances between the village of Plodovitovo and settlements (https://www.bgmaps.com/map/ …)

Village	The shortest distance between the settlement and the village of Plodovitovo, km	Time to cover the distance, min
Gradina	3.5	5
Orozovo	5.7	7
Krushevo	5.7	8
Mirovo	6.3	7
Parvomay	8.6	11
Opalchenets	9.8	12
Chirpan	10.2	11
Milevo	10.3	10
Cherna gora	11.1	14
Granit	11.6	14
Dobri dol	12.5	18
Vinica	14.1	16
Popovitsa	14.5	14
Turkmen	14.7	18
Karadjalovo	16.8	18
Selci	16.9	17
Zetyovo	17.2	18
Rupkite	17.4	25
Spasovo	17.8	20
Tsenovo	18	21
Ahmatovo	18.1	19
Gorno Belevo	18.2	23
Tatarevo	18.3	24
Partizanin	18.8	17
Boyalino	18.5	23

Pravoslaven	21.6	25
Bratya Daskalovi	22.2	27
Dalbok Izvor	22.2	28
Izvorovo	22.4	26
Cheshnigirovo	22.9	20
Darjava	23.1	28
Sredno Gradishte	23.6	27
Brezovo	23.8	29
Konush	24.7	28

* when driving on the A1 motorway.

According to the data in Table 2, there are 42 settlements within a radius of 25 km from the village of Plodovitovo. It is noteworthy that the time to cover 1 km is different for individual sections. This is due to a difference in the geometric characteristics of the road sections and the degree of wear of their coating.

Salad makers

The collected data for small farmers of lettuce from all 42 settlements that work with the exchange are placed in Table 2.

Table 2. Small farmers of lettuce

Village and farmer number	Area planted with lettuce, da	Yield from the area, kg
Gradina 1	0.9	1524.87
Gradina 2	1.1	1863.73
Orizovo 1	2	3388.6
Orizovo 2	0.5	847.15
Orizovo 3	1.6	2710.88
Krushevo 1	1.2	2033.16
Krushevo 2	1.3	2202.59

In Table 2, the agricultural producers from the 42nd settlement, namely Plodovitovo, are not marked. In the period 21 - 30.03.2023, 200 lettuces taken from different manufacturers were measured randomly. The average value of 1 piece of salad is m_z = 684g (0.684 kg). In the seeding scheme shown in fig. 1 the average yield is ***Qcc*** = 1,694.3 kg/da (16,943 kg/ha);

The obtained value is close to the official data published in the Annual Report on the State and Development of Agriculture 2021 of the Ministry of Agriculture, Food and Forestry, namely: for 2021 ***Qcc*** = 17,062 kg/ha (https://www.mzh.government.bg …).

30 packages (empty cartons with the plastic bags inside them) were weighed. The mass of the package is m_{op} = 1.986 kg

The total mass of a full box of salads is m_k = 7.368 kg.

Transport scheme

The transport scheme compiled on the basis of the data placed in table 1 is shown in fig.3:

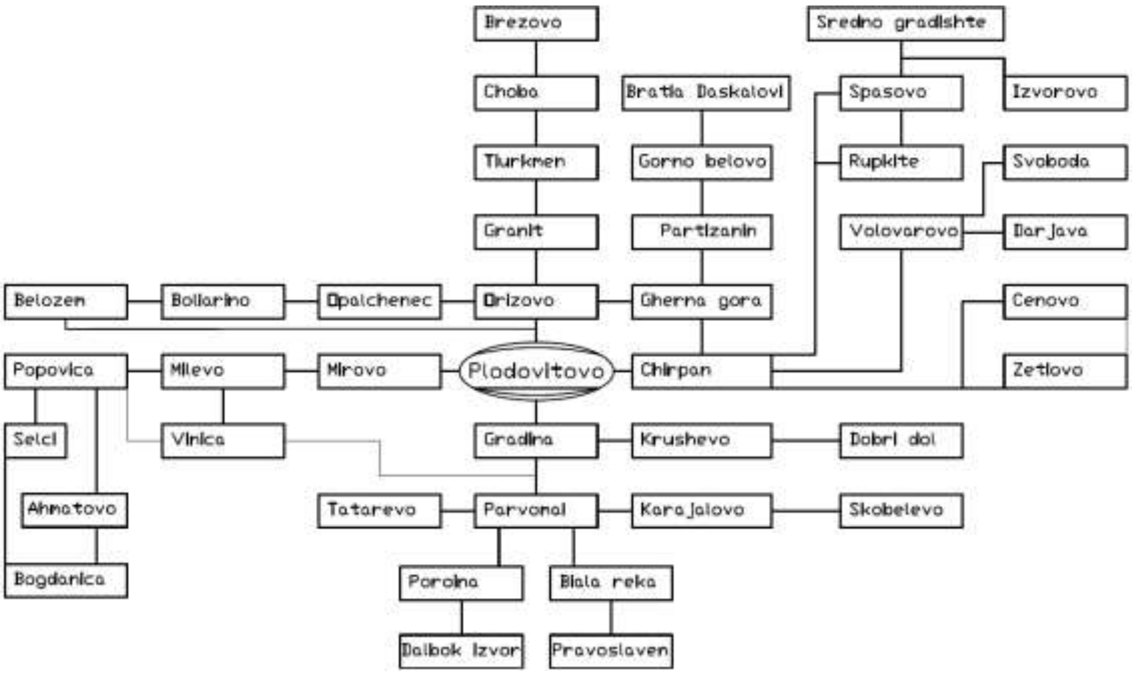

Figure 3. Transport scheme between the village of Plodovitovo and the villages

From fig. 3. the road connections between the village of Plodovitovo and the rest of the settlements in the study are visible. The main road connections are given with thick lines, and the minor ones with thin ones. It is noteworthy that the village of Plodovitovo is located at a crossroads. There are four exits in the four geographical directions.

Road routes and amount of cargo

To determine the parameters of the road routes, the distances between all points on the routes and the amount of cargo needed to be transported during the day were taken into account.

N1. Plodovitovo - Brezovo - Choba - Turkmen - Granit - Orizovo - Plodovitovo (47.6 km);

N2. Plodovitovo - Bratia Daskalovi - Gorno Belovo - Partizanin – Cherna Gora - Orizovo - Plodovitovo (44.4 km);

N3.1. Plodovitovo - Belozem - Bolarino - Oplchenets-Orizovo - Plodovitovo (39 km);

N3.2. Plodovitovo - Belozem - Plodovitovo (44.2 km);

N4.1. Plodovitovo - Sredno Gradishte - Izvorovo - Spasovo - Rupkite - Chirpan - Plodovitovo (53.1 km);

N4.2. Plodovitovo - Sredno Gradishte - Spasovo - Rupkite - Chirpan - Plodovitovo (50.3 km);

N4.3. Plodovitovo - Sredno Gradishte - Spasovo - Chirpan - Plodovitovo (47.2 km);

N4.4. Plodovitovo - Izvorovo - Spasovo - Rupkite - Chirpan - Plodovitovo (47.9 km);

N4.5. Plodovitovo - Izvorovo - Spasovo – Chirpan – Plodovitovo (44.8 km);

N4.6. Plodovitovo - Rupkite - Chirpan - Plodovitovo (34.8 km);

N5.1. Plodovitovo - Cenovo - Chirpan - Plodovitovo (36 km);

N5.2. Plodovitovo - Zetivovo - Chirpan - Plodovitovo (34.4 km);

N5.3. Plodovitovo - Cenovo - Zetovo - Chirpan - Plodovitovo (42.4 km);

N6.1. Plodovitovo - Svoboda - Chirpan - Plodovitovo (42.6 km);

N6.2. Plodovitovo - Darjara - Volovarovo - Chirpan - Plodovitovo (46.2 km);

N6.3. Plodovitovo - Svoboda - Volovarovo - Chirpan - Plodovitovo (48.1 km);

N6.4. Plodovitovo - Svoboda - Volovarovo - Darjjara - Volovarovo - Chirpan - Plodovitovo (56.9 km);

N7. Plodovitovo - Dobri dol – Krushevo – Gradina – Plodovitovo (25 km);

N8. Plodovitovo - Skobelevo – Karadjalovo – Parvomai – Gradina – Plodovitovo (42.6 km);

N9. Plodovitovo – Pravoslaven - Byala Reka - Parvomai - Garden - Plodovitovo (43.2 km);

N10. Plodovitovo - Dalbok Izvor - Poroina - Parvomai - Gradina - Plodovitovo (44.4 km);

N11. Plodovitovo - Tatarevo - Parvomai - Gradina - Plodovitovo (36.6 km);

N12.1. Plodovitovo - Bogdanitsa - Seltsi - Popovitsa - Milevo - Mirovo - Plodovitovo (38.6 km);

N12.2 Plodovitovo - Akhmatovo - Popovitsa – Milevo – Mirovo – Plodovitovo (36.2 km);

N12.3. Plodovitovo – Akhmatovo – Bogdanitsa – Seltsi – Popovitsa – Milevo – Mirovo – Plodovitovo (40.2 km);

N12.4. Plodovitovo - Vinica – Milevo – Mirovo – Plodovitovo (28.2) km;

It is noteworthy that there is only one route (N1, N2, N6, N7, N8, N9, N10 and N11) from the settlements to the vegetable market, with several others possible. In the presence of one route, the possibilities of combining are small. With variant N4, there are 6 sub-variants, which makes it possible to combine.

Transport work, t*km

Based on the routes defined above, the yield from each grower and the harvest period of lettuce ready for sale, the transport work for each route is determined daily. The data are presented in tabular form (Table 3) and shown in figures 4 and 5.

Table 3. Transported cargo and transport work daily for the period of harvesting the ready-to-market salads - 22 days

Transport route	Total cargo transported daily, t	Daily transport work, t*km	Coefficient, t/km
N1	4,13	68,28	0,250
N2	2,44	43,64	0,136
N3.1	1,81	31,57	0,104
N3.2	0,92	20,35	0,042
N4.1	1,08	23,35	0,050
N4.2	0,83	16,09	0,043
N4.3	0,55	10,13	0,030
N4.4	0,84	16,18	0,044
N4.5	0,57	10,17	0,032
N4.6	0,42	6,25	0,028
N5.1	0,71	11,52	0,044
N5.2	1,27	21,66	0,074
N5.3	1,83	35,77	0,094
N6.1	0,44	7,78	0,025
N6.2	0,63	11,29	0,035
N6.3	0,73	14,25	0,037
N6.4	0,93	21,79	0,040
N7	0,67	4,35	0,103
N8	1,73	21	0,143
N9	1,77	20,2	0,155
N10	1,63	21,06	0,126
N11	1,61	19,13	0,135
N12.1	1,81	27,87	0,118
N12.2	1,47	20,06	0,108
N12.3	2,19	37,14	0,129
N12.4	1,06	12,28	0,091

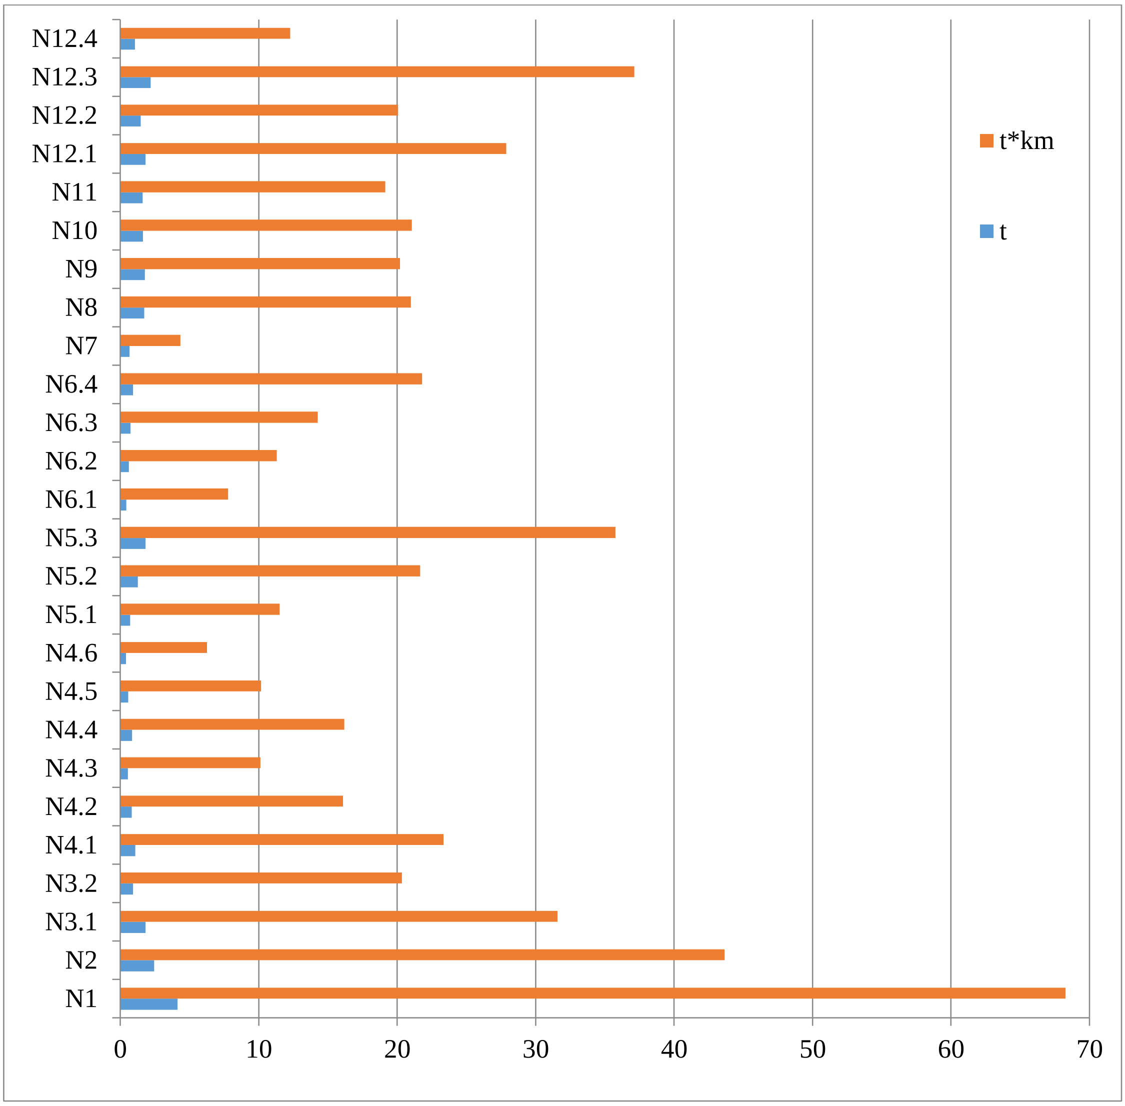

Figure 4. Transport work and the amount of salads transported daily

From the graph in Fig.4. it is evident that only on 3 routes (N1, N2 N12.3) there is a total load over 2t. For the rest, this value is not exceeded, which means that it can be transported by small trucks, for which a license and payment of "toll" fees are not required, but annual vignettes for using the road network outside populated areas.

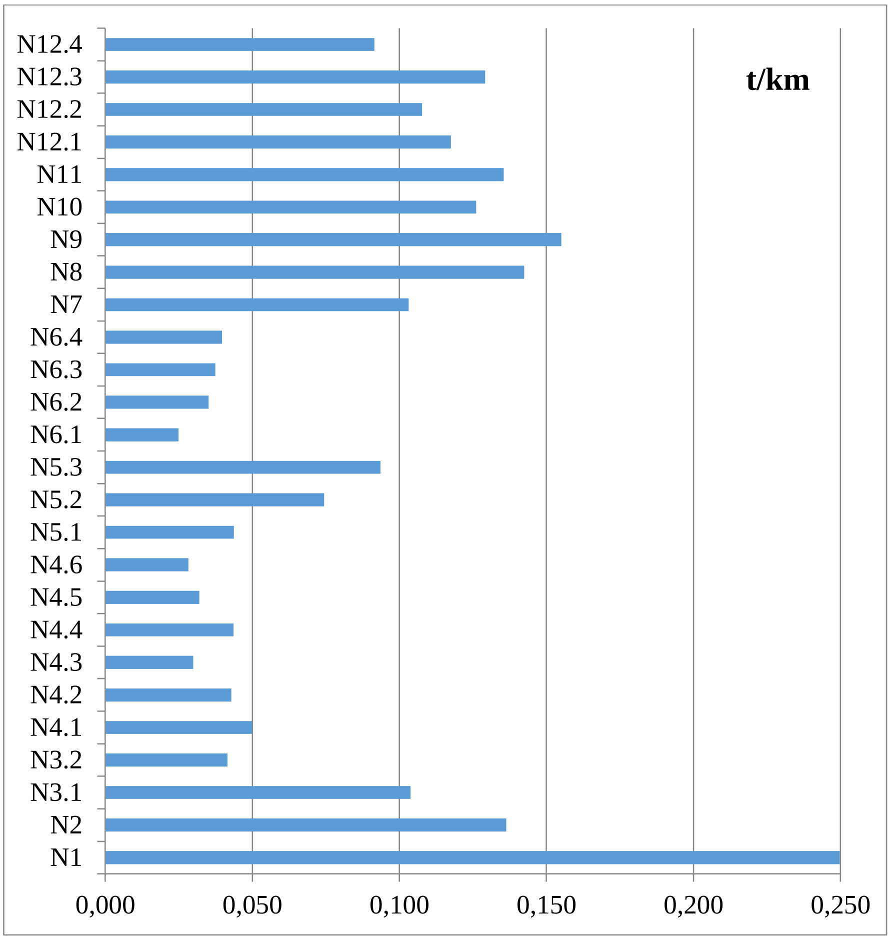

Figure 5. Coefficient φ, t/km

From figure 5 it is clear that the greatest value of the coefficient φ=0.250 is for route N1, followed by N9 φ=0.155, N8 φ=0.143, N2 φ=0.136 and N11 φ=135. The smallest value is reported for route N6.1 φ=0.025 followed by N4.6.

When choosing a route for the movement of a means of transport from several options, it should be taken into account that the coefficient φ has the largest possible value. That is, the largest amount of cargo to be transported over the shortest distance. Another factor that must be taken into account is the carrying capacity factor of the means of transport Kt.

Due to the fact that the cargo is salad, which requires fast delivery from the field to the end user, it is necessary to agree in advance the prepared daily amount of salad from each point. This indicator is also influenced by the market situation during the previous two days. If there is a product in the warehouse, it is not necessary to take the expected average quantity for the day, as the salad can be left in the field and in the following days be prepared for transport, depending on the agreements. In this way, losses from scrapped or revalued goods - salad will be reduced.

CONCLUSIONS

On the basis of the above, can be formulating the following conclusions:
1. The settlements within a radius of 25 km from the village where the vegetable market is located have been determined - 42;
2. The small agricultural producers of lettuce in each of 42 villages and their areas planted with lettuce were determined;

3. The average value of one salad and the yield in the used planting scheme were determined;
4. The transport scheme between the 42 villages and the vegetable market has been drawn up, and the routes for the movement of means of transport have been determined. Some routes have sub-variants, while others do not.
5. The transport work for each individual route is determined;
6. Due to the fact that lettuce quickly withers and loses its freshness, a recommendation has been made for a daily advance agreement to prepare different quantities depending on the availability in the warehouse and the market situation, which will lead to a reduction in losses from scrapped or revalued (reduced) salads.

ABSTRACT

Although mineral fertilizers are essential for vegetable production, their use can have negative consequences both on the quality of production and on the health of the soil and the environment. Therefore, organic fertilization is a good alternative to mineral fertilization and attracts a wide range of research related to food quality. This publication investigates the influence of mineral and organic fertilization on the growth and productivity of cabbage under abiotic stress conditions during the hot summer months. A three-year experiment with mid-early head cabbage variety "Ergensko" used different fertilization was introduce into practice in the field of the Agricultural University of Plovdiv. In the harvestable maturity phase, important productive indicators were evaluated. It has been established that plants grown under organic fertilization conditions have a significant biological potential, with their biometric indicators approaching those of mineral fertilizers.The variant fertilized with the organic fertilizer (Vitaorganic) was determined to have the highest sensory assessment and most preferred taste qualities. The study looks upon to Vitaorganic fertilizer as promising in growing mid-early cabbage with planting in June.

Key words: Cabbage, organic fertilization, productivity, vegetative behavior.

INTRODUCTION

In spite of the use of innovative agricultural techniques and methods, future yields can still be influenced by unfavorable climatic conditions. The size of the harvested area, planted with cabbage in Europe, reached its peak in 2012. Then, in the period 2013 – 2022 this area size had a lower value (Europe's Cabbage Market Report 2024). It is important to note that the rate of its growth in Bulgaria was fastest in 2016, when the harvested area increased compared to the previous year. From 2017 to 2022 the rate of its increase in our country remained a bit lower. To meet the demand for this product, it is important for the agricultural producers to optimize the cultivation technology, including optimal planting times, plant fertilization and irrigation standards, as well as choice of varieties and hybrids (Lapasov et al., 2017; Shokirov et al., 2021). Cabbage (*Brassica oleracea L.*) is a member of the family of cabbage crops and an important fresh and processed vegetable in most countries of the world. Cole crops are biennials, but are generally grown as annuals. They are suitable for the climate of many regions (Chiang et al., 1993; Hasan and Solaiman, 2012). They are known for their nutritional benefits because they are high in carotenoids, vitamins A, B_1, B_2 and C (Drozdowska et al., 2020), calcium, iron, magnesium, and dietary fiber (Guerena, 2006). Cole crops also contribute a substantial amount of protein to the diet (Traka & Mithen 2009; Colon et al, 2016). Cabbage has high requirements for all nutrients, especially nitrogen, and cabbage demands for achieving high yields ranged from 13 to 31 kg N/da (Sanderson and Ivany, 1999; Lešić et. al. 2004; Dumicic et al, 2014). Cabbage accumulates a large amount of organic matter in a short period. It is particularly demanding toward nitrogen and potassium, and also to phosphorus and calcium. It belongs to the group of plants, extracting the most nutrients from the soil. At the moment of harvesting, 39-44% of nitrogen, 42-48% of phosphorus and 38-51% of potassium are drawn from the soil. Nitrogen contributes to yield increase but fertilization only with nitrogen should not be allowed, as the deficiency of phosphorus and potassium worsen the quality and longevity of the cabbage produce (Kostadinov and Borisov 2017). Although mineral fertilization is essential for crop production, the excessive use of mineral fertilizers has negative consequences not only on yield quality but also on agroecosystems (Dumicic et al, 2014; Ahmed el-Henawy et al, 2018). In addition, overdosing of mineral fertilizers is a type of energy loss and can affect the nutrients in the soil (Kaushik and Djiwanti 2017). Nitrogen overuse in modern agriculture is of major importance for the quality of plant products (Dumicic et al, 2014). Therefore, organic fertilization is a good alternative to mineral fertilization and attracts a wide spectrum of research activities, related to studying the nutritional value, quantity and quality of foods. Organic fertilization increases soil biological activity, improves nutrient mobilization and soil structure, and increases soil water retention (Dumicic et al, 2014). Several studies have illustrated the positive effect of the combined use of mineral and organic fertilizers in fields, which for years in a row have continuously received only N, P and K, without any trace elements or organic fertilizers (Kaur et al. 2005; Chand et al. 2006). Last, but not least, the cultivation of field vegetable crops, including cabbage, is directly related to climate change and the trend for air temperature increase in the studied region (Slavcheva et al. 2020), and to the change of the main agrometeorological conditions in the country (Georgieva et al., 2022). The aim of the present study is to determine the effect of organic fertilization on the vegetative behavior, yields and quality of cabbage plants under conditions of abiotic stress during the hot summer months in three consecutive years.

MATERIALS AND METHODS

The experimental work was conducted in the period 2021-2023 in the Experimental Base of the Department of Vegetable Farming at the Faculty of Viticulture and Horticulture of the Agricultural University of Plovdiv with mid-early head cabbage variety "Ergensko" and planting date at the beginning of June.

Meteorological data. The meteorological conditions were monitored during the studied period by means of an automatic station in the experimental area. Daily meteorological data, including daily maximum and average air temperatures in °C and relative air humidity in percent were measured and processed in the period 2 June – 25 September. The phenological development of the cabbage was monitored in accordance with the international BBCH classifier (Meier, U. (2001), i.e., the plants were planted in the growing stage (4th true leaf unfolded-5th true leaf unfolded) and harvested in the stage of development of the harvestable vegetative parts (80% < typical size, form and firmness of heads reached). The growing technology included a drip irrigation system, meaning that measured rainfall had a lower influence.

Seedling production. Sowing was carried out in a nursery at the beginning of May. Organic mixture for seedlings was used - 80% perlite, 20% lumbricompost, developed for seedling bioproduction (Kostadinov and Filipov, 2013).

Planting. The plants were planted in the phase of growth at the moment of 4-5th leaf formation (4th true leaf unfolded - 5th true leaf unfolded) on the 2nd of June in the open air in a

2-row planting strip, by the scheme 90+70/50cm, with a profile of the soil surface high flat bed. The experiment was conducted by a block method in three variants (1. Control – unfertilized; 2. Mineral fertilization (NPK); 3. Vitaorganic) in four repetitions, with 20 plants for each repetition and size of the experimental area of 10 m^2. Fertilizers were used as main fertilization with preparation of the soil before planting in doses: N- 17.6 kg/da, P_2O_5- 7.2 kg/da, + K2O – 17.6kg/da, Vitaorganic - 100kg/da. The measurements were performed in the growing stage development of harvestable vegetative plant parts about the end of September.

Biometric studies. By means of biometric studies and morphological analyses, the most important sides of the cabbage vegetative behavior in the growing stage development of harvestable vegetative plant parts (80% < typical size, form and firmness of heads reached) has been tracked for 16 plants per variant for each variety. The assessment of the vegetative development of the plants in harvestable maturity (growing stage development of harvestable vegetative plant parts - 80% < typical size, form and firmness of heads reached) was made for 16 plants per variant about the end of September. The studied parameters were: fresh mass of the whole plant (kg); rosette – diameter (cm), mass (kg); number of leaves; stem - diameter (mm), mass (kg); and height (cm).

Production quality. An average sample of 16 well-ripened cabbage heads for each cultivation variant was analyzed by the parameters: dry matter content determined by weight (by drying ground plant material at 500 °C to constant weight); ascorbic acid by Tillman reaction with 2,6-dichlorophenolindophenol (Ghenadiev et al., 1969); total sugars by Schoorl Regenbogen (Gennadiev et al., 1969). A 5-point scale (taste Ranking test) was used, with the lowest score being 1 and the highest score being 5.

RESULTS AND DISCUSSION

Meteorological conditions. Local climate conditions greatly affect cabbage production, primarily plant growth, occurrence and development of diseases, harmful insects, and weeds (Cervenski et al, 2022). These authors report that certain abiotic stresses can be minimized by irrigation and fertilization, whereas others, such as fluctuating air temperatures, are more difficult to overcome. Although adapted to different climatic and soil conditions, cabbage prefers colder and wetter growing regions (Matotan, 2006). It is a cool season crop, which tolerates light frost and even short-term hard freezes, but prolonged deep freezes are fatal for it (Capinera, 2020). The following temperature ranges are pointed out by the different authors as optimum for the head formation phenophase: 17.7 to 20°C (Howe and Waters, 1994), 16 to 20°C (Hara and Sonoda, 1982, Criddle et al., 1997), 15 to 18℃ (Lešić et al., 2004), 17.2 to 19.9°C (Žnidarčič et al., 2007), 14 to 24°C (Toth et al., 2011), 16.1 to 16.8°C (Kołota et al., 2015), 17°C and 22°C (Nurhidayati et al., 2016), 17.5-19.1°C (Paranhos et al., 2016) and 15 to 18°C (Červenski and Medić-Pap, 2018). The temperatures, which can cause heat stress and adversely affect cabbage head formation and yield, according to various sources, are: above 19°C (Everaats, 1990),above 25°C (Matotan, 2006), above 24°C (Kahn et al., 2007) and above 30°C (Červenski and Medić-Pap, 2018). Optimal growth occurs at an average daily temperature above 16°C with an average daily maximum of 24°C and daily amplitude of about 14°C.

The average temperatures in all considered months of the three experimental years significantly exceeded the optimal values of 17°C (Figures 1 and 2).

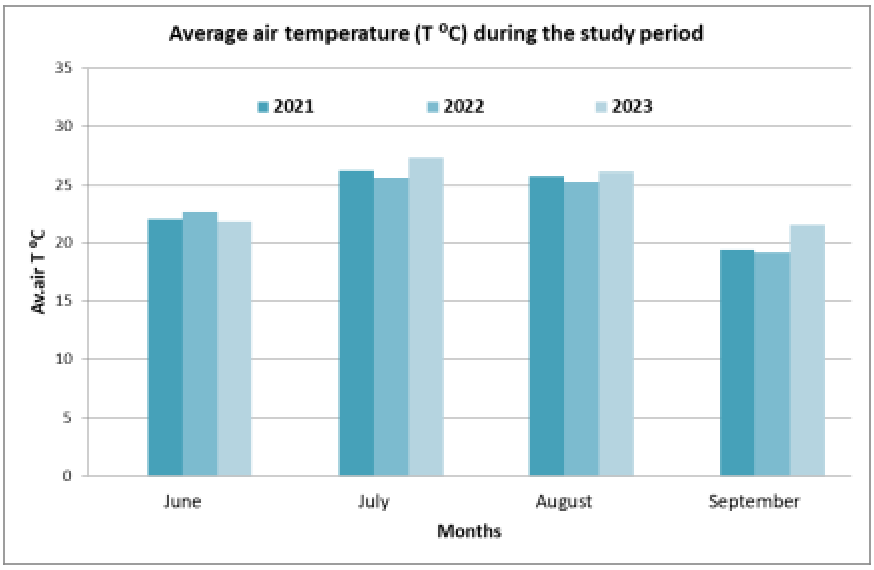

Figure 1. Average daily temperatures AU-Plovdiv

The last of the years – 2023 – was with the lowest average temperature in the initial period of rooting and adaptation of the seedlings in June, which had a favorable effect on the cabbage development in its later phases.

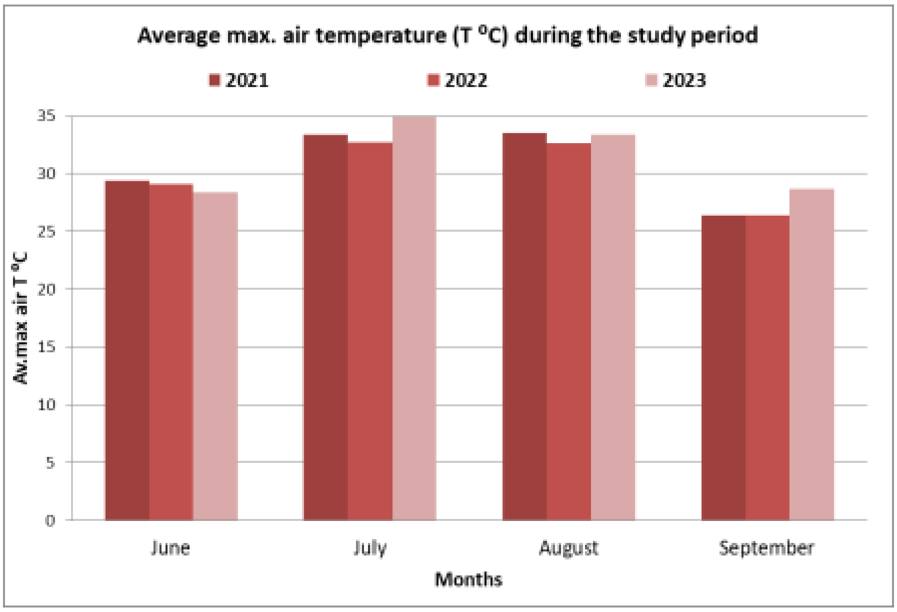

Figure 2. Average of daily maximal temperatures AU-Plovdiv

The highest temperatures in 2023 were seen in July and August, but combined with optimal irrigation, they had no adverse effect on the major morphological parameters. That same year, September was warmer, which favored the late stages of the cabbage development. The average of the maximum values was highest in July 2023, when it reached 35°C.

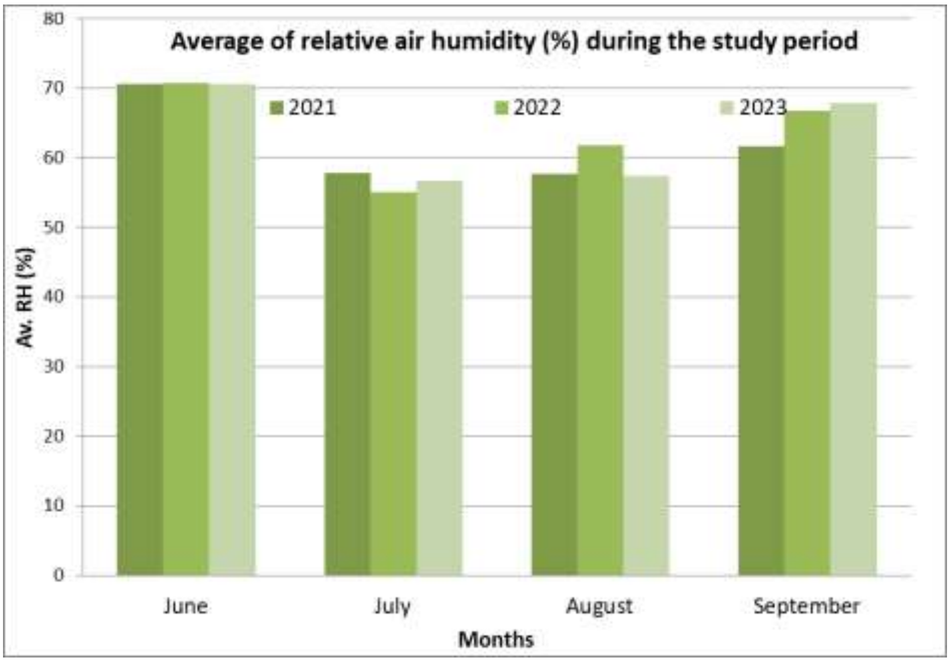

Figure 3. Average of relative air humidity % AU-Plovdiv

Relative air humidity (RH%) is an important meteorological parameter during the period of growth and formation of the product part (cabbage head). The crop requirements for average relative humidity are within 60 to 90 %. The values for the three experimental years were close – about 71% in the initial period (June), as well as in the period of harvestable ripeness – about 80% (Figure 3).

During the warmest months every year, the values were between 62% and 55%. According to FAO the yield under irrigation conditions reaches 2500 kg/da to 3500 kg/da with a maximum of 5000 kg/da in case of spraying and good fertilization. The duration of the growing season of cabbage varies depending on the climate, variety, and planting date, and in the particular case of the experiment it was 115 days. Typical of the species is the slower rate of development in the early phases (the first half of the growing season), which shows up well here even at the measured above-normal temperatures. During the next phase of growth, the plant doubles its weight every 9 days for about 50 days. The period of ripening is 15 days, and the harvest is collected around the 25th of September.

Vegetative parameters

The number of leaves together with the diameter and mass of the leaf rosette determine to a great extent the biological potential of the plant and the amount of its yield. Fertilization and climatic conditions during the growing period strongly influence on the biometric parameters of the leaf rosette. A variance analysis of the change in the factors fertilization and year conditions was made (Table 1). From the obtained average values and in accordance with the three measured parameters (number of leaves, diameter and mass of the leaf rosette), the best growth stands out in the option with conventional fertilization compared to the other variants. The increase in the weight of the leaf rosette is the highest. Dumičić et al., 2014 declared obtaining similar results for the leaf rosette in an experiment with mineral and organic fertilizers. The values of the biological parameters with biological fertilization are also higher than those with the control plants. The statistical analysis of the influence of this factor shows significant differences between the two types of fertilization and the control, on the one hand, and between the conventional and biological fertilization, on the other hand. The meteorological conditions year by year also have a statistically significant influence on the values of the parameters, considered in the study. The strongest influence of this factor has been recorded for the diameter of the leaf rosette, with an increase from the first to the last year seen with the three variants of fertilization. A reason for this result can be the lower air temperatures in June 2023, and the warmer autumn season in the same year. The plants, grown at a cooler initial period and higher temperatures during ripening, have the largest diameter of their leaf rosette. The influence is weaker for the number of leaves and weight of the rosette, and there is no positive gradation in the years, especially regarding the number of leaves per leaf rosette.

Table 1. ANOVA: two factors with replication of the leaf rosette biometric indicators

Control

Biological fertilization						
year	Diameter, cm		Number of leaves		Weight, kg	
2021	82.8	lsd interaction	17.0	lsd interaction	1.39	lsd interaction
2022	92.8	**5%=8.81**	21.4	**5%=3.54**	1.30	**5%=0.27**
2023	95.6	**1%=11.69**	17.4	**1%=4.70**	1.50	**1%=0.36**
average	**90,40**	**0,1%=15.16**	**18.60**	**0.1%=6.10**	**1.40**	**0.1%=0.46**

The measured biometric indicators height of the whole plant, diameter of the leaf rosette, weight and diameter of the cabbage stem and average mass of the whole plant, are presented in Tables 2 and 3.

Obtaining similar results was reported by Haque et al., 2022 in a comparative study with organic and NPK fertilizers for cabbage plants. The variant with biological fertilization is also with higher values compared to the unfertilized option. The calculated variance for this factor shows statistically significant differences for all taken parameters between the conventional fertilization and the control, on the one hand, and between the conventional and biological fertilization, on the other hand, except for the stem dimeter indicator in biological fertilization. Similar to the results, concerning the leaf rosette, the biological fertilization is statistically significantly different, compared to the control. Ahmed el-Henawy et al. 2018 concluded in a study of red cabbage with nano-Se, nano-Cu, compost tea and NPK fertilizers that the vegetative parameters were higher compared to the unfertilized control plants. The meteorological conditions by year have a strong and statistically significant influence on the values of the cabbage weight and height and the average mass of the whole plant. As with the leaf rosette diameter, the weight goes up, reaching its peak in 2023. For the parameters cob diameter and diameter of the entire plant, the influence is weak, and, in most cases, statistically not significant. The analysis of the results shows the strongest growth in the leaf rosette and the highest average mass of the whole plant in the conventionally fertilized plants (Table 3).

Table 2. ANOVA of the two factors on the cabbage head biometric indicators

Cabbage productive behavior in the period 2021-2023. From the two-factorial variance analysis, performed for determining the yield variation in accordance with the factors meteorological conditions/year and type of fertilization, F values, higher than the critical F values were registered, the same being true also for the interaction (Tables 4 and 5).

Table 4. ANOVA of the cabbage productivity

Source of Variation	SS	df	MS	F	P-value	F crit	μ influence
Type of fertilization	13382568.04	2	6691284	192.25	7.15E-13	3.55	37.90
years	20073059.28	2	10036530	288.36	2.13E-14	3.55	56.85
Interaction	1224759.147	4	306189.8	8.80	0.000405	2.93	3.47
Error	626490.5548	18	34805.03				
Total	35306877.02	26					

This indicates a very good confidence at the 0.1%/p<0.001 level for the difference between the yield values under the influence of the two factors and the interaction. The calculated percentage of the total variation for the influence of each factor individually and the interaction between them, shows that the strongest influence on the yield has the factor year conditions, while the interaction between the factors is with the weakest effect. We can conclude from these results that both factors (the meteorological conditions and the applied types of fertilization), considered independently of each other, have affected the cabbage variety yield (Tables 4 and 5) in the studied period.

Table 5. Cabbage yield when applying different types of fertilization over a three-year period

Variant of fertilization	**Repetitions**	**Yield, kg/da**			**Average fertilizing variants**
		2021	**2022**	**2023**	
1 control	I	5566.1	6106.01	7120.3	6264.1
	II	5850.97	6418.51	7484.72	6584.7
	III	5674.3	6224.71	7258.72	6385.9
	Average values 2021	5697.1	6249.7	7287.9	**6411.6**
2 NPK	I	6711.979	8181.9	9014.19	7969.4
	II	6986.966	8517.11	9383.5	8295.9
	III	6849.246	8349.23	9198.54	8132.3
	Average values 2022	6849.4	8349.4	9198.7	**8132.5**
3 Vitaorganic	I	6153.583	6892.02	8473.49	7173.0
	II	6530.333	7313.98	8992.28	7612.2
	III	6279.103	7032.6	8646.33	7319.3
	Average values 2023	6321.0	7079.5	8704.0	**7368.2**
	Average values by year 2021-2023	**6289.2**	**7226.2**	**8396.9**	
LSD 5% Fertilization Type	184.8	lsd 5% year	184.8	lsd 5% interaction	320.0
lsd 1% Fertilization Type	253.2	lsd 1% year	253.2	lsd 1% interaction	438.4
lsd 0.1% Fertilization Type	344.9	lsd 0.1% year	344.9	lsd 0.1% interaction	597.3

The continuation of the analysis with the calculated least significant differences of the average yield values is given in Table 5. It becomes clear from the results that the average value of the yield for all types of fertilization and the control is the highest and significant to the level of 0.1% during the growing season of 2023. From the obtained significance of the differences, we can also conclude that the meteorological conditions for each individual year have affected the yield differently and significantly up to 0.1%. The variance of the typical yield with the type of the fertilization factor is in a similar trend, with the average yield value for a three-year period for the variant with mineral fertilization being the highest and significant up to 0.1% compared to the other options. The yield in the biological fertilization variant, on the other hand, is higher than the control, and significantly different not only from the control but also from the case with mineral fertilization. The biologically fertilized plants outperform the control and are similar in their productive performance, compared to the conventionally grown plants in all three experimental years for the three planting dates.

Impact of organic fertilization on the quality of production 2021-2023. Analyses showed that organic production systems, which omit the use of agrochemicals, produce crops with lower yields, but superior nutritional composition (Rempelos et al., 2023; Gelaye, 2024). The same studies confirm that higher concentrations of phenolics and other nutritionally desirable phytochemicals are found in organic vegetables. In this study, the fertilization options were compared in terms of Dry matter (%), Ascorbic acid (mg %), Total sugars (%) and a sensory assessment was made (Table 6). The content of dry matter in the unfertilized plants is the lowest – 8.92%. After biological fertilization, it increases by 4.04% compared to the control, and approaches the level, contained in the plants, fertilized with NPK (Table 6).

Table 6. Average value of chemical components and sensory assessment on a 5-point scale

Variant	Dry matter (%)	Ascorbic acid (mg %)	Total sugars (%)	Sensory assessment (1-5)
1. Control (unfertilized)	8.92	36.84	4.06	4.5
2. NPK (MT)	10.15	38.75	4.68	4.1
3. Vitaorganic	9.28	31.11	4.18	4.8

The biologically fertilized plants with Vitaorganic have a 2.96% higher content of sugars compared to the control plants. The concentration of the total carbohydrates is comparable to the option with mineral fertilization. The lowest value – 4.06% - is the value, measured in the control variant. The sensory assessment shows that the cabbage plants, grown after biological fertilization with Vitaorganic, have the most preferred taste quality, and the value of this indicator is close to the maximum 4.8. The plants, grown without fertilization, are next in order with 4.5. The lowest is the assessment of the plants, fertilized with mineral fertilizers – (4).

CONCLUSIONS

This study considers the influence of different variants of fertilization on the biological behavior of cabbage within a period of three consecutive years – 2021-2023. The main chemical components in the harvested cabbage produce and its taste quality have been assessed for plants, fed with mineral (NPK) and organic fertilizers (Vitaorganic).

1. Organically fertilized plants (Vitaorganic) have a substantial biological potential and productive parameters, close to those, of plants, grown with mineral fertilization (NPK),

under different climatic conditions. Both fertilization variants show statistically significant differences with respect to the control.

2. The meteorological conditions for each individual year affect the yield differently and significantly up to 0.1%.
3. Organic fertilization leads to accumulation of amounts of dry matter and total sugars, similar to the ones, accumulated in plants, grown with mineral fertilization.
4. The sensory assessment shows that the most preferred taste qualities have the leaf rosette, grown after biological fertilization with Vitaorganic, followed by the unfertilized control plants.
5. The conducted study gives grounds to recommend the biological fertilizer Vitaorganic as a promising option for growing mid-early cabbage with planting in June.

ABSTRACT

The objective of this study was to determine the relationships between field capacity moisture content (FC) and some soil physicochemical properties in 80 surface soil samples (0-20 cm) taken from arable fields around Samsun, Türkiye. After analyzing clay (C), silt (Si), sand (S), organic matter (OM) contents, electrical conductivity (EC), field capacity (FC) and bulk density (BD) of soil samples, FC values were estimated using the other soil properties by linear regression models using stepwise analyses in SPSS program. The FC values varied between 13.80% and 46.00% with a mean of 31.00%. While EC, C, Si, OM contents had significant positive correlations with FC, BD and sand content had negative correlations with FC. To estimate FC value, the multiple linear regressions were produced by stepwise analyses using the soil properties. Producing linear regressions with using only soil textural fractions had lower linear regressions to predict FC. When BD and OM was added into the linear regression models, precision for the estimation of FC increased. According to stepwise analyses, three linear multiple regression models were produced using BD, C, Si and OM contents. While the first model including C and Si contents as variables had 0.876** R^2 and 3.052% RMSE, the second model including BD, C and Si contents had 0.898** R^2 and 2.796% RMSE. The highest R^2 value (0.916**) and the lowest RMSE (2.498%) were estimated with a linear multiple regression model including BD, C, Si and OM contents. It was determined that BD, C, Si and OM contents are most effective soil properties on FC. The FC values of arable fields can be estimated precisely using these soil properties as variables in multiple linear regression models.
Keywords: Soil moisture, multiple regressions, soil texture, bulk density, organic matter.

INTRODUCTION

In sustainable soil management, it is important to know the continuity of soil and water quality which depends on the relationships among soil properties. Soil moisture characteristics should be determined in studies related with soil hydrological properties and plant relations (Rawls, 1982, Puckett et al. 1985). Laboratory measurement of soil moisture characteristic generally takes long time (Rawls, 1982). Multiple linear regressions are used to determine relationships between soil moisture constants and soil properties (Salchow, 1996). The soil properties used in multiple regressions as variables are generally clay, silt sand fractions, EC, soil pH, exchangeable cations, soil organic matter content, bulk density and total porosity (Gülser and Candemir, 2008; Candemir and Gülser, 2012; Gülser and Candemir, 2014; Gülser 2016; Gülser and Ekberli, 2019). Field capacity (CF) defines soil moisture content retained by the soil particles gravimetrically at a pressure of 0.33 bar. Gülser (2004) used pedotransfer functions to determine field capacity and permanent wilting point of cultivated fields. He reported that soil moisture constants can be predicted much more precisely when using soil physical and chemical properties together in the multiple regression models. The objective of this study was to determine the multiple linear regression models between field capacity (FC) values and some soil properties using stepwise analyses to predict moisture content at FC.

MATERIAL AND METHODS

In this study, the relationships between field capacity (FC) moisture contents and some soil physicochemical properties were determined in 80 surface soil samples taken arable fields around Samsun, Türkiye. Some basic soil properties were analyzed as follows; particle size distribution by hydrometer method, bulk density core method (Demiralay, 1993), organic matter (OM) content was determined using the modified Walkley-Black method, electrical conductivity (EC) in the same soil suspension by EC meter, exchangeable cations by ammonia acetate extraction (Kacar, 1994). Field capacity (FC) moisture constants were determined by keeping soil samples saturated for 24 hours on ceramic plates of 1 bar, after than under 0.3 bar pressure until the moisture content of soil samples reached equilibrium (Klute, 1986). Soil moisture contents at FC were taken as dependent variables and stepwise regression models with measured soil properties were created using the SPSS 17.0 program. The accuracy of the multiple regression models were tested with determination coefficient (R^2) and root mean square error (RMSE).

RESULTS AND DISCUSSION

The soil properties, except EC, are generally showed normal distribution (Table 1). According to the EC values, soil samples are generally non-saline, organic matter contents of samples are around moderate level (Soil Survey Staff, 1993). The FC values varied between 13.80% and 46.00% with a mean of 31.00%.

Table 1. Descriptive statistics of soil properties (n=80).

	Minimum	Maximum	Mean	Std. Deviation	Skewness	Kurtosis
Field Capacity, %	13,80	46,00	31,00	8,72	-0,437	-0,894
Clay,%	9,99	68,73	34,71	16,72	0,347	-0,834
Silt,%	3,05	48,74	27,33	9,09	0,127	-0,290
Sand,%	6,84	81,71	37,96	19,73	0,350	-1,017
OM,%	0,58	3,87	1,90	0,73	0,341	-0,259
EC, dS/m	0,11	2,65	0,65	0,46	1,933	5,251
BD, g/cm^3	1,06	1,60	1,39	0,15	-0,498	-0,853

While EC, C, Si, OM contents had significant positive correlations with FC, BD and sand content had negative correlations with FC values. De Macedo et al. (2002) reported that the moisture constants in the multiple regression equations were positively correlated with clay and porosity, and negatively correlated with sand content of soil samples. In another study, Bauer and Black (1992) found significant correlations between the moisture values at field capacity and the organic carbon, sand and clay contents.

To predict FC values, the multiple linear regressions were produced by stepwise analyses using the BD, C, Si and OM contents of soil samples (Table 2). Producing linear regressions with using only soil textural fractions had lower regressions to predict FC. When BD and OM was added into the linear regression models, precision of the FC prediction increased. While the first model including C and Si contents as variables had 0.876** R^2 and 3.052% RMSE, the second model including BD, C and Si contents had 0.898** R^2 and 2.796 RMSE. The highest R^2 (0.916**) value and the lowest RMSE (2.498%) were obtained with a multiple linear regression model including BD, C, Si and OM contents (Figure 1). Gülser (2004) reported that total porosity calculated from the bulk density had the highest direct effect on FC moisture content and using physical properties in pedotransfer models had higher relationships with the measured values compared to chemical properties. He concluded that using physical properties with chemical properties together in the equations increased the accuracy of models increasing R^2 values from 0,706** to 0,853**.

Table 2. Linear multiple regression models used to predict field capacity (FC) values.

Model	Linear Regressions	R^2	RMSE, %
1	FC = 9,163 + 0,464*C + 0,210*Si	0.876**	3,052
2	FC = -26,907 + 0,613*C +0,316*Si + 20,134*BD	0.898**	2,796
3	FC = -36,218 + 0,588*C + 0,301*Si +24,741*BD +2,198*OM	0.916**	2,498

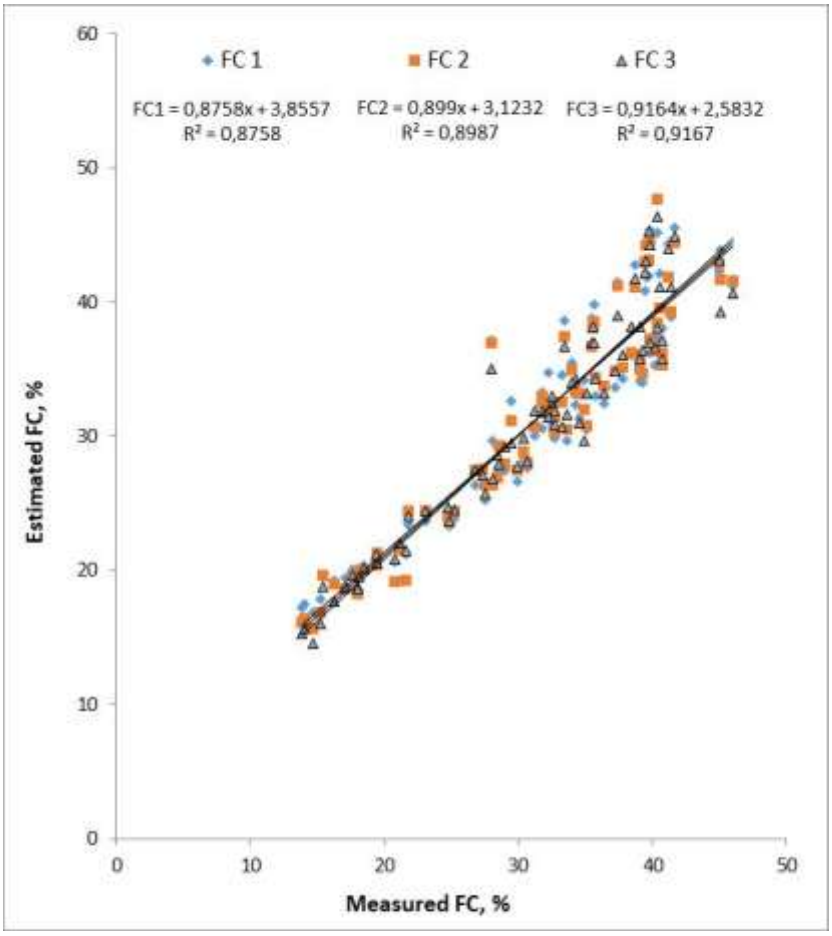

Figure 1. Comparison of measured and estimated field capacity (FC) by three multiple linear regression models.

CONCLUSION

In this study, FC values of the soils had significant positive relationships with EC, C, Si, OM contents, and significant negative relationships with BD and sand contents. It was determined that BD, C, Si and OM contents are most effective soil properties on FC. The FC values of arable fields can be estimated precisely using these soil properties as variables in linear multiple regression models. The equations found in this study can be used to estimate the FC values of agricultural soils in the sampling region having similar properties. However, the success of models in determining moisture characteristics for larger soil groups depends on the results of studies to be conducted with more samples containing greater range for physical and chemical values. Also, the reliability of the models should be examined with other soil sample data set.

ABSTRACT

In this study, the relationships between soil electrical conductivity (EC) and some soil physicochemical properties were determined in 200 surface soil samples (0-20 cm) taken from cropland fields around Samsun, Türkiye. After analyzing clay, silt, sand, soil reaction (pH), electrical conductivity (EC), organic matter (OM), exchangeable Ca, Mg, K and Na contents of soil samples, regression models using stepwise analyses in SPSS program were done between soil EC values and soil properties. The EC values varied between 150 and 1885 µS/cm with a mean of 616 µS/cm. While exchangeable cations (Ca, Mg, K, Na), pH and clay content had significant correlations with EC, Si and sand contents showed negative correlation with EC. Soil EC values did not show a significant relationship with soil organic matter content. To predict soil EC value, the multiple linear regressions were produced by stepwise analyses using the soil properties. Producing multiple regressions with using only clay, silt, sand, OM and soil pH as variables had lower prediction of EC. When including exchangeable cations in multiple linear regression models, precision of the EC estimation increased. According to stepwise analyses, three multiple linear regression models were produced using only clay, exch. Na and Ca contents. While the first model including just exch. Na as a variable had 0.438** R^2, the second model including exch. Na and clay content as variables had 0.574** R^2. The highest R^2 value (0.595**) and the lowest RMSE (187,28 µS/cm) were estimated with a linear regression including clay and exch. Na and Ca contents. It was determined that clay and exch. Na and Ca contents are the most effective soil properties on predicting of soil EC values.

Keywords: Salt, EC, exchangeable cations, soil texture.

INTRODUCTION

Soluble ion concentration in soil suspension is known as soil salinity which influences soil fertility (Pitman and Läuchli, 2002). Generally, soil salinity level is determined in soil solution via electrical conductivity (EC) measurement. It is an indicator of dissolved ion concentration in soil solution (U.S. Salinity Laboratory Staff, 1954). Gorji et al. (2015) reported that prediction of soil salinity is important to explain soil degradation. Wang et al. (2018) studied several regression models for estimating soil salt content. Multiple linear regressions are generally used for modeling and simulation in most of soil physical, chemical and biological processes researches. Basic soil properties such as clay, silt, sand, organic matter contents, exchangeable cations, total porosity, and bulk density are used as variables for developing multiple regression models (Gülser 2004; Gülser and Candemir, 2008; Candemir and Gülser, 2012; Gülser and Candemir, 2014; Gülser 2016; Gülser and Ekberli, 2019). Benke et al. (2020) reported that most frequently occurring predictors for EC in multiple regression models were soil depth, soil reaction, soil texture and geomorphological mapping unit. In many studies to predict soil EC values, soluble ions in soil solution were used as majajor variables (Shrestha, 2006; Lake et al. 2009; Andrade Foronda and Colinet, 2023). The objective of this study was to predict soil EC values using some soil physical and chemical properties as variables in linear multiple regression models.

MATERIAL AND METHODS

In this study, the relationships between soil electrical conductivity (EC) and some soil physicochemical properties were determined in 200 surface soil samples (0-20 cm) taken from cropland fields around Samsun, Türkiye. Some basic soil properties were analyzed as follows; organic matter (OM) content was determined using the modified Walkley-Black method, particle size distribution by hydrometer method (Demiralay, 1993), soil reaction (pH, 1:1 (w:v) soil:water suspension) by pH meter, electrical conductivity ($EC_{25°C}$) in the same soil suspension by EC meter, exchangeable cations by ammonia acetate extraction (Kacar, 1994). To predict the EC values of soils, linear multiple regression equations between EC and the soil properties were obtained with stepwise analyses using the SPSS statistic program.

RESULTS AND DISCUSSION

Physical and chemical properties of the soil samples used in the study are given in Table 1. The soil samples are generally showed normal distribution, except EC, pH and exch. Na content. According to the EC values of soil samples, 89,1% is none saline, 9,7% is very slightly saline and 1,2% is slightly saline (Figure 1). Soil reaction (pH) of 90% samples is classified as from neutral to moderately alkaline. Organic matter contents are generally classified as low to moderate (Soil Survey Staff, 1993).

Table 1. Descriptive statistics for the properties of soil samples (n=200).

	Minimum	**Maximum**	**Mean**	**Std. Deviation**	**Skewness**	**Kurtosis**
EC, µS/cm	150,00	1885,00	616,39	292,10	1,17	2,11
Clay, %	10,18	68,73	35,56	13,88	0,23	-0,64
Silt, %	3,05	66,37	28,65	9,02	0,53	0,76
Sand, %	4,27	81,71	35,78	16,27	0,55	-0,50
Org. Matter, %	0,20	4,19	1,99	0,75	0,27	-0,15
pH(1:1)	4,85	8,33	7,50	0,61	-1,76	3,36
Ca, cmol/kg	2,36	52,53	21,84	9,74	0,04	-0,49
Mg, cmol/kg	0,52	19,83	6,89	4,20	0,86	-0,09
K, cmol/kg	0,11	1,79	0,58	0,33	0,97	0,64
Na, cmol/kg	0,08	2,52	0,54	0,47	1,80	3,07

Correlations between EC values and soil properties are given in Table 2. Exch. Ca, Mg, K, Na, pH, OM and clay content had significant positive correlations with EC values while sand content had a negative correlation. The correlation values between EC and exch. cations were ordered as follows; Na (0,662**) > K (0,468**) > Mg (0,451**) > Ca (0,332**). In many studies, other researchers determined similar relationships between EC and exch. cation contents (Taghizadeh Mehrjardi et al. 2008; Lake et al. 2009; Candemir and Gülser, 2011; Gülser et al. 2015; Gülser and Candemir, 2015).

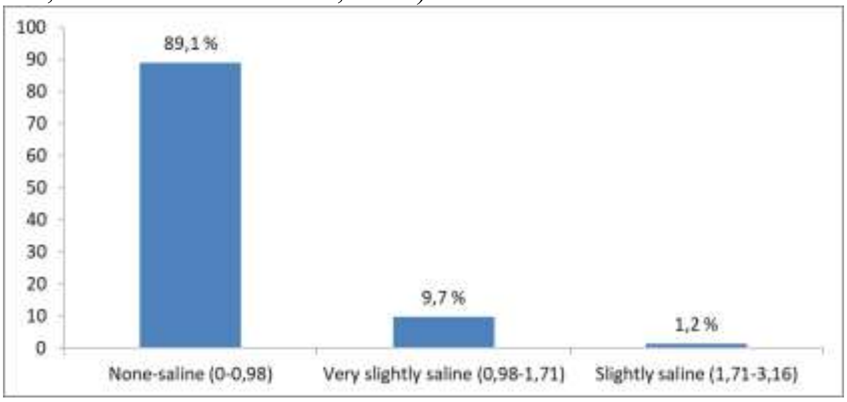

Figure 1. Frequency of EC range (mS/cm) values of the soil samples.

Table 2. The correlation matrix among EC values and soil properties.

	C	Si	S	pH	OM	Ca	Mg	K	Na
EC	0,521**	0,004	-0,447**	0,217**	0,272**	0,332**	0,451**	0,468**	0,662**
C		-0,037	-0,832**	0,561**	0,258**	0,497**	0,403**	0,509**	0,248**

pH					0,116	0,395**	0,326**	0,440**	0,015
OM						0,584**	0,488**	0,237**	0,187**
Ca							0,555**	0,522**	0,028
Mg								0,500**	0,345**
K									0,235**

**Correlation is significant at the 0.01 level, *Correlation is significant at the 0.05 level.

To predict soil EC value, the multiple linear regressions were produced by stepwise analyses using the soil properties as variables. Producing multiple linear regressions with using only clay, silt, sand, OM and soil pH as variables had lower relationships to predict EC. When including exchangeable cations in multiple linear regression models, precision of the EC estimation increased. According to stepwise analyses, three linear regression models were produced using only clay, exch. Na and Ca contents as variables (Table 3).

Table 3. Multiple linear regression models used to estimate soil EC values.

Model	Multiple Linear Regressions	R^2	RMSE, µS/cm
1	EC = 352,40 + 416,39*Na	0,438**	219,56
2	EC = 139,74 + 351,77*Na + 8,00*C	0,574**	191,72
3	EC = 88,80 + 362,48*Na + 6,13*C + 5,11*Ca	0,595**	187,27

While the first model including just exch. Na as a variable had 0.438** R^2, the second model including exch. Na and clay content had 0.574** R^2. The highest R^2 value (0.595**) and the lowest RMSE (187,27 μS/cm) were estimated with a multiple linear regression including clay, exch. Na and Ca contents (Figure 2). The comparison of model 1 and model 3 is giving in Figure 2. When using the more soil variable in the multiple linear regression models, the slope of regression line is getting close to 1 and accuracy of the model increasing with reducing RMSE from 219,56 μS/cm to 187,27 μS/cm. Similarly, Candemir and Gülser (2012) reported that using physical and chemical soil properties together in the multiple regression models increased the accuracy and reliability of multiple regressions to estimate soil hydraulic properties.

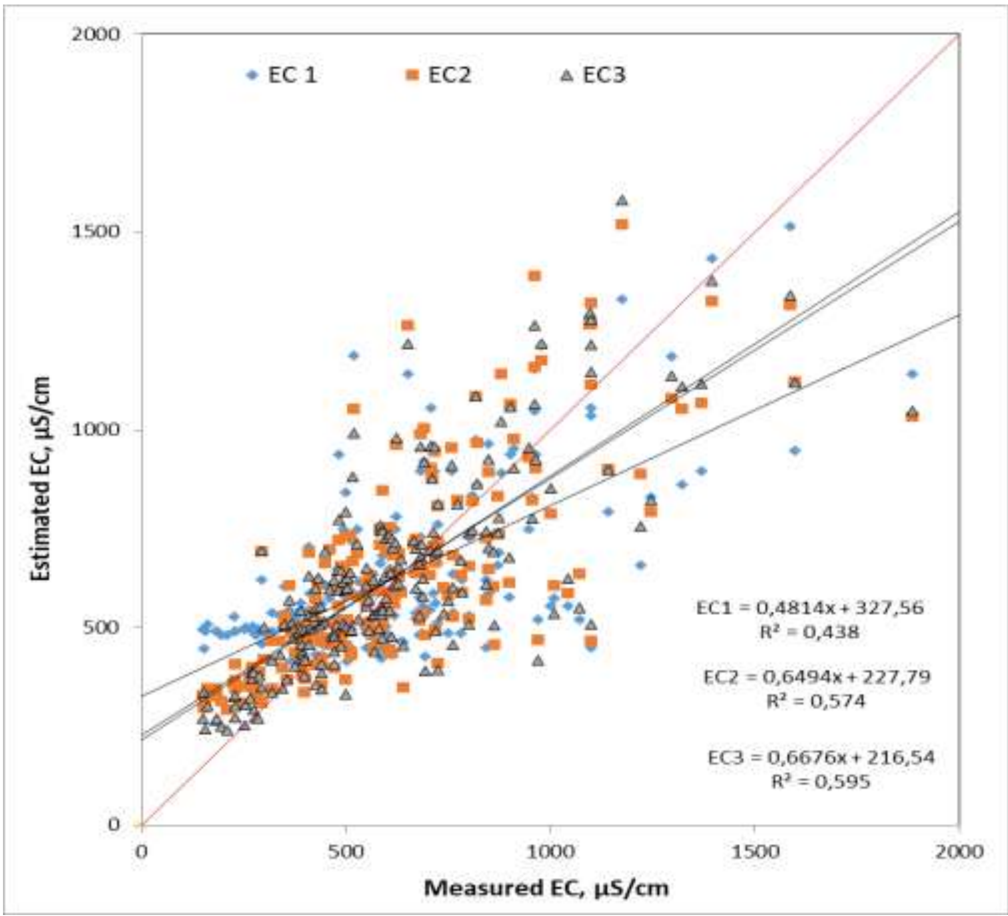

Figure 2. Comparison of measured and estimated EC values by the 3 linear model

CONCLUSION

In this study, EC values of the soils had significant positive relationships with exchangeable cations (Ca, Mg, K, Na), pH, OM and clay content, and a significant negative relationship with sand content. According to the stepwise analyses, it was determined that clay and exch. Na and Ca contents are the most effective soil properties on predicting of soil EC values. When using clay content with exc. cations (Na, Ca) in the multiple regression models, accuracy of the model increased with increasing determination coefficient (R2) and decreasing RMSE values.

ABSTRACT

Global biodiversity loss and mass extinction of species are two of the most critical environmental problems the world currently faces. Loss of biodiversity causes the degradation of various ecosystems that are of central importance to the ecological cycle and human health. It is our responsibility to preserve biodiversity as effectively as possible. It has been stated in research conducted by scientists in recent years that if the loss of biodiversity is ignored, it will have consequences that may even threaten the existence of the human race. In new studies, it is necessary to understand the main reasons responsible for the loss of various species on our planet. One of the many factors causing biodiversity loss is heavy metal pollution. Among various pollutants, heavy metals are of concern due to their environmental persistence, biogeochemical recycling and ecological risks. They are considered among the most dangerous environmental pollutants because they do not break down through physical processes and therefore remain in nature for a long time. Through the process of biomagnification and bioaccumulation, heavy metals have a significant impact on biological systems. Therefore, heavy metal pollution can cause a decrease in pollination in certain populations, difficulties in breeding or feeding certain species, and changes in the physiology, anatomy of organisms and biotope characteristics of local populations. In this study, the factors that cause the decrease in biodiversity and the negative effects of heavy metal pollution on biodiversity were discussed.

Keywords: Biodiversity loss, heavy metal pollution, soil pollution, climate change

CONCEPT OF BIODIVERSITY

Biodiversity is the diversity of different life forms on Earth, including various plants, animals, microorganisms, their genetic makeup, and the ecosystems they create. It refers to the genetic diversity, ecosystem diversity, and species diversity (the number of species) within an area, biome, or planet. Biodiversity is vital in various ways, such as promoting the aesthetic value of the natural environment and contributing to our material well-being through utilitarian values by providing food, feed, fuel, timber, and medicine. Biodiversity is a life-support system. Organisms depend on air to breathe, food to eat, and water to drink. Wetlands filter pollutants from water, trees and plants absorb carbon to reduce global warming, and bacteria and fungi decompose organic matter to enrich the soil. It has been experimentally shown that local species richness is linked to the health of ecosystems and is connected to human quality of life. The ecosystem services of biodiversity are maintained through soil formation and conservation, water conservation and purification, sustaining hydrological cycles, regulating biochemical cycles, absorbing and breaking down pollutants and waste materials through decomposition, and determining and regulating the natural world's climate. Despite the benefits of biodiversity, threats to species and ecosystems are increasing at an alarming rate today, most of which stem from the mismanagement of biological resources by humans, often driven by reckless economic policies, pollution, and faulty institutions, in addition to climate change. It is essential to protect biodiversity to ensure intergenerational equity. Some of the current biodiversity conservation measures include afforestation, zoos, botanical gardens, national parks, biosphere reserves, germplasm banks, and the adoption of breeding techniques, tissue culture techniques, and social forestry to minimize the stress on forest resource exploitation.

BİODİVERSİTY LOSS

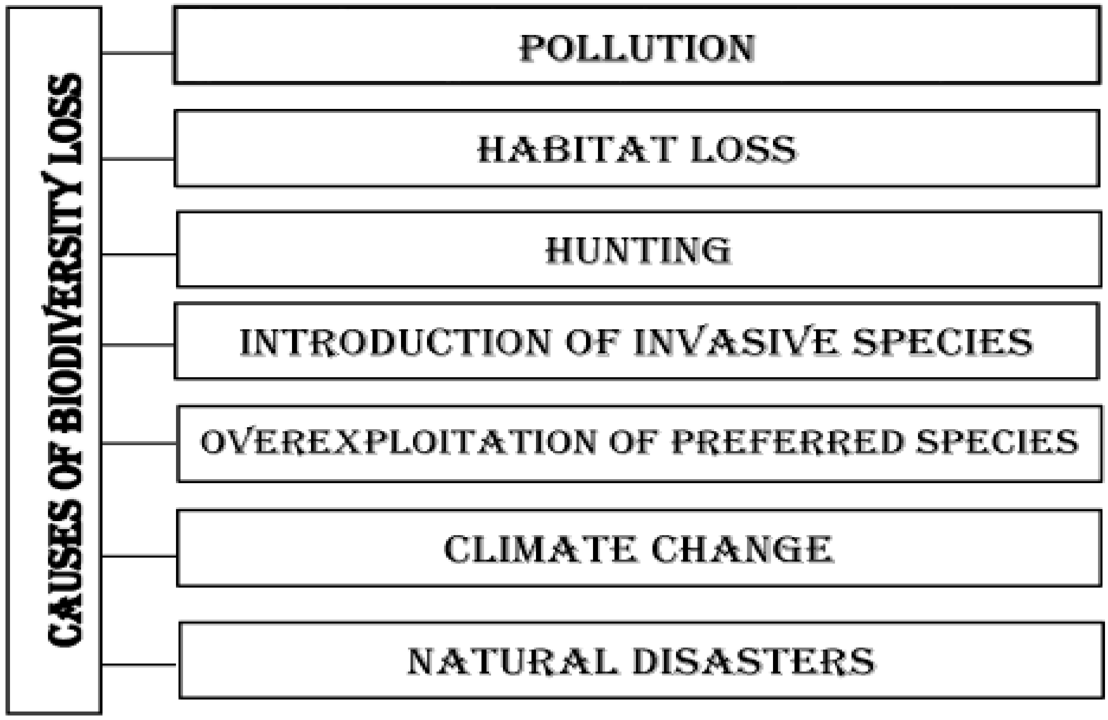
Humans are now a dominant force in the restructuring of the Earth's biosphere (Vitousek et al. 1997; Dobson 2005). With a growing human population of 90 million each year, it could reach 9 billion or more by the middle of the twenty-first century (Cohen 1995, 2005). Humans are rapidly overconsuming natural resources, disproportionately utilizing a significant portion of the Earth's primary production, and transforming natural habitats into human-dominated landscapes (for example, Imhoff et al. 2004). The environmental impacts of human activities are evident worldwide, encompassing striking changes in species composition, abundance, and organism diversity in various ecosystems (Biesmeijer et al. 2006). The unprecedented changes in biodiversity described by Dirzo and Raven (2003) as the sixth great extinction in the history of life on Earth include both the global-scale extinction of species (Mittermeier et al. 2000; Myers et al. 2000) and the loss (i.e., extinction) and introduction of species at a smaller, more local scale (Ehrlich 2004). Such changes contribute to biotic homogenization, which could have significant secondary economic effects (an increase in the similarity of biological diversity patterns between locations) (Olden and Rooney 2006). Biodiversity has been declining at a concerning rate in recent years. According to Van Klink et al. (2020), terrestrial insect abundance is showing a similarly alarming rate of decline.

The human species, like other species, cannot survive independently of its interactions with other organisms. Edward O. Wilson coined the term biophilia to describe humans' "innate tendency to be attracted to other forms of life and to connect with natural living systems". Biophilia means "human dependence on nature" (Kellert and Wilson 1993), and the fate of other species cannot be considered completely separate from our own sustainability. The diversity of living plants, animals, and microorganisms is a fundamental resource for humans because other organisms provide food, medicine, clean water and air, recreational spaces, and other ecosystem services (e.g., Daily 1997 Kremen 2005). We cannot afford to continuously lose our resources and ecological partners, as their loss jeopardizes the stability of ecosystem services and our ecological life support systems (Rosenzweig 2003). In the face of rapidly increasing human population and associated global environmental changes, there is a need for innovative strategies to ensure the conservation and preservation of biodiversity on our planet (Dower et al. 1997).

As the human population increases and economic development occurs in a specific geographical area, the human-induced transformation of ecosystems often destroys natural habitats and biodiversity, and also alters ecosystem services, regardless of the consequences of losses in the near and distant future (Balmford et al. 2002). At both global and local scales, humanity is compelled to redirect demographic and land use patterns to avoid ongoing negative changes in local and global biodiversity and ecosystems, that is, to prevent the irreversible destruction of our life support systems. This challenge requires the participation of each of us who is concerned about the future of humanity and the biosphere (for example, Ehrlich and Wilson 1991; Brown 2006).

FACTORS CONTRİBUTİNG TO THE DECLİNE OF BİODİVERSİTY

The decline of biological diversity (Figure 1) is attributed to numerous factors such as pollution, habitat loss, hunting, the introduction of invasive species, overexploitation of preferred species, climate change, and natural disasters.



1. Habitat Loss

Habitat and wildlife are causally related. We cannot risk neglecting wildlife to obtain the benefits we rely on for the active functioning of the ecosystem. The degradation, deterioration, and fragmentation of habitats are the three dominant categories of habitat loss (Klappenbach, 2020).

Habitat degradation refers to severe damage to a species' natural habitat to the extent that it can no longer support local ecosystems and species. This ultimately leads to the extinction of species, which means the loss of biological diversity. Examples of habitat degradation include deforestation for agricultural purposes, filling wetlands, clearing land for residential or commercial areas, harvesting fossil fuels, and so on (Martins et al., 2018).

Habitat fragmentation is another massive issue that arises due to human development activities. Humans transform vast wild areas into smaller land parcels to meet their endless needs for development, even at the cost of their own species' extinction. These fragmented areas disrupt the living spaces of animal and plant species, isolate animal populations, and compress genetic diversity (Bright, 1993).

2. Hunting

Hunting is a primary cause of the extinction of many animals within the food web. As a result, various species in the region are negatively affected due to facing food shortages or a complete lack of food compared to normal conditions. Hunting activities impose a significant burden on wildlife, leading to a substantial decline in wildlife populations and resulting in degraded and unproductive ecosystems. Overhunting can lead to the disappearance of large mammals in healthy and undisturbed habitats (Symes et al.,2018).

3. Overexploitation of Certain Species

Overexploitation refers to the collection of species from their natural habitats at rates higher than local communities can sustainably recover. Currently, approximately one-third of the world's vertebrates facing the threat of extinction are vulnerable due to overexploitation. Overfishing and hunting are examples of overexploitation. The once-abundant passenger pigeons are victims of excessive hunting (Hammerschlag and Gallagher, 2017).

The overharvesting of plants with medicinal value has led to their disappearance from natural habitats. Many plants, such as Drosera sp., Gnetum sp., pitcher plants, Psilotum sp., and Nepenthes khasiana, are relentlessly hunted and collected for academic training and laboratory experiments. Similarly, various orchids have also been overexploited (Bodeker, 2014).

4. Climate Change

Biodiversity and climate change are strongly interconnected. Although climate has continuously changed throughout the entire history of the world, along with the evolution and extinction of ecological communities and species, the accelerating climate change disrupts ecological systems and the ability of species to adapt, thereby increasing the loss of biodiversity. Rapid climate change, which promotes biodiversity loss, jeopardizes the security of clean water, air, and the natural resources we depend on. It will be difficult to access these natural resources due to the reduction or extinction of the flora and fauna from which they are derived. Climate change emerges as a significant threat to biodiversity on Earth, alongside other factors such as habitat loss, land degradation, hunting, and the overexploitation of certain species (Linders et al. 2019).

5. Invasive Species

The introduction of invasive species poses a significant threat to the biodiversity crisis. Invasive species are those that are not native to the ecosystem, often arriving or being introduced through human activities, and begin to reproduce. These species are harmful because they disproportionately affect the ecosystem compared to other species. Most of the new species introduced to an ecosystem do not become invasive; however, a few do turn into invasive species and negatively impact the ecosystem. Invasive species disrupt local ecosystems in many ways, such as altering habitats, importing pathogens, grazing on local plants, hybridizing with native species leading to a reduction in genetic diversity, and preying on local species for resources (Kilpatrick et al. 2017).

6. Natural Disasters

Natural disasters such as volcanoes, wildfires, floods, hurricanes, droughts, epidemics, tsunamis, etc., lead to a significant loss of biodiversity. Flooding is common in humid tropical regions like Central Africa and eastern and northern Australia, as well as in some areas of South America. Tropical regions host a vast amount of vegetation and animal species. Flooding washes away large quantities of nutrients from the soil, while drought causes the soil to dry out and lowers groundwater levels. In this situation, both animals and plants are harmed. Similarly, wildfires in dense forested areas and earthquakes significantly disrupt the lives of organisms, thereby affecting biodiversity. Volcanoes often destroy animals and plants in adjacent areas. The occurrence of epidemics in nature typically remains limited to a specific animal or plant population, as the pathogens are usually species-specific, resulting in the extinction of a large majority of that population (Chapin and Diaz, 2020)

7. Pollution

Living organisms have evolved over a long period, yet they struggle to adapt to life on a polluted planet.

7.a) Air Pollution

Air pollutants such as soot, dust, ammonia, and carbon dioxide can directly and indirectly affect biodiversity. Air pollution affects the respiratory apparatus of animals and negatively affects their welfare, including egg-laying ability and behavioural changes (Sanderfoot and Holloway, 2017) Air pollution is also known to affect the reproductive ability of animals and thus reproductive success. The massive release of greenhouse gases such as nitrous oxide, carbon dioxide and methane is rapidly changing the earth's climate. Acid rain is another pollutant and causes increased mucus in fish gills leading to suffocation. Soil prone to acid rain has reduced the activity of microbes (Pennanen et al., 1998). This also affects the food chain and other forms of life.

7.b) Water Pollution

Nitrogen and phosphorus contained in chemical fertilisers added to the soil to increase crop productivity are transported from the soil to water bodies or underground. The presence of these nutrients in water bodies leads to eutrophication or excessive plant growth. Eutrophication leads to reduced oxygen levels, which is detrimental to biodiversity, and due to lack of oxygen, fish and other aquatic animals die. Like fertilisers, pesticides can also accumulate in water bodies. Pesticides adversely affect non-flowing water bodies such as lakes and ponds as fertilisers are not washed away and animals in water bodies have difficulty in reproduction (Bhateria and Jain, 2016).

Various anthropogenic activities such as cement, car production; mining, etc. lead to the entry of heavy metals such as arsenic, cadmium, mercury into water bodies [9]. Heavy metals affect the behaviour and survival rates of aquatic animals, especially fish. In addition, events such as oil spills greatly affect wildlife, especially in deep oceans, causing impaired animal senses, drowning, disruption of vital organs of organisms, reduced growth rates and higher mortality rates of larvae. Plastic that remains in the environment for longer periods of time also causes internal injuries leading to death in animals, especially turtles. It has been noticed that seabirds such as the Layson's albatross die before flying from the nest after consuming plastic. (Wright et al. 2013).

7.c) Soil pollution

Soil pollution is another factor that negatively affects biodiversity. Excessive use of fertilisers, pesticides and antibiotics used in agriculture is also very harmful for biodiversity. These agricultural pollutants, such as nitrogen in fertilisers, change the pH and nutrient level of the soil. The increased presence of nutrients in the soil causes weed species to grow strongly and leads to the inhibition of the growth of wild flowers, which are essential for bees and other pollinating insects (Klein et al., 2007). This greatly affects biodiversity. Soil contaminated with heavy metals greatly affects the well-being of microorganisms, which are essential for the sustainable life of living organisms. The excess of heavy metals in soil is not easily degraded and accumulated by plants (Singh et al., 2015).

Heavy Metal Pollution

One of the many factors causing biodiversity loss is heavy metal pollution. Among various pollutants, heavy metals are of concern due to their environmental persistence, biogeochemical recycling and ecological risks. They are considered among the most dangerous environmental pollutants because they do not break down through physical processes and therefore remain in nature for a long time. Therefore, heavy metal pollution can cause a decrease in pollination in certain populations, difficulties in breeding or feeding certain species, and changes in the physiology, anatomy of organisms and biotope characteristics of local populations.

Heavy metals can be emitted into the environment through natural resources and anthropogenic activities; anthropogenic activities are the main causes of emission. Among them, mining activities represent the greatest threat to ecosystem integrity due to the persistence of heavy metals in the environment, which persist for hundreds of years after the end of mining activities (Duruibe et al., 2007)). In environmental exposures, these toxic substances show their effects in the following ways Different mechanisms, chronic exposures at low doses of complex metal mixtures are responsible for the effects observed in wild animal populations and communities, and have ecosystem-level implications (Mussali-Galante et al., 2014). Therefore, this type of exposure poses a threat to biodiversity.

Exposed individuals integrate exposure to the pollutants in their environment and react in a measurable and predictable way; these reactions are observed at different levels of biological organization (Bickham et al., 2000). Therefore, it is necessary to use biological markers or biomarkers to better understand the ecological consequences of metal exposure. Biomarkers are tools that allow the degree of exposure and the effects of environmental chemical contamination to be analyzed (Handy et al., 2003). These measurements offer valuable estimators of ecologically relevant impacts. However, in ecotoxicology, where exposed populations, communities and ecosystem-level consequences are the focus of attention, the use of biomarkers is not an easy task, as responses to toxic chemical stress become less specific and many variables interfere with physiological responses. In this context, Bickham and colleagues explain that although the damage caused by xenobiotic exposure is at the cellular or genetic levels, the effects can be observed at higher levels of biological organization (emergent effects) (Bickham et al., 1994). Especially if biomarkers are to be used as indicators of action, it is important to take into account that the biomarker response should be tightly and regularly linked to the responses at these higher levels (Forbes et al., 2006). Also, biomarkers of exposure (external dose, internal dose; bioaccumulation levels), biomarkers of biological effective dose (DNA adducts) and biomarkers of effect (DNA breaks) must be used to analyze the relationship between the cellular and genetic effects with ecological responses.

At the population level, some considerations should be taken into account when analyzing the resulting effects. Some of these effects are: changes in sex ratios, changes in age structure, low reproductive success, inbreeding, changes in genetic structure and diversity, low fitness and population declines (Mussali-Galante et al., 2013). However, these effects are not specific to environmental metal exposures. Therefore, differences in biomarker response between populations of a species can be carefully addressed by analyzing geographical influences, habitat influence, population fragility (specific to the population in question) and exposure history (Forbes et al., 2006). The differences in biomarker response between populations of a species can be carefully Deciphered. In the last decade, one of the emerging effects evaluated in environmentally exposed populations is changes in genetic pools, which have been identified by Mussali-Galante and collaborators as persistent biomarkers (Mussali-Galante et al., 2014).

At the community level: Changes in diversity and species richness, changes in dominant species, changes in species composition, and biodiversity loss may be some of the emerging effects. However, due to the complexity of species interactions, as was realized many years

ago, such effects cannot be accurately predicted from population-level effects (Hopkin, 1993; Lagadic et al., 1994).
Studies evaluating community-level responses to environmental metal stress are mostly conducted in aquatic ecosystems using invertebrate and fish communities. Among the few studies conducted in terrestrial ecosystems, insect communities are the focus of interest (Nahmani et al., 2014). In such studies, the bioaccumulation levels in different invertebrate groups are analyzed and the relationship between bioaccumulation levels and community effects (especially species richness and composition) is examined.
At the ecosystem level, biomagnification (bioaccumulation at successive trophic levels) is well documented for some metals. Trophic chain effects have been observed in which individuals fed at lower levels in the food chain are usually exposed to lower metal concentrations. In such studies, primary producers (plants) represent an important step in metal transfer, as they form the basis of the food chain. Therefore, some metals can be transported from plants to higher layers of the food chain, posing a threat to biodiversity and ecosystem integrity (Peralta-Videa et al., 2009).
Chronic environmental metal exposures exert their negative effects on individuals health, having consequences at the population and community levels, putting ecosystem integrity at risk. However, the recognition and use of biomarkers in ecotoxicology has been a difficult task, due to the unspecific responses and multiple variables that affect physiological responses to toxic. Therefore, it becomes necessary that ecotoxicological studies include: HM concentrations in soils, bioaccumulation parameters in vertebrate and invertebrate species, the relationship between these biomarkers with morphological, anatomic and physiological alterations that may alter population parameters. In particular, the use of bioindicator or sentinel species is necessary in order to evidence the consequences of HM exposure in wild populations.

CONCLUSİONS AND PERSPECTİVES

It is essential to protect biodiversity to ensure intergenerational equity. Some of the current biodiversity conservation measures include afforestation, zoos, botanical gardens, national parks, biosphere reserves, germplasm banks, and the adoption of breeding techniques, tissue culture techniques, and social forestry to minimize the stress on forest resource exploitation.
Chronic environmental metal exposures have negative effects on the health of individuals, have consequences at the population and community level, and put ecosystem integrity at risk. However, the recognition and use of biomarkers in ecotoxicology has been a difficult task due to non-specific responses and multiple variables affecting physiological responses to toxicants. Therefore, it becomes necessary for ecotoxicological studies to include the following: HM concentrations in soil, parameters of bioaccumulation in vertebrate and invertebrate species, the relationship of these biomarkers to morphological, anatomical and physiological changes that may change population parameters. In particular, it is necessary to use bioindicator or sentinel species to prove the consequences of HM exposure in wild populations.
Terrestrial invertebrates have been used as an ideal system to assess community responses to environmental chemical stress due to their easy capture, wide distribution, abundance, low mobility and close contact with HM from the soil. Especially earthworms and arthropods are the most studied organisms. In contrast, studies assessing the effects of HM on vertebrate community structure are rare, probably due to their body size, mobility and sampling difficulties. However, when working with vertebrates, the study of small mammal species, which serve as good bioindicators, has been an excellent alternative and the results can be easily compared with humans. Furthermore, a methodological strategy in many studies has been the use of pollution gradients to visualise subtle changes in HM concentrations along a soil gradient

and to relate these changes to some community structure parameters. At present, we can conclude that HM differentially affects the community structure and community functioning of the different animal groups studied so far.

At the community level, the search for new biomarkers continues. In this context, abundance changes in different guilds that fit into the community can also be used as biomarkers, since changes in abundance or disappearance of guilds in exposed communities may serve as an ecological response to chemical stress.

At the ecosystem level, ecotoxicological studies are very limited. Trophic chain alterations, biomagnification and modifications in nutrient and energy cycles have been reported. Studies generally asses HM transfer along three trophic levels, such studies have concluded that metal flux depends on the biology of the species, on the trophic position in the chain and on the metal type or metal mixture in question. Mainly, HM transfer from plants to invertebrate herbivores (insects) and from insects to other invertebrates (spiders) or predator vertebrates (small mammals) has been the point of interest. The information from these studies has gained attention, especially because human beings represent the last level of the trophic chain, such as in the case of agroecosystems. It is desirable to use as biomarkers in ecosystem studies, measures of stable carbon and nitrogen isotopes for evaluation of HM transfer along terrestrial trophic chains.

Ecotoxicological studies at the ecosystem level are very limited. Trophic chain changes, biomagnification and modifications in nutrient and energy cycles have been reported. Studies generally assess HM transfer across three trophic levels, with such studies concluding that metal flux depends on the biology of the species, the trophic position in the chain and the metal type or metal mixture in question. Of primary interest has been HM transfer from plants to invertebrate herbivores (insects) and from insects to other invertebrates (spiders) or predatory vertebrates (small mammals). The information obtained from these studies has attracted attention, especially since humans represent the last level of the trophic chain, as in agricultural ecosystems. It is desirable to use biomarkers, measures of stable carbon and nitrogen isotopes, in ecosystem studies to assess HM transfer along terrestrial trophic chains.

Finally, as a result of biomarker approaches, future efforts need to integrate different biological and ecological responses at all levels of biological organization. Furthermore, study designs should be more rigorous, including multiple species and multiple biomarkers, allowing for more realistic assessment of HM exposure, which will allow for better prediction, understanding, and resolution of HM pollution problems worldwide.

ABSTRACT

The conservation of endemic plants is very important for the diversity of flora and their use in medicine. The fact that some endemic plants are endangered due to various reasons increases this importance even more. For this reason, endemic plants need to be identified and protected. The identification process can sometimes take much longer due to regional conditions. In order to prevent this, an algorithm that detects endemic plants in a region with UAV images will make this process much easier. In order for the algorithm to detect the plants of the region, it must first be trained. Since the training data will be from UAV images, the altitude and camera resolution of the UAV images will be of great importance. Because if the pixel quality is low, the endemic plant will not be able to show its distinctive features with other objects in the region and the plant will not be detected.

Keywords: Endemic Plants, Detection Algortihm, UAV, Camera Resolution, Flight Altitude

INTRODUCTION

Aerial image quality generally depends on two factors, camera resolution and flight altitude. In high altitude such as satellite imagery can cover wider area but will give lower level of detail and a view that can often be blocked by clouds or other obstacles (Rees, 2013). In low altitude such as UAV imagery will give high level of detail and accuracy but may not store a lot of images due to limited card memory. Especially compared to manned fixed-wing aircraft, drones provide lower GSD which is Ground Spacing/Sample Distance (Wallace, Lucieer, Watson & Turner 2012; Watts, Ambrosia & Hinkley, 2012). GSD ratio refers to the size of a pixel in a photo taken from a certain height, so it depends on the flight altitude and the camera resolution. As the flight altitude increases, GSD will also increase but the level of detail will decrease. In order to an algorithm recognize the pattern of the endemic plant in the training process and validation, the edges of the plant parts should be clearly visible and recognizable. More detailed visual data will increase the algorithms detection rate and increase the ability to distinguish from other plants in the area. To achieve this the GSD should be lower as possible. Lowering GSD is possible with using UAV with better camera resolution and taking the UAV images at a low flight altitude. Lowering the flight altitude can increase the time spent since the coverage will be smaller. This will have an impact on the flight duration because of the limitation of battery power.

MATERIAL AND METHOD

The main material for this research will be UAV images of *Centaurea kilaea* in different taken in different flight altitudes and resolution. *Centaurea kilaea* is a perennial endemic plant with morphology of its papi being 3-5 mm. Flowering period is from June to August. It has been found to be effective against breast, cervical, prostate (Şen et al., 2017) and liver cancers

(Şekerler et al., 2020) and has been recommended as a strong candidate for anti-cancer drugs in researches. Currently it is in the EN (Endangered) category on the IUCN Red list due to tourism activities in its habitat.

UAV images were taken by multicopter type UAV named DJI Mini 4 Pro at İğneada Coast. 16 total UAV images of *Centaurea kilaea* were taken in 3, 4, 5, 6, 7, 8, 9 and 10 meter altitudes, 12MP and 48MP resolutions in order to compare the detection rates. The selected algorithm for the research was YOLOv11s, which is a CNN based algorithm. The algorithm was trained with 16 UAV images to analyze the detection rate according to altitude and resolution. Detection rate, detail level and GSD values were compared to see which flight altitude and resolution is the most efficient for algorithm detection and visual detection.

RESULTS AND DISCUSSION

The GSD values for each flight altitude and resolution can be seen in Table 1. As it can seen the image (Figure 1) with 3 meter altitude and 48MP resolution has the lowest GSD which will have the most detail for *Centaurea kilaea*.

Table 1. GSD values for each flight altitude and camera resolution

Flight Altitude/ Resolution	48MP	12MP
3m	0,05	0,10
4m	0,07	0,14
5m	0,09	0,17
6m	0,10	0,21
7m	0,12	0,24
8m	0,14	0,27
9m	0,15	0,31
10m	0,17	0,34

Figure 1. UAV image of dormant *Centaurea kilaea* with lowest GSD value (flight altitude:3m, camera resolution: 48M)

The level of detail can be seen in Figure 2 which has a comparison of zoomed UAV images with 3 meters, 6 meters and 10 meters of altitude in 48MP. Details are very important for distinguishing plants from each other. In 3 meters of altitude, the dormant *Centaurea kilaea* flowers have a shape that can be identified much more easily than other altitudes. When there are similar species in the immediate vicinity of an endemic plant, it helps the observer to distinguish them by providing this detailed information.

Figure 2. Comparison of zoomed UAV images at 48MP (left 3m altitude, middle 6m altitude, right 10 meter altitude)

Algorithm detection rates are shown in Table 2 for each flight altitude and camera resolution. At Figure 3, an example of detection can be seen. Comparing the detection rates the YOLO v11s algorithm which was trained with 16 UAV images of *Centaurea kilaea*, the image taken at 5 meters of altitude and 12MP resolution had the best result. For flight altitudes, images taken at 5 meters, 9 meters and 10 meters performed better than others. For image resolution 48MP had an overall %76,87 success rate and 12MP had %75,75 success rate.

Table 2. Algorithm detection rates for *Centaurea kilaea*

Flight Altitude/ Resolution	**48MP**	**12MP**
3m	%56	%70
4m	%78	%74
5m	%93	%94
6m	%83	%69
7m	%49	%52
8m	%75	%71
9m	%95	%88
10m	%86	%88

Figure 3. Algorithm detected the dormant *Centaurea kilaea* from UAV image taken at 9 meters of altitude and 45MP resolution with %95 percent accuracy.

CONCLUSIONS

Low level of altitudes can provide important details for visual inspection, especially for distinguishing similar species in the same area. However, the UAV flight duration might be an issue according to the battery limitations. This may result in the UAV operator being unable to photograph the entire area in one battery. High altitudes allow you to photograph a larger area in a shorter time. But the trade-off will be the details. Increasing the camera resolution can improve the details while increasing the flight altitude. The observer must find an optimum GSD value that gives the desired details in the UAV image of the endemic plant.

ABSTRACT

Endemic plants are plants that are distributed in a narrow area and belong only to a certain region. For this reason, they need protection due to their flora diversity and their use in the field of health. Endemic plants can be easily identified and protected by algorithms that can detect them from UAV images. The rarity of most species of endemic plants can make it difficult to create such algorithms. The data set is of great importance in algorithm training. It is only possible for an algorithm to achieve a high level of detection with a large number of data. The rarity of endemic plants will ensure that the image data to be captured will be small, thus making it difficult to train the endemic plant detection algorithm. However, this problem can be solved with various data augmentation methods. In this way, the small number of image data can be increased with data augmentation methods to reach a sufficient number for training.

Keywords: Data Augmentation, Endemic Plant Detection, UAV Imagery, Algorithm Training

INTRODUCTION

Endemism is the state of a species being found only in a single defined geographic location, such as an island, state, nation, country or other defined zone. Endemism is an important concept in conservation biology for measuring biodiversity in a particular place and evaluating the risk of extinction for species. Some of the plants face this risk of extinction very highly and it affects their rareness. When using endemic plant identification algorithms for these rare plants, the data for training will be very low. With the limitation of data, the algorithm cannot recognize the pattern very well which will affect the algorithm accuracy. The experimental results demonstrated that data augmentation-based deep learning approach achieves superior object detection and recognition accuracy compared to traditional training methods without data augmentation (Kaur, Kehehra & Mavi, 2021; Abdulkareem, AL-Shammri, Khalid & Omran, 2024). Data augmentation techniques are used to increase detection accuracy in different areas such as galaxy (Gonzalez, Munoz & Hernandez, 2018), marine organisms (Huang et al., 2019), pedestrian (Liu, Su & Wei, 2022), floating objects in maritime (Mahmoud, Kurniawan, Aneiba & Asyhari, 2024), underwater environments (Noh, Jang, Ha & Park, 2019), railways (Franke, Gopinath, Ristic-Durrant & Michels, 2022), aircraft automatic landing systems safety (Vidimlic, Levin, Loni & Daneshtalab, 2021) and artwork detection (Jeon et al., 2020).

MATERIAL AND METHOD

One individual endemic plant located in the Thrace Region is the main material in this research. This endemic plant is particularly selected due to its rarity rate and endangered status. The endemic plant is *Dianthus ingoldbyi.*

Dianthus ingoldbyi is a perennial plant having petal length 17.48-19.4 mm as morphological data. Flowering period is from June 2nd week to October 3rd week. It is classified as CR (Highly Endangered) according to the IUCN threat category. Since this plant grows on limestone it is heavily threatened by mining activities. The plant can be found in Papaz Beach/Yeniköy, Zunguma Cape/Bozcada, Coast of Dalyan and İbrice Port/Keşan.

Figure 1. Photograph of *Dianthus ingoldbyi* in İbrice Port/Keşan

Figure 2. UAV image of *Dianthus ingoldbyi*

Data augmentation is a technique of artificially increasing the training set by creating modified copies of a dataset using existing data. When collecting images from rare endemic plants, because of the rareness, the data collected will be insufficient for training. In order to increase the amount of image data, image augmentation techniques can be applied. The techniques that will be used are top-down mirroring, left-to-right mirroring, color saturation and random rotation.

The algorithm that will be used is YOLOv8n, a CNN based algorithm that can provide fast and efficient solutions. Algorithms will be trained with two separate datasets which one will be existing dataset and the other one will be augmented dataset. 30 UAV images with different altitudes of *Dianthus ingoldbyi* will be the existing training data and 116 augmented images that was created using augmentation techniques on the existing data will be the augmented training data. After training, two algorithms will be be compared with each other to see which one is more accurate of detecting *Dianthus ingoldbyi*.

RESULTS AND DISCUSSION

As it was mentioned in material and method part 120 augmented images were created using selected augmentation techniques from existing 30 UAV images. 4 of the 120 augmented images were removed from dataset due to similarity. The probability of top-down mirroring was %30, left to right mirroring was %30, color saturation was %20 and random rotation was %30.

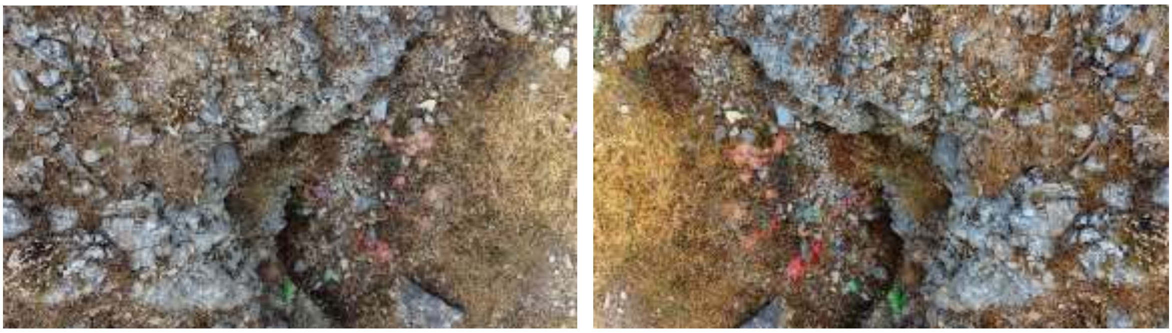

Figure 3. Data augmentation technique (original image on the left, color saturated and left to right mirrored image on the right)

The YOLO algorithm trained with existing data which involved 30 UAV images at 100 epochs. Another same YOLO algorithm was trained with augmented data which involved 116 images at 100 epochs. It has been seen that the first algorithm trained with existing dataset had %67,9 accuracy for detecting *Dianthus ingoldbyi* in easy detection and %27,1 in hard detection.

Class	Images	Instances	Box(P	R	mAP50	mAP50-95)
all	30	52	0.652	0.612	0.679	0.271

Figure 3. Validation of algorithm trained with existing data at Pycharm software

The algorithm that was trained with augmented data had %95,3 accuracy for detecting *Dianthus ingoldbyi* in easy detection and %51,3 in hard detection.

Class	Images	Instances	Box(P	R	mAP50	mAP50-95)
all	116	144	0.892	0.915	0.953	0.513

Figure 4. Validation of algorithm trained with augmented data at Pycharm software

CONCLUSIONS

Data augmentation can increase the detection accuracy for rare objects such as rare and endangered endemic plants which one of them was issued on this study. The algorithms detection accuracy for *Dianthus ingoldbyi* had a %27,4 increase in easy detection and %24 increase in hard detection.

Other image augmentation techniques can be used to see the different results and get more detailed information of which image augmentation techniques can be more efficient. Overfitting can be a serious problem when training an algorithm so removing similar augmented images with a much more precise can avoid overfitting problems.

ABSTRACT

People's energy consumption is increasing significantly as the world's population grows and technology and comfort improve. Fossil resources are still largely used in electricity production. This situation causes the reserves of natural resources to decrease and also causes many environmental problems. For this reason, the transition to renewable energy has gained great importance in the current period and in the future. Direct current produced by photovoltaic panels from solar energy is converted to alternating current with inverters. The choice of inverter to be used in the design for this conversion significantly affects the system efficiency and cost. In this study, the technical and economic analysis of the inverter selection to be used in the solar energy system of a farmhouse located in İskenderköy, close to the center of Edirne, was made in the PV sol application. Upon analysis of the simulation results, it was determined that the initial investment cost for both inverter types in the designed solar energy system is 240.000 TL Furthermore, the payback period of the system was identified as 3.5-3.6 years at an equivalent point in time for both designs.

Keywords: Energy, Photovoltaic Panel, Inverter, Analysis

INTRODUCTION

The widespread use of fossil energy sources in electricity generation brings many problems even in today's conditions. On the other hand, the increase in energy demand and the decrease in fossil resources with the increasing population also increase the interest in cleaner, more environmentally friendly and reliable energy sources (Ikkurti and Saha, 2015, Ekins, 2004). Recent research and developments in renewable energy sources are seen as a source of hope for many countries. In order to meet the energy, need in changing natural conditions, alternative energy sources need to be found and used. Among renewable energy sources, solar energy is known as a sustainable and inexhaustible source with its clean, safe and environmentally friendly features (Ikkurti and Saha, 2015, Goetzberger et al., 2013, Kazmerski, 2006, Nema et al., 2009). Photovoltaic panels are used in converting solar energy into electrical energy. Since photovoltaic panels produce direct current, the obtained energy needs to be converted into alternating current. Inverters are used in solar energy systems for this purpose. Two types of inverters are used in applications. The first of these is the string inverter and the other is the micro inverter. Inverter selection is made according to the power that the solar energy system to be installed will produce. Inverter selection affects the system and its efficiency and investment cost. When the studies on inverter selection in the design of solar energy systems in the literature are examined; System design and micro inverter selection to meet the daily energy needs of low-income households in rural India have been analyzed. It has been confirmed that the use of micro inverter instead of traditional inverter in the proposed design is a more economical solution (Ruchira et al., 2022). In a different study, the total number of active components in photovoltaic systems was reduced and a new microinverter topology was proposed. The simulation results showed that the proposed microinverter provided a higher conversion efficiency (Ternifi et al., 2017). A statistical study carried out in France compared the performance rates of 100 photovoltaic installations using a central inverter and 100 photovoltaic installations using microinverters. According to the data obtained from 200 photovoltaic installations, the performance rate was found to be 79% in both types of inverters. Although the results were almost the same, it was found that microinverters were more preferred due to their lifetime and price, and that the safety of the system in case of fire was better (Lagarde et al., 2023). A resonant high efficiency DC-DC flyback inverter design is proposed for rooftop PV systems. In this study, a 250 W prototype inverter model was implemented and analyzed under different load conditions. According to the results of the study, it was emphasized that the proposed micro-inverter for photovoltaic systems is superior to existing topologies under different weather conditions (Hasan et al., 2017).

In this study, unlike the literature, the technical and economic effects of the inverter type to be selected in the solar energy system to be installed on the roof of a farmhouse in Edirne İskenderköy were analyzed.

MATERIAL AND METHOD

For the 8 kW solar energy system at the current site, 2 different inverter designs were created and simulated using the PV sol application. In the first design, conventional inverters were selected and analyzed, and in the next stage the same analyses were carried out using 5 micro-inverters. All system components are selected and designed in PV sol application and their technical specifications are given in the simulation results.

The configurations of the standard inverter selection in the system installation are given in Table 1.

CONCLUSIONS

In this study, the effect of the inverter type to be used in the solar energy system to be installed in a small-scale individual farmhouse is analyzed with PV sol application. The investment cost for each inverter type is determined as 240 000 TL. When the data obtained from the simulation results are evaluated, it is seen that the investment cost for both inverter types is almost the same for 3.5-3.6 years. However, it is observed that 53 kWh more electricity is generated every year in the design using micro inverter. Therefore, when the system is operated under real conditions, it is understood that the use of micro inverter will be more advantageous in terms of performance and failure.

ABSTRACT

Our country is in an advantageous position compared to many other countries in terms of solar energy use. However, solar energy systems require a significant investment budget in terms of initial installation costs. Due to the lack of incentives for rooftop installations in some countries, small-scale solar energy conversion systems on individual balconies are promising. However, the amount of energy produced by balcony solar energy systems varies depending on the tilt angle of the photovoltaic panels. In this study, the effect of the tilt angle of a 100W photovoltaic panel mounted on the facade wall of a solar energy conversion system installed on the campus of Trakya University Faculty of Engineering was experimentally investigated for one month. When the results were analyzed, the instantaneous maximum power output of the photovoltaic panel was measured as 25W when the inclination angle was 90° even on the day with the highest solar radiation, while this value was measured as 65W when the inclination angle was 30°. It was found that energy efficiency decreased significantly when a 90° photovoltaic panel was applied to the facade or balcony wall. For this reason, it is necessary to specify the tilt angle of the photovoltaic panels in balcony solar energy system installations.

Keywords: Energy, Photovoltaic panel, balcony wall, tilt angle

INTRODUCTION

Recently, solar power has become one of the most popular renewable energy sources in many countries. Our country is in a more advantageous position than many countries due to its location and climate characteristics. In addition, the installed power of a system designed for a specific location and the amount of energy that can be produced according to climate characteristics can be analyzed quite easily with the simulation programs developed today. When people think of solar energy systems, they usually think of solar power plants and rooftop photovoltaic panels.

In today's conditions, solar energy systems have started to be used not only on roofs, but also in more accessible areas such as terraces, balconies, car parks and facade systems. In addition to the use of existing roof areas, building-integrated photovoltaic panel applications offer the opportunity to benefit from some advantages (Skandalos and Karamanis, 2021; Aguacil et al., 2019). Especially in high-rise buildings, where the roof area covered by photovoltaic panels is limited, the usability of the facade area should be evaluated (Tian et al., 2023). With this in mind, the application of photovoltaic panels on the facades of high-rise buildings in China has been commercialized and its use has become widespread. In addition, photovoltaic panels with different characteristics are produced to meet the needs of building façade applications (Aguacil et al., 2019). The use of building integrated photovoltaic panels also reduces greenhouse gas emissions by reducing the use of fossil fuels (Aguacil et al., 2024). In addition, cantilevered balconies, balcony railings and building shading also offer benefits for photovoltaic panel applications. These applications need to be promoted, and architectural studies are needed (Xiang et al., 2023). The integration of photovoltaic panels into the building, especially in adjacent apartments, and the presence of air conditioning units on the external facades pose some installation difficulties. In these cases, architectural solutions and building-specific designs are required. When transparent and semi-transparent photovoltaic panels are used in building components such as windows and balcony railings, they provide lighting as well as electricity. Despite all this, there are still incorrect applications that reduce the energy efficiency of photovoltaic panel installations. The most common mistakes are the failure to carry out technical and economic analyses, the incorrect selection of system components in the design and the incorrect tilt angle of the photovoltaic panels. It should be remembered that the maximum conversion efficiency of photovoltaic panels can be obtained by avoiding these most common errors. To support the use of building-integrated photovoltaic systems in Scandinavian countries and to estimate the solar energy potential, solar radiation values from balconies, external staircases and between buildings have been analyzed (Xiang et al., 2023). A similar approach has been used in Beijing to conduct extensive research on the renovation and optimization of balconies in old residential buildings. The characteristics and models of residential balconies were simulated and new designs were optimized (Li et al., 2023). A simulation case study found that although the roofs of buildings are generally suitable for photovoltaic panels, energy losses occur due to shading, especially in large cities and high-rise buildings, and in such cases photovoltaic panels installed on the south facades of buildings give better results (Vulkan et al., 2018).

In this study, unlike the literature on solar electricity generation, the effect of a photovoltaic panel mounted on the balcony railing of a house with a 90° vertical and 30° inclination angle on energy efficiency was experimentally investigated.

MATERIAL AND METHOD

The installation shown in Figure 1 was carried out in order to investigate the effect of the inclination angle given to the photovoltaic panels on the energy production in the balcony applications on the south facade of the Trakya University Faculty of Engineering campus. Photovoltaic panels with the same characteristics and equivalent output power of 100W were used in this experimental study. As seen in Figure 1, one of the photovoltaic panels was mounted on the balcony railing at a 90° vertical angle (PV panel B) and the other PV panel C was mounted on the balcony railing at a 30° inclination. Then, the power output cables from both PV panels were connected to the data logger. The power outputs of the PV panels were measured every 15 minutes for 30 days starting from June 01, 2024, and recorded on the system's memory card. At the end of the experiments, a random day and the best day in June were selected and the energy value graphs obtained from the PV panels were drawn.

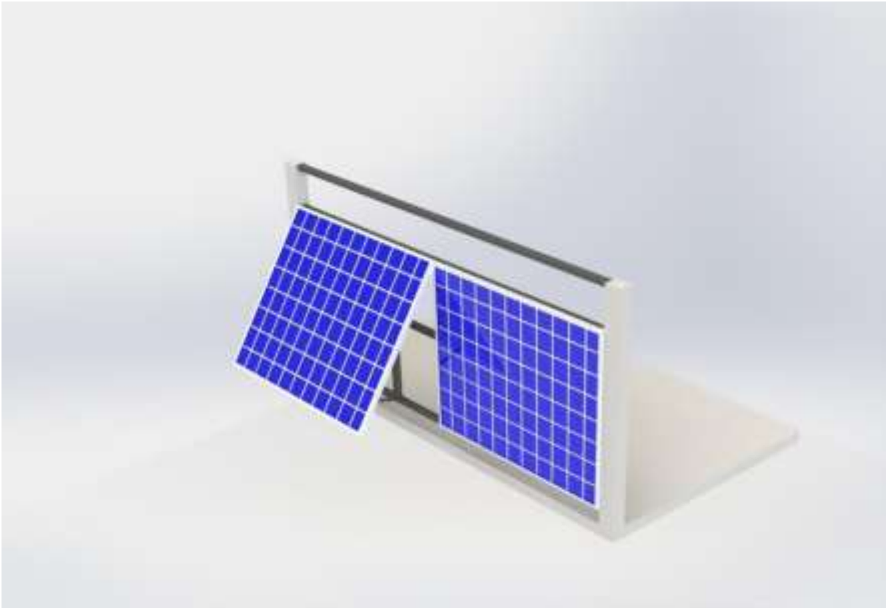

Figure 1. Installation of PV Panels in Balcony Application

RESULTS AND DISCUSSION

At the end of the study, the total energy production was calculated as a function of the voltage and current values obtained from the photovoltaic panels. It was observed that the power output of the photovoltaic panel applied at a 30° angle was higher on all days in June. It was also observed that the total amount of energy obtained from the photovoltaic panel applied at a vertical angle of 90° (PV panel C) was much lower than that of PV panel B applied at an angle of 30°.

Figure 2 shows the power output of the photovoltaic panel mounted on the balcony railing at a tilt angle of 30°. When analyzing the data in June, the maximum power output was around 65W. This power value was obtained on 16 June 2024.

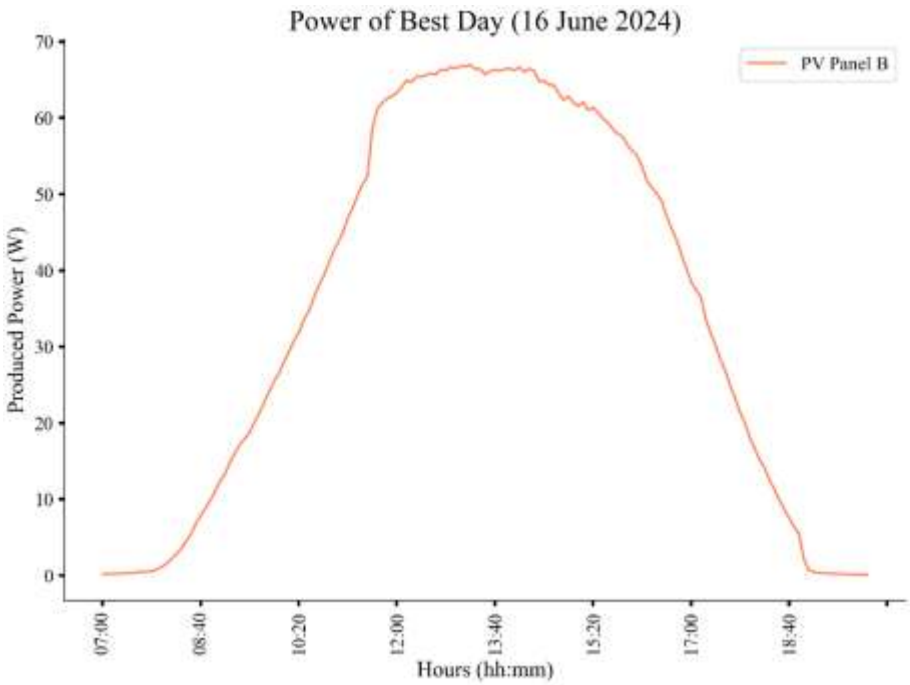

Figure 2. The day when the PV Panel B achieves the highest power output

A random day in June (June 9, 2024) was chosen and the power output from the PV panels was analyzed. The output power levels of the PV panel on the randomly selected day are shown in Figure 3. It was observed that a maximum power output of 60W was obtained from PV Panel B, which was applied at a tilt angle of 30° on a randomly selected day.

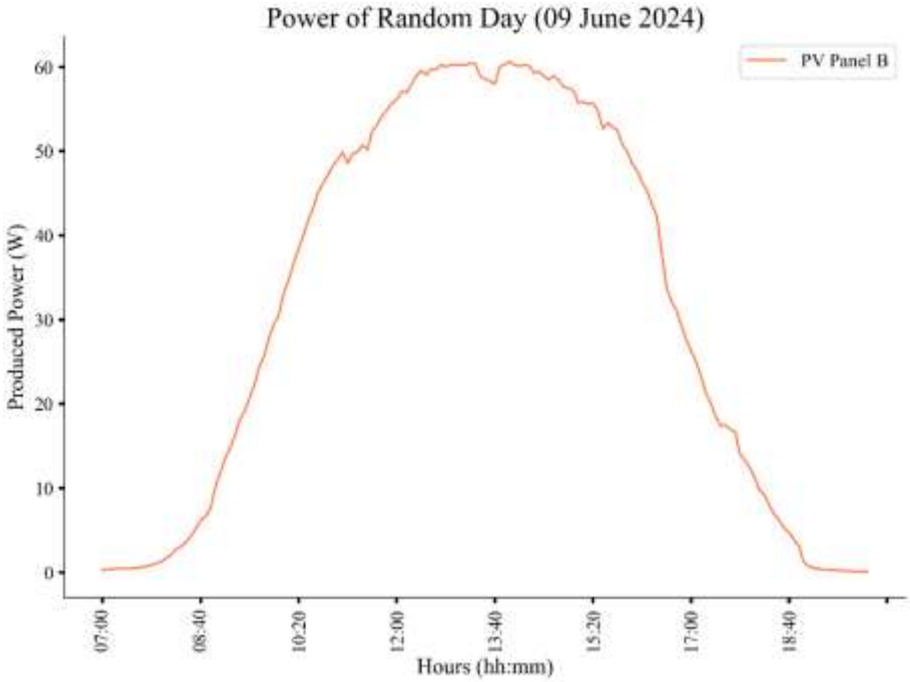

Figure 3. PV Panel B power output on a random day

Figure 4 shows the power output of the photovoltaic panel mounted vertically at 90° to the balcony railing. When the data in June was analyzed, the maximum power output was about 25W. This power value was obtained on June 16, 2024.

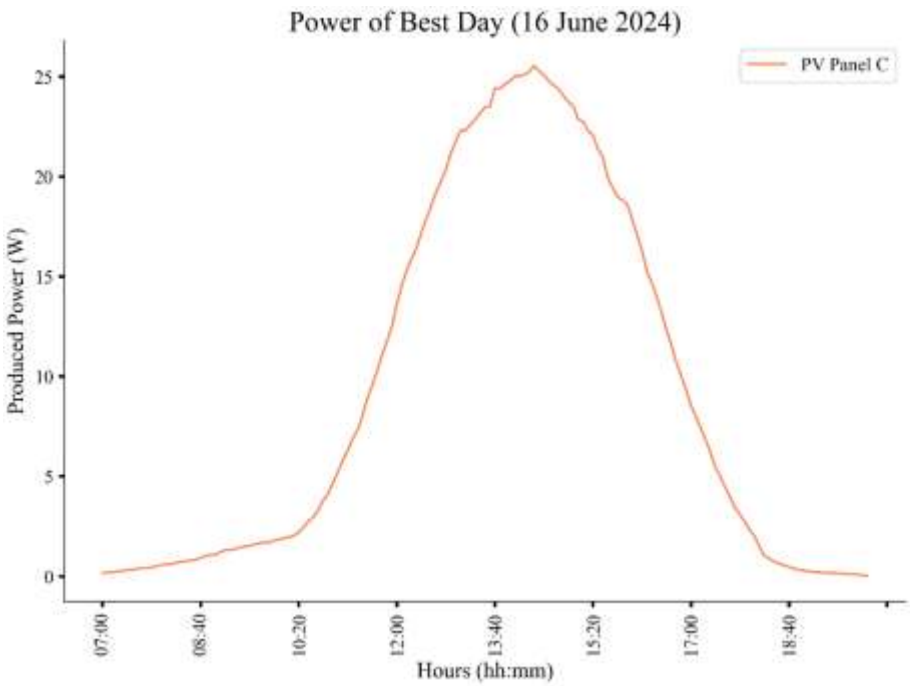

Figure 4. The day when the PV Panel C achieves the highest power output

A random day in June (June 9, 2024) was selected and the power output from the PV panels was analyzed. The output power levels of the PV panel on the randomly selected day are shown in Figure 5. It was observed that a maximum power output of 6.3W was obtained from PV Panel C applied at 90° vertical on a randomly selected day.

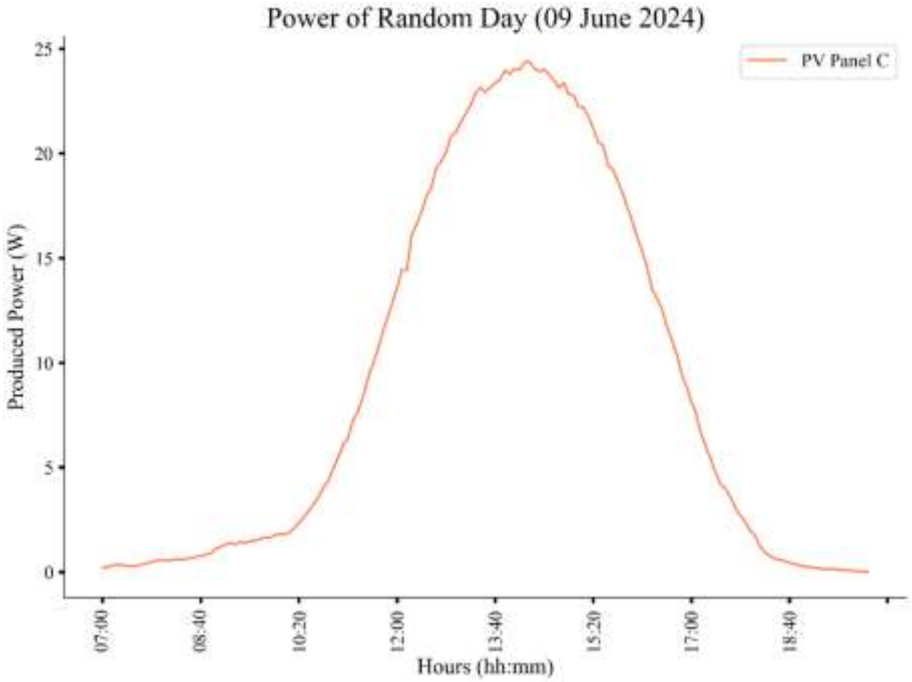

Figure 5. PV Panel B power output on a random day

It can be seen that when the photovoltaic panel is applied vertically at 90° (PV panel C), the power output is at a very low level compared to PV panel B with an inclination angle of 30°. At the end of the study, the total amount of energy obtained from the PV panels was calculated and given graphically in Figure 6. When Figure 6 is examined, it is seen that when the photovoltaic panel (PV Panel B) is given a 30° inclination angle, it produces twice as much energy as the photovoltaic panel (PV Panel C) applied vertically at 90°.

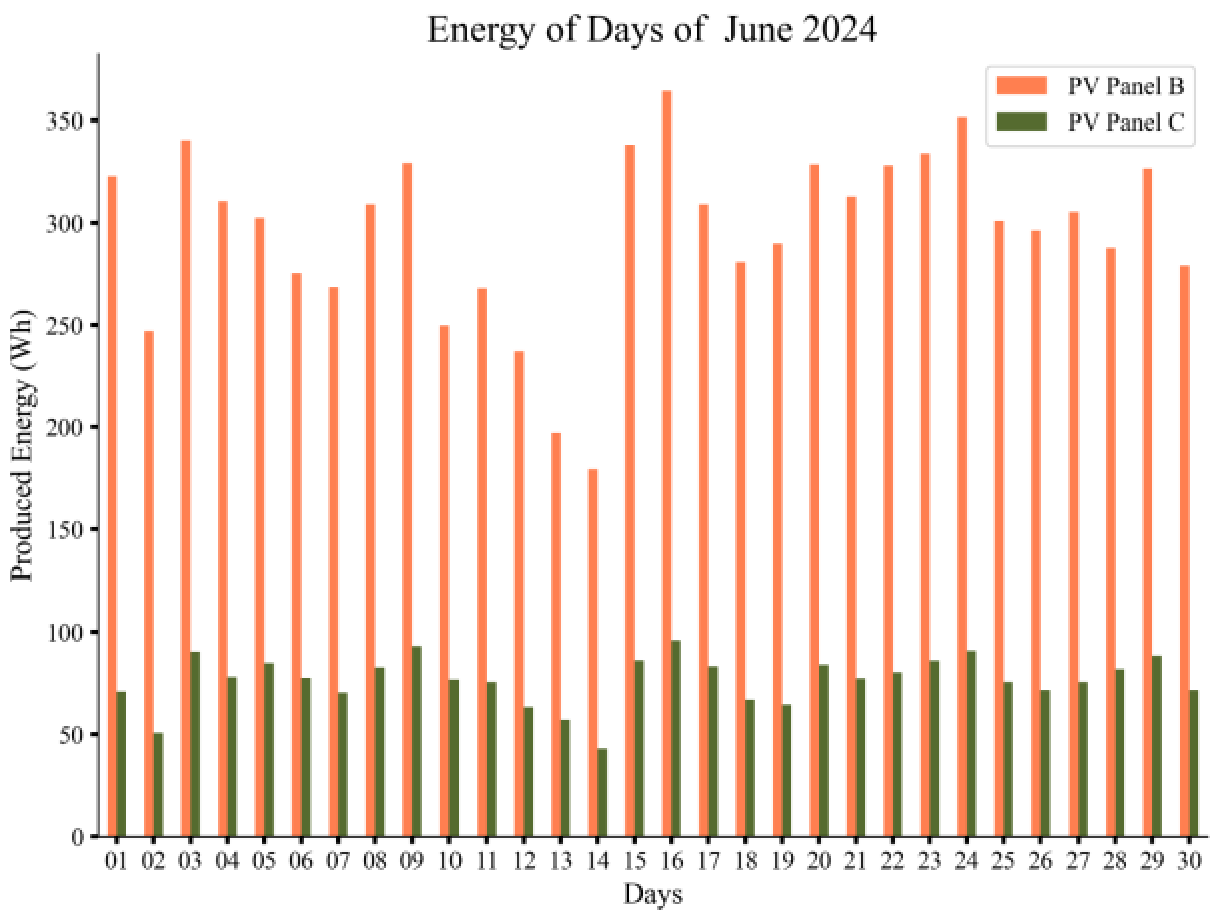

Figure 6. Monthly total energy levels produced in PV panel B and PV panel C

When Figure 6 is examined, it is seen that the photovoltaic panel (PV Panel C) applied at a 90° vertical angle could not even reach the 100Wh level in daily energy production in June.

CONCLUSIONS

In this study, the effect of the tilt angle of photovoltaic panels mounted on the balcony wall on the power output of a solar energy system installed in the campus of Trakya University Faculty of Engineering was investigated. The effect of the tilt angle of 100W monocrystalline photovoltaic panels on the power output and energy production in the designed system was analyzed. According to the results obtained from the experiments, even on the day when the solar radiation was at its highest, the instantaneous maximum power output was measured to be 25W when the tilt angle of the photovoltaic panel was 90°, and this value was determined to be 65W when the tilt angle was 30°. It was found that the energy efficiency decreased significantly when 90° photovoltaic panels were mounted on the facade or balcony wall. Therefore, when installing solar energy systems, the tilt angle of the photovoltaic panels should be determined according to the geographical location of the dwellings and the architectural features of the balcony/facade.

ABSTRACT

With the gradual depletion of fossil fuel resources, costs and environmental problems, the use of renewable energy is becoming more important every day. Recently, there has been a growing interest in solar energy as one of the renewable energy sources. However, problems still occur in solar power plants due to incorrect design and application in operating conditions. In particular, when mistakes are made in the selection of system components and in the economic analysis, both the investment cost and the payback period are adversely affected. In this study, the aim is to produce electrical energy and cost analysis by using photovoltaic panels in agricultural fences to be used at the borders of land in Edirne central location for site selection in a solar power plant. The economic analysis of the photovoltaic panel fence system designed for a 100 kWh solar power plant at the determined site was carried out using the PV sol program. According to the simulation results obtained, the investment cost of the designed system was found to be 3 278 880TL and the payback period was 7.1 years.
Keywords: Energy, economic analysis, solar panel, fence.

INTRODUCTION

Recently, the environmental damage caused by the global use of fossil fuels, the depletion of resources and increasing global warming have accelerated the interest in renewable energy sources. In this context, if we look at the types of renewable energy sources, we can see that solar energy installations have increased significantly. Considering its geographical location and annual sunshine hours, Turkey has a higher solar energy potential than many other countries. In addition, the conversion efficiency of solar energy varies depending on the installation conditions. The climatic conditions of the installation region, the correct angle and orientation of the solar panels, the selection of the inverter and the correct selection of other system components are of great importance. Therefore, before installing solar power plants in any location, the production and amortisation periods must be analysed using simulation programs. Important parameters to evaluate are efficiency, performance ratio and system losses. The performance ratio varies depending on the environmental conditions, installation characteristics and design (Kumar el al, 2021; Nwaigwe et al, 2019; Sarraf et al, 2016; Vaka and Talukdar, 2020).[1-2-3-4]
As a result of the evaluation of all these parameters, wrong applications in the installation of solar power plants will be prevented. Many different simulation programmes are used for the installation and analysis of solar power plants. When some studies in the literature on this subject are examined; PVsyst simulation program was used for PV system installation and loss analysis at Bikaner University in India. While the annual average energy requirement was 1086.24 kWh for the office in mechanical engineering, the energy obtained from the solar panel was determined as 1143.6 kWh. At the end of the analysis, it was found that different power

sources caused losses in the system and the annual average performance rate was found to be 72%(Kumar el al, 2021). There are some difficulties in selecting the simulation programs to be used in applications. In order to review the existing programs, four system-based (System Advisor Model (SAM), PVsyst, PV*Sol and Solarius PV) and three online software tools (Helioscope, PV-Watts and PV-GIS) were examined under seven categories. It was observed that the least errors occurred in the data recorded with PV*Sol and Solarius PV (Kaleshwarwar and Bahadure, 2023). In a study conducted in Bangladesh, a comprehensive technical and economic analysis was conducted for the configuration of PV modules to benefit from solar energy in the best conditions. For this purpose, the effects of different solar modules such as monofacial, bifacial, dual-axis solar tracker and seasonally inclined solar module were examined. Similarly, in this study, energy efficiency in Bangladesh was evaluated using PV*SOL, PVsyst and System Advisor Model (SAM) software. According to the results obtained from this study, the highest annual energy production was achieved with the dual-axis solar tracker system, but it was stated that there may be difficulties in implementation due to the higher investment cost. It was observed that the simulation programs used in this study have great importance in terms of energy efficiency and economic analysis (Oyshei et al, 2024). In a study where comparative economic analyses of residential solar photovoltaic systems in Canadian provinces were conducted, investment cost, payback period and efficiency concepts were evaluated using data from 2013 and 2016. The results were presented in summary tables showing selected major cities classified into different categories, classified according to financial viability. In this study, sensitivity analyses were conducted to determine new values for electricity sales price, investment cost of the proposed project and required subsidy in order to make the project attractive for a short payback period of 5 years for residential buildings (Sow et al, 2019). In another study, the University of Jordan conducted a technical and economic analysis of a grid-connected solar energy system for the transition to renewable energy due to high electricity consumption. After evaluating parameters such as performance analysis, economic analysis, efficiency and land use, it was found that the payback period was 3 years with a return of 32% (Ayadi et al, 2018). Techno-economic analysis was performed using RETScreen simulation program for a 50 MW solar energy system in a selected field in Afghanistan. Based on this study data, it was stated that the highest annual energy production potential (166336 MWh/year) could be obtained with the dual-axis tracking system (Hamad et al, 2024).

In this study, unlike the literature, in case of using PV Panels instead of normal fences on the borders of a selected site in Edirne, electrical energy production, investment cost and depreciation period of the system were analyzed.

MATERIAL AND METHOD

It was aimed to generate electricity from solar energy by applying photovoltaic panels instead of normal steel wire fence material in determining the boundaries of the field whose location is shown in Figure 1 in the center of Edirne province. In the fence design, 144 CW brand CWT690-132TNB12 Bifacial Monocrystalline PV Panels were selected, 90° angle was applied, inverter and other system components were selected and modelling was done. Using the current location information for the design, investment cost, electrical energy production amount and depreciation period were analysed for grid connected self-consumption solar energy conversion system in PV sol simulation program.

Figure 1. PV panel application location

An example of a fence to be built from solar panels to be applied to the land border area is shown in Figure 2. Thus, electrical energy will be produced with solar panels by utilising the area on the border line.

Figure 2. Application model of a fence made of solar panels (www.next2sun.com).

All data and technical details included in the system installation are explained under detailed headings in Table 1.

Table 1: Configurations for system installation

1.1.Climate Data

Location	Edirne , TUR (2001 - 2020)
Values source	Meteonorm 8.2(i)
Resolution of the data	1 h
Simulation models used:	
- Diffuse Irradiation onto Horizontal Plane	Hofmann
- Irradiance onto tilted surface	Hay & Davies

1.2. Module Area (PV Generator, 1. Module Area)

Name	
PV Modules	144 x CWT690-132TNB12 (v1)
Manufacturer	CW Enerji Müh. Ticaret ve San. Ltd. Şti.
Inclination	90°
Orientation	South 200°
Installation Type	Mounted - Open Space
PV Generator Surface	447,3 m^2

1.3.Configuration

Module Area	Modül Alanı 1
Inverter 1	
Model	SUN2000-40KTL-M3（480Vac） (v2)
Manufacturer	Huawei Technologies
Quantity	2
Sizing Factor	124,2 %
Configuration	MPP 1: 1 x 18
	MPP 2: 1 x 18
	MPP 3: 1 x 18
	MPP 4: 1 x 18

1.4.Production Forecast

PV Generator Output	99,36	kWp
Spec. Annual Yield	957,46	kWh/kWp
Performance Ratio (PR)	62,13	%
Grid Export	95.182	kWh/Year
Grid Export in the first year (incl. module degradation)	95.182	kWh/Year
Standby Consumption (Inverter)	48	kWh/Year
CO_2 Emissions avoided	44.713	kg / year

RESULTS AND DISCUSSION

In this study, the simulation results obtained when the data belonging to the design system components were evaluated are explained in detail in Table 2.

Table 2: Simulation results

2.1.System Data		
Grid Export in the first year (incl. module degradation)	95.182	kWh/Year
PV Generator Output	99,4	kWp
Start of Operation of the System	1.07.2024	
Assessment Period	20	Years
Interest on Capital	1	%

2.2.Economic Parameters		
Internal Rate of Return (IRR)	65,21	%
Accrued Cash Flow (Cash Balance)	22.533.883.646,67	₺
Amortization Period	7,1	Years
Electricity Production Costs	1,91	₺/kWh

2.3.Payment Overview		
Specific Investment Costs	33.000,00	₺/kWp
Investment Costs	3.278.880,00	₺
One-off Payments	0,00	₺
Incoming Subsidies	0,00	₺
Annual Costs	0,00	₺/Year
Other Revenue or Savings	0,00	₺/Year

2.4.Remuneration and Savings		
Total Payment from Utility in First Year	24.909,05	₺/Year
Validity	28.07.2024 -	27.07.2044
Specific feed-in / export Remuneration	0,1873	₺/kWh
Feed-in / Export Tariff	24909,0545	₺/Year
Inflation Rate for Feed-in	71,60	%/Year

The electric energy obtained according to the months through the designed system is given in Figure 3.

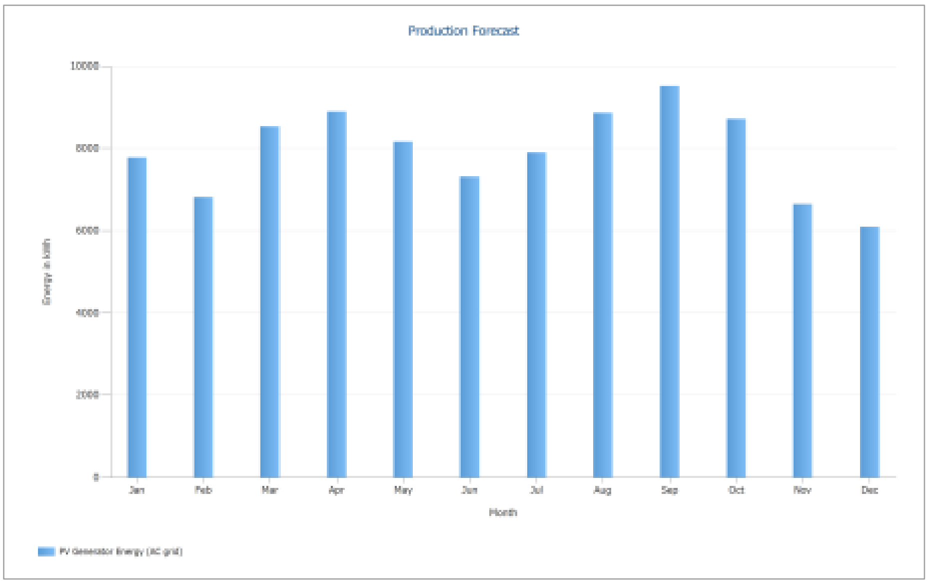

Figure 3. Total electrical energy levels generated by month

The graph showing the amortisation period of the designed solar fence system is given in Figure 4. When Figure 4 is analysed, it is seen that the cash flow and amortisation period obtained from the system is 7.1 years.

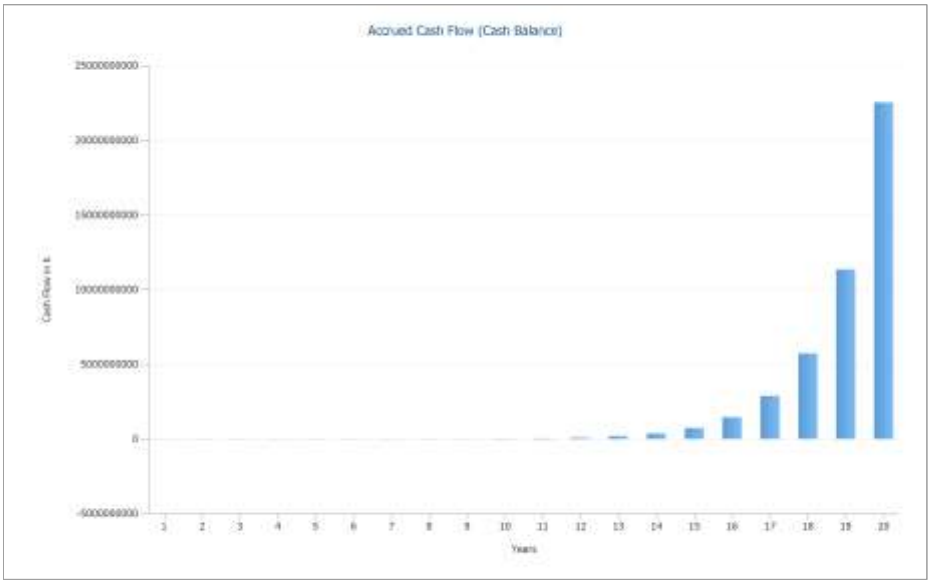

Figure 4. Accumulated Cash Flow

CONCLUSION

In the study, the investment cost and the depreciation period according to the cash flow obtained with the solar fence application in determining the boundaries of a land in the central location of Edirne were analyzed. When the PV Sol simulation results were evaluated; the total investment cost was found to be 3278880 TL the internal rate of return was 65.21%, the electricity production cost was 1.91TL and the amortization period was 7.1 years. Another important result is that the 447.3 m² area required for 100 kW electricity generation in the solar energy conversion plant will be obtained by the photovoltaic panel fence application designed without the need for any land. Finally, for this application, an investment budget of 3278880 TL and some security measures must be taken to prevent damage to the fence system designed with photovoltaic panels.

ABSTRACT

Bio-electrochemical systems (BES) are eco-friendly systems that are being used for various of purposes such as water treatment, resource recovery, biogas and biohydrogen production from various of biomass resources. In the bio-electrochemical process (BEP), biomass is decomposed and break into smaller components by both biological and electrochemical reactions. The biological activities of the bacteria and electrochemical reactions involved in this process can cause some environmental effects. Moreover, waste materials resulting from the BEP have the potential to pose a hazard to the environment and public health. Therefore, a detailed life cycle assessment (LCA) covering the entire duration from raw material supply to the management of waste generated at the end of the process should be carried out and the environmental impacts of this process should be evaluated. LCA for a BES should be “Cradle to Grave” approach and include transportation of waste material, pre-treatment of waste, inflow of waste into BEP, reactions occurring in BEP, outputs (product and waste), processing-making usable-transportation of the product, processing-transportation-disposal or recycling of waste. In LCA, system boundaries should be defined clearly and comprehensively and environmental impacts should be analysed based on various criteria such as energy consumption, fuel type and consumption, greenhouse gas emissions, and toxic substances released into water and soil, to help design and manage products, services and waste in a more sustainable way.

Keywords: Bio-electrochemical systems, energy, environmental impact, life cycle assessment, sustainability.

INTRODUCTION

Bio-electrochemical systems

Bio-electrochemical systems (BES) are the promising technologies that can be used for electricity generation, synthesis of chemicals, production of biogas, biohydrogen, and biofuels, wastewater treatment, and resource recovery. In a BES, both biologic and electrochemical reactions occur at the same time. In the biologic reactions, bacteria and microorganisms take role and digest the organic material and decompose it. In the electrochemical reactions, electrical energy is used to break the chemical compounds to the smaller and shorter compounds. During and after bio-electrochemical process (BEP), various of end-products and by-products are produced. Some of the main BES are microbial fuel cell (MFC), microbial desalination cell (MDC), bio-photovoltaic systems (BPV), photosynthetic microbial fuel cell (photoMFC), enzymatic fuel cell (EFC), microbial electrolysis cell (MEC). Moreover, BES are promising technologies due to their specific advantages such as sustainability, scalability, energy efficiency, and versatility (Ahmadi, Rezae et al. 2023).

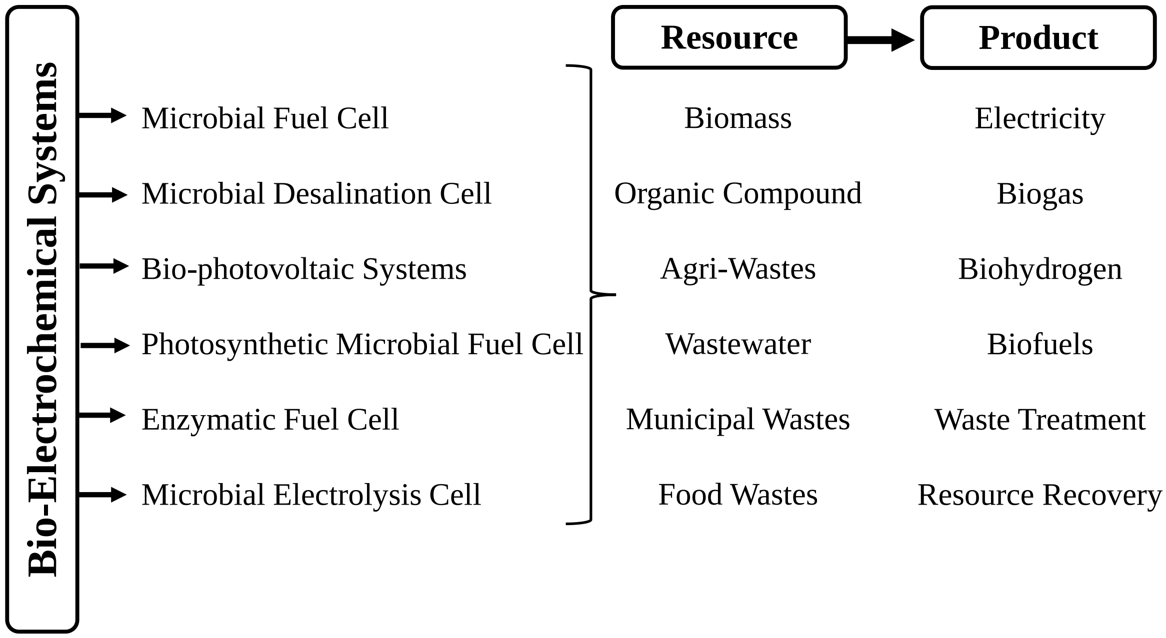

Figure 1. BES reactor, resources, and products.

BESs can be used for different purposes in many sectors. The operating conditions of BESs, the raw materials used, and the organisms involved in the process should be determined according to the intended use of the BES and optimized for the intended output. Table 1 shows the recent studies in which different BES types are used for different purposes.

Table 1. Recent studies on sustainable BES.

Organism	Substrate	Anode	Cathode	Reactor	Output	Ref.
Acorns tatarinowii	Silica sand + Water	Graphite	Pt-graphite	MFC	21 mW/m2	(Liu, Ji et al. 2018)
Mixed consortia	Petroleum refinery wastewater	Graphite	Pt-carbon	MEC	789 mW/m$_2$	(Mohanakrishna, Al-Raoush et al. 2019)
Sludge	Corn stover + Torrefied biomass	Carbon	Carbon	MEC	Bio-H_2 (123.72 mL/g TS)	(Li, Fan et al. 2022)
Anaerobic sludge	Sludge	Pt-Ir-Ti	Graphite	BES-AD	CH_4 (4.3 CH_4/ g COD)	(Jadhav, Yu et al. 2024)
Proteobacteria	Domestic wastewater	Carbon	Carbon	MDC	COD Removal (%55)	(Varjani 2022)

When Table 1 is examined, it can be seen that different organisms, substrates, anode and cathode materials, reactor setups and outputs are obtained. Organisms are actively involved in the biological reactions of BEP and the digestion kinetics of each organism are different from each other. In this context, it is important to create a synergy between the organism and the substrate to be used. If the substrate cannot be digested by the organism, it will disrupt the biological reactions of BEP.

The selection of materials used in electrodes is also a critical parameter for BESs. It is very important that ionic conductivity is high and ohmic resistance is low in the redox reactions that will occur between the electrodes and the substrate. In this context, when selecting the substrate, the electrical conductivity values of the waste should be taken into account, and in addition, the electrode material should be selected from materials with low internal resistance. In addition, electrodes should be selected from biocompatible, low-cost, corrosion-resistant, stable and safe materials. Therefore, the electricity production, biogas, biohydrogen, waste treatment and chemical treatments can be done with the help of BES. The fact that the raw materials used in these processes consist of organic waste and the system is environmentally friendly allows these outputs to be realized in a sustainable way.

However, along with advantages, BES's also has some disadvantages. These systems require technological equipment, knowledge of both biology and electrochemistry, system instabilities depending on the microbial activity, can be easily affected by environmental factors (temperature, pressure, humidity, light), impurities depending on biomass type, and environmental impacts. To prevent these disadvantages, biomass type should be selected carefully, operation conditions should be set meticulously, end and by-products should be observed, and waste management procedures must be implemented caution (Ramanaiah, Chandrasekhar et al. 2023).

LIFE CYCLE ASSESSMENT APPROACH in BIO-ELECTROCHEMICAL SYSTEMS

Life cycle assessment (LCA) is a systematic and holistic method used to assess all life stages of a product, from raw material (cradle) to production, distribution, use and disposal or recycling (grave), and the environmental impacts of these stages. It involves compiling an inventory of energy-material inputs and emissions, pollution and toxic substance releases of the product or service to be assessed, assessing the potential impacts of these inputs and releases on the environment, and interpreting the results to help make more informed decisions aimed at reducing negative environmental impacts. LCA provides a comprehensive analysis of environmental aspects and potential impacts throughout a product's life cycle, enabling a more sustainable approach to product design, development and management (Arvanitoyannis 2008).

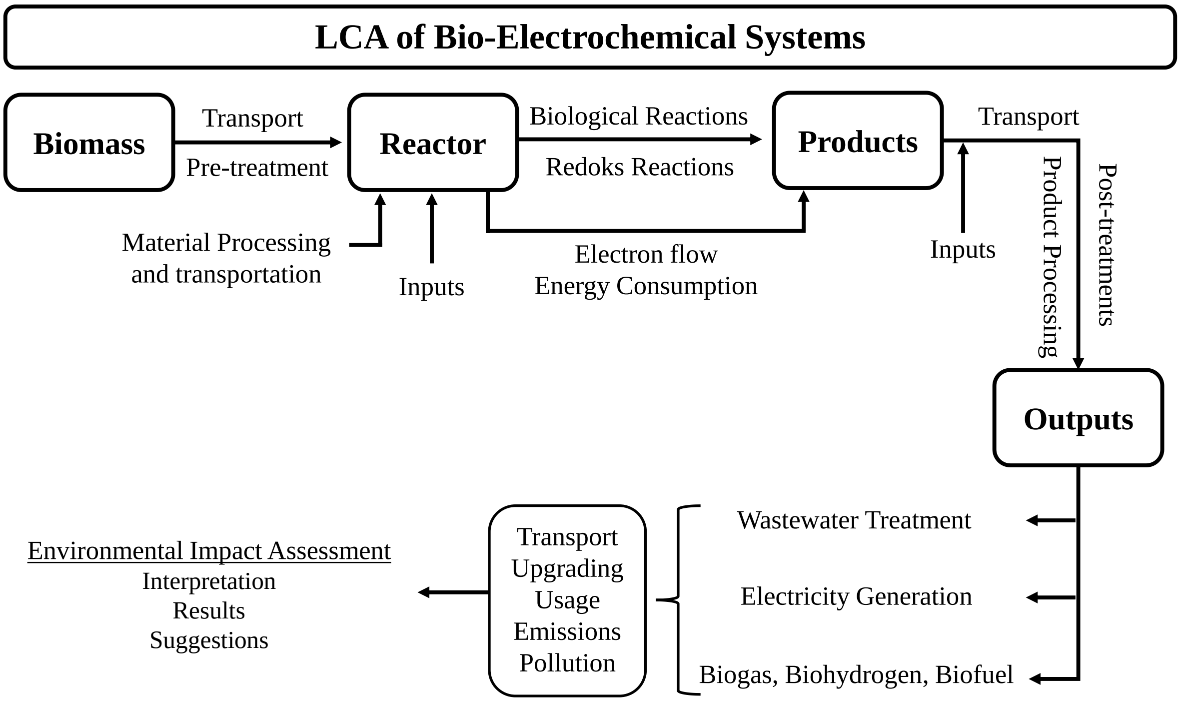

Figure 2. LCA of a BES.

As mentioned earlier, BES are innovative technologies that are used in various applications such as biofuel production, electricity generation, wastewater treatment and synthesis of valuable chemicals through the combined utilisation of metabolic activities of microorganisms and electrical energy. However, BESs also have serious environmental impacts and the sustainability of these systems is of great importance for the future utilisation of these technologies. To ensure the environmental and economic sustainability of these systems, LCA is used as a critical assessment tool. LCA can be used to systematically and comprehensively assess the environmental impacts of BES covering all stages from extraction of raw materials, transport, pre-treatment, inclusion in the production process, final and by-product production to final waste management. LCA can provide a sensitive, realistic and consistent assessment of the environmental impacts of BES in various environmental impact categories such as energy consumption, greenhouse gas emissions, water use, toxic substance releases. The application of LCA helps to identify areas for improvement in the design and operation of the BES, while at the same time enabling strategic decisions to be taken to achieve sustainability goals. Therefore, the relationship between BES and LCA is vital to minimise the environmental impacts of these technologies and ensure long-term sustainability. By providing a scientific and objective basis for optimising the environmental performance of BES, LCA contributes to the development of more sustainable and efficient bio-electrochemical applications (Savla, Pandit et al. 2021).

Stages of Life Cycle Assessment Studies in BES

1. Defining Goal and Scope

The aim of LCA is to realistically assess the environmental impacts of BESs. The study covers the life cycle of BES starting from raw material extraction to production, utilisation and waste management stages.

2. Inventory Analysis

Inventory analysis is carried out to detail the inputs used and outputs produced at each stage of the RPS. At this stage, various sources such as official data, literature reviews, producer data and laboratory measurements are utilised (Zhang, Yuan et al. 2019).

2.1. Inputs

- Raw materials: Anode and cathode materials (carbon-based, metal, ceramic materials), membrane materials (Nafion), cable and connection materials, nutrient media and microorganisms.
- Energy: All kinds of energy consumed during raw material pre-treatment and BES installation and BEP.
- Water: The amount of water required for the operation of the BES.
- Chemicals: Chemicals (phosphate buffer, nutrient solutions) used for raw material preparation, operation of the BES.

2.2. Outputs

- Electricity Generation: The amount of electricity generated during the operation of the BES.
- Biogas, biohydrogen production.
- BOD, COD, and heavy metal removal.
- Emissions: Greenhouse gases (CO, CO_2, CH_4, H_2S, NOx) released to the atmosphere during operation of the BES.
- Wastes: Waste and non-recyclable materials generated before, during and after the process.

3. Impact Assessment

In this stage of LCA, the environmental impacts of BES are analysed in various environmental impact categories using the data obtained from the inventory analysis. The main impact parameters analysed are as follows:

- Global Warming Potential (GWP): Impact of GHG emissions of BEP on climate change.
- Energy Consumption: Total amount of energy used during the installation and operation of the raw material and BES.
- Water Use: The amount of water consumed by BES throughout its entire life cycle.
- Toxicity: Potential impacts on the environment and living health of toxic substances released before, during and after operation of the BES, taking into account raw material pre-treatment.

4. Interpretation

By analysing the impact assessment results, inferences can be made on the environmental performance of BES. Furthermore, recommendations and suggestions are made to minimise the environmental impacts of BES. Recommendations include the selection of more environmentally friendly materials, measures to improve energy efficiency and waste management strategies (Chin, Phuang et al. 2022).

CONCLUSION

Life cycle assessment (LCA) of bio-electrochemical systems (BES) focuses on comprehensively assessing the environmental impacts of these sustainable and environmentally friendly green energy technologies. Similar studies and evaluations on this topic reveal that BESs can generate significant environmental impacts such as greenhouse gas emissions, high energy consumption, intensive water use and toxic substance release. To minimise such environmental impacts, environmentally friendly materials should be selected, strategies to increase energy efficiency should be identified and implemented, water-soil-waste management and energy recovery-recycling practices should be increased, and these measures should be taken, and toxic substances should be monitored. These recommendations provide concrete steps to improve the sustainability and efficiency of BESs by optimising their environmental performance.

THE PATH OF ADVANCEMENT FOR FEMALE PHYSICIANS: FIGHTING AGAINST GENDER INEQUALITY

Gülden Aynacı[1]

[1]*Department of Health Science, Trakya Unıversity, Edirne, Turkey*

guldenaynaci@hotmail.com

ABSTRACT

Gender inequality is one of the most important problems faced by female physicians in the healthcare sector. Female physicians face various obstacles in their medical education and professional careers, and this can also affect the quality of healthcare services. In this article, we will discuss the current status of gender inequality for female physicians and the approaches developed to reduce this inequality. Female physicians may generally face more discrimination than their male colleagues in medical education. Female students are often subjected to prejudiced evaluations such as "weak" or "insufficient" in medical schools, which can negatively affect their self-confidence and academic success. In addition, female medical students and young physicians receive less mentoring support than their male colleagues. Female physicians have difficulty balancing work and family life. Childcare, housework and other family responsibilities in particular can directly affect female physicians' job performance and career advancement. In order to eliminate gender inequality, awareness should be raised on gender equality issues in medical education. Educational institutions should organize seminars and workshops for students on gender equality and combating discrimination. Supportive measures such as child care services and flexible working hours should be taken for female physicians to balance their work and family life. Such arrangements can enable female physicians to be more successful in their careers and have a more satisfying experience in their work life. Gender equality will improve the quality of not only women physicians but the entire healthcare system and create a more equitable working environment. The healthcare sector should take important steps to achieve gender equality and be a part of this process.

Keywords: Education and Awareness, Gender Awareness, Women Physicians, Gender Inequality, Medical Education and Gender, Career Advancement and Gender

INTRODUCTION

Gender inequality at work is an old and complex issue needing multidimensional analysis. Healthcare fields present similar problems of variousness in terms of rates throughout each occupational scale. The reasons may be related to some peculiar items that uniformly characterize the world of care but have been largely underinvestigated. There is an important body of evidence underlining how the intersection between age, gender, identity, and – if one has kids – motherly status may have significant implications for professional experiences and opportunities of physicians. Both societal norms and institutional prerogatives concurrently contribute to defining what should be a fair professional environment among the healthcare workforce. Qualitative analysis reveals distinct societal dynamics that act in the informants' narratives, producing two levels at which a discussion of gender inequality arises. The career advancement of female physicians often involves a more challenging process than that of male physicians. Women have more difficulty than men in advancing to leadership positions, and their competence is often questioned. Women's social role and the difficulties in establishing a work-life balance can hinder their career advancement.

Female physicians generally receive lower salaries and are exposed to more difficult working conditions than their male colleagues. Wage inequality can negatively affect women's motivation and commitment to their profession. In addition, female physicians' job security and promotion opportunities are often more limited than men's. The ascending path of women towards equality in the workforce has been defined by the successive overturning of restrictive gender policies. The figure of the doctor is at the peak of competing dualities. While the profession has undergone a social upgrade from a mere trade to an elite and cerebral occupation, women can provide nurturing care and reassurance, coinciding with the medical profession's expectations of a counselor and confidante. Societal beliefs and gender roles became a turning point in women's advancement in medicine. Societal stigmas and gender roles suggest that medicine is better suited for males with their allegiance to one duty and their brains, whereas women are seen as homemakers, focusing solely on family life and their nurturing qualities rather than tackling the intense medical formations. Although women were outliers, winning the approval of these renowned teachers when others believed in the limitations of the female skull brought them self-respect. Simultaneously, these beliefs were passed down, compelling both students and faculty to conform in agreement. Presently, women and men are indistinguishably shaped inside the womb.

Social structure and the cultural environment intersect to create situations wherein the bridging of gender gaps becomes the contributors to uneven enrollment and career advancement in medicine. The synergy of such an environment can be hampering for career progression for women in medicine.

RESULTS

The experiences of women in medicine often significantly differ from those of their male colleagues. Female doctors must clear higher interpersonal and emotional hurdles in their professional pursuits. They are faced with bias from the beginning, receiving more negative feedback than men during the hiring process. Additionally, there exists a significant gender pay gap, reflected in both the types and amounts of compensation male and female doctors receive.

Women in medicine also experience microaggressions and outright sexism, which add up to create a hostile and uncomfortable work environment. These disparities aren't just detrimental to female doctors' job performance—they can also contribute to feelings of impostor syndrome and self-doubt. Especially when it comes to leadership positions in academic medicine and medical organizations, female doctors must sometimes wait significantly longer than their male counterparts to be given either the responsibility of their male peers or the professional recognition that makes pursuing further education worthwhile. These delays can contribute to what has been called the leadership labyrinth, making the risk-reward of the substantial research and financial investment necessary to advance in these areas difficult to justify. Combined with existing cultural norms, which stereotype and undervalue both physicians' nurturing qualities and women in the workplace, the evidence suggests that the dual discrimination facing physicians who are both female and weigh in favor of their personal lives leads to decreased representation at higher levels in medicine. In turn, the degree of self-doubt and stress placed on physicians, and in turn, the powerful impact on one's career, are often compounded by work-life conflict, in which individuals feel that their vocational expectations conflict with family or personal pursuits. In a more effective response, all of those barriers must be quantified and addressed.

The issue of work-life balance is one of the most challenging ones in the life of female physicians. However, being important for men as well, it is inevitably women who bear the brunt of the responsibility. There is no doubt that both the nature of the medical profession and the journey towards the position of a physician are very stressful and often lead to burnout. As the expectations of society are still higher on women, being a female physician frequently elevates stress as well. Although in Hungary, women generally invest less time than men in paid work, the study of job burnout in a physician's community has shown that the phenomenon is more common among female doctors. This fact is explained by multiple inequalities and barriers that women's professional advancement must break through worldwide. There are also indications showing that stress and sleep disorders are even more severe for female physicians. Furthermore, this problem affects medical students as well. This is the key moment when those who reject the heavy overtime load arising from the engagement of the profession on the part of the employer leave the profession or adopt a lower workload. Women are less likely to choose positions that prevent them from having a healthy work-life balance. An unrealistic anticipation of economic growth is behind the lack of structural response in the developed world; that is, the nature of the work of male physicians has not changed even in the face of these trends, and women are simply expected to already do double responsibility while working longer.

A professional organization can function as a support system and advocate for female physicians. They provide several advantages to women and men who are members, as well as the medical community at large. Among the resources professional organizations offer are targeted online databases listing speakers and honorees, and resources for women in health care. Many organizations offer lectures, panel discussions, awards, and programs designed to increase mentorship, visibility, and leadership of females in healthcare. In general, joining a professional organization can enhance visibility and afford networking and mentoring opportunities. Female physicians are encouraged to become members of grant-making agencies and to target joining and succeeding within local, state, and national professional organizations. These committees and work groups can help raise the visibility of women and their issues in medicine, improve role modeling for future leaders, disseminate role-appropriate career and professional development resources, and change organizational culture. The Gender Equity Task Force has worked for almost 30 years to increase the equitability of evaluative and climate-related measures of success. These changes affect women, but they also help males in their careers. The ideation and concept for the mission and goals for this paper resulted from work in leadership roles within multiple professional organizations over the past two decades. These guiding principles have improved the organizations and the careers of both men and women. A favorite task was reviewing and voting upon the candidates for professional society senior membership.

Gender equality trainings and awareness-raising activities should be carried out for all individuals working in the health sector. These trainings can help both women and men become informed about gender inequality issues and combat these issues more effectively. Women physicians play an important role in the healthcare sector, but they face various challenges due to gender inequality. Comprehensive approaches and solutions should be developed to eliminate inequalities in areas such as education, career advancement, wage inequality, and work-family balance.

The mentoring programs should be established for female medical students. In order to provide equal wages and working conditions for female physicians, gender equality policies should be developed in the health sector. Legal regulations and policies combating gender inequality should be implemented in workplaces. In addition, incentives should be provided to support female physicians to advance to leadership positions.

Undergraduate and postgraduate medical training are important gateways that regulate, to some extent, the pathway between personal and professional development in the face of gender inequality. In an academic setup, the presence of bias influences the course of events, facilitating mentorship in favor of males. This is what we see occurring within higher education among faculty members. The presence of role models alone, combined with the social psychological principle of self-appearance, affects professional goals for students. Major interventions need to be made in medical school; the strategies for this will be discussed in detail later.

CONCLUSION

Women still need to overcome many types of gender injustice on the medical path to equality with men up to this day. These issues of justice can be tackled by addressing the level of resistance women feel to inequality in the workplace. Organizations and society as a whole can assist many women willing to stay in the workforce by understanding the invisible and tangible barriers that exist and hinder advancement into the profession of medicine, as well as personal activities outside of medicine. Stakeholders at the individual, organizational, and public policy levels must continue to work together to create an environment where women can have equality of opportunity, fair exposure, and fair compensation, rather than being expected to mimic male standards of success. There is reason to be optimistic since many actionable solutions are emerging. Advocates in various regions of the world propose a gender equality approach, with actionable advocacy reforms in mentorship, architecture, and education. As ideas for these reforms emerge from our gender and career path analysis, we find offerings potential stakeholders can accept so women receive fair outcomes. These differences that prescribe and proscribe what individual females should or should not bring from home to their careers and the workplace serve as our critical refutation to arguments that choose to pigeonhole the issue of unequal paths as an insufficient desire on the part of female physicians. With the benefit of the current knowledge base from successful appeals or unexpected revelations, researchers and implementers alike can attempt to subject laws, local and regional policies, and other reforms to reform and replication, data collection, and more educational theories, replacing those that failed, advancing and ultimately winning the fight. People, interest groups, institutions, and systems all play a critical part in the future of gender issues in medicine. Every day holds opportunity for better resolution, so we challenge the people today to continue the fight for tomorrow's advantage.

URINARY INCONTINENCE ISSUES IN WOMEN AFTER COVID-19

Gülden Aynacı[1]

[1]*Department of Health Science, Trakya Unıversity, Edirne, Turkey*

guldenaynaci@hotmail.com

ABSTRACT

The Covid-19 pandemic has had extensive effects on health and social life, and women's health has also been affected by these effects. The increase in urinary incontinence problems in women after the pandemic requires investigation of the causes and management strategies of this situation. This study examines in detail the causes of the increase in urinary incontinence problems in women after Covid-19, potential risk factors and treatment approaches. The Covid-19 pandemic has affected the health status of millions of people worldwide, as well as causing significant changes in women's health problems. Urinary incontinence is a common health problem among women and has become more pronounced with the impact of the pandemic process. This article will discuss the causes of the increase in urinary incontinence problems after Covid-19 and management strategies.

Keywords: Covid-19, Lifestyle changes, Women's health, Urinary incontinence, Post-Pandemic, Access to health care

INTRODUCTION

The effects of the pandemic on women's health are multidimensional: Physical Health: In addition to the direct effects of Covid-19, inactivity, weight gain and other health problems have also been experienced during the pandemic. This has affected women's physical health and paved the way for conditions such as urinary incontinence. Psychological Health: The pandemic has caused an increase in stress, anxiety and depression levels. Psychological health problems can affect bladder control and increase the risk of urinary incontinence. Access to Healthcare: Access to healthcare has become difficult during the pandemic, causing disruptions in the management of chronic health problems such as urinary incontinence.

Urinary incontinence is defined as the involuntary leakage of urine. There are three main types in women: Stress Type Urinary Incontinence: Occurs when the pressure on the bladder increases during physical activity, coughing or sneezing. Urgent Urinary Incontinence: Occurs as a result of sudden and strong contractions of the bladder, usually associated with a sudden and uncontrollable need to urinate. Mixed Urinary Incontinence: Shows both stress and urgent symptoms.

Reduction in Physical Activity: The obligation to stay at home and social isolation have caused a decrease in physical activity. Inactivity can lead to a weakening of the pelvic floor muscles and therefore an increase in the risk of urinary incontinence. Weight Gain: Weight gain was observed during the pandemic period due to changes in eating habits and physical activity. Obesity is an important factor that increases the risk of urinary incontinence. The pandemic process has caused an increase in stress and anxiety levels. This situation can have negative effects on bladder control and trigger urinary incontinence. Access to healthcare has become difficult due to the pandemic, which has led to a delay in the timely diagnosis and treatment of health problems such as urinary incontinence. Hormonal changes after menopause and childbirth can increase the risk of urinary incontinence. During the pandemic, women may have difficulty accessing the necessary healthcare services during these periods.

Managing urinary incontinence problems usually requires a multidisciplinary approach. Kegel exercises strengthen the pelvic floor muscles and can reduce urinary incontinence problems. Biofeedback: This method can help understand and control how the muscles work. Psychological Support: Stress Management: Stress and anxiety management can reduce urinary incontinence problems. Therapies and counseling services can provide support in this regard.

Cognitive Behavioral Therapy: This therapy method can help develop stress coping skills. Medications that relax the bladder muscles and control urinary incontinence may be used. In severe cases, surgical options may be considered. These methods may include bladder or urethral support procedures. Exercise and Weight Management: Regular exercise and weight control can reduce the risk of urinary incontinence. Dietary Adjustments: Regulating water intake and avoiding foods that can irritate the bladder, such as caffeine, may be helpful.

RESULTS

Urinary incontinence (UI) is highly prevalent in women, affecting about one in three. The global prevalence rate of UI is approximately 200–400 million, with an estimated worldwide cost of $65–77 billion annually, as UI has significant economic, health, and social consequences. In virtually all UI management guidelines, pelvic floor muscle training is considered the first-line therapy, emerging as an effective noninvasive treatment option. The pathophysiology is often multifactorial (e.g., menopause, hormone alterations, pregnancy delivery, trauma, and urinary tract infections). Evidence shows that women are at higher risk for severe respiratory syncytial virus and influenza virus infections, especially if they are pregnant, due to the widespread use of sex steroids in this population. Epidemiological data on the impact and pathophysiology of the novel coronavirus disease have been published, but there are unknown long-term complications. It is known that a woman’s immune response is higher than a man’s, which could have a harmful effect on patients with excessive immune response to SARS-CoV-2 infection. Promising studies are showing that female sex hormones are very important in preventing and supporting anti-sepsis responses due to lower serum testosterone in men, and the central nervous system immune regulatory role of estrogen and progesterone, which downregulates cytokine production. Due to its pathophysiology, complications, and high prevalence, we aimed to evaluate whether women who have COVID-19 have or will develop UI by evaluating the EMG activity of the pelvic floor muscle in the suspicion or diagnosis phase of COVID-19.

The SARS-CoV-2 (COVID-19) coronavirus pandemic continues to impact the lives of individuals at a global level. At this stage, literature on the impact of COVID-19 on lower urinary tract symptoms is scarce. However, the risk of urinary incontinence, predominantly in the older population following a COVID-19 infection, potentially has immediate and far-reaching welfare and economic consequences. A significant potential physical and psychological comorbidity due to COVID-19 infection is through disruption of the pelvic floor muscle system, leading to urinary incontinence. An increase in pneumonia, a potential outcome of a COVID-19 infection, may also predispose the development of urinary incontinence.

Several medical observations provide some explanations of how SARS-CoV-2 negatively affects pelvic floor muscle function. A relationship between COVID-19 infection and pelvic floor impairment mediated by the cytokine storm, with the lower urinary tract symptoms including low urinary stream, frequent urination, weak stream, painful urination, and incontinence is strongly suspected. It is reasonable that COVID-19 pneumonia may trigger a stimulus urge to diaphragmatic contraction via a stretch reflex elicited by alveolar distension and reduced lung compliance. This urge to diaphragmatic contraction decreases intra-abdominal pressure transmission to the pelvic floor muscles through a delay in pelvic floor muscle activation, which is a predisposing factor for urinary incontinence development. In addition, recent reports of prostate infection and the possible transmission of the coronavirus through seminal fluid and/or urine indicate some warnings in developing and implementing strategies to promote physical health and well-being for adult women who have been infected by SARS-CoV-2. There is a lack of evidence assessing combined conservative management and therapies for women developing urinary incontinence post COVID-19 infection. At present, there is no efficacy in using both together. However, the use of conservative management prior to prescription or any therapy in these women will improve the signaling through behavior, i.e., sensation to inhibit and initiate bladder emptying, restore a stimulated regular micturition habit, and reduce the possible relapse effect associated with antimuscarinic therapy. In the future, studies should examine COVID-19 women completely adhering to conservative therapy with the addition of selective drug therapies. In this clinical scenario, there are significant uncertainties about other selective medical therapy effects, ignoring valsalva non-classic voiding leakage or valsalva associated with storage orgasmic leakage, for example, which could also be considered. The most concerning uncertainty is the need to provide a longer-term follow-up in COVID-19 affected incontinent women beyond the bladder health program, due to the possibility of other illnesses due to virally established vascular and nervous damage.

It is important to remember that women experience different presentations of urinary incontinence due to their unique pelvic structures. Consequently, there are several surgical procedures to address their individual requirements. When counseling women post-COVID-19 infection and considering surgical treatments for urge urinary incontinence, it is important to evaluate patient suitability. Burch colposuspension has a good long-term cure benefit, but evidence from before the mesh era is increasing its acceptable use. Women aged 40 and over with no immediate desire for further children or who have completed their families are most suitable. Providing careful pre-operative counseling and informing patients about available alternative procedures, including retropubic and transobturator mid-urethral slings, which also have good short and medium-term outcome data, aids decision-making. It is important to counsel women about the possible post-operative de novo urge incontinence, as well as the need for concomitant mid-urethral slings during pelvic organ prolapse repair. Mid-urethral slings should be performed for suboptimal success because the alternate urodynamic approach is not likely to substantially influence the final surgical approach. When discussing surgical treatments for stress urinary incontinence following a COVID-19 infection, it is important to assess patient suitability for the procedures to ensure good patient satisfaction. Age and comorbidity are significant factors. However, counseling patients carefully before undergoing surgery and informing them of other surgical alternatives aids in the decision-making process. It is important to counsel women about the possible occurrence of de novo urge incontinence post-sling and to discontinue the mid-urethral sling at the time of the pelvic organ prolapse repair. Do VRAM slings demonstrate greater efficacy than TVT? The subject is then covered by a scientific discourse. These surgeries stress the significance of associating in discussion within pelvic floor multidisciplinary teams and making sure that the judicious approach offers as much effective prevention as it provides treatments to optimize outcomes simultaneously. However, a further randomized controlled trial is warranted.

The problem of urinary incontinence must always be addressed in a comprehensive understanding of the woman’s life and in the context in which she is inserted, whether they are personal, family, residential, educational, and/or work relationships, as well as emotional and love relationships and her free social life, absorption, and sexual transmission. The social restrictions associated with the infection may affect each affected woman in various dimensions, whether it is the impossibility of performing health care or the displacement to seek treatment, individual or group leisure activities, educational dynamics, the ability to work, engaging in studies, shopping, and household tasks, or in religious behaviors. These limitations may also factor in gender inequalities based on the fact that the role of primary caregiver for dependents is more often played by women. Such socially ingrained influences affect the Western femininity model and female self-representation, which are influenced by characteristics and behavioral patterns of women, with values and interests absorbed and incorporated from their perspective and mainly related to care for the body with outward and genital identity provided by the muscles of the perineal floor, body shape, and flawless skin, which are pre-established based on multiple sources and conflicts, producing paradoxical distress and pleasures. The intimate values that female patients develop, where the self is valued through continuous disclosure of herself, will have a direct impact on her sexual health, and the benefits and suffering provided and caused by the woman as a woman with the construction of her identity. The construction of her own meaning, without affecting the meaning it carries. This illness is part of a medicalization that must be addressed, not investigated in the abstract, because it is immersed in political, economic, social, and gender issues in the public and private dimensions.

Quality of life considerations are paramount in the management of urinary incontinence. There is increasing recognition that urinary incontinence may be bothersome and have a negative effect on a woman’s quality of life. It has been shown to adversely affect emotional well-being, physical, and social functioning in a highly symptomatic population of women, with women presenting with urinary incontinence and an overactive bladder having a similar quality of life impairment as other chronic conditions. Area-based cohorts have demonstrated that increasing the number of urinary incontinence episodes is directly associated with a poorer quality of life, and individuals with a more bothersome incontinence score a lower quality of life. Nocturnal urinary incontinence has been reported to have the greatest adverse effect on quality of life, with individuals experiencing higher levels of emotional distress and an overall impact on all quality of life domains.

Information on long-term sequels as well as data from over 50,000 recently recovered confirmed COVID-19 patients has almost just been analyzed. The importance of early rehabilitation in local communities becomes even more urgent in the face of this massive, growing, and permanent chronic illness. Of these, there were also more patients with proven previous urinary incontinence and new urinary incontinence following a COVID-19 infection. Furthermore, the ratios of new instances of urinary incontinence are disproportionately likely to occur in those without previous urinary incontinence. During primary and secondary prevention of worsening urinary incontinence, the role of physical activity and rehabilitation-based intervention in the local community should not be underestimated in the early stage of rehabilitation, especially in women.

Understanding the influence of COVID-19 could help in better rehabilitating patients following COVID-19 where urinary incontinence is concerned. During both primary and secondary prevention, it is important that high-quality guidance is provided regarding physical load and occupational stimulation that can be given safely. In this large cohort of women surviving a COVID-19 infection, the risk ratios were significant. What is needed immediately are further studies. Information on long-term sequels as well as long-term PTSS and PTSD studies is thus warranted. A previous history of urinary incontinence would significantly increase the risk of new COVID-19 urinary incontinence, and some socio-economic groups of women are particularly vulnerable to this.

CONCLUSION

Urinary incontinence (UI) is independently associated with increased risks of other major bladder and bowel symptoms in women following a recent COVID-19 infection and may be a vital symptomatic marker. Unrecognised sequelae including UI may contribute to increased healthcare usage and lead to irreversible morbidities. Importantly, there are safe and effective treatments for incontinence that can be initiated without the need for hospital referral and further invasive testing. Further work is needed to evaluate the strength of the association between UI and COVID-19, and if the presence of UI following a recent infection acts as a prognostic factor for other bladder or bowel related symptoms or indeed long-haul COVID-19. Establishing UI as a potential predictor could therefore avoid potential over-referral for vitally important lung function clinics, including prolonged wait times. Future work could also investigate if other novel therapies could help improve UI following a COVID-19 infection. Medics evaluating patients following infection should be alerted to the potential for UI and be confident in the safety and efficacy of the range of successful management options, targeting symptom improvement for both conditions.

RELATIONSHIP BETWEEN SEXUAL DYSFUNCTION (SD) AND RESTLESS LEGS SYNDROME (RLS) IN WOMEN: A CURRENT LITERATURE REVIEW

Gülden Aynacı[1]

[1]*Department of Health Science, Trakya Unıversity, Edirne, Turkey*

guldenaynaci@hotmail.com

ABSTRACT

Female sexual dysfunction (FSD) is a broad spectrum that includes various problems such as sexual arousal, orgasm and discomfort during sexual intercourse. Restless legs syndrome (RLS) is a neurological disorder characterized by discomfort and a need to move the legs, usually while lying down or at rest at night. The relationship between these two conditions may be of interest in terms of both physiological and psychological factors. RLS is characterized by discomfort and a feeling of restlessness in the legs. These symptoms usually occur in the evening or at night and are relieved by the need to move. RLS is generally more common in women and can significantly affect sleep quality. The prevalence of RLS varies between 5-10% in the general population, but this rate may be higher in women. RLS is thought to be caused by genetic, biochemical and environmental factors. SD includes problems such as sexual arousal, orgasm, and discomfort during sexual intercourse. Types of SD include sexual desire disorder, sexual arousal disorder, orgasmic disorder, and sexual pain disorder. SD is common among women and is seen in various age groups. The prevalence of SD may vary depending on the age of the women and their physical and psychological health status. There may be a psychological link between RLS and SD. Constant discomfort and insomnia may increase the risk of anxiety and depression. These psychological conditions may contribute to sexual dysfunction. The relationship between RLS and SD in women requires a multidisciplinary approach. Treatment strategies should be developed considering the effects of both physiological and psychological factors. Understanding the effects of RLS on sexual function is important in terms of coping with this condition and developing treatment strategies. The literature on this subject is still developing and more comprehensive studies are needed. In particular, longitudinal and control group studies may be useful to understand the mechanisms of the relationship between RLS and SD. Research on this subject is very important in terms of its effects on women's sexual health.

Keywords: Female Sexual Dysfunction (SDY), Restless Leg Syndrome (RLS), Sexual Dysfunction, Hormones and Sexual Function, Women's Health

INTRODUCTION

Restless legs syndrome (RLS) has lately been reviewed to have a relationship with different diseases, both in terms of organic and psychiatric diseases. In addition, in the etiopathogenesis of the mentioned diseases, organic and psychiatric causes like metabolic, hormonal, and ischemic causes play a role in the pathways. It has been noted that RLS is associated with sexual dysfunction. There is not enough data on RLS's etiopathological status. Therefore, the studies that would be conducted are very significant in terms of practical and social developments on RLS that could be performed by the findings, prevention, and treatment of the illness.

RLS is known to be associated with sleeplessness and constant restlessness at night. This condition can affect the general quality of life and lead to sexual dysfunction. Insomnia can cause symptoms such as lack of sexual desire and fatigue.

According to the current data, the relationship between RLS and sexual dysfunction is also known throughout the prevalence studies. The low quality of the investigations has been noteworthy when evaluating the relationship between RLS and sexual dysfunction. Additionally, the distinguishing symptoms or the difficulties of sexual dysfunction related to RLS could not be clarified in the studies when the comorbidities of RLS were mostly excluded or not. In a multitude of RLS cases, when the RLS symptoms before and during sexual activity were questioned, the sleep and feelings of restlessness were negatively affected. During sexual activity, the interactions of the proper physical and emotional symptoms and sexual dysfunction of RLS patients negatively impacted their desires, while the possibility of sexual dysfunction increased when RLS symptoms during sexual intercourse were added to the emotional factors. Women suffered from inability to sleep, instability, anxiety, sexual incompatibility, and depression. When RLS was included, a significant increase in the possibility of difficulty falling asleep or having agitated sleep was reported. The role of dopamine was evaluated in the sexual processes as well. A certain medication was reported to have a sexual side effect as an inhibitor agent on the dopaminergic transmission, and, as known, certain effects are well-established. The results of the therapeutic treatment with inhibitors of the dopaminergic transmission were variably reported. While some studies stated that a significant percentage of some dopamine agonists suppressed sexual desire and orgasmic response, others countered the claim that they had no effect on the scores of sexual function. As a result, it has been determined that RLS and dopaminergic treatment have a negative impact on sexual dysfunction in women with or without RLS.

RESULTS

Sexual life has an important impact on a couple’s life, playing a significant role in interpersonal relationships. Sexual dysfunction is an important source of distress, with relevant clinical implications. It often causes interpersonal relationship difficulties and contributes to a reduction in the quality of life. Furthermore, sexual relationships are an important goal for human beings, with a role in their general functioning and well-being. There are, however, limited data about restless legs syndrome and its relationship with female sexual dysfunction. This review aims to evaluate the current state of research on sexual dysfunction in women with restless legs syndrome. Restless legs syndrome is a very common sensorimotor disorder. It frequently leads to a reduction in the quality of life and has been found to have a significant impact on sleep, mood, exercise, and social activities. Female sexual dysfunction is characterized by significant difficulties experienced during one or more of the sexual responses. Its importance is due to the fact that it might be considered an expression of general health problems, such as endocrine, neural, vascular, or emotional disorders, and, therefore, it makes sense to subject these patients to specific investigations in order to identify any underlying causes.

The substantial evidence from neuroscience and psychophysiological research on the role of dopamine in preparing for and promoting sexual motivations supports the aberrant functions of the dopaminergic system in the occurrence of sexual dysfunctions and the high prevalence of restless legs syndrome in women. One suggestion has been to consider evaluating dopamine levels or urinary dopamine excretion in such women. Because obesity has been linked to other sexual dysfunctions, weight maintenance could also be considered as an option to prevent or improve sexual dysfunction due to restless legs syndrome. In the case of psychological mechanisms, attention and cognitive function, estrogen levels, and the expectations of sexual pleasure may contribute to female sexual function through physiological pathways. The co-occurrence of sexual dysfunctions and restless legs syndrome is believed to result from frequent daily stressors or aging, as suggested by the findings that one in three women with restless legs syndrome experience sexual dysfunction and depressive mood. Both sleep disturbances, due to periodic limb movement disorder, and low sex hormone levels resulting from reduced energy due to low sleep quality, could impact the sexual function of regularly stressed women by causing and aggravating anxiety and pain concomitantly. Disturbances in restorative sleep due to alterations in the release and metabolism of neurotransmitters in affected brain centers, similar to what occurs in sexual dysfunction, have also been suggested as potential mechanisms.

CONCLUSION

The significant impact of RLS on the well-being and health-related quality of life has been recognized widely. RLS primarily causes adverse effects on subjective sleep quality and daytime functioning, including activity impairment, work productivity loss, and negative effects on mood and sex life. The presence of RLS engenders higher functional disability, increased medical care utilization, and a reduced quality of life in women. Therefore, we can speculate that the presence of a concurrent physical and/or mental health problem, such as impacts on relationships, partners, and family, employment loss, and decreased productivity, could initiate difficulties in sexual function, even if the physiopathology of RLS is not directly involved. In this context, RLS can result in negative effects on sexual life, while less attention has been paid to the sexual dimension of RLS despite the significantly reduced health-related quality of life. RLS causes unpleasant sensations in the limbs, and the resulting discomfort is exacerbated at rest and relieved by active movement, for example, walking or stretching. In many cases, the symptoms occur in the evening and at night, causing patients difficulties in initiating and maintaining sleep, resulting in sleep disturbances with a substantial impact on the patients' behavior, relationships, and overall quality of life. Given the diurnal and nocturnal symptoms, RLS can affect couples' lives significantly, but information on sexual life has been mostly reported secondarily. The current review is not aimed at systematically analyzing the evidence of the negative effect of RLS on sexual life and couple relationships, but to speculate on the potential mechanisms of this sexual impairment.

Various studies have suggested that gabapentin and opioid antagonists may improve RLS symptoms, and the use of these medications for women with RLS who do not want to interfere with their sex lives could be considered. For example, gabapentin enacarbil sometimes causes headache, dizziness, and sedation, demonstrating a profile similar to that of the antidepressants proposed as a second-line treatment for SDY.

Personalized treatment strategies are also essential to improve symptoms, reinforcing the importance of communicating effectively with patients to ensure they feel comfortable discussing any sexual difficulties that may have developed over time. To our knowledge, useful recommendations for the treatment of symptoms associated with both disorders would also be helpful, and it may be feasible to meld two clinical guidelines on a multimodal treatment method. Patients with this comorbidity would prefer to receive treatment simultaneously rather than sequentially; that is, so they only have to see one physician for all their conditions rather than having to consult various specialists. This recommendation might be particularly applicable for some women diagnosed with both conditions.

CURRENT LITERATURE REVIEW ON MENSTRUATION-RELATED MIGRAINE

Gülden Aynacı[1]

[1]*Health Sciences, Trakya Unıversity*

guldenaynaci@hotmail.com

ABSTRACT

Migraine is the second leading cause of disability globally, affecting women 2 to 3 times more than men. Migraine stands out as the single largest factor leading to the loss of years of healthy life, especially in women of childbearing age. Menstrual cycle-related migraine (MM) constitutes an important subgroup in this context, occurring in approximately 18% to 25% of women. MM is an important component of migraine that affects women's quality of life. This literature review will address current issues encountered in the diagnosis and management of MM and innovations in the literature. The ICHD-3 diagnostic criteria have some limitations in defining menstrual-related migraine. For example, the criteria do not appear to adequately address migraine frequency and timing. First, the criteria required by ICHD-3 require migraine to occur in two out of three consecutive menstrual cycles. However, this may lead to misdiagnosis in women with high frequency of migraine attacks, i.e., those with chronic migraine (CM) or high frequency episodic migraine (HFEM). This may affect the diagnostic criteria, as women with 8 or more migraine days per month must have a migraine attack within the perimenstrual window, simply by chance. Cases defined as rare pure MM refer to rare migraine attacks that occur only during the menstrual period. Migraine, and especially menstrual-related migraine, causes significant disability and loss of quality of life in women. The current ICHD-3 criteria present some difficulties and uncertainties in the diagnosis of this type of migraine. However, hormonal treatments and other medical approaches offer important steps in migraine management. Future research and updating of diagnostic criteria are critical for a better understanding of migraine and the development of effective treatment methods.

Keywords: menstrual-related migraine, women's health, migraine attacks, perimenstrual window, women's quality of life

INTRODUCTION

Of particular interest to researchers and clinicians in the field of women's health is menstruation-related migraine (MRM). This affliction, which presents with a predilection for menstruating women, has been the subject of increased attention in the literature over the past several decades. The necessity of its documentation has been varied, owing to an interest in symptom presentation, rate of occurrence, socioeconomic significance, and associated complications with contraceptive therapy. Accordingly, notable effort has been made to demonstrate, through rigorous scientific investigation, the importance of MRM's distinctions over and above migraine outside of the menstrual cycle. As will be extensively addressed below, current literature on this topic is primarily preoccupied with demographic characteristics, clinical presentation, and management strategies to evoke positive patient outcomes.

Recognition of menstruation-related migraine (MRM) is especially important as this type of headache is estimated to affect a significant 72.9% of females in the United States, with a somewhat decreased prevalence occupying the rest of the world (48.2%). Such niche diagnostic categories can hold significant implications for overall headache prevalence at approximately 11.7%. As such, our desire to document the experience of such a large population of potential patients is somewhat of a stretch. Nonetheless, MRM represents the processes of several cycles and complements our understanding of headache conditions—particularly as MRM patients can expect to spend 30% of their lifetime experiencing migrainous symptoms.

The current literature points to the observation that, in addition to menstruation-induced attacks, hormonal effects appear to be associated with the onset of migraines in initial cases as well as the course of chronic headache.

RESULTS

Menstruation-related migraine (MRM) is classified as migraine without aura but is associated with at least one menstruation-related episode of migraine without aura in at least two out of three menstrual cycles. In contrast to menstrual migraine, which refers to migraine without aura fulfilling the above symptom criteria occurring from two days before to three days after the onset of menstruation (day 0), MRM can occur at any point during this period. MRM is a universal phenomenon observed across racial and ethnic boundaries. When and how often it occurs shows considerable variability across and within populations, translating into individual risk for those affected. Most literature has focused exclusively on the female sex as subjects, specifically ascribing it to ovarian menstruation, reproduction, and contraceptive practices.

These cases may be difficult to accurately identify and manage because they do not have migraine attacks frequently enough to be diagnosed according to current criteria. In addition, there is a lack of clarity regarding the timing of migraine attacks. The term "occurring" in current criteria does not clarify whether they begin or end on days 1 ± 2 of the menstrual cycle. This uncertainty is a significant barrier to accurate diagnosis and treatment. In recent years, some innovations have emerged in the treatment and management of MM. Hormonal therapies play an important role, especially in the management of menstrual cycle-related migraine. Methods such as oral contraceptives and hormone replacement therapies can reduce migraine attacks in some women. In addition, various drug therapies, antidepressants and antiepileptic drugs are used to reduce the association of migraine with the perimenstrual period. These approaches may be especially effective in managing menstrual cycle-related migraine. Current research is conducting various studies to improve current diagnostic criteria and to make more accurate diagnoses. For example, large population-based studies and cohort studies are important to improve the definition and management of menstrual-related migraine. In addition, research on the role of biomarkers and genetic factors supports a better understanding of migraine and the development of personalized treatment approaches.

Prevalence in adult females Estimates from the general adult female population place the prevalence of MRM at 7–19%. Adolescent MRM attacks per patient per year occurring in individuals under 21 years of age were associated with a relative risk of 2.2 compared to adults. Women with MRM were shown to have a 1.33-fold increased risk of developing migraine in the future compared to women without MRM, after adjusting for age, hormonal contraceptive use, smoking, and migrainous family history. Women who frequently experience perimenstrual or menstrual-like headaches were overrepresented in patients presenting to a headache center. Compared to family doctor consultations, which demonstrated lower rates of MRM consultation, the proportion of women with a migraine onset around puberty was higher among headache center attendees. These individuals will often have a heavier individual and family burden of migraine. A woman's healthcare provider can use this data to provide patient education and explore individual maternal history and present comorbid health conditions.

Menstruation and hormonal headache are a leading cause of disability worldwide, and at a population level, more disabled days result from menstrual or hormonal headache than from any other disorder. Despite the current pandemic status, menstruation-related migraine is a major global public health issue. In contrast, non-migraine headache, including menstrual tension-type headache, did not have a negative impact on health.

There is extreme variation in the reported prevalence rates of menstruation-related migraine; this variability may be the result of regional differences, unstandardized populations, or the use of unreliable data. A meta-analysis of data from multiple studies reported pooled median rates of menstruation-related migraine of 17.0% and 5.5%. The upper range of the reported prevalence rates clearly indicates the extent to which this problem has been ignored in the wider public arena over recent years.

Potential risk factors for the development of menstruation-related migraine that have been investigated include both demographic factors such as sex, older age of onset of menstrual bleeding, greater number of pads required during menses, or a history of severe acne, alcohol, or chocolate craving. That cyclic hormonal changes can precipitate migraine in susceptible individuals has been appreciated for decades and is highlighted in the current classification for headache disorders. Estrogen has been shown to be essential for the development of menstrual migraine attacks, and therefore, many women who experience these episodes are candidates for preventive therapy. The role of lifestyle factors such as diet has not been fully explored in relation to hormonal headache or menstruation-related migraine. Stress of moderate to moderately severe intensity in women who have a menstrual attack is often mentioned negatively. Furthermore, women with menstruation-related migraine have a higher incidence of common medical comorbidities than those who do not. Long-term increased risk of depression and generalized anxiety disorder, stroke, and myocardial infarction is modestly but significantly increased in women with a history of migraine with or without aura. Women with a history of migraine at ages 40-74 have subclinical vascular brain injury as evidenced by imaging scans.

DISCUSSION

Menstruation-related migraines can significantly impair a woman's or a person's quality of life and productivity. The migraines are often described as severe and debilitating, interfering with daily activities and performance at work or school. It has been recognized that people suffering from chronic migraines report decreased quality of life and experience anxiety, depression, hopelessness, and several other comorbid medical conditions. Menstrual migraines and the often unpredictable early attack can cause significant emotional distress, difficulty concentrating, anger, and depression in affected persons, all of which can interfere with daily activities, work, productivity, and leisure. A close association between the severity or frequency of menstruation-related migraine attacks and missed workdays, days with reduced work productivity, and days when household duties or social activities were compromised has been demonstrated.

Significant social and professional consequences of menstruation-related migraine, and in particular, menstruation-predominant migraine have been previously reported. A significant percentage of employers reported that employees with migraines are less productive, and a portion reported that people affected by migraines had a higher absentee rate. It is also suggested that specific assessment of quality of life is needed in people with menstruation-related migraine, as using less comprehensive measures of life satisfaction causes part of the total estimated burden of chronic headache to be underestimated. Feelings of loss of productivity and frequent failure to meet life goals centered around career and job satisfaction, as well as problems with interpersonal relationships and leisure, were in part related to the burden of chronic migraine. Moreover, the personal environment and the need for the availability of support systems were perceived as important and may include work accommodations as part of an individually tailored therapeutic approach, job accommodations, and modification of the environment if people with menstruation-related migraine seek care, help, and relief from their often chronic disorder.

Migraines are complex and chronic headaches that usually affect only one side of the head and can last between 4 to 72 hours with a combination of symptoms, such as photophobia, nausea, and the presence of an aura prior to an attack. Despite the extensive list of symptoms, the primary symptom is throbbing pain that affects the quality of life. Emotional effects are related to menstruation-related migraines. Menstruation-related migraines affect the quality of life by causing emotional effects such as frustration, anguish, isolation, helplessness, and people often worry about the impact of migraines on family, career, and personal life. The throbbing pain, along with the multiple symptoms mentioned above, can cause people with migraines to be more debilitated than women with non-menstrual migraines. This is corroborated by a study where premonitory symptoms were more frequent in women with menstrual migraines than in women without menstrual migraines. In the same study, women reported aura symptoms, and similarly, in another study, subgroups of women complained of a lack of ability to work or perform social duties. Even though there is no recent article describing the social life of women living with menstrual migraines, it is extremely possible that due to the severe and frequent nature of the headaches, someone could feel more isolated from their friends and peers. Literature from other chronic pain conditions suggests that social life can be impacted by severe pain, with someone slowly withdrawing from society and also not participating in social activities. When the individual did not submit an answer to the closed question, there was a reduction in social activities. It is possible that the frequency and severity of attacks have also led to a degree of withdrawal from social circles. Thirty-one patients concurred that they would cancel various planned family, social, and work functions due to increased headaches on menstrual days.

Migraine episodes may result in challenges maintaining employment. The majority of the literature in the area of menstruation-related migraine and work and social impairment relates to lost productivity. A survey of employed women found that 97% reported absenteeism from migraine necessitating days off work and that 28% reported presenteeism with migraines. MH-associated presenteeism within the workplace leads to reduced effectiveness in workplace productivity, represented by presenteeism. In a study of migraines, just over half of working-age individuals with daily or near-daily episodic migraine worked fewer days due to migraine within the past year.

It is crucial that the understanding of the work and social implications of migraine expands from an economic perspective alone. Migraine leads to productivity losses and absenteeism. Although presenteeism was briefly mentioned, there is not much attention dedicated to this. To encourage a prevention-based workplace culture that promotes productivity and flourishing work environments, policymakers need to appreciate the challenges associated with presenteeism. It is vital to recognize that menstruation-related migraines can also have implications outside the workplace. Data showing that migraines reduce work productivity are certainly interesting, but what about the social activities and underlying routines that really contribute to our vast workforce? Mental load, such as housework, is also relevant to the educational sector, with findings showing that 24-29% of students reported that menstruation substantially reduced their learning capacity.

Menstruation-related migraines have multiple pathophysiological mechanisms; thus, the discovery of a novel target for treatment should provide additional options to identify individuals who respond to novel medication. The novel therapeutic targets and approaches on menstrual migraine focus attention on medication enhancing estradiol levels, reducing menstrual withdrawal response, recovering the desensitization of postsynaptic receptors, preventing presynaptic release of neuromediators, and antagonizing glutamine-induced central sensitization. The potential of personalized therapy has been demonstrated for certain groups of substances, including triptans and NSAIDs. This observation opens new therapeutic avenues based on the concept of individually tailored and targeted therapies. Still, a substantial amount of work is required to develop these findings.

This subsection shows that, in the coming years, we may expect a shift in the understanding and management of menstrual-related migraine (MR-M). Real-world evidence suggests that most women living with migraine self-identify which are MR-M almost via trial and error, for example, by trying to add triptans or nonsteroidal anti-inflammatory drugs outside of a suspected menstruation window. The advent of several mobile health applications empowering patients to track, for example, migraine episodes, steroid hormone levels, and incoming menses, based on their forecasting algorithms, points in a different direction. Specifically, the coupling of the natural history and presenting features of individual patients with that of historical cohort data offers the possibility to predict in advance when is the most likely day across the cycle a given person could develop a migraine attack and to intervene in a personalized, targeted, and proactive way. Remarkably, such proof-of-principle applications alerted the user several days before the expected visit of the attack, suggesting non-pharmacological lifestyle changes to implement, as well as pharmacological options.

CONCLUSION

The role of specialists for women with MR-M or refractory migraine is also clear. However, there is no cure for MR-M, and even with a clear suspected link, larger numbers of subjects were unable to have their condition improved. These individuals might not be accessing specialists early enough, in line with what was found for the time to this clinic, suggesting the need for a smoother clinic pathway. The effect of lifestyle changes was not under investigation, and this is an area of growing interest and potential. The Australian Federal Government has announced an initiative that will allow for access to digital mental health services. Digital health enables the integration of technology-based interventions into routine clinical practice and empowers people to manage their health. However, it also comes with challenges, including privacy of data and accessibility of technology support.

Future work and emerging technologies in this field include telehealth services. However, there was no evidence of these capabilities at the beginning of the survey. Emerging technologies that leverage wearable sensors and integrated algorithms to monitor real-time health changes may offer real-time feedback to prevent a migraine attack. Recommendations include increasing awareness and understanding of migraine headache approaches and severity, including available digital health solutions. Studies investigating digital health solutions for women with menstrual-related migraine are limited by sample sizes and heterogeneity of the interventions and outcome measures. The results of this review cannot be conclusively used to guide clinical practice, and the best method of applying digital health to the management of menstrual-related migraine is yet to be determined.
